Introduction

The world economy, that collection of human activities spanning national borders, touches us all. The banking executive organizing global financial services and the poor agricultural worker cultivating an export crop are both strongly influenced by global economic forces beyond their control. The banking executive operates within a financial services protocol of the World Trade Organization and in financial markets that increase in importance with every passing year and yet remain stubbornly volatile in new and not always predictable ways. The agricultural worker sees her fortunes rise and fall with the world price of the export crop she produces and the remittances she receives from her son who works abroad in a country she will never visit. The value of these remittances changes with her country's exchange rate, as well as with the business cycle where her son works. The banking executive and the agricultural worker do not know one another, but both are participants in what we call the world economy.

This work conceives of the world economy as the interaction among countries in four broad areas: international trade, international finance, international production, and international economic development. Some decades ago, considerations of the world economy neatly fit into only two of these four areas, namely international trade and international finance. Not today. Significant changes in the way production is taking place in the world, the emergence of new regions as active locations of this production, and conceptual and theoretical advancements in our understanding of economic growth

necessitate a more inclusive view. What we conceive of as the "world economy" here is more than just traditional international economics. Integration among countries in the four broad areas considered here has progressed to the extent that it is appropriate to conceive of the world as having characteristics of a single global economy.

Despite the importance of the modern world economy, people around the globe face a number of challenges in their attempts to understand it. Foremost among these challenges is a tendency for the relevant published works to be either too general or too specialized to suit the needs of students in economics and the broader social sciences, public policy and public affairs, international studies, and business, as well as the large and growing number of professionals working in international economic policy. Works intended for a popular audience tend to focus on broad themes and theories, often with a political point of view. Articles in academic journals often use terminology and mathematics beyond the reach of the nonspecialist.

This encyclopedia is intended to bridge the gap between the general and the specialized. It explains the structure and workings of the world economy, summarizes issues and debates related to economic globalization, and provides suggestions for further reading on more than 300 topics. With a few necessary exceptions, the entries in this book eschew the broad sweep. Instead, we have chosen topics we consider essential to a real understanding of forces at play. The entries for the most part do not employ

advanced mathematics or highly technical language. Their aim is to accurately educate and inform, not overwhelm.

Structure and Coverage

The entries fall into six major categories: concepts and principles; models and theory; institutions and agreements; policies and instruments; analysis and tools; and sectors and special issues. Our selection of topics in the last of these categories, sectors and special issues, was based on policy relevance rather than on theoretical considerations. We have not included biographical entries, but individuals who have played a significant role in the world economy are mentioned in the relevant topical entries; their names also appear in the index.

The *Encyclopedia* is informed by the modern history of international economic relations since the introduction of the gold standard in the late 19th century. This is widely considered to be the beginning of the modern era of economic relations and, as such, offers a useful starting point. We have tried to select topics that will continue to be important   essential concepts, perennial issues, and long-term trends   regardless of the particular future course of the world economy.

International Trade

Around 1980, our understanding of international trade   the exchange of merchandise and services among the countries of the world   began to change. In response to emerging patterns of trade within (rather than between) manufacturing and service sectors, new theories emerged based on imperfect competition and economies of scale, supplementing the old stories of comparative advantage based on factor or resource endowments in which, for example, a country with a relatively large amount of labor would export labor-intensive goods. At the same time, trade policy agendas rapidly expanded into new areas such as trade in services, intellectual property, a new generation of preferential trade agreements, and the settlement of disputes. Trade economists and trade lawyers became acquainted. Unforeseen issues emerged out of or alongside of trade negotiations such as trade and the environment, trade and labor, and trade and public health.

Trade-related entries in this *Encyclopedia* reflect this new reality. Standard models of international trade (the Ricardian model, the Heckscher-Ohlin model, and the specific-factors model) are given their due by world-renowned trade theorists. New Trade Theory (i.e., based on oligopoly and monopolistic competition) also receives attention, as do its applications in areas such as the New Economic Geography. We supplement these core models with entries on a large set of basic concepts, from absolute and comparative advantage to terms of trade and fragmentation. A host of trade policy instruments are covered, from basic tariffs to nontariff measures, including quotas, tariff rate quotas, and technical barriers to trade. A large number of institutions and agreements are covered, from the obvious (e.g., the World Trade Organization) to the less well known (e.g., the Convention on Biological Diversity and the Convention on International Trade in Endangered Species). We also give attention to commonly used tools of analysis, such as revealed comparative advantage, effective protection, and gravity models. Finally, we cover a range of special issues such as access to medicines, gender, and the illegal drugs trade.

International Finance

Changes have been even more dramatic in the realm of international finance than in international trade. The liberalization and integration of global financial markets began in the 1980s, but accelerated significantly in the 1990s. For example, data from the Bank for International Settlements indicate that global foreign exchange turnover increased from U.S. $620 billion in 1990 to U.S. $3.2 trillion in 2007. Potential benefits that can emerge from these changes include improved resource allocation from countries specializing in financial services; increased portfolio

diversification; improved competition in the financial sector; and increased market discipline on policymakers. Such changes can have positive effects on the overall growth and development of the countries involved.

That said, these changes in the landscape of global finance have also been associated with repeated episodes of significant turbulence. For example, in 1992 93, Europe was faced with the very real possibility of a complete collapse of the European Exchange Rate Mechanism (ERM). In 1994 95, the Mexican currency crisis involved a steep devaluation of the peso and brought Mexico to the brink of default, with spillover effects on Argentina and Brazil. Between July 1997 and mid-1998, the world experienced the effects of the East Asian crisis, which started somewhat innocuously with a run on the Thai baht, but spread swiftly to a number of other regional currencies, most notably the Indonesian rupiah, Malaysian ringgit, Philippine peso, and Korean won. Other large emerging economies, such as Russia and Brazil, also experienced periods of significant market weakness and required the assistance of the International Monetary Fund. The Russian ruble was devalued in August 1998, while the Brazilian real's fixed rate to the U.S. dollar was eventually broken in January 1999. A number of other smaller emerging economies, such as Turkey and Ecuador, also experienced currency and financial crises in the 1990s.

Another striking change has been the reversal of capital flows from developed to developing countries. Due in large part to the emergence of a significant current account deficit (i.e. spending in excess of national saving) in the United States and involving the official transactions of central banks, the developing world is now an *exporter* of capital to the developed world rather than an importer. In fact, the flow of international capital from developing countries to developed countries is now one of the key paradoxes of the global economy, as is the fact that foreign governments and central banks have become major participants in global financial markets via the creation of sovereign wealth funds.

Finance-related entries in the *Encyclopedia* reflect these important changes. Standard models of inter-

national finance and open-economy macroeconomics are covered, including the interest parity conditions and the Mundell-Fleming model, and a host of basic concepts such as balance of payments, capital flight, currency crisis, and sterilization. These are supplemented with more recent theoretical contributions such as the New Open Economy Macroeconomics. Entries on policy instruments include capital controls, hedging, and foreign exchange intervention, to name a few. Coverage also includes the basic analytical tools of the field, such as early warning systems and exchange rate forecasting, as well as special topics such as financial services, sequencing of financial sector reform, recycling of petrodollars, and money laundering.

International Production

As mentioned earlier, a key change in the world economy has been in the structures of international production of goods and services, as multinational enterprises (MNEs) engage in varieties of foreign direct investment (FDI) with managerial influence over foreign-based productive enterprises. Drawing on both the work of earlier theory in international business and new developments in trade theory, economists have incorporated MNEs and FDI into the theory and practice of international economics. At the same time, issues such as outsourcing and offshoring have attracted public attention and increased political interest in this area. This has occurred both in high-income countries, where outsourcing has moved to white-collar as well as blue-collar occupation categories, and in developing countries, where new income-generating possibilities have emerged outside of manufacturing.

When deciding to become a MNE, a firm chooses the mode that maximizes its profits, typically considering such options as exporting and licensing a local firm (outsourcing/offshoring) as alternatives. Consequently, models usually revolve around the trade-offs between FDI and at least one alternative. In these models, the location of production differs between FDI and exporting, and whether transactions

occur within the firm differs between FDI and licensing.

Like trade, much FDI occurs between similar, developed countries and is often two-way, but FDI has grown even more rapidly than trade. A large share of world trade (about 30 percent) occurs *within* firms and is known as intrafirm trade. MNEs tend to arise in industries with large research and development expenditures relative to sales, significant product differentiation, and substantial intangible assets such as intellectual property and brand value. FDI is mostly horizontal   with MNEs creating local production facilities in each country and selling within each country or region   rather than vertical, in which MNEs allocate production processes across countries and ship the products back home.

Our coverage of international production begins with issues of theory, from long-standing pursuits such as location theory to emerging issues of importance such as FDI under monopolistic competition and oligopoly. These more formal considerations are again supplemented with a set of entries on basic concepts, from FDI and MNEs themselves to intangible assets and technology licensing. Coverage of policy instruments includes entries on domestic content requirements, foreign equity restrictions, and trade-related investment measures more broadly. We also cover specific analytic tools such as market size and exchange rates as they relate to FDI. Finally, the book addresses several special issues related to FDI, such as FDI and export performance and FDI and labor markets.

International Economic Development

Due to the huge disparities in standards of living around the globe and the tremendous impact, for good or ill, of international economic transactions in the development process, the ideas and policies that shape economic development are subject to ongoing and highly charged debates. In entries on influential development institutions, such as the World Bank, and policy frameworks, such as import substitution industrialization and the Washington consensus, our

goal is to explain these debates without attempting to resolve them. Entries on economic development and the evolution of development thinking are designed to provide the reader with a conceptual framework and a context for understanding the issues addressed in entries such as international migration, international trade and economic development, and technological progress in open economies.

Since the 1990s, development thinking has shifted toward recognizing the central importance of political processes in structuring and potentially limiting economic development. Reflecting this shift, the *Encyclopedia* attempts to view the economic processes of development in the broader context of political decision-making. This emphasis on political economy is apparent in many of the entries on economic policy and takes center stage in entries that address the linkages between economic and political systems, such as those on democracy and development, corruption, and international aid and political economy. Finally, while most of the development entries take the national economy as their starting point, entries on global poverty, global income inequality, and international income convergence take a deliberately transnational approach, reflecting the growing consensus that it is now meaningful to view some issues from the perspective of a single global economy.

Using the Encyclopedia

There are a number of ways to engage with the encyclopedia. Entries are arranged in alphabetical order. If you are uncertain of the particular entry that may be most appropriate to your interest, you can consult the Topical List of Entries, which groups the entry terms by category. You also can consult the index to find topics that are covered in related entries but do not have entries of their own.

At the end of most entries you will find "See also" references to other entries related to the topic at hand. Each entry concludes with an annotated Further Reading list to guide readers with an interest in additional research.

◼ absolute advantage

A country is said to have an absolute advantage over another country in the production of a good or service if it can produce that good or service (the "output") using fewer *real* resources (like capital or labor, the "inputs"). Equivalently, using the same inputs, the country can produce more output. The concept of absolute advantage can also be applied to other economic entities, such as regions, cities, or firms, but we will focus attention on countries, specifically in relation to their production decisions and international trade flows. The fallacy of equating absolute advantages with cost advantages is a never-ending source of confusion. Deviations between the two are caused by the fact that real resources may receive different remunerations in different countries.

In reaction to the mercantilist literature of the 17th century (which advocated state regulation of trade to promote wealth and growth), a doctrine of free trade emerged at the end of the 18th century, culminating in 1776 in Adam Smith's masterpiece, *An Inquiry into the Nature and Causes of the Wealth of Nations*. Drawing on the work of others, Smith was able to put many different arguments and elements together in a coherent and systematic framework, organized using a few general principles, and thus providing a new way of thinking about political economy (Irwin 1996). Smith thus provided the first *analysis* of economic reasons for advocating a policy of free trade and, according to Joseph A. Schumpeter (1954, 374), "seems to have believed that under free trade all goods would be produced where their absolute costs in terms of labor are lowest."

Smith's arguments can be summarized as follows. First, he points out that regulations favoring one industry draw away real resources from another industry, where they might have been more advantageously employed (opportunity costs). Second, he applies the opportunity cost principle to individuals in a society   for example, by pointing out that the tailor does not make his own shoes (which would cost him a lot of time) but buys them from the shoemaker (who can produce them more efficiently). Each individual is therefore specializing in the production of those goods and services in which he or she has some advantage. Third, Smith applies the same principles of opportunity costs and specialization to international commercial policy and nations. It is better to import goods from abroad where they can be produced more efficiently, because this allows the importing country to focus production on the goods it can itself produce efficiently. The primary (classical) reason for international trade flows is therefore a difference of technology between exporter and importer.

Principle of Absolute Advantage To illustrate the principle of absolute advantage, suppose that there are two countries (the United States and Japan) producing two goods (food and cars), using labor as the only input. Assume that goods can be traded without costs and workers are immobile between the two countries, but mobile between the two sectors within a country. All workers in a country are equally productive. Production technology in Japan differs from that in the United States (see table 1). We assume that Japan requires three units of labor to produce one unit of food, whereas the United States

Table 1
Productivity tables, an example of absolute advantages

	a. Units of labor required to produce one unit of output		b. Units of output produced with one unit of labor	
	food	cars	food	cars
USA	2	8	1/2	1/8
Japan	3	6	1/3	1/6

requires only two units of labor. Similarly, Japan needs six units of labor to produce one car, whereas the United States needs eight units of labor. Since Japan is more efficient in the production of cars and the United States is more efficient in the production of food, Japan has an absolute advantage in the production of cars and the United States has an absolute advantage in the production of food.

To show that specialization of production, coupled with international trade flows according to absolute advantage, can be advantageous, in our example suppose that the United States produces one car less. This frees up eight units of labor, which can now be used to produce $8/2 = 4$ units of food (opportunity cost of car production in the United States). The United States has now produced one car less and four units of food more. Suppose that the United States wants to consume the same number of cars as before. It must then import one car from Japan. To produce this car Japan needs six units of labor. These laborers must come from the food sector, where production therefore drops by $6/3 = 2$ units of food (opportunity costs of car production in Japan). Now note that the total production of cars has been unchanged (one car less in the United States and one car more in Japan), while the total production of food has increased by two units (four units more in the United States and two units less in Japan). These extra units of food reflect the potential gains from specialization if both countries concentrate in the production of the good they produce most efficiently. In principle, both countries can gain: for example, if they exchange three units of food for one car.

Complications and Limitations There are several caveats to the foregoing analysis, some of which we discuss now.

Absence of absolute advantage: The example discusses a situation where one country has an absolute advantage in the production of one good and the other country in the production of another good. It is frequently argued that developing countries may lack the technology to gain an absolute advantage in the production of *any* good, such that they cannot possibly compete on the global market and benefit from free trade (in table 1, for example, if the United States needs four laborers to produce one unit of food). This conclusion is wrong, however, according to David Ricardo's model of comparative advantage (which emphasizes labor as the primary production factor and attributes the costs and benefits of trade to the differences in opportunity costs among countries), since technologically disadvantaged countries can compete on the global market by paying lower wages. It turns out that absolute advantage is neither a necessary nor a sufficient condition for exporting a certain good and gaining from international trade.

More factors of production: In reality, goods are produced using several factors of production simultaneously, such as capital, land, and various types of labor. Usually, goods then cannot be ranked according to absolute advantage as their production in one country requires more of one input and simultaneously less of another input than in another country. These issues are analyzed in the Heckscher-Ohlin (factor abundance) theory of international trade.

Intra- versus interindustry trade: The example discusses interindustry trade, which is the exchange of one type of good (cars) for another type of good (food). Many countries engage in intraindustry trade, the exchange of similar types of goods (e.g., simultaneously exporting and importing car parts). This type of trade is becoming ever more important. It can be based on market power and economies of scale, as analyzed in New Trade Theory.

Absolute Advantage, Income, and Wages Despite the limitations and complications just discussed, absolute advantages (as reflected by differ-

ences in technology) *are* important for explaining current international trade flows and differences between countries in terms of income levels and wage rates. Daniel Trefler (1995) systematically analyzes these issues by combining the Heckscher-Ohlin model with technology differences, while taking into consideration the empirically observed home country bias (a consumer preference for domestically produced goods over otherwise identical imports). This combination explains about 93 percent of international trade flows. It also shows that technology differences are largely responsible for the deviations in income levels (and wage rates) between, say, the African countries and the high-income countries of the Organisation for Economic Co-operation and Development. For this reason absolute advantage does retain relevance for understanding the modern world economy.

■ **access to medicines**

The term *access to medicines* encompasses the array of problems faced by the world's lowest-income inhabitants, who often cannot afford, or do not have access to, medications that could greatly reduce the disease burden under which they suffer. The problems include deficient medical infrastructure, imbalances between prices and ability to pay, and the lack of incentive to develop medicines that would treat diseases endemic to low-income nations.

During the 20th century, numerous technological breakthroughs in pharmaceutical therapy made it possible to cure or at least alleviate most of the diseases that have killed or debilitated millions of people each year. But the ability to purchase those medicines is concentrated in relatively affluent nations, where the vast majority of pharmaceutical sales occur. At the other extreme, roughly 60 percent of the world's population live in nations defined by the United Nations in 2000 as "low income," with per-capita gross national product averaging less than $530 (at prevailing exchange rates) a year in 1998. The World Health Organization (WHO) (2004, 61) estimates that in 1999 those nations made only 2.9 percent of the world's pharmaceutical purchases. The WHO has predicted that by expanding access to available health interventions, and especially essential medicines, 10.5 million lives could be saved annually by the year 2015. Lack of access to medicines and complementary health care in turn perpetuates a vicious spiral: poor health impairs productivity and economic development, while low productivity keeps the citizens of the least-developed nations too poor to afford appropriate health care.

Affordability The medicine access problem has several facets. The overriding problem is inability of individuals to afford medicines. Health insurance is an absent corrective; an estimated 90 percent of the people in developing nations lack such insurance. Inability to pay restricts not only the demand for medicines but also the supply of physicians able to diagnose diseases and recommend appropriate therapies. Nations classified as low income in 1998 by the United Nations had 70 physicians per 100,000 population; those classified as high income, 252. In

many instances, the only advice available comes from traditional practitioners whose herbal remedies may work for some indications, but with at best erratic success due to the lack of evidence from controlled experiments. For diseases such as AIDS, malaria, and tuberculosis, carefully administered therapy regimens must be maintained to inhibit the emergence of resistant strains. Counterfeit versions of first-world drugs continue to be a significant problem, in part because third-world health-care authorities lack systematic testing and approval institutions.

In their efforts to combat the burden of disease, health authorities at the WHO and in individual less-developed nations have since 1977 published "model lists" of so-called essential drugs. Drugs have been included on the list in part because of their proven efficacy and partly because of their relatively low cost. Low cost in turn has been achieved by emphasizing generic drugs, that is, those on which patent rights restricting supply to a single firm have expired. Historically, more than 90 percent of drugs on the WHO's model lists have been generics. However, this emphasis was threatened by the emerging epidemics of HIV/AIDS and related opportunistic diseases such as resistant tuberculosis and cryptococcal meningitis. Virtually all of the drugs effective against those diseases were patented and, at least initially, available only at costs for a year's treatment exceeding total average incomes of citizens in low-income nations.

The Trade-Related Aspects of Intellectual Property (TRIPS) agreement culminating the World Trade Organization's (WTO) Uruguay Round Treaty, signed at Marrakech in April 1994 and implemented in 1995, exacerbated this situation. Up to that time, many less-developed nations, emulating some more prosperous countries, were able either to produce or, more likely, import patented drugs because they granted no patent rights on pharmaceutical product inventions. TRIPS required that signatories to the Marrakech treaty begin awarding such patents within one year for the wealthiest nations, five years for middle-income countries, and ten years (later extended to the year 2015) for the least-developed nations. Transitional provisions also re-

quired grants of marketing exclusivity for post-1994 inventions on which initial patent applications were filed. Especially for AIDS and AIDS-related diseases, this posed special problems. Up to that time, the newest and most effective drugs might be available generically from India and other nations that had not awarded pharmaceutical product patents. But as the TRIPS provisions began to bind on India, Brazil, South Africa, and other nations, their ability to continue supplying low-cost generics atrophied.

The combination of TRIPS and the AIDS epidemic precipitated a crisis. Two main solutions emerged. First, at a joint WHO WTO conference in Høsbjør, Norway, in April 2001, a consensus emerged encouraging the world's leading research-oriented pharmaceutical companies to practice "differential" or "Ramsey" pricing. The companies would charge high prices in rich nations and make life-saving drugs available to consumers in low-income nations at prices approaching marginal cost. From what had been near parity of AIDS drug prices across rich and poor nations (Scherer and Watal 2002), wholesale prices were shown by Lucchini et al. (2003) and the UK Department for International Development (2005, 22) to have plummeted in the least-developed nations, in some cases by as much as 98 percent. One consequence of such discriminatory pricing was the reexport of low-price drugs to high-price nations, but steps to suppress this "parallel trade" were quickly implemented. Donations from multinational pharmaceutical firms to organizations providing health care in less-developed nations in effect, sales at a zero price also helped increase access to essential medicines.

Second, because of exceptions written into the original TRIPS agreement, nations were able to threaten or actually implement compulsory licensing of existing or new patents on AIDS and other epidemic disease drugs in order to authorize generic production. Threats of compulsory licensing induced multinational patent holders to reduce sharply the prices of their branded drugs in the third world and enter into voluntary agreements with such nations as Brazil and South Africa to permit generic supply. A limitation in the original TRIPS text was

that production under a compulsory license was to be "predominantly for the supply of the [Member's] domestic market." However, many of the world's least-developed nations lacked both the technological know-how and sufficient market scale to produce generics for their own use. A permissive amendment to the TRIPS agreement accepted in August 2003 following a mandate issued at the Doha Round of international trade negotiations in 2002 alleviated this problem. The TRIPS agreement does not require nations formally to report compulsory licensing decrees, and as of 2006, only an AIDS drug license by Thailand to a government entity, minimally controversial under TRIPS, had come to light publicly. The existence of other unreported cases cannot be ruled out. Alternatively, post-2000 price and voluntary license developments may have been sufficient to satisfy the limited ability of low-income nations to distribute drugs effectively.

Incentives for Drug Development Another fundamental problem preventing access to medicines is the lack of innovative drugs targeted specifically toward diseases prevalent only in the third world, for instance, sleeping sickness, Chagas disease, and leishmanisais. Because low-income nations have limited purchasing power, multinational pharmaceutical firms lack demand-based incentives for research and testing on drugs targeted toward the so-called tropical diseases and the resistant strains that continue to evolve. A study for Medicins sans Frontières (2001) revealed that among 1,393 new drug chemical entities introduced into world markets between 1975 and 1999, only 13 (or 15 counting tuberculosis) drugs were indicated for tropical diseases. Also deficient has been the development of vaccines that could *prevent* diseases curable using modern medicines, but at costs too high to be sustained by overstressed third-world medical care providers.

Here too the AIDS crisis played an important role in inducing corrective initiatives. Some large multinational pharmaceutical companies, seeing the problem as a moral challenge, increased research and development (R&D) efforts targeted at third-world diseases and established new laboratories nearer the potential markets. Private philanthropic organiza-

tions such as the Gates Foundation have provided generous subsidies to support R&D on new drugs and vaccines to combat third-world diseases. Their efforts complemented the work of the UN AIDS initiative and similar programs by national governments. In 2005 6, delegates from the world's eight largest market economies (the G-8) approved in principle a program to stimulate the development of vaccines by agreeing to purchase at generous pre-specified prices $3 billion worth (in each category) of new vaccines effective against AIDS, malaria, and tuberculosis. However, as of 2006, the G-8 member nations were tardy in backing their good intentions with actual purchase guarantees and the national budget commitments necessary to implement them.

Progress is being made in increasing the supply of affordably priced medicines to low-income nations, but much remains to be done. Overcoming the remaining barriers to access to medicines could alleviate disease worldwide and contribute to economic development.

■ **African Caribbean Pacific–European Union (ACP-EU) partnership agreements**

The trade and development relationship between the European Union (EU) and the African, Caribbean, and Pacific (ACP) countries has been shaped by a number of formal treaties and agreements since the end of World War II. The aim of these agreements has been to promote, with EU participation, opportunities for growth and development among the ACP countries by both direct and indirect policy measures. The more direct methods have included development funds, investment loans, and compensatory payments, while indirect methods have centered on trading arrangements and protocols that favor exports from ACP countries in a bid to generate growth. Underpinning these specific aspects, though, has been a more general focus on engendering wider social, political, and economic development as part of an understanding (often referred to as the *acquis*) between the EU and the ACP countries, which reflects the fact that the relationship is not only a trading club.

The Treaty of Rome, which established the European Economic Community (EEC) in 1957, included a section entitled "The Association of the Overseas Countries and Territories." This made specific provisions for the relationship between the EEC and the overseas territories and former colonies of member states under Articles 131 to 136. The association with former colonies of the six members of the EEC was designed "to promote the economic and social development of the countries and territories and to establish close economic relations between them and the Community as a whole" (Article 131, Treaty of Rome). In practice, these arrangements had their greatest effect on the former French colonies in West Africa and the Caribbean. Preferential trading arrangements formed the major part of the association with a commitment to review the policy after five years.

The Yaoundé Conventions The first review produced a new set of arrangements embodied in the first Yaoundé Convention (or Yaoundé I) signed on July 20, 1963, in the Cameroon capital by 18 countries of the Association of African States and Madagascar (AASM) and the six EEC states. Yaoundé I aimed to encourage the development of the AASM countries mainly by allowing preferential treatment of their manufactured exports into the EEC, but with only limited preference for agricultural exports. In return, the EEC was permitted to export limited volumes of manufactures to the AASM with similar duty arrangements. In addition to trade provisions, there was also agreement on technical and financial issues, on rights of establishment that allowed for, among other commercial features, the establishment of companies in associated states, and also on the institutions that would oversee the governing of the convention. The agreement ran from 1964 to the end of 1969.

Countries that were not part of the Yaoundé I sought associate status. Under the Arusha Agreement signed in Tanzania on September 24, 1969, Kenya, Tanzania, and Uganda negotiated associate status with the EEC. This came into force at the same time as the second Yaoundé Convention (Yaoundé II), which was in effect from 1971. While reenforcing the preferential and reciprocal trade arrangements, Yaoundé II also included provision for investment by the EEC in the associated states. Specifically, funds were provided mostly for the European Development Fund (EDF) with a small amount going to the European Investment Bank (EIB) for loan-supported project work. The specific aim was to broaden the relationship between the two groups, from trade policy to wider development areas. The Arusha Agreement only contained trading elements and none of the financial aid offered under Yaoundé II.

From Yaoundé to the ACP In 1975, the developing country signatories to the Yaoundé Conventions formed a new alliance with the 20 Commonwealth countries associated with the United Kingdom (UK). The new body was called the African Caribbean and Pacific (ACP) Group. The terms of this new body were established within the Georgetown Agreement. The main aim was to coordinate negotiations for ACP countries with the EEC, a process that had begun in 1973 as part of a review of Yaoundé II. The negotiations were concluded with the signing on February 28, 1975, of the first Lomé Convention (Lomé I) in Togo, by 46 ACP countries and the then nine EEC Member States.

Lomé I had a number of provisions but the key ones again related to trade. Free access for most ACP exports to the EEC, although unlike Yaoundé II without reciprocal terms, lay at the heart of it. In addition, the agreement introduced specific protocols for sugar, rum, bananas, and beef and veal. In the Sugar Protocol, for example, the EEC agreed to volume import quotas of raw (cane) sugar from ACP producers at a guaranteed minimum price. The protocol reflected the UK's entry into the EEC and its established trading agreements with its former colonies. ACP sugar producers were allocated quotas for exports with the aim of aiding their producers

without harming EEC producers of beet sugar. The other commodities had similar export quota and guaranteed price arrangements, although beef and veal saw refunds of tax at 90 percent on imports.

In addition to these trade arrangements, the convention also provided for a Council of Ministers. This body was drawn from members of the Council and Commission of Ministers for the EEC and representatives from each ACP country, with the presidency alternating between the two groups. The other significant innovation was a change in the nature of EDF financing. The STABEX (shorthand for stabilization of export earnings) scheme aimed to provide stabilizing finance when export earnings fell due to a decline in prices for a producer's main (often primary) exports. This reflected the concerns about volatility in world commodity prices and the impact on exporters and countries' macroeconomic planning and policies. Coupled with further EDF and EIB monies, the convention moved explicit financial aid more prominently into the relationship between the EEC and the ACP, albeit with a continued emphasis on expenditure on infrastructure.

Lomé II was agreed and signed in 1979. Although it did not offer new trading provisions, within its EDF provisions it did introduce SYSMIN (stabilization of export earnings from mining products), a system of loans for helping the mining industries in those countries that relied heavily on exports of minerals for revenue generation, to diversify into other sectors. Lomé III (1984) signaled a shift from direct encouragement of export-led growth to encouragement of self-sufficiency and especially security of food supplies. Rural development was promoted as a means of achieving these goals. Finally, Lomé IV (1990) covered a 10-year period with a five-year review of financial support. However, it also became apparent that wider social issues, such as the environment, women's roles, and diversification of the economy were given much greater prominence as the ACP countries continued to develop. The EU recognized a desire for greater self-determination of policy.

A major review of the Lomé Convention came in 2000. The Cotonou Agreement of 2000 was signed

in Benin and built on the Lomé acquis but took a new, longer-term approach to the political, trade, and development aspects of ACP-EU relations. Globalization had appeared to pass many ACP countries by, with their share of foreign investment flows being very small and their trade shares equally limited. Tied to decreasing donor aid, this presented a problem that the Lomé IV had not dealt with. Indeed, compliance with World Trade Organization (WTO) rules meant protective trade arrangements could no longer provide an answer even if they were desired. Instead, focus on poverty reduction via good governance, macroeconomic stability, and new trading arrangements increased. To integrate ACP countries more fully with global markets, the EU liberalized virtually all imports from least-developed countries (LDCs), not just ACP countries, under a General System of Preferences (GSP). The protocols for sugar and beef and veal remained, however. Funding was now via grants totaling 11.3 billion euros and for risk capital, which totaled 2.2 billion euros.

In 2001 the EU concluded its amendment of the GSP and developed its "Everything but Arms" policy. This policy extended duty-free access to all LDC exports apart from arms and munitions, with some restrictions still applying over a longer period for bananas, rice, and sugar. Of the 48 LDCs, 39 were ACP (Cotonou signatory) countries.

The WTO continued to put pressure on the EU to move away from preferential treatment of ACP exports, and in 2002 Economic Partnership Agreements (EPAs) became the focus for ACP-EU trading relationships. The negotiations with regional groupings sought to encourage partnership, regional integration, development, and ultimately integration of the ACP countries into the WTO. EPAs were scheduled to be in place by 2008.

Given the scope, scale, and relative complexity of the various ACP-EU agreements, it is possible to view them as central to a continuing process of different countries working together for mutual benefit. Although not comprehensive in either geographic or economic coverage, ACP-EU agreements have played a major role in shaping trading policies for many countries and have offered possible options for others to follow.

■ African Union

Open to all countries in the African continent, the African Union (AU) is an organization designed to foster political and economic cooperation and development among its member countries. To such ends, it stands ready to address any and all issues relevant to state building, security, and economic development and integration among countries on the African continent. Hence the AU can contribute to factors deemed essential to greater integration of the continent in the world economy. It was officially launched on July 9, 2002, replacing the Organization of African Unity (OAU), whose charter was signed on May 25, 1963, with an original membership of 33 countries; the AU has 53 members. The headquarters are in Addis Ababa, Ethiopia, although the various organs can be located in other member states; for example, the Pan-African Parliament is in Midrand, South Africa.

Political Stability and Security In order to advance political stability and security, the AU focuses on conflict resolution within and between states, peer review among the African states to facilitate state building and the democratization process, and building solidarity to increase the leverage exercised by African countries at the international level. Still, the AU has found it difficult to speed up democratic transition in the continent; impediments to this transition include the manipulation of institutions by elites or breakdowns in the democratic political process because of ethnic conflicts or political fragmentation. The AU has also been handicapped in dealing with the resolution of conflicts in which the sources of conflict are deep seated and the combatants well armed.

With few exceptions, the AU has supported the territorial integrity of the African states since independence from colonialism, as well as noninterference in the internal affairs of those states. Enshrined in the Constitutive Act of the AU are the "condemnation and rejection" of "political assassinations," "subversive activities," and "unconstitutional changes of governments." Moreover, the AU has pronounced resolutely in favor of human rights. Thus one of the tenets of the Constitutive Act is the "right of the union to intervene in a Member State pursuant to a decision of the Assembly in respect of grave circumstances, namely war crimes, genocide and crimes against humanity."

Economic Integration The economic integration program of the AU is contained in the June 1991 Treaty Establishing the African Economic Community (AEC) signed in Abuja, Nigeria. That treaty has been operational since May 1994. The plan contained in the treaty calls for the AEC to reach fruition after a period of 34 to 40 years from 1994. The consequence, among other things, would be a single domestic market and a Pan-African Economic and Monetary Union, a single African Central Bank, and a single African Currency. A number of regional economic communities (RECs) operate under the aegis of the AEC, as part of the transition to full, continentwide union, namely, the Arab Maghreb Union (AMU), the Economic Community of the Central African States (ECCAS), the Common Market for Eastern and Southern Africa (COMESA), the Southern African Development Community (SADC), and the Economic Community of West African States (ECOWAS).

Progress in economic integration has been hampered by certain political and economic strains, overlapping membership among the RECs, competing subregional groupings within RECs, and a lack of clear commitment to integration among the populations and the political leadership. Political difficulties have included personal animosity among heads of states and governments; ideological differences among leaders; deep-seated disputes such as that over the Western Sahara (independence for a Sahrawi Arab Democratic Republic), in the case of the AMU; and regional conflicts, as in the Great Lakes area for ECCAS. But prospects are improving in these respects: Increasing democratization and acceptance of market solutions to economic problems are reducing ideological differences. Conflicts involving many states simultaneously are diminishing in number and those that remain are being better handled by the AU. Moreover, proponents of integration have been working hard to ensure that institutions and organizations of regional economic communities can function in spite of temporary personal hostilities in high political circles.

There is need to rationalize membership of RECs by encouraging countries to join only one. Also, subregional organizations with the same goal of economic integration exist. The best example is the East African Community (EAC), the three members of which are also members of either COMESA or SADC. In addition, the Francophone African countries are apparently happy with their monetary union arrangements. But they have been expanding their cooperation objectives in the direction of general economic integration, despite their membership in ECOWAS and ECCAS.

Economic obstacles to integration include (1) fear of a loss of national sovereignty over macroeconomic policy to some union authority or body; (2) disagreements over the nature and content of protection of local industries through tariffs and nontariff

barriers, which reduce certain imports of commodities and services from outside an REC; and (3) concern about unequal distribution of gains and losses of REC membership. The RECs continue to make progress toward resolving these issues.

For instance, a common external tariff is an important objective of the RECs, and the structure of a tariff system has important implications for the protection bestowed on different commodities. If a simple rule were established, such as equal protection for all commodities, then the determination of tariff rates could be left to technical experts to decide. But to assist infant industry and foster industrial development, African countries want differential protection. Given the economic structure and the state of development of the various countries concerned, different schedules of tariff rates have dissimilar implications for comparative advantage of the countries. Hence, such considerations seriously affect discussions of the detailed tariff schedules to be put into effect.

Many in the continent fear that gains to countries from economic unions will be positively related to the degree of their economic development and/or the size of their domestic economies. The allegedly "unfair" distribution of gains and losses is widely believed to have been at the root of the breakup of the first EAC, where it was felt that Kenya's industrialization was greatly helped but, in the process, Tanzania's may have been adversely affected. An attempt to use differential intraunion tariffs designated transfer taxes could not alleviate the problems, at least not to the satisfaction of Tanzania.

In general, many want some kind of internal (intraunion) tariff structure that protects some national domestic production activities from direct competition within an REC. But once the principle is accepted (and applied) that the location of industries among countries should be determined in a world of open competition and free mobility of all factors of production including labor, rather than in an arena of negotiated industrial planning buttressed by restricted mobility of factors, especially labor, the case for transfer taxes becomes weak.

A challenge would still remain as to how to balance such a market-oriented approach to the location of industries with permitting selective intervention of governments for economic development of the countries, as deemed useful by all the countries. The difficulty would be compounded by the need to observe certain macroeconomic constraints set by the union as a whole for example, limits on government budget deficits and on government debt in relation to gross domestic product.

Differences in taxation systems and structures also continue to engender issues of unequal gains and losses. In particular, countries have different reliance on import taxes as sources of government revenue. This fact has slowed down reduction of intraunion tariffs, since a formula to compensate those who will lose tax revenue from large intraunion tariff reductions is not easy to negotiate. Thus countries realize they need to reform their tax systems to lessen their dependence on import taxes if substantial and rapid intraunion tariff reductions are to occur in practice. The attempts of countries to reform their tax systems and to move toward greater reliance on income, profits, and value-added taxes should be of help in this regard.

One theme in the integration debate in the African continent is the degree to which African leaders are committed to full economic integration in the foreseeable future. For many of the countries, intraregional trade is very small in relation to extraregional trade, and the countries in each of the regions often produce similar goods. Hence countries sometimes do not feel an urgent need for a common market, given the widespread belief that integration would not yield substantial economic benefits for some time.

Still, every single leader of the countries voices the view that, in time, the benefits of integration will be substantial, as the effective size of domestic markets will greatly enlarge, so that technological economies of scale can be realized and the returns to investment enhanced. Hence it is along these lines that the most fervent proponents of integration have argued their case. Those who prefer a slower pace are content to

push now for (1) promotion of greater intraregional trade, employing the instrument of a common external tariff, probably supplemented by some form of transfer tax or *taxe de coopération regionale*, until full labor mobility becomes socially and politically feasible; (2) cooperation in infrastructure and industrial "regional" projects; and (3) some harmonization of policies (especially macroeconomic) as feasible. This could be followed, in the eyes of the gradualists, by some form of monetary union. Only later, when mass support for integration is strong and ideological obstacles are minor, according to this perspective, should full integration be pursued.

Governance and the African Peer Review Mechanism The AU aims at improving *governance* in African countries, in a context of enhanced country *ownership* of policymaking. In 2001, the AU launched the Millennium Partnership for the African Recovery Program (MAP). It was billed as a pledge by African leaders to take decisive steps to improve governance, reduce poverty, and enhance economic growth of their countries. In particular, it claimed that a new crop of leaders was emerging in Africa committed to democracy and the integration of their countries into the world economy. It called for "a new relationship" with the international community, especially the industrial countries: African countries would take charge of their own destiny, and the rest of the international community was called on to make a concerted effort to enhance resource flows to the continent via "improvements" in aid, trade, and debt relationships. Several goals were specified, including most notably achieving a 7 percent average annual growth rate of gross domestic product over the following 15 years. Among the "policy thrusts" to achieve the objectives would be negotiating "a new partnership" with the industrialized countries and multilateral organizations. African "ownership, leadership, and accountability" were thus highlighted as central elements of the MAP. The African peoples were henceforth going to set and direct their agendas and shape their own destinies. This, then, is the idea of the New Partnership for Africa's Development (NEPAD).

Within the NEPAD framework, the African countries have instituted the African Peer Review Mechanism (APRM). Participating countries will do self-assessments, using the services of domestic autonomous bodies and individuals who in turn involve business and civil society groups throughout the countries. The governments will then draw up programs of action to address weaknesses identified in the self-assessments in the areas of political governance, economic governance, corporate governance, and socioeconomic governance. Review teams of African experts will visit the countries to assess the integrity of the self-assessment exercise and make recommendations, including on the action plans of the governments. Future expert teams will visit to review progress in implementing the action plans. Central in this arrangement will be a panel of eminent persons of the continent, overseeing the APRM processes to ensure their integrity and guiding the preparation of the country reports drafted mainly by the experts to be presented to the African Peer Review Forum. This forum comprises heads of state and government of participating countries (the "peers").

If high and transparent standards are maintained, the APRM can be an effective means of separating those African countries committed to good policies from the rest, because only those countries whose leaders are committed to implementing good policies will want to have their progress continuously reviewed and made known to the global community. In this respect, the APRM could address a major credibility problem: Africa as a region is considered high-risk for investors, and the credit ratings of countries within the region are adversely affected simply by their being there. The APRM can contribute to separation of African countries into those with good policy environments and those without. In addition, if the reports get widely circulated within the continent, and especially in those countries that have chosen not to participate, the APRM will help provide essential information to potential actors in civil society.

Moreover, if the APRM is to have any effect on NEPAD, and especially influence the aid and debt

relationships, it would be important that it become credible among aid donors, who then allow it transparently to influence their aid policies. Those of the international community interested in providing aid to support good policies may want to see evidence that the APRM is influencing governance in the right direction, for recent research in the social sciences has concluded that good policies emerge exogenously, when countries own such policies and voluntarily adopt them.

Future of the African Union The AU is poised to have an enhanced, though still limited, role in the world economy in the foreseeable future. Its efforts are bringing peace, political stability, and democratization to African states. Peace and political stability are good for economic growth and democratization improves governance. But good political leadership remains elusive and this ultimately is the route by which the political regime has its greatest influence on economic growth. The AU is not likely to have much influence on political leadership in individual African countries. Economic integration also will proceed more slowly than envisaged by official AU pronouncements. But economic cooperation will accelerate, leading to faster infrastructure development, policy harmonization within the regional economic communities, and more efficient and development-oriented industrial, agricultural, and service projects. Moreover, in arenas such as the International Monetary Fund, the World Bank, and the World Trade Organization, African countries more frequently will speak with one coherent voice under the aegis of the AU.

See New Economic Geography

■ **agglomeration and foreign direct investment**

The spatial clustering of foreign direct investment (FDI) is clearly visible in the location of multinationals investing in the United States, the European Union, China, and other regions. This agglomeration is at least partly the result of policy, as in China's special economic zones, but spatial concentration is also characteristic of domestic firms and of FDI in economies with few controls. These observations suggest that market forces, as well as policy, lead to clustering.

That new establishments tend to go to the same locations as earlier entrants suggests that productivity rises with the level of economic activity, especially as firms often must pay higher land prices to locate in clusters. If such productivity-enhancing effects, or

agglomerative economies, exist and spill over to domestic activities, a case may be made for government incentives to multinationals to induce local affiliate production. Indeed, dozens of countries favor FDI through tax breaks and subsidies. Through these incentives, governments hope to begin a self-reinforcing process whereby subsidized early entrants attract additional investment.

To better design such policies, researchers have sought evidence that agglomerative economies exist and, if they do, the extent of their benefits to local productive factors. Location-choice studies seek to measure the attractiveness of local characteristics for foreign investors and thus provide a way to estimate the self-reinforcing power of FDI. Virtually all location-choice studies find that the existing stock of foreign investment is a significant predictor of the location a multinational will choose for new local affiliates. However, most countries receive a relatively small number of new multinational affiliates in a given year and for these projects there is often limited information, constraining our ability to identify the specific sources of agglomerative economies.

Head and Ries (1996) observe a relatively large number of investment projects, 931 equity joint ventures in 54 Chinese cities from 1984 to 1991. Their study is noteworthy for its careful modeling of the agglomerative process, emphasizing local input sharing as the source of positive firm spillovers. Using conditional logit analysis to estimate the likelihood that a particular city is chosen as the investment site, Head and Ries find that agglomerative economies greatly magnify the direct impact of government incentives. Their simulation analysis suggests that two-thirds of the gains from incentives can be attributed to the self-reinforcing nature of earlier investments. Not all locations gained equally, however, as cities considered attractive for other reasons, such as infrastructure and industrial base, gained the most. Similarly, Devereux, Griffith, and Simpson (2007) find that firms are less responsive to government subsidies in areas where there are fewer established plants in their industry.

Evidence that past investment increases the likelihood of new investment does not necessarily imply the existence of agglomerative economies. Agglomeration arises because there are benefits to locating near similar firms and because certain locations have natural advantages features of a location that are independent of firm location decisions. A common example of how natural advantages influence location choice is the North American steel industry, which concentrated in the Great Lakes region largely because of the location of iron ore and coal deposits. In measuring the extent of agglomerative economies, researchers confront an identification problem: Are firms choosing a common location because its inherent characteristics make them more productive or are they more productive because they have all chosen the same location?

Head and Ries (1996) try to separate the roles played by natural advantages and agglomerative economies in two ways. First, they include in their logit analysis a set of variables that attempt to control for local characteristics that influence firm productivity, particularly infrastructure. Second, they allow for spatially correlated errors by including provincial fixed effects. These two approaches are standard in the literature, and data limitations often make it difficult to do more to avoid bias caused by omitted local characteristics or endogeneity. For example, it is often impossible to include fixed effects at the same geographic scale as the unit of location choice (e.g., city fixed effects in the Head and Ries study) because they cannot be estimated for regions that received no investment. However, to fully control for all features of a location that attract investment is impossible, and even in the most careful studies omitted variables likely remain a problem.

Some studies have tried to assess the relative attractiveness of various kinds of prior investment for new entrants. Examining Japanese investment in the United States electronics industry from 1980 to 1998, Chung and Song (2004) ask whether firms agglomerate with their competitors or with their own prior investments. They find that firms tend to colocate only with their own prior investments, with the exception of firms that have little of their own experience, who do tend to colocate with competitors.

More recent work emphasizes the role of trade costs and market access as an alternative explanation for FDI clustering. Head and Mayer (2004) develop a theoretical model in which firms prefer to locate where demand is highest and serve smaller markets by exporting. They confront the data with this hypothesis, measuring market potential by a term that weights demand in all locations by its distance from the proposed investment site. Head and Mayer use standard logit techniques to analyze the European regions chosen as the sites of 452 Japanese investments. They decompose existing investment in each region into three firm counts distinguished by their relatedness to the new entrant: domestic establishments in the same industry, Japanese affiliates in the same industry, and Japanese affiliates with the same parent or network. They find that all three measures of prior investment have a large and positive influence on the likelihood that a region will be chosen by a new entrant, with this effect larger the closer the relations between firms. Thus there are strong agglomeration effects even when controls for market potential are included in the analysis.

An important issue for policy is whether domestic productivity is enhanced by the presence of foreign-owned firms. Most productivity-spillover studies are of specific industries or are case studies, both of which are limited as a guide to policy. Haskel, Pereira, and Slaughter (2007) offer evidence on domestic spillovers from FDI using a plant-level panel of all UK manufacturing firms from 1973 to 1999. Several previous studies using plant-level data find a negative or insignificant effect of industry-level FDI on local productivity. The UK data are unique in that they cover the whole of manufacturing in a developed country. Haskel, Pereira, and Slaughter estimate plant-level productivity and regress it on industry-level FDI, controlling for inputs and the level of competition. They estimate that a 10-percentage-point increase in foreign presence in a UK industry raises the total factor productivity of that industry's domestic plants by about 0.05 percent. They compare the value of these estimated spillover effects to per-job incentives offered in specific cases and find that these expenditures outweigh the benefits.

Haskel, Periera, and Slaughter (2007) use a variety of methods to deal with identification problems. In addition to explaining variation in gross output, they time-difference the data, explaining the change in output as a function of changes in inputs and foreign industry presence. This method accounts for plant-specific effects. The authors also include time, industry, and region fixed effects in their regression analysis. They also worry about the possibility that changes in industry FDI levels are correlated with changes in domestic productivity, and use instrumental variable techniques to minimize endogeneity bias. Their findings provide the strongest evidence to date that foreign investment does raise domestic productivity, but more work is needed before we have a clear guide to policy.

In sum, locations are more attractive the larger the existing stock of foreign investment, especially when the existing investments are by firms that are closely related (same industry, nationality, or parent firm). Government incentives are a significant determinant of multinational affiliate location choice but incentives are most effective when a location is desirable for other reasons. Although recent evidence suggests that foreign-owned firms enhance the productivity of local establishments, the value of these domestic spillovers appear to be less than the incentives used to attract foreign investment.

■ Agreement on Agriculture

The Uruguay Round Agreement on Agriculture (URAA) came into effect in 1995 as a part of the Marrakesh Agreement that established the World Trade Organization (WTO). Contained in Annex IA of the Marrakesh Agreement, the URAA both modifies and greatly elaborates on those Articles of the General Agreement on Tariffs and Trade (GATT) that specifically dealt with agricultural trade by specifying significant constraints on government behavior in this area. The scope of the URAA covers all agricultural products (defined as products in Chapters 1 24 of the Harmonized System of tariff headings, excluding fish and fish products but in cluding cotton, wool, hides, flax, hemp, and a few other products as specified in Annex 1). The agree ment, by internal reference, also includes the country schedules that were appended to the WTO Treaty (Articles 3.1, 4.1, and 6.1). These schedules con tained maximum permitted levels for export sub sidies and for certain types of domestic subsidies, as well as commitments for the reduction of "bound" tariffs (tariff levels that cannot be exceeded without negotiating compensation for effected exporters).

The central elements of the URAA are often re ferred to as the three "pillars" market access, do mestic support, and export competition. In all three areas, new rules and reductions in trade barriers form a comprehensive framework for the regulation of measures that restrict trade in agricultural products.

Market access rules include the conversion of all nontariff import barriers (quotas and restrictive li censes) to tariffs (Article 4.2), and a footnote to Ar ticle 4.2 specifies some of the nontariff measures that are prohibited. Moreover, it was agreed that tariff levels were to be bound and that tariff rate quotas (TRQs, or quantities that can be imported at a zero or low tariff) were to be established to maintain market access as tariffication (replacement of nontariff bar riers with tariffs) took place. These TRQs were to represent "current access" in cases of existing trade or a "minimum access" of 3 percent of domestic con sumption (rising to 5 percent over the implementa tion period) in cases where there were no imports in the base period. Tariffs were to be reduced from the base period (1986 90) by an (unweighted) average of 36 percent, with a minimum cut of 15 percent for each tariff line, over a six-year period (1995 2000). In addition, the agreement established a special safeguard regime that countries could use to counter import surges or price drops in markets in which they had newly established tariffs (Article 5).

Domestic support was defined to include pay ments to farmers in addition to the transfers from consumers through border policies. These included deficiency payments, direct income supplements, administrative price systems, and subsidies for agri cultural research and government advisory programs for farmers for conservation compliance, and for other programs that benefited farmers directly. These elements of domestic support were put into three categories, which have become known as the Amber Box, the Blue Box, and the Green Box.

Amber Box measures were those tied to output or input prices or to current output levels. These were to be reduced by 20 percent (in aggregate) relative to the base period (1986 90) subject to de minimis amounts that were excluded from the commitment. The Blue Box contained subsidies that were tied to supply control programs: such subsidies were regarded as less obviously output-increasing. There was no reduction obligation for Blue Box policies, but such subsidies were restricted to payments based on fixed acreage and yield or paid on a maximum of 85 percent of production (Article 6.5). Green Box subsidies were defined (in Annex 2) as those unrelated to price and output ("decoupled"), which included research and extension, payments designed to compensate farmers for the cost of compliance with environmental regulations, and domestic food assistance programs. Both the general criteria (that they be provided from public funds and not act as price supports) and the specific criteria for each type of subsidy identified have to be met. Those subsidies that qualified as Green Box payments were not constrained, though they had to be notified by governments to the WTO Committee on Agriculture.

The domestic support commitments were implemented by means of a calculation of the Total Aggregate Measure of Support (Base AMS) (Article 6) for the base period. This included market price support given by administered prices (calculated by a price gap relative to a reference price), nonexempt direct payments, and other subsidies. Exemptions included the Blue Box and Green Box subsidies and a de minimis amount of 5 percent of the value of production for non-product-specific subsidies and 5 percent of the value of the output of an individual commodity for product-specific payments. The reduction commitments were applied to the Base AMS to give the annual commitment levels included in the country schedules, and each year the Current Total AMS is compared to this commitment.

The rules regarding export competition included a prohibition on new export subsidies (Article 8) and a reduction of existing subsidies by both volume and expenditure. A list of export subsidy practices that are covered is given in Article 9.1. Following the agreed modalities, country schedules were drawn up that provided for subsidy reductions relative to the base period of 36 percent by expenditure and 21 percent by quantity subsidized. In addition, rules were made more explicit with regard to food aid (Article 10.4), and countries agreed to negotiate limits on export credit guarantees (government underwriting of sales to purchasers that might lack creditworthiness) (Article 10.2).

To provide for "special and differential treatment" for developing countries, the level of reductions for tariffs and subsidies was set at two-thirds of that of developed countries, and the period of transition was extended from 6 to 10 years (i.e., 1995 2004). Developing countries were also allowed to exempt de minimis subsidies of up to 10 percent of product value for product-specific payments and 10 percent of total agricultural production for non-product-specific payments. In addition, certain additional categories of both domestic support (Article 6.2) and export subsidies (Article 9.4) were allowed. In the case of least-developed countries, no reduction commitments were required (Article 15.2). These least-developed countries are defined as the 48 countries eligible for World Bank/International Development Association assistance, and developing country status is self-declared.

In addition to the three pillars, the URAA mandated the formation of an Agricultural Committee (Article 17), charged with the monitoring of adherence to the agreement. Countries were to notify the committee in a timely fashion of their subsidy levels and any new subsidies that were introduced. Notifications have lapsed, however, and some major countries have not notified beyond the year 2001. The Agriculture Committee became the locus for new negotiations on the continuation of trade reform, meeting in special session.

In addition, the URAA provided a degree of shelter for domestic programs through a "Peace Clause" (Article 13) that limited the scope for the challenge of agricultural subsidies under the Agreement on Subsidies and Countervailing Measures. The Peace Clause was to operate for a period of three

years after the implementation period; it expired in 2003.

A further innovation in the URAA was the inclusion of a clause (Article 20) that mandated a continuation of the process of reductions in support and protection. To this end, there were to be new negotiations by the end of the period of transition (in effect, before 2000). Negotiations did indeed start in March 2000, and were incorporated in the Doha Development Agenda (DDA) at the Doha Ministerial in November 2001. The DDA talks were suspended in July 2006 and revived in January 2007.

The need for the development of new rules for agricultural trade in the Uruguay Round reflected both the unsatisfactory nature of the constraints incorporated in the GATT articles and the "disarray" that had characterized these markets for decades. The three GATT articles that had caused the most conflict were Article XI, which prohibits nontariff measures; Article XVI (as modified in 1955), which limits export subsidies; and Article XX, which permits the use of trade barriers in support of a range of domestic health and safety measures.

The part of Article XI that was considered unsatisfactory was the clause (Article XI.2(c)(i)) that allowed an exception to the prohibition of nontariff trade barriers in cases where the domestic production of an agricultural product was subject to supply control. Many countries had relied on this clause to restrict imports by quantitative trade barriers when domestic markets were being managed. As it was difficult to monitor the extent to which the domestic supply control was effective, exporters of the products concerned claimed that the import restrictions were in effect the dominant policy rather than just an adjunct to help reinforce the domestic production limits. Examples were quotas on Canadian dairy and poultry imports and those imposed by the United States under Section 22 of the Agricultural Adjustment Act (as amended), which mandated quantitative restrictions on imports of a number of goods when domestic programs were "materially interfered with" by imports.

Another complication related to Article XI was whether a "variable levy" (a tariff that changed frequently depending on the level of import prices, so as to stabilize domestic markets) was an "ordinary customs duty." If not, then it would have been constrained by Article XI. The European Economic Community (EEC, later the European Union, EU) had built its Common Agricultural Policy on such an import policy instrument. So the question as to whether the EEC was acting within the limits of the GATT was continually raised by exporting countries   though it was never resolved.

In the case of export subsidies, the problems revolved around the ambiguous nature of Article XVI. Though the original GATT article subjected both primary and manufactured product export subsidies to the same notification and consultation procedures, in 1955 it was agreed to add an explicit prohibition on export subsidies on manufactured goods. Agricultural export subsidies were constrained only by the obligation not to use such subsidies to capture "more than an equitable share" of world markets. Successive GATT panels failed to come up with a satisfactory definition of this concept, and agricultural export subsidies in effect escaped any discipline.

The problems that had arisen in the application of Article XX centered on the difficulty posed by the need to distinguish between those measures that were legitimate and effective regulations to protect against disease and those that were largely inspired by the desire to protect the economic interest of domestic producers. The clarification of Article XX was addressed by the Sanitary and Phytosanitary (SPS) Agreement, which was complementary to the URAA. By requiring risk assessment in the case of all health and safety regulations related to trade in plants and animals, the SPS Agreement created a greater degree of accountability. Regulations that are clearly motivated by economic rather than health protection can now be (and have been) challenged in the WTO.

The URAA has rendered the provisions in Article XI regarding supply control moot, as quantitative import restrictions are now prohibited. Similarly, the variable levy is explicitly included in the list of import barriers that are not allowed. By banning new export subsidies and including existing subsidies in

schedules to be reduced, the URAA has largely resolved the issue of the "exception" for primary products. And the constraints on domestic support have had the effect of restricting the ability of countries to reproduce by domestic subsidies the protection levels previously granted by reduced tariffs and export subsidies. Thus the rule changes have to a large extent met the need to incorporate agricultural trade in a rules-based trade system.

The impact that the URAA has had on individual countries varies greatly. All countries converted nontariff barriers to tariffs and bound those tariffs with the sole exception of rice quotas in Japan and Korea, which were allowed as temporary exceptions. Developing countries were allowed to declare "ceiling bindings" in place of product-by-product calculations of tariff equivalents, however. These ceiling bindings were commonly set at levels up to 100 percent or more, and thus had little impact on the actual level of tariffs used and the degree of market access. Tariffication had more impact in developed countries, where the quantitative restrictions were usually associated with sensitive products. In these cases the degree of market opening depended on the size of the TRQ agreed upon and the administration of that quota. Many countries considered the increased trade generated by the market access provisions of the URAA disappointing, and this increased the pressure for substantial market opening in the Doha Round.

The constraints on export subsidies have generally been successful, in that countries have appeared to stay within their scheduled limits for those subsidies included in their schedules. WTO panels have found (notably in the Canada dairy, U.S. cotton, and EU sugar cases), however, that there have been subsidies that were not included in the schedules, and the panels have declared these to be prohibited. Domestic subsidy constraints have also been generally respected, mainly because domestic policies in developed countries have tended to switch away from Amber Box subsidies. But there is continued concern that such subsidies cause considerable harm to other countries, and this has been confirmed by the panel in the U.S. cotton case.

Agreeing on disciplines on agricultural trade (as well as ending the quota system for textile imports) was a major step in completing the agenda embodied in the GATT of bringing all sectors in goods trade under the same regime. All agricultural tariffs are now bound, though they remain at a level several times higher than for manufactured goods. Nontariff barriers are no longer used, though TRQs still restrict market access. Though it does not directly mandate the type of policy instruments countries can use, the URAA has in effect provided a template for domestic policymakers: if they use WTO-compatible policies for their farm sectors they will be free from the constraints of the URAA. Export subsidies are still used but in much more restricted ways. The agricultural talks in the DDA have attempted to build on the achievements of the URAA.

■ Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS)

The Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) has become the most important and far-reaching international accord in the field of intellectual property. It establishes workable global standards of protection and enforcement for virtually all of the most important intellectual property rights, such as patents, copyrights and related rights, and trademarks, in a single agreement. As such, it has major implications for knowledge-based industries seeking to trade profitably in many different countries.

History Strictly speaking, TRIPS is annex 1C of the Agreement Establishing the World Trade Organization, which was the main outcome of the Uruguay Round trade negotiations held under the auspices of the General Agreement on Tariffs and Trade (GATT). It resulted from a considerable amount of lobbying by certain industries that were keen to expand their activities in emerging economies where intellectual property protection was either lacking or was weakly enforced.

The first attempt to frame intellectual property as an issue to be discussed in wider trade negotiations was made by a group of trademark-holding firms organized as the Anticounterfeiting Coalition, which lobbied for the inclusion of an anticounterfeiting code in the 1973 79 GATT Tokyo Round. Although this initial attempt was unsuccessful, the copyright, patent, and semiconductor industries decided during the early 1980s to frame the lack of effective intellectual property rights protection in overseas markets as a trade-related issue *and* a problem for the U.S. economy that the government ought to respond to. By the time the contracting parties of the GATT met in Punta del Este, Uruguay, in September 1986 to launch another trade round, U.S. corporations had forged a broad cross-sectoral alliance and developed a coordinated strategy.

For those seeking high standards of intellectual property protection and enforcement throughout the world by way of the GATT, the strategy had three advantages. First, if successful, the strategy would globalize these standards much more rapidly than could be achieved through the conventions administered by the World Intellectual Property Organization (WIPO). This is because it allowed for the possibility of including all the main rights in a single agreement, which could also incorporate by reference provisions of the major WIPO conventions. Also, once it was agreed that the Uruguay Round agreements had to be accepted as a package (i.e., a "single undertaking"), countries could not opt out of any one of them and be a member of the new World Trade Organization (WTO). Second, the GATT already had a dispute settlement mechanism. WIPO has no enforcement or dispute settlement mechanisms except through the treaties that it administers, and these treaties do not provide much recourse for countries concerned about the noncompliance of other parties. Third, the broad agenda of the Uruguay Round provided opportunities for linkage-bargain diplomacy that WIPO, with its exclusive focus on intellectual property rights, did not allow. Hard bargaining by the United States, Europe, and Japan on intellectual property could thus be linked to concessions in such areas as textiles and agriculture, where exporting countries in the developing world were eager to achieve favorable settlements.

The Punta del Este Declaration of September 1986 included "trade-related aspects of intellectual property rights, including trade in counterfeit goods" as a subject for negotiations in the forthcoming trade round, which became known as the Uruguay Round. In full, the declaration's provisions on intellectual property were as follows:

> In order to reduce the distortions and impediments to international trade, and taking into account the need to promote effective and adequate protection of intellectual property rights, and to ensure that measures and procedures to enforce intellectual property rights do not themselves become barriers to legitimate trade, the negotiations shall aim to clarify GATT provisions and elaborate as appropriate new rules and disciplines.
>
> Negotiations shall aim to develop a multilateral framework of principles, rules and

disciplines dealing with international trade in counterfeit goods, taking into account work already underway in GATT.

These negotiations shall be without prejudice to other complementary initiatives that may be taken in the World Intellectual Property Organization and elsewhere to deal with these matters.

According to Susan K. Sell (2003), TRIPS is a case of 12 U.S. corporations making public law for the world. This makes sense only if one takes it to mean that the active engagement of these firms was a necessary, but not a sufficient, condition for there being a TRIPS Agreement. And actually she does not claim that the alignment of so much economic power and political influence made their victory inevitable or complete. Similarly, as John Braithwaite and Peter Drahos (2000) have noted, "It was a remarkable accomplishment to persuade 100 countries who were net importers of intellectual property rights to sign an Agreement to dramatically increase the cost of intellectual property imports."

So how was such a difficult feat achieved? Certain individuals played a decisive part in mobilizing support for the inclusion of trade-related intellectual property rights as a major Uruguay Round agenda item with the aim of formulating a legal instrument that would bind all members of what would become the WTO. These included chief executive officers of major corporations, lawyers, and a private consultant, all of whom were instrumental in conceptualizing intellectual property as a trade-related issue and then developing the political strategy that would ultimately result in TRIPS.

The interest groups succeeded in influencing the development of trade law and policy by incorporating their demands in the relevant legislation and by working closely with the key government agencies engaged in trade policy, especially the Office of the United States Trade Representative (USTR). Once the USTR had been persuaded that it was in the interests of the country to pursue the intellectual property demands coming from these groups, at least for the time being, at GATT rather than at WIPO, the next task was to form an international alliance

including the businesses and governments of Western Europe and Japan while neutralizing resistance from opposing countries.

Initially, the Group of Ten developing countries within the GATT India, Brazil, Argentina, Cuba, Egypt, Nicaragua, Nigeria, Peru, Tanzania, and Yugoslavia took a determined stand against the use of GATT as a forum for negotiating global intellectual property standards. But from 1985 and especially 1989 onward, the United States used its own trade rules to publicly criticize, threaten, and punish individual countries whose intellectual property standards were lower than its own and therefore "inadequate." Section 301 (Actions by U.S. Trade Representative) of the U.S. Trade Act was amended in 1984. The amended section 301 specifically included failure to protect intellectual property as one of the "unfair trade practices" that could result in a USTR investigation and possible sanctions, and authorized the USTR to initiate its own cases so as to protect U.S. firms from retaliatory action by foreign governments.

The 1988 Omnibus Trade and Competitiveness Act in its special 301 provision further strengthened the authority of the USTR in order to insulate decision-making on trade retaliation from foreign policy or national security considerations, and required the USTR annually to "identify those foreign countries that deny adequate and effective protection of intellectual property rights, or deny fair and equitable market access to United States persons that rely upon intellectual property protection." It is largely due to the mandate of the USTR to actively pursue the complaints of U.S. firms and business associations that the developing countries eventually accepted TRIPS.

Nonetheless, representatives of the United States, Europe, and Japan did not just sit down together and write the TRIPS Agreement themselves. Not only did divisions emerge between Europe and the United States that required compromises, but developing countries were much more involved in the drafting than they are often given credit for. As Jayashree Watal (2001) explains, they achieved favorable language in 10 of the 73 articles, albeit with the necessary

support of a few developed countries. The 10 include those dealing with the objectives and principles of TRIPS, limitations and exceptions to copyright, exceptions to patents and compulsory licensing, and control of anticompetitive practices in contractual licensing.

The Agreement's Key Provisions The preamble affirms the desire of member states "to take into account the need to promote effective and adequate protection of intellectual property rights," while "recognizing the underlying public policy objectives of national systems for the protection of intellectual property, including developmental and technological objectives." Dealing with counterfeiting is clearly considered as important. Its main importance lies in the fact that the trade in counterfeit goods is what makes intellectual property most clearly trade related. The preamble indicates that members recognize "the need for a multilateral framework of principles, rules and disciplines dealing with international trade in counterfeit goods." Yet the objectives as stated in Article 7 make no reference to the eradication of counterfeiting. Rather, TRIPS is explicitly aimed at promoting public policy objectives, the nature of such objectives presumably being left to national governments, though technological development is given priority.

Article 8.1 allows member states implementing their intellectual property laws and regulations to "adopt measures necessary to protect human health and nutrition, and to promote the public interest in sectors of vital importance to their socio-economic and technological development." These measures are not obligatory but, again, they highlight the socioeconomic welfare implications of intellectual property. On the other hand, the proviso that such measures be consistent with the provisions of TRIPS appears to narrow their possible scope quite considerably.

By virtue of Article 3, members accept the principle of national treatment, that is, that each country must treat nationals of other members at least as well as it treats its own nationals. In other words, intellectual property protection and enforcement must be nondiscriminatory as to the nationality of rights holders.

Article 4 upholds the principle of most-favored-nation. This means that any concession granted by one member to another must be accorded to all other members "immediately and unconditionally." So if country A agrees to take special measures to prevent the copying of the products of a company from country B, but turns a blind eye when the company is from country C, D, or E, such inconsistency of treatment will violate this principle. Although this principle of international law dates back in history, TRIPS is the first multilateral intellectual property treaty that refers to it.

Part II of TRIPS deals with the actual rights. These are very comprehensive, comprising the following:

1. Copyright and related rights
2. Trademarks
3. Geographical indications
4. Industrial designs
5. Patents
6. Layout-designs (topographies) of integrated circuits
7. Protection of undisclosed information
8. Control of anticompetitive practices in contractual licenses

To some extent the provisions are based on existing agreements. Thus WTO members are required to implement substantial parts of the Paris Convention on the Protection of Industrial Property and the Berne Convention of Literary and Artistic Works whether or not they are signatories to them. Nonetheless, while most developed countries were required only to make cosmetic changes to their intellectual property laws, most developing countries needed to reform their laws quite drastically. This is not surprising since the intellectual property standards provided in TRIPS tend to be modeled on the laws of the United States, Europe, or are a hybrid of the rules of the two jurisdictions.

All countries had to apply Article 3, on national treatment and on most-favored-nation status, and Article 5, concerning multilateral agreements on acquisition or maintenance of protection, within one

year of the entry into force of the WTO Agreement. But the developing countries and the former centrally planned socialist states were allowed a period of five years from the date of entry into force of the WTO Agreement, that is, until January 1, 2000, to apply the full provisions of TRIPS. Developing country members that were required to extend patent protection to areas of technology not hitherto covered in their laws were permitted to delay such extension until January 1, 2005. The least-developed countries (LDCs) were allowed until January 1, 2006, to apply TRIPS in full. Countries that have joined the WTO since then are required also to comply with these deadlines.

However, the LDCs have managed to secure two extensions. The 2001 Doha Declaration on the TRIPS Agreement and Public Health allowed them to delay implementation of patent protection for pharmaceutical products and legal protection of undisclosed test data submitted as a condition of approving the marketing of pharmaceuticals until January 1, 2016. In November 2005, the TRIPS Council extended the deadline to LDCs for fully implementing the rest of TRIPS by a further seven and a half years to July 1, 2013.

TRIPS places much emphasis on enforcement. With respect to the general enforcement obligations, procedures must be fair, equitable, and not unnecessarily complicated, costly, or time consuming. The judicial authorities must be granted the power to require infringers to pay damages adequate to compensate the right holder for the injury suffered due to the infringement. Members are required to provide for criminal procedures and penalties "at least in cases of willful trademark counterfeiting or copyright piracy on a commercial scale."

The agreement sets out the role of the Council for Trade-Related Aspects of Intellectual Property Rights (TRIPS Council). Accordingly, the council is responsible for:

   Monitoring the operation of TRIPS, and in particular members' compliance;
   Affording members the opportunity to consult on matters relating to trade-related intellectual property rights;

   Assisting members in the context of dispute settlement procedures; and
   Carrying out other duties assigned to it by the members.

The council is supposed to review the implementation of TRIPS at two-year intervals from January 2000. Article 71.1 states in addition that "the Council may also undertake reviews in the light of any relevant new developments which might warrant modification or amendment of this Agreement."

TRIPS-Related Developments at the WTO TRIPS was, and continues to be, highly controversial. Indeed, for both developing and developed countries, it represents unfinished business. Developing country representatives continue to express concerns that TRIPS raises prices of drugs and educational materials in poor countries, legitimizes the "biopiracy" of genetic resources and traditional knowledge, and blocks transfers of much-needed technologies. They have successfully resisted the further tightening of TRIPS rules and have had some small victories along the way. They have enhanced their capacity to put forward substantial counterproposals relating to such matters as public health, least-developed countries, traditional knowledge, and the compatibility between TRIPS and the Convention on Biological Diversity's provisions concerning benefit sharing, protection of traditional knowledge, and technology transfer. As for the developed countries and international business, which are constantly seeking ever higher levels of intellectual property protection and enforcement, TRIPS has to some extent been a disappointment.

It is in fact far from clear that making the intellectual property rules more or less identical whether you are a very rich country with enormous balance of payments surpluses in intellectual property protected goods, services, and technologies, or a poor country with highly burdensome trade deficits, is beneficial for the latter type of nation. While it is impossible to reliably calculate the long-term economic impacts of TRIPS on developing countries and their populations, we can be certain that they will incur short-term costs in such forms as rent transfers and administration and enforcement outlays, and that these

will outweigh the initial benefits. The cost-benefit balance will vary widely from one country to another, but in many cases the costs will be extremely burdensome.

At the November 2001 Doha Ministerial Conference of the WTO, members agreed on the texts of two very significant documents with provisions concerning intellectual property: the Ministerial Declaration, and the Declaration on the TRIPS Agreement on Public Health. The former declaration's TRIPS-related matters concerned geographical indications, the relationship between TRIPS and the Convention on Biological Diversity (CBD) and the protection of traditional knowledge and folklore, and technology transfer. The latter declaration dealt exclusively with TRIPS, primarily its public health provisions relating to compulsory licensing and parallel importation.

TRIPS Article 27.3(b) concerns exceptions to patentability in the area of biotechnology. It permits WTO members to exclude from patentability "plants and animals other than micro-organisms, and essentially biological processes for the production of plants or animals other than non-biological and microbiological processes." At Doha, ministers representing WTO members clarified their commitment to opening up negotiations on issues relating to Article 27.3(b) to include the relationship between the TRIPS Agreement and the CBD, and the protection of traditional knowledge and folklore.

The key challenge for developing countries is that many of them remain unclear about how to tailor their patent regulations to promote their interests in the acquisition, development, and application of biotechnology, and therefore how best to exploit the flexible language of Article 27.3(b). Understandably, though, much of the discussion has focused not specifically on this issue, but on how best to address a wide range of moral, political, and economic concerns about "patenting life" and "biopiracy."

The CBD-TRIPS relationship and the protection of traditional knowledge and folklore have proved to be quite controversial. One key developing country demand that has been pushed quite strongly is that of disclosure of origin. Disclosure of origin would re-quire inventors to disclose the source of genetic resources and/or traditional knowledge relevant to an invention being patented. In May 2006, Brazil, India, Pakistan, Peru, Thailand, and Tanzania proposed in the WTO General Council that new text be incorporated into the TRIPS Agreement under Article 29, which deals with conditions on patent applicants, to require such disclosure.

Geographical indications (GIs) are defined in the TRIPS Agreement as "indications which identify a good as originating in the territory of a Member, or a region or locality in that territory, where a given quality, reputation, or other characteristic of the good is essentially attributable to its geographical origin." In November 2001, the WTO members attending the Doha Ministerial Conference agreed "to negotiate the establishment of a multilateral system of notification and registration of geographical indications for wines and spirits by the Fifth Session of the Ministerial Conference." With respect to the possible extension of the enhanced protection of geographical indications to products other than wines and spirits, it was agreed that issues related to this matter would be addressed in the Council for TRIPS, an indication of the lack of consensus.

Despite the fact they are in TRIPS largely at the instigation of the European Commission, GIs have for several years been promoted as a concession to developing countries that they ought to take advantage of. Supposedly, they provide the means by which developing countries can use intellectual property to protect categories of local rural knowledge that they possess in abundance. In particular, the European Union and the Swiss government are very keen to promote GIs worldwide by arguing that this part of TRIPS can potentially provide substantial gains for developing countries. This seems plausible when one considers that GIs are especially appropriate for the produce of small-scale producers and cultivators, and, it should be underlined here, not just for foods and beverages but also handicrafts and other hand-made items.

Many developing countries are rich in traditional knowledge having applications in agriculture, food

production, and small-scale manufacturing. So GIs would appear to have real potential in terms of developing and exploiting lucrative markets for natural product based goods, including those manufactured by resource-poor farming communities. Such countries tend to favor the extension of the additional protection to cover all products, not just beverages. Are they right to be so pro-GI with respect to products they wish to export? Possibly they are, but caution should be exercised. GIs are useless without good standards of quality control and marketing, and up-to-date information on markets including foreign ones if the products are to be exported. At present the potential of geographical indications for developing countries is somewhat speculative because this type of intellectual property right has been used only in a few countries outside Europe. Moreover, many GIs have quite small markets, and a relatively small number are traded internationally.

Other developing countries do not have an abundance of traditional knowledge and are key exporters of products that compete with well-established GI-protected goods coming from Europe. For those countries, GIs may be more of a threat than an opportunity.

Multilateralism, Bilateralism, and the Future of TRIPS Developing country WTO members have been very reluctant to engage in negotiations to raise levels of intellectual property protection at the WTO. In order to hold these countries to more rigid and higher standards of intellectual property protection than TRIPS compliance requires, the United States and the European Union have gone outside the multilateral WTO forum. One of the most effective strategies being employed is that of bilateral and regional free trade agreements, which generally contain so-called "TRIPS plus" intellectual property right provisions, which place obligations on governments to provide more extensive protection than TRIPS actually requires. A growing number of developing countries seeking to enhance access to developed world markets for goods produced in their nations have proved willing to overcome their reservations about strengthened intellectual property rights through such deals in order to achieve this.

As a WTO agreement, and one which deals with arguably the most valuable assets of modern corporations, intangible ones, the importance of TRIPS to the world economy is immense and will remain so for several years. However, there are early signs that it is outliving its purpose for those corporations that successfully lobbied for an intellectual property agreement in the Uruguay Round and the governments that took up their demands. There are three reasons for this. First, the WTO system of trade governance currently does not make it easy to achieve radical revision of existing agreements or, for that matter, consensus on the need for new ones. Second, developing countries have tended not to implement TRIPS with much enthusiasm, and enforcement measures continue to be inadequate from the view of the intellectual property owners. Third, for the developed countries and transnational industry, other forms of trade diplomacy including those presented above seem to further their interests more effectively. Thus one may reasonably question whether TRIPS in the coming years will continue to be such an important agreement as it is today.

■ **agricultural trade negotiations**

Opening up markets for agricultural products has proved a stumbling block for trade negotiations at both the regional and the multilateral levels. The primary reason is the political sensitivity of more open markets for farm and food products. Most governments share a concern for the security of their countries' food supply and the income level and stability of their rural sectors. In importing countries, this concern has led to caution about relying on imports for basic foodstuffs and a conviction that protection from overseas competition is necessary for the health of the rural economy. Those countries with export potential have long decried such sentiments, arguing that they can provide a regular supply of foodstuffs at lower prices and that supporting inefficient domestic production is not a sound basis for development. But, as one might expect in a sector where governments still have considerable control over markets, negotiations to open up trade in farm products have tended to proceed at the pace of the most reluctant importers.

Since the 1980s, this cautious attitude toward trade in farm goods has begun to give way to a more confident approach that sees imports as complementary to domestic production and exports as a natural extension of domestic markets. Consumers are becoming used to the greater choice of foodstuffs that comes with trade, and producers are setting their sights increasingly on foreign markets for new sources of revenue. In the process, many countries have become both importers and exporters of farm products and foodstuffs. This has blurred the easy categorization of a country's trade policy by its trade balance. Developing country importers often join with developing country exporters in voicing concerns about trade issues, particularly about the subsidies given to domestic producers in rich countries. Developed country exporters have "sensitive" sectors that apparently need to be sheltered even while they advocate more open markets for other products. Developed country importers with high protection barriers are often major importers of farm products needed for processing or for animal feed. Perhaps only in the market for tropical agricultural products is it still possible to identify typical "importer" and "exporter" views, but even in this case there are clear distinctions between those that have preferential access to markets in industrialized countries and those that do not benefit from such preferences, and between those that sell the raw materials and those that successfully add value in the domestic economy.

Along with this shift in political perceptions on agricultural trade has come a change in the nature of trade in farm products. In the 1980s, much of

the trade in primary agricultural products passed through sales or purchasing agents for producers and wholesalers, or of companies whose function was to distribute temperate-zone and tropical products through established channels. The role of state trading has shrunk markedly, with the adoption of policies to allow more private activity in marketing. Large companies now have a considerable role in the processing and marketing of farm products, as they have had for some time in the trading function. Most of these private actors operate in several countries, and thus food trade has become much more of a global business. The share of such trade that is categorized as "high value added" has correspondingly increased, leaving the trading of commodities and raw materials a smaller part of agricultural trade. Such trends explain the growing interest by large food and retail firms in removing trade barriers that act to inhibit worldwide marketing. As a result of these changes, in both political perception and structural reality, agricultural trade negotiations have been somewhat more successful in recent years in opening markets and have even made some progress in the past decade in reducing trade-distorting subsidies.

The change in the attitudes toward trade negotiations in agriculture is closely tied to reform of domestic policies. In developed countries, such policies were usually built on (and have been facilitated by) tariff and nontariff protection at the border and have employed a wide range of instruments to manage domestic markets and supplement farm incomes. Thus trade reform and market liberalization could not proceed as fast as in manufactured products in the postwar period. Domestic policies would have been impossible to maintain if trade liberalization had extended to agriculture. Reform of the domestic farm policies in developed countries started in the mid 1980s and continued apace for more than a decade. Policies that lowered support prices and substituted direct payments to farmers were found to be more easily amended to meet new targets, such as environmental stewardship, and tended to lower the incentive to produce unwanted surpluses. Developing countries, for different reasons, also relaxed their control over domestic markets and lowered trade barriers. In this case the motive was to correct macroeconomic and structural problems that were inhibiting development.

These reforms allowed countries to institute, as part of the Uruguay Round in 1994, a wide-ranging Agreement on Agriculture, which acted as a framework in which domestic policies could operate. This framework was consistent with lower protection at the border and less trade-distorting subsidies at home. It helped to lock in domestic reforms and put pressure on countries that were lagging in the reform process. But it also simplified the task of negotiating reductions in trade barriers and importantly changed the dynamic of such negotiations.

The same reform of developed-country farm policies also made it easier to negotiate bilateral and regional trade pacts. For years, most of these agreements had avoided the problem of negotiating reductions in tariff barriers for agriculture by explicitly excluding sensitive agricultural sectors from the full impact of market opening. This became insupportable when agricultural export interests, even in net importing countries, began to ask for market access (and preferences) within the regional or bilateral agreement. In addition, the rules of the World Trade Organization (WTO) (Article XXIV of the General Agreement on Tariffs and Trade 1994) oblige countries to grant tariff-free access on "substantially all trade" within bilateral and regional trade agreements. As a result, the inclusion of agriculture in such agreements is now the norm rather than the exception. Safeguards and slowly increasing tariff quotas still give some protection to sensitive domestic farm sectors, but few agreements exclude agriculture altogether.

It would be misleading, however, to suggest that these processes of globalization in farm and food trade and of reform of domestic policies have removed all the obstacles to open trade in agricultural goods. The process of reform has taken place at different speeds in different countries. So the pace of trade negotiations is still controlled to a large extent by the slowest reformers. Among the developed countries this includes Japan, Norway, and Swit-

zerland. Not only is protection high in these countries but the types of policies used still rely heavily on protection at the border. Hence they have been prominent members of the Group of 10 in the context of the WTO Doha Round, arguing for generous exclusions for "sensitive products," more modest tariff cuts, and no cap on the height of tariffs. Among the developing countries, the reluctant importers have formed the Group of 33, which emphasizes the need for adequate provision for "special products" and the inclusion of a "special safeguard mechanism" to allow them to reimpose tariffs if domestic markets are disrupted. These two groups, though negotiating actively, have effectively limited the "level of ambition" of the market access talks on agriculture.

Importantly, the process of trade and domestic reform has been uneven among sectors. The so-called white goods rice, cotton, sugar, and milk have among the highest tariff barriers and the most pervasive domestic subsidies. The sensitivity of these goods extends to exporting countries. The United States, normally a supporter of low tariffs, has come under pressure to reduce subsidies on each of these products. This has complicated the position of the United States in trade talks, arguing for others to open up markets but being more cautious in offering to cut support or lower tariffs where domestic interests are vocal. The European Union (EU) also has its sensitive products, including dairy and beef, though it has modified its domestic policies for rice, sugar, and cotton. The Uruguay Round did relatively little to improve the situation in the "white goods" markets, and their inclusion in regional trade agreements has often been politically sensitive. Sugar, for instance, was left out of the U.S.-Australia Free Trade Agreement, and was given a "temporary" exclusion from the Mercosur trade arrangements.

The implications of these changing political and economic forces can be seen with respect to the Doha Round of trade talks. Agriculture has been the biggest hurdle to an agreement, and the principal reason why talks were suspended for a time in July 2006. But the agricultural negotiations themselves are quite different from those in 1986, at the start of the Uruguay Round. At that time, the main protagonists were the United States and the EU, and the issues were whether to bring agricultural trade under the disciplines of multilateral rules and how to include rules for domestic policy that would be consistent with the trade disciplines. The United States, as a prominent exporter of temperate-zone farm products, favored such a move, in large part to circumscribe the Common Agricultural Policy of the EU. The EU had previously argued against this, on the grounds that domestic policy was a national issue and that the trade rules should give adequate scope for such internal choices. By the end of the talks, seven years later, the EU had agreed to rules that covered domestic policy instruments, categorizing them into "boxes" depending on their degree of trade distortion, and that eliminated quantitative trade barriers and limited export subsidies. The United States had achieved its objective of introducing binding rules but had to settle for only modest tariff reductions. The EU had to reform its own Common Agricultural Policy in 1992 in order to be able to live within the new constraints of the WTO.

The Doha Round is not about whether to develop rules for agricultural trade, or whether to extend trade rules to cover domestic policy. It was intended as a more "traditional" trade negotiation, to complement the outcome of the Uruguay Round by reducing tariffs by a substantial amount and by agreeing on a further reduction in subsidies. There is no longer any objection to the inclusion of domestic support in the trade talks and of curbing export subsidies. The focus has been on the depth of the tariff cuts and the extent to which certain "sensitive" products could be sheltered from the full cuts. In this sense it is much more in keeping with the negotiations in manufactured trade in the Kennedy Round (1963 67).

But one aspect of the Doha Round has made for more complex and difficult negotiations on agricultural trade. In contrast to the Uruguay Round, where with the exception of those in the Cairns Group few developing countries played a major role, the number of such countries that have been active has been remarkable. Spurred by the attempt (in August 2003) by the United States and the EU to develop a

common position, Brazil, India, and China, together with South Africa and a number of other developing countries, formed the Group of 20. The main demand from these countries was that the EU and the United States commit themselves to significant cuts in domestic support (subsidies) as well as eliminating export subsidies and cutting tariffs on farm goods. This coalition has stayed together and played a major role in the search for solutions to the agricultural negotiations.

Multilateral negotiations on agricultural trade have changed in nature as globalization has broken down the easy categorization of countries as reluctant importers and aggressive exporters. The scope for talks to open markets has been enhanced by the conversion of nontariff trade barriers to tariffs and the move to direct subsidies to support farm income. But the emergence of the major developing countries as players has moved the emphasis from transatlantic tensions to North-South conflicts. And so 21st-century trade negotiations, both in the WTO and in regional and bilateral trade pacts, have revolved around the extent to which developing countries need special rules to reflect their development status, how to continue the reduction of trade-distorting subsidies, and when to finally end the exception to normal trade rules that has allowed the continuation of export subsidies for primary products.

■ agriculture

Agriculture is the systematic raising of plants and animals for the purpose of producing food, feed, fiber, and other outputs. Historically, agricultural production has been linked to the use of the land and the tillage of the soil, and it is agriculture that allowed humans to initially establish permanent settlements. Such establishments were possible because agriculture provided the food necessary to meet human nutritional requirements. Because of its connection to the development of human societies, agriculture is closely associated with culture through the food that it produces and the manner in which it alters the landscape. This tie to culture gives agriculture special status in society and has led it to be treated differently from other commodities in international economic relations.

With economic development, the share of agriculture as a percentage of a country's gross domestic product (GDP) tends to decline (Chenery and Syrquin 1975). This trend is magnified on a global level. As countries have developed, the importance of agriculture in the global economy has declined, with agriculture in the early 21st century representing approximately 6 percent of global GDP.

This aggregate measure, however, masks the continued importance of agriculture for many

countries and households, particularly in developing countries. Because of its social, cultural, and economic importance, the treatment of agriculture in global economic relations has always been controversial. In Latin America, for example, approximately 20 percent of export earnings comes from agricultural products; in Africa it is 14 percent. Additionally, more than 40 percent of the world's economically active population still works in agriculture, with these workers mostly concentrated in developing countries (FAO 2005). Therefore, the operation of the global economy and its influence on the agricultural sector can influence the lives of billions of people.

Disputes over agricultural trade and domestic agricultural policies have continued to plague trade negotiations, including recent meetings of the World Trade Organization (WTO). These disputes have come at a time when agricultural markets have undergone significant changes, particularly in developing countries. A clear understanding of the role of agriculture in the global economy requires consideration of the importance of agriculture in global trade, its role in multilateral trade negotiations, its particular importance to developing countries, and recent trends that have transformed agricultural markets.

Agriculture in Global Trade The value of world agricultural trade nearly doubled between 1980 and 2000, from U.S. $243 billion to U.S. $467 billion. While average annual growth in agricultural exports was substantial during this period 4.9 percent in the 1980s and 3.4 percent in the 1990s it occurred at a time of generally increasing trade volumes and at a slower pace than growth in the manufacturing sector, particularly in the 1990s when manufacturing grew at an annual rate of 6.7 percent. This difference was even greater in developing countries, where agricultural export growth was 5.3 percent in the 1990s compared to 10.9 percent for manufacturing growth (Aksoy and Beghin 2005). Thus, while agricultural trade continues to expand and is clearly important to the world economy, there has been a general decline in its relative significance over time. For both the world in general and for

developing countries in particular, the share of agriculture in global trade has declined to just around 10 percent.

Along with a decline in the relative importance of agriculture, the composition of agricultural trade has shifted. First, there has been a movement away from the export of raw materials to greater export of processed products. Final agricultural products made up a quarter of world exports in 1980 81, but by 2000 2001 they had increased to 38 percent. Second, the commodities being produced and exported have changed from traditional tropical products (such as coffee, cocoa, tea, nuts, spices, fibers, and sugar) and temperate products (meats, milk, grains, feed, and edible oils) to nontraditional, higher-value products (seafood, fruits, and vegetables) and other products such as tobacco and cigarettes, beverages, and other processed foods. Tropical products, in particular, have declined from 22 percent of agricultural exports in 1980 81 to 12.7 percent in 2000 2001 (Aksoy and Beghin 2005). The expectation is that there will be a continued shift away from raw materials and traditional products toward these nontraditional higher valued products and processed items.

These overall trends in agricultural trade and volumes also mask the fact that much of the trade in agricultural commodities occurs within key trading blocs, particularly within the European Union (EU) and the member countries of the North American Free Trade Agreement (NAFTA). Table 1 shows the flows of global agricultural trade between different sets of countries in 2000 2001. Of the U.S. $181 billion in agricultural exports from the EU countries, U.S. $131 billion or 73 percent went to other EU member countries. Similarly, of the U.S. $90 billion in agricultural exports from the NAFTA countries, 39 percent occurred between Canada, Mexico, and the United States.

Agricultural policies account for part of the reason why agricultural trade stays within trading blocs. Historically, developing countries have often taxed agriculture, whereas developed countries have protected agriculture from outside competition and subsidized agricultural production. During the past two decades, changes in policies in many developing

countries such as the devaluation of overvalued exchange rates, the reduction of import restrictions on manufactured goods, and the elimination of agricultural export taxes have removed the anti-agricultural bias in these countries, leading to greater incentives to produce agricultural products. Developed countries, however, have continued to protect and promote agriculture through price supports and tariffs as well as direct subsidies. Within trading blocs, these protections are either not applied or are less restrictive and thus lead to greater agricultural trade within these regions.

The protection and subsidies to agriculture in developed countries influence their competitiveness in domestic and foreign markets. As discussed in the next section, this has become an important point of contention in trade negotiations. To calculate the degree of agricultural protection for farmers in these countries, the Organisation for Economic Co-operation and Development (OECD) has developed a method for estimating the total support to agricultural producers provided by a range of policies. The OECD's producer support estimate (PSE)

measures the monetary value of total gross transfers to agricultural producers arising from agricultural policies (OECD 2006). Compared with total gross farm receipts, this measure can be used to identify the share of farmer revenue that results from government policies. Table 2 provides the estimated percent PSE in farmers' revenue for selected OECD countries as well as for the OECD as a whole. The table also shows the share of support coming from market price supports, such as border tariffs, and the share coming from direct payments to farmers. The data indicate that with the exception of Australia, a significant share of farmers' revenue in developed countries is the result of agricultural policies in those countries. Furthermore, a substantial portion of the PSE is due to market price supports such as tariff and other forms of trade protection. However, there has been a decline in the PSE for each country in the table and the OECD as a whole between 1986 88 and 2003 5, and with the exception of Japan, there has been a shift away from market price supports toward direct subsidies. These agricultural policies, however, continue to influence the trade flows of agriculture into

and out of developed countries. The sheer size of the economies where these policies are in place means they have a significant impact on global agricultural trade.

Agriculture and the World Trade Organization
The protection and support of agriculture in a number of developed countries has been justified on the grounds that agriculture deserves special consideration because it is linked to national culture. This special status has been recognized by the multilateral trade negotiations that have occurred under the General Agreement on Tariffs and Trade (GATT) and later under the WTO. Under the GATT, at the initial urging of the United States, certain agricultural sectors were exempted from the general prohibition in the agreement against quantity restrictions, as were export subsidies. As the EU took shape, it developed a Common Agricultural Policy (CAP) that provided general protection and support to farmers in all member countries and led to strong and increasing support by the EU for the special status of agriculture in multilateral trade negotiations.

The EU, the United States, and Japan remain strong supporters of the special status of agriculture. Countries that wish to export their agricultural products to these markets, however, argue that these policies are unfair since not only is access limited for certain commodities, but the subsidies provided to

producers in these protected markets give them an advantage over producers in countries without such subsidies. Developing countries tend to be particularly critical of agricultural supports since they are not in a budgetary position to support agriculture and believe agriculture is one area where they may have a comparative advantage.

When the WTO was created as part of the Marrakesh Agreement in 1994, a specific Agreement on Agriculture was designed to align agricultural trade rules with those of other products. The Agreement on Agriculture dealt with three general issues that influenced global agricultural trade: market access, domestic support, and export subsidies. For market access, the agreement required countries to convert quantity restrictions to tariffs. Once tariff equivalents of quantity restrictions were established, they were to be reduced. For domestic support, the agreement distinguished between trade distorting measures, which countries were required to reduce, and nontrade distorting measures. As part of the Agreement of Agriculture, developed countries agreed to reduce the total aggregate measure of support (AMS) by 20 percent by 2000, while developing countries agreed to reduce it by 13 percent by 2004. Nontrade distorting measures were exempt from reduction commitments. A final special category of domestic support measures was also exempt from reductions. These measures, which were used especially in the

EU, covered payments under programs designed to reduce the overproduction that occurred under other traditional market support payments. For export subsidies, no new subsidies could be introduced and existing subsidies had to be reduced by 36 percent in value by 2000 for developed countries and by 24 percent by 2004 for developing countries, although special conditions applied in some cases (Ingno and Nash 2004). The changes in the rules governing agriculture are reflected in the data presented in table 2, which shows a general reduction in producer support among OECD countries and a shift from market price support to direct subsidies.

The Agreement on Agriculture has generally been viewed as a step forward for trade negotiations; although it did not bring about substantial changes in the short run, it did set up a framework that aligned agriculture with other products. Its supporters hoped that setting up this framework would lead to further liberalization of agricultural markets in future rounds of WTO negotiations, particularly in the current Doha Round of trade negotiations. In fact, the Ministerial Declaration launching the Doha Round put agriculture as the first item on the agenda, indicating its priority in the negotiations. However, the Doha Round has failed to make substantial progress and the negotiations have faltered largely because of disputes over agricultural issues. For example, prior to a WTO meeting in Cancun in 2003 a group of developing countries, referred to as the G21, stated clearly the importance of dealing with agriculture issues such as protectionism and farmer subsidies. The Cancun meeting made no progress on these agricultural issues and was generally viewed as a failure. Following a WTO General Council meeting in July 2006 and the continued failure to make progress, the chairman of the WTO's Trade Negotiation Committee noted that agriculture is "key to unlocking the rest of the agenda" and that there was "no visible evidence of flexibilities" that would help solve existing problems (WTO 2006). Agriculture, thus, remains the principal stumbling block to further trade liberalization.

Complicating the disputes over protection and support of agriculture are additional issues that have emerged as the Doha Round of negotiations has progressed. First are market access barriers that have been put in place because of domestic concerns about methods used for production. While this is a broader concern for trade negotiations, it is particularly important for food products where health and safety concerns are significant and where countries may legitimately claim a right to protect their consumers. Although international agreements and standards exist, separating legitimate from illegitimate standards imposed by particular countries is not straightforward. The case of genetically modified organisms (GMOs) is a good example. Because of concerns over the health and environmental impacts of such products, the EU has enacted laws requiring the labeling and traceability of GMOs. However, the United States has challenged these policies as illegitimate restrictions on trade, arguing there is no evidence to support such concerns. The dispute remains unsettled (Zarrilli 2005). A second issue is the protection of geographical indications (GIs), names or labels used to indicate the geographic origin of certain products and, by extension, to indicate that these products have certain qualities or meet certain standards of production because they are from a certain region. Many food and beverage terms   such as Parmesan and Gorgonzola cheeses, Parma ham, Chianti, and Champagne   have come to be used generically although they have specific geographic origins. The EU and a number of developing countries argue that if the products are produced through a traditional, controlled manner in a specific region, their names should be protected and that existing protection is insufficient. The EU has proposed amending the current protection under the Trade-Related Aspects of Intellectual Property (TRIPS) agreement in favor of a mandatory multilateral system of registering these types of products (Evans and Blakeney 2006).

Food, Agriculture, and International Development Of the 1.2 billion poor people in the world, 75 percent live in rural areas (IFAD 2001). Therefore, although the contribution of agriculture to global GDP continues to decline in importance, it remains a fundamental component of the livelihood

strategies of these households and is critical to the advancement of the less-developed countries. Not only does agriculture provide food for the survival of the rural poor, it may be an important path out of poverty, particularly if the poor can take advantage of opportunities to produce nontraditional, high-value crops, which tend to be labor-intensive. The manner in which the global economy operates can alter the prices farmers fetch for their products, thus offering them incentives to produce more or less depending on the direction of price effects. Trade policies in developed countries therefore have an impact not only on developing economies, but potentially on the level of rural poverty in those countries.

Other than altering the incentives for farmers in developing countries, the policies of developed countries affect developing countries' agriculture through food aid. As a result of incentives for over-production in their agricultural policies, many developed countries have food surpluses. A portion of these surpluses is often used as food aid to developing countries. Although this seems a reasonable response to hunger, critics of food aid have argued that the provision of food creates disincentives for local production and policy. Increasing the supply of food commodities may cause prices of food to decline, thereby leading to lower incentives for farmers, rich and poor alike, to produce. The provision of food aid may also limit investment in agriculture by developing country governments that count on a regular supply of food aid to overcome limitations in food availability. This can limit the development of the rural economy and perpetuate a state of dependency. Most of these issues can be overcome with the judicious use of food aid in emergency situations and the careful management of aid programs when implemented, but the use of surpluses for food aid has the potential to cause significant problems for developing economies (Barrett and Maxwell 2005).

Given the importance of agriculture as a productive activity in developing countries, particularly in the poorest countries, the manner in which it is treated in global economic relations, and the agricultural policies enacted by key players in devel-

oped economies, can have a profound impact on economic development. Trade controversies are then closely linked to broader global issues of poverty and equity.

The New Agricultural Economy in Developing Countries In recent years, agricultural production in many developing countries has undergone profound changes, leading it to become increasingly oriented toward high-value global and urban product markets. These changes have mirrored many of the changes that occurred in developed countries earlier and have been driven largely by changes within developing countries. On the demand side, these include increased urbanization, the expanded entry of women into the workforce, and the development of a middle class all of which have led to greater demand for higher-quality and processed foods (Reardon et al. 2003). On the supply side, the opening of markets to foreign direct investment (FDI) influenced not only manufacturing sectors but also the domestic food market and the role of agro-industry in those markets. These domestic changes, combined with the expanded trade in processed and nontraditional products, have had a profound effect on the workings of the agricultural sector in many developing countries.

Referred to by some as the "new agricultural economy," these changes have led to new organizational and institutional arrangements within the food marketing chain as evidenced by new forms of contracts as well as by the imposition of private grades and standards for food quality and safety. Where open markets with a variety of sellers of different food commodities used to operate, there are now frequently supermarkets. Where small-scale processors of goods for the domestic consumer market such as potato chips used to exist, multinational corporations have taken over. Other multinationals have invested in the production of high-value crops such as fresh flowers and vegetables for immediate export to foreign markets. These supermarkets, processors, and exporters have specific requirements for the commodities they wish to purchase in terms of the quality of the goods and the timing of receipt. Products destined for the food market, in particular,

often must meet certain sanitary and phytosanitary standards. To ensure those requirements are met, these buyers often procure their goods through contracts with producers rather than through spot markets.

These rapid changes have brought new challenges and opportunities to farmers and policymakers in developing countries. These new markets provide significant opportunities because they tend to provide a price premium for quality and high-value products. But they also may be difficult to access and, in some cases, involve substantial risk. Often, new inputs and varieties are required and farmers must have sufficient information on grades and standards to be successful. Governments can play a critical role in facilitating access to information as well as providing assistance with the transition into these markets. This is particularly important for poorer farmers who often lack the resources to take advantage of new opportunities. Governments also play a critical role in verifying and certifying that sanitary and phytosanitary measures are in place. Furthermore, since such standards are often used as a mechanism to limit trade, governments may be called on to ensure that limits to market access are legitimate under the WTO rules.

The Role of Agriculture in the World Economy
While agriculture continues to decline in its overall economic importance in global trade, its special status in trade negotiations and its critical role in economic development and global poverty alleviation make it a sector that will continue to play a critical role in the world economy. In the short run, agricultural issues are likely to dominate trade negotiations. In the long run, global and domestic agricultural policies will influence the ability of countries to develop, and for the poor within those countries, to exit poverty. Agriculture will continue to be part of any discussion of global economic relations.

■ aid, bilateral

Bilateral aid is official development assistance that flows directly from a donor country government to a recipient country. This is in contrast to multilateral aid, in which many donor governments pool their contributions via intermediary institutions that then disburse aid to recipient countries. Yet another category is private aid that individuals, corporations, and foundations donate voluntarily, often through nongovernmental organizations (NGOs). Typically, bilateral aid accounts for two-thirds to three-quarters of all official aid; estimates of private aid put it at about one-tenth the size of official aid.

Although bilateral aid of one form or another is as old as the nation-state, the modern era of bilateral aid began with U.S. aid to reconstruct Europe under the Marshall Plan following World War II. Over time, governments of other major developed countries joined the United States in providing bilateral aid, sometimes following U.S. pressure to share the burden. In some cases, aid programs developed out of colonial administrations during the 1960s as more and more colonies became independent. In other cases, notably Japan, the bilateral aid program evolved from war reparation payments. A number of developing countries notably China, India, and Venezuela are also aid donors.

Bilateral aid is most often government-to-government, although in some circumstances donors may fund NGOs directly. Many aid donors are members of the Organisation for Economic Co-operation and Development (OECD). The Development Assistance Committee (DAC) of the OECD is the international body that sets aid reporting standards, monitors aid flows, and urges donors to improve the quality and quantity of their aid. The DAC's main focus is on official development assistance (ODA), which it defines as official concessional flows for developmental purposes to low-income countries. This includes grants as well as loans that are at least 25 percent concessional as compared to a commercial alternative (35 percent for "mixed credits," where aid is used to finance a commercial venture). Over the life of an ODA loan, repayments of principal and interest must be at least 25 percent lower than for a comparable commercial loan. ODA normally excludes grants and loans for military purposes and funds not directed to poor countries. In contrast to multilateral aid, most bilateral aid is given as grants; Japanese aid is the exception. The DAC's long-standing goal is for donors to contribute seven-tenths of 1 percent of gross domestic product (GDP) as ODA, though only a few of the most generous donors attain this target. In general, the United States has been the largest donor but among the least generous as a share of GDP. Under the Marshall Plan, U.S. aid was as high as 2 percent of GDP, but it has been one-tenth of that in recent times. France, Germany, and Japan also have been major donors, while the Netherlands and the Scandinavian countries have been the most generous DAC donors relative to their GDPs.

Bilateral aid can fund a specific project (project aid), provide more general budgetary support for the recipient government (program aid), or flow through an NGO. Although reconstruction aid to Europe was often program aid, bilateral aid to developing

countries has more often been project aid. Since the 1980s, multilateral aid agencies, particularly the World Bank, have become heavily involved in program aid, which aims to promote policy and institutional reform in developing countries; most bilateral donors put less funding into program aid.

Controversies Despite its apparent humanitarian nature, aid especially bilateral aid has been heavily criticized as insufficiently humanitarian and relatively ineffective. Critiques begin with the low volume of aid, both relative to the size of donor economies and relative to the need of the recipients. Critics also point to donor behavior that suggests that need can take a backseat to more narrowly defined donor interests such as geopolitics and commercial advantage. The geopolitical imperative is particularly pronounced for the United States with top recipients (Israel, Iraq, South Vietnam, South Korea) reflecting U.S. military interests rather than recipient need. For European donors former colony status dominates need, while Japanese aid often flows to countries rich in raw materials that Japan lacks.

The composition of aid also undercuts its development potential, as much bilateral aid is tied to purchases of donor products that are often expensive and inappropriate. Where aid funds projects, researchers have documented a bias toward large import- and capital-intensive undertakings that suit donors' needs but fail to reflect the relative scarcity of capital and foreign exchange in recipient countries. Aid levels are generally contingent on the donor's budget position so that aid tends to increase when the world economy is doing well. The result for many developing countries is procyclical aid fluctuations that can have the unintended consequence of destabilizing the recipient economy. The multiplicity of donors, each with their own priorities, procedures, and teams of visiting experts, can create a huge operational burden on a developing country government. All of these factors can reduce the development effectiveness of bilateral aid.

In response to the shortcomings of bilateral aid, the DAC and others have pushed for more multilateral aid. But if the main developmental short-comings of bilateral aid arise from its use as a geopolitical and commercial tool, why would donors be willing to redirect funds from bilateral to multilateral agencies? One argument is that the greater apparent independence of multilateral agencies makes them more efficient at some tasks (e.g., promoting sensitive institutional changes and providing a credible signal to private capital markets about the investment climate in the recipient country). A second argument is that donor country taxpayers favor developmental rather than geopolitical aid and that the donor government can demonstrate its developmental orientation most clearly through multilateral contributions. Neither argument, however, explains why some donors both contribute to and then work to undermine the independence of multilateral agencies. In any event, supporters of bilateral aid argue that the multiplicity of domestic interests served by bilateral aid helps to maintain a coalition in favor of larger budgets so that the net developmental impact of catering to domestic donor interests may be positive.

A recent trend in aid allocation has been toward selectivity. Research from the World Bank has argued that aid generally fails to promote growth and development when recipient government policies are poor and also that aid fails to promote policy change. Thus the implication is that more aid should be directed to countries that have already adopted appropriate (i.e., progrowth) policies. The empirical basis for these conclusions has proven weak. The original approach to estimating the link between aid and growth conditional on policy is not robust to small changes in specification or in which countries and years are examined. Other approaches have found a variety of results: aid has no impact regardless of policy; aid has a positive impact regardless of policy; aid has positive but diminishing returns regardless of policy; aid has a positive impact everywhere but the effect is larger when policies are good; and aid has a greater impact when policies are bad. Competing studies use different measures of aid, different approaches to deal with the potential for reverse causation, and different time horizons. The estimated impact of aid ranges from zero to eco-

nomically substantial (a several percentage point increase in the growth rate of GDP).

Despite this uncertainty, many bilateral donors have increased the country selectivity of their aid programs. In the United States, the Millennium Development Account is a direct application of aid selectivity with 16 indicators of good governance used as criteria for aid eligibility. Other donors, including Scandinavian countries, have moved toward using governance criteria to reduce the number of countries receiving funds. Although such a policy might seem to abandon poorly governed countries to their fate, advocates of selectivity maintain that incentive effects (the desire to qualify for aid) will induce better governance so that eventually all would benefit. In the past, however, political changes in donor governments have led to changes in bilateral aid allocation. If developing country governments expect such changes to continue, the incentive effects of current selectivity criteria will be undermined.

Opponents of aid have frequently rallied behind the slogan "trade not aid," pointing out that protectionist trade policies in donor countries cost developing countries far more than they receive in foreign aid. In addition, they argue that trade is likely to improve the efficiency of developing country economies whereas aid could introduce perverse incentives and promote rent seeking or corruption. Yet the arguments in favor of more trade do not weaken the case for aid as the slogan's "either/or" dichotomy seems to suggest. The distributional impact of trade is likely very different from that of aid, as the poorest in most need of aid are unlikely to be the main beneficiaries of increased trade.

■ aid, food

Food aid is a resource provided on concessionary terms in the form of, or for the provision of, food. In accounting categories, international food aid is a cross-border flow that is an entry into a country's balance of payments. National governments do provide food aid within their own borders, however. Generally, food aid is thought of as assistance provided by donor governments and humanitarian agencies to address the problems of hunger, food insufficiency, and malnutrition and indeed *some* food aid is expressly for this purpose. Over the history of modern food aid, however, substantial amounts of food aid have had little to do with addressing hunger.

History and Origins Food assistance throughout history has included attempts to address famine in

Venezuela in the 1830s, Ireland in the 1840s, and the Ukraine in the 1930s all of which involved significant shipments of food. The India Famine Codes in the late 19th century may have been the first systematic attempt to balance market forces and free food distribution. But the origin of large-scale contemporary food aid traces to the post World War II period in North America, when technological advances led to dramatic increases in production that resulted in significant surpluses and declining prices for farmers. Politically obligated to purchase the surpluses, the U.S. and Canadian governments found it less costly to give away the surplus food than to store it. United States Public Law 480, enacted in 1954, formalized this process. Hence the origin of modern food aid was a means of addressing domestic surplus production not a means of addressing hunger or poverty. Over the past 50 years food aid has served multiple objectives: disposing of surplus production, supporting farm income, maintaining a maritime shipping fleet, supporting domestic agribusiness and food processing industries as well as addressing hunger in foreign countries.

Types of Food Aid Classically there have been three kinds of food aid. *Program food aid*, for almost 40 years the largest single category, is subsidized deliveries or free grants of food on a government-to-government basis. The recipient government usually sells the food and uses the proceeds for many purposes not necessarily for food assistance or anything to do with addressing hunger. The main purpose of program food aid has been to provide budgetary support or balance-of-payments relief for recipient governments.

Project food aid provides support to field-based projects in areas of chronic need through deliveries of food, usually on a grant basis, to a recipient government, a nongovernmental organization, or the U.N. World Food Programme. The recipient agency then uses the food either directly in projects such as mother and child health, school feeding, or food-for-work projects that provide an employment guarantee using food for wages, or by "monetizing" the food aid selling it in the recipient country market and using the proceeds for project activities that require cash as an input rather than food.

Emergency or humanitarian food aid consists of deliveries of free food to populations affected by conflict or disaster, with a host country government, the World Food Programme, or a nongovernmental organization acting as the distributing agency.

Trends in Food Aid The total annual flow of food aid in the years 1981 through 2005 was around 8 10 million metric tons (see figure 1) a relatively tiny amount compared to the more than 300 million tons of commercially traded food of the same commodity groups. Since 1980, humanitarian food aid has become the most dominant form, amounting to about 60 percent of the total, whereas prior to 1980, it was in the range of 10 15 percent. Since the beginning of the 21st century, program food aid or government-to-government food assistance has declined sharply, and by 2007 seemed likely to be phased out altogether soon. Project food aid tended to be relatively stable in volume terms in the period 1980 2005. In the post World War II years, food aid comprised as much as 15 percent of total overseas assistance in the early 21st century, by contrast, it accounted for only 2 3 percent of the total.

Food Aid Policy Debates International food aid has been subject to weak regulatory mechanisms, many of which are outdated or dysfunctional. As a result, many of these mechanisms were being renegotiated as of 2007, or their roles were being taken over by other, newer institutions. The Food Aid Convention originally signed in 1967 and renewed
Figure 1

in 1998   existed on one-year extensions for several years in the first decade of the 21st century, and was up for a major renegotiation by 2007. Much of the impact of food aid on trade has come up for negotiation at the World Trade Organization.

The extent to which food aid undermines international trade or local incentives for agricultural production is also a subject of controversy. Overall, there appears to be no significant impact of food aid on domestic production, but different kinds of food aid have different effects   well-managed emergency food aid can actually lead to an increase in food production (with a lagged time effect, because well-managed emergency food aid can enable farmers to cultivate a crop when they might otherwise be unable, thus resulting in a greater harvest available at the end of the season). But poorly targeted food aid that ends up being consumed by people who would otherwise be able to grow or purchase food may undermine production or trade incentives. Open "monetization" (the sale of food aid in the recipient country) is thought to be one example that causes trade or production displacement.

Traditionally food aid was provided in kind by donor governments, to be used or distributed either by recipient country governments or by humanitarian agencies. Beginning in the 1990s, food aid from some donors has been "untied" from market sources in donor countries, meaning that a proportion of food aid budgets are now in cash for purchasing food either within the country where food aid is needed, or in a nearby developing country called local and regional purchase. European donors and Canada devote significant proportions of their funding to local or regional purchase of food, which is believed to save both time and expense when responding to acute need, thus enabling more rapid response and a relatively greater volume of response within fixed budgets. United States food aid continued to be tied to procurement in U.S. markets as of late 2007, and the extent to which "aid-tying" of food assistance continued to be allowed was a subject of considerable controversy in World Trade Organization negotiations over a new Agreement on Agriculture. In addition to pressure for untying

food assistance, there was also considerable evidence that cash transfers are a more effective and efficient means of ensuring access by poor or disaster-affected populations to adequate food under some circumstances.

■ **aid, humanitarian**

Humanitarian aid is assistance provided directly to people affected by conflict or disasters. Traditionally it is in-kind material assistance   food, shelter, or

medical care   but it also can take the form of cash assistance. The primary intent of humanitarian aid is to save lives, reduce suffering, and protect human dignity in times of crisis. Often, additional objectives are to protect people's livelihoods and assets or other indirect life-saving goals. Humanitarian aid is different from development aid, which has longer-term objectives and sometimes greater conditionality but the distinction is not always clear, and in chronic emergencies may become quite blurred.

History and Origins Although there are humanitarian antecedents in many different religious and cultural traditions, the history of modern independent humanitarian aid traces to the Battle of Solferino in 1859. There, Swiss businessman Henri Dunant was horrified by the impact of industrialized warfare and organized a local effort to assist wounded soldiers on the battlefield. Dunant essentially struck a deal with the belligerent armies that he would not interfere with their conflict provided they would grant him safe passage to assist the wounded who were incapable of continuing to fight. In 1863, Dunant founded the International Committee of the Red Cross (ICRC) in Geneva, based on the same principle. The ICRC is the organization mandated by international humanitarian law to provide protection and assistance to wounded or captured soldiers, and especially to civilians and other noncombatants caught in conflict. National chapters of the Red Cross soon grew up as well, usually mandated by law in the host country. In Islamic countries, these are known as Red Crescent societies. The International Federation of Red Cross and Red Crescent Societies (IFRC) is made up of these national chapters.

Other Humanitarian Agencies Under international law, the state has the first responsibility for the protection and provision of assistance to citizens within its borders. But often the government of an affected country either cannot provide adequate assistance or, in some cases, may be one of the parties causing a humanitarian emergency in the first place. In such cases, other agencies may be called on (or take it on themselves) to provide assistance. Following each of the major crises of the 20th century, other agencies were founded to provide humanitarian

assistance for the victims of war as well as people affected by natural disasters or other crises. These include specialized UN agencies and nongovernmental organizations (NGOs). UN agencies mostly formed in the aftermath of World War II include the United Nations Children's Fund and the Office of the UN High Commissioner for Refugees. The largest of the UN humanitarian agencies, the World Food Programme was founded in 1963, and the Office for the Coordination of Humanitarian Affairs was founded in 1998, reorganized from the former Department of Humanitarian Affairs.

Major NGOs were also formed in response to the crises of the 20th century: Save the Children was formed in the aftermath of World War I, CARE and Oxfam in response to World War II, and World Vision in response to the Korean War. Médecins sans Frontières was formed in 1969 after French doctors split with the ICRC over the issue of raising public awareness about the plight of civilians during the Biafran war. More recent crises have seen the advent of increasing numbers of nontraditional providers of humanitarian aid   including the military, private for-profit companies, and contractors.

Defining Characteristics In principle, humanitarian assistance is based on the premise that no human caught in a life-threatening situation should be denied assistance (or conversely   and more controversially   that all humans in a life-threatening situation have a right to receive assistance). This was formalized by the ICRC in 1965 as the principle of *humanity* or the *humanitarian imperative*. This principle now informs humanitarian assistance across most if not all humanitarian agencies. The ICRC also formally articulated six other principles on which it had based its work for nearly a century and which followed logically. The first is *impartiality*, or the imperative to provide assistance on the basis of need alone, without respect to nationality, race, religion, gender, or political point of view. The second is *neutrality*, or a refusal to take sides in a conflict or to engage in "political controversies." This was seen as a principle in its own right and the means to gain access to conflict-affected populations. A third principle is *independence*, meaning that the offer of humanitarian

assistance should be independent of government policies or actions. *Voluntary service*, *unity*, and *universality* are the other principles. These principles are codified for the entire humanitarian community in the Red Cross Code of Conduct and the Sphere Guidelines.

Humanitarian Policy Debates Up to the 1980s, humanitarian action was seen to be largely beyond reproach — a form of altruism that was neither a threat nor of serious political consequence. After the end of the cold war, humanitarian action became, for a time, a substitute for major powers' political engagement in problems affecting other countries — for example, in the Balkans wars of the 1990s. Since the onset of the global war on terrorism, humanitarian action has come to be seen, both by major powers and, in some cases, by popular perception in host countries, as part of a larger political and security agenda. Most humanitarian agencies still refuse to take sides in conflicts, but neutrality — especially the admonition against "political controversy" — is the subject of intense debate and many humanitarian agencies do not claim to be apolitical (although the ICRC still does). And as public sources of funding for humanitarian aid become more and more dominant, the capacity for independent humanitarian action has declined.

The principle of impartiality is intended to govern the provision of humanitarian aid in all circumstances, but political considerations often trump humanitarian principles in practice, and there are large discrepancies in the level of response by the humanitarian community to similar levels of human suffering by affected populations — from as little as a few dollars per person in some forgotten crises in Africa to more than $7,000 per person affected by the Indian Ocean earthquake and tsunami emergency in late 2004.

With larger budgets and greater scrutiny have come calls for the humanitarian enterprise to be more accountable — not only to the donors that provide funding, but for the behavior of agency staff in emergencies, for the development of industry standards for humanitarian response to which all actors should be held responsible, and to the recipient communities that are affected by war and disaster. To this end, in the early 21st century several interagency initiatives, including the Sphere Project, the Action Learning Network for Accountability and Performance, and the Humanitarian Accountability Partnership International, developed to hold humanitarian action to higher standards of accountability.

■ **aid, international**

International aid, or official development assistance (ODA), comprises a wide range of financial and nonfinancial components. These may take the form of cash transfers as well as grants of machinery, technical advice, and analysis and assistance in capacity-building support. Although foreign aid is often envisaged as transferring resources from rich to poor countries, the reality is more complex, with more than half of all ODA actually going to middle-income countries.

Early Foreign Aid The history of modern aid and colonialism are in many ways intertwined. In order to extract raw materials and exploit economic activity abroad, the colonial powers provided investment capital, technology, and personnel to colonies. Examples include the Belgian-initiated railroads in the Congo, the French design of the Suez Canal, and railroads and roads built under British rule to transport primary commodities in southern and eastern Africa.

Explicit reference to aid became more widespread in the 1940s. During this period, the wealthier countries began considering broader economic development as a goal, focusing on aspects of engagement that were not directly or exclusively related to extraction and exploitation. This reflected an evolution of economic and strategic interests (and in part was associated with the decline of mining relative to other sectors and also with the development of air and other military capabilities). It also reflected a changing understanding of human dignity in which human rights and self-determination emerged in strong opposition to earlier Darwinian notions, which had reinforced colonial notions of superiority. The 1940s also brought to the fore arguments for the need to invest in strategic alliances and in peace.

The period immediately following World War II saw a concerted effort to avoid a repeat of the post World War I peace process and reparations, which had served at best as a short-term palliative. It was recognized that peace required economic integration and this required both financial flows and policy changes to bring about closer economic integration. The new vision for sustained peace through economic opportunity gave rise to the Marshall Plan, as well as to the Bretton Woods conference and the creation of multilateral institutions such as the United Nations (UN), the World Bank, and the International Monetary Fund, whose goal was to increase international cooperation and assistance. This architecture largely remains in place today.

Increasingly, broad goals such as education were supported by emergent foreign aid programs and endorsed in parliamentary acts of the time, such as the 1948 British Overseas Development Act. In 1949, President Truman's inaugural address proposed the creation of a program for development assistance. The UN's 1951 report on *Measures for the Economic Development of Under-developed Countries* (with Arthur Lewis as the lead author) advocated the creation of a dedicated UN fund to support development, as well as an International Finance Corporation (IFC) to underpin private investment (five years later the IFC was established as part of the World Bank Group). In the 1950s and early 1960s, following the granting of independence to most colonies, many former colonial civil servants were employed in newly established aid projects, so that while the expatriate personnel remained, the nature of the relationship changed.

The initial focus of these institutions was on rebuilding war-torn Western Europe and Japan and on stabilizing the world financial system, rather than on broader notions of development. Indeed, the first four of the World Bank's loans were devoted to postwar reconstruction. In addition to supporting

the activities of the multilateral agencies, the wealthiest countries began to set up their own bilateral initiatives to provide aid flows and technical assistance to developing countries. In 1960, Canada created an External Aid Office, and in 1961 the United States created the United States Agency for International Development, France inaugurated a Ministry for Cooperation, Japan created the Overseas Economic Cooperation Fund to provide loans for developing countries, and Germany established its development bank, the Reconstruction Credit Institute (KfW). Sweden and the United Kingdom established bilateral aid agencies in 1962 and 1964, respectively. These agencies at first focused on former colonies, leaving broader global reconstruction and development to the multilateral institutions such as the World Bank. Over time, however, the objectives and strategy of multilateral institutions and national agencies converged, and there is now a significant degree of overlap.

From the outset, nongovernmental and other groups had ambitions that were often ahead of governments' views on aid. For example, the World Council of Churches in 1958 called on the rich countries to allocate 1 percent of their national income to aid for developing countries. This was later taken up by the Development Assistance Group, which was established in 1960 as a forum for consultation among aid donors at the Organisation for European Economic Co-operation (OEEC), which became the Organisation for Economic Co-operation and Development (OECD) later that year. A target of 0.7 percent was agreed by the UN General Assembly in 1970, but by 2006 it had been reached by only five countries, despite the fact that rich countries are much wealthier and poor countries are much better managed than when the pledge was made.

Foreign Aid during the Cold War Chilling relations between the West and the Soviet Union meant that from the 1950s to the fall of the Berlin Wall in 1989, Cold War politics became a key determinant in all foreign policy, and not least aid. Increasingly aid was used as a means to support and bolster friendly states. Where geopolitical interests were involved, economic and military support were often closely interconnected.

In Zaire (now Democratic Republic of the Congo), for example, aid was used as a strategic tool. Between 1960 and 1990, more than $10 billion was disbursed in aid to Zaire in support of an increasingly brutal and corrupt dictatorship. Maintaining a strategic alliance, rather than development effectiveness, was the objective. Similarly, political and economic factors were the main drivers of large aid donations in support of the transition to a market economy in Eastern Europe and Central Asia. Not surprisingly, such aid was not correlated with long-term poverty reduction. Such cases have lent support to aid skeptics.

A key characteristic of foreign aid during the Cold War period was its "tied" nature: aid was allocated to the purchase of specific goods and services from the donor country. In this way, much aid never left the donor countries, as it ended up paying for consultants or services (such as foreign-language radio broadcasts).

Food aid also became prevalent. In part this reflected the growing agricultural subsidies in Western Europe, the United States, and Japan, which rose to more than $300 billion per annum. These rich countries protected their markets from competitive imports and subsidized their farmers, dumping surpluses on world markets, often as food aid. Poor countries were unable to compete in agriculture and trade, and the dumping of food on world markets undermined and destabilized agricultural prices and production in developing countries. As outlined by Goldin and Knudsen (1993) and Sen (1982), the distortion of markets and policy failures contributed to price instability, long-term decline in agricultural prices facing developing country farmers, and even famines. While protectionist trade policies in the rich countries undermined the potential for sustainable growth in many developing countries, rich countries' aid policies provided at best a partial response to short-term humanitarian needs. Similarly, while significant quantities of aid were directed into investments in irrigation and other agricultural infrastructure in developing countries, the undermining

of the rural economy as a result of protectionism by rich countries provides a classic example of a failure to achieve policy coherence.

Although there has been some progress in untying aid since the end of the Cold War, tying persists in many aid programs today. Meanwhile, agricultural protectionism continues to have a pernicious influence on world agricultural markets and trade, with the negative impact far exceeding the aggregate poverty-reduction impact of aid (Goldin and Reinert 2007).

Adjustment Programs Adjustment (or macroeconomic policy-based) aid was developed in the 1970s. This was designed to respond to the severe macroeconomic imbalances experienced by many poor countries, characterized by ballooning deficits and debt that were aggravated by exogenous shocks from oil prices, interest rates, and other sources. The constellation of conservative political leadership in the United States (Reagan), the United Kingdom (Thatcher), and Germany (Kohl) was also important, with aid acting as an agent of reform and bolstering the private sector. By the late 1970s, aid was increasingly predicated on the recipient country's acceptance of conditions that sought to enforce macroeconomic and trade reforms, and to facilitate private (particularly foreign) investment. The focus on structural economic reforms was not accompanied by corresponding attention to institutional reform or investments in education and health, and neglected demands of social cohesion. This limitation, along with the mounting assertions of self-determination by rapidly democratizing governments, as well as the pendulum swing in rich countries away from their former preoccupation with market solutions, meant that by the mid-1990s, following the end of the Cold War, adjustment lending had become far less common.

Poverty Reduction and Recent Development Models The reform of aid policies in the 1990s responded to a range of factors. These included the end of Cold War preoccupation with strategic allies, the success of the growth paradigms in China and India, the failure of major aid efforts (not least in Africa),

and intellectual evolution   particularly in the areas of understanding around economic growth, poverty reduction, and development. Perhaps the most striking belated change was the recognition that to reduce poverty, aid should be focused on those countries where poor people lived and in which the governments were willing and able to act to overcome poverty. In addition, as poverty increasingly was recognized as multifaceted, the policy discussions and interventions around poverty reduction became more nuanced.

By the late 1990s, the goals of development began to embrace the elimination of poverty in all its dimensions, by improving education, health, and other human capacities, not simply focusing on income. Scholars such as Sen (1999) gave intellectual form to the emerging understanding that development means increasing the control that poor people have over their lives. This is derived through a combination of education, health, and greater participation in politics and community decisions, as well as from improvements in access and income. It is also clear, and beginning to be reflected in aid policy, that the various dimensions of poverty are related, and that income growth generally leads to progress in the nonincome dimensions of poverty and vice versa.

From the early 1990s, this rethinking of development was associated with an increase in aid flows to health, education, and infrastructure. Due mainly to improvements in two countries, China and India, where government policies are largely but not entirely independent of aid, social indicators such as health and education on average have improved very quickly since the mid-1970s in developing countries.

Direct targeting of health and education goals, rather than waiting for improvements to follow income gains, has led to a virtuous circle that has improved the welfare of individuals and families. On average, at every level of income in developing countries, infant mortality fell sharply during the 20th century, and life expectancy increased by 20 years (from mid-forties to mid-sixties) over a period of only 40 years. The global trend in life expectancy remains very positive, although HIV/AIDS has dra-

matically reversed this trend in a number of countries, particularly in southern Africa.

Developing countries also experienced dramatic improvements in literacy: whereas in 1970 nearly two in every four adults were illiterate, now the proportion is only one in four. Particularly important is the greater focus on female literacy, as this has been shown to be pivotal in improving the health and human development levels of children and communities. These achievements cannot solely or even primarily be attributed to aid, but rather to a combination of national policies (not least in China and India) along with growing integration and the adoption of new health and other technologies.

The unevenness of the performance of developing countries, and ability of some very poor countries to grow despite resource constraints and others to squander abundant resources, has led to a growing focus of the aid community on governance and institutions. Increased attention to governance and institutions also has been associated with growing interest among academics in this topic. In the pragmatic world of aid agencies, attention to governance, and to institutional development more broadly, has been translated into growing budget allocations for the development of civil servants and building of regulatory authorities and judiciaries. It also has been associated with a growing emphasis on the allocation of aid in light of the performance of the recipients.

Millennium Development Goals In 2000 heads of state of both rich and poor countries committed themselves to achieving the Millennium Development Goals (MDGs). These are:

- eradicate extreme poverty and hunger
- achieve universal primary education
- promote gender equality and empower women
- reduce child mortality
- improve maternal health
- combat HIV/AIDS, malaria, and other diseases
- ensure environmental sustainability
- develop a global partnership for development

The Millennium Declaration marked a major step in the history of aid. For the first time, the international community came together to establish clearly defined common goals with a set of agreed measurable targets and results for developing countries, donor agencies, and the multilateral institutions. Building on this declaration, the 2002 Monterrey Conference established a new partnership for development in which the rich countries promised to increase both the volume and the quality of aid in return for commitments from developing countries to undertake vital reforms to enhance aid effectiveness. Despite the remarkable achievements in many countries, not least in China, it is becoming clear, however, that many or most of these goals will be missed, except perhaps that of halving income poverty, which will be met at the aggregate global level. Many developing countries have failed to live up to their Monterrey commitments on poverty reduction and good governance. Similarly, the rich countries have fallen well short of their commitments. Aid flows have increased, but these remain far short of the agreed targets, and the Doha Development Round of trade negotiations appears to be a long way from meeting even minimal expectations. The tremendous achievements of the MDGs, not least in terms of mobilizing public opinion in many rich countries, are therefore at risk of dissipating due to inadequate political will.

Types of Aid and Harmonization As figure 1 shows, only around 20 percent of bilateral aid in fact ends up as a cash transfer into the hands of the recipient country ("other bilateral"). Around 80 percent takes the form of aid to multilateral organizations, debt relief for countries such as Afghanistan and Iraq, administrative costs, costs for refugees living in donor countries, and technical cooperation including support to students from developing countries studying in donor countries (imputed student costs). Although this indirect assistance may make an important contribution, it is often driven by the priorities of the donors and is no substitute for predictable, multiyear flows of aid mobilized behind government programs that are agreed upon by governments and across the donor community. Such

harmonization and coordination are vital to reduce the currently high transaction costs of aid, which divert scarce resources   including the time demands on the most competent civil servants   into projects and activities that have too often been donor priorities rather than recipient national priorities.

Considerable progress has been made in harmonizing approaches to aid. The 2005 Paris conference and subsequent Declaration on Aid Effectiveness brings together multilateral and bilateral donor agencies around common standards. While the MDGs provided a landmark in terms of defining common goalposts for development, the harmonization agenda aimed to ensure that the donors played as one team. Significant improvements in coordination among a number of the traditional major donors point the way forward. As diverse aid flows are increasingly combined into broad multidonor activities, the challenge for donors is

to convince their skeptical voters that their taxes have been spent wisely. Although attributing the impact of aid to individual donors may be counterproductive, in that it suggests that development is not a national responsibility, aid   like all public expenditures   requires accountability.

Levels of Aid, Aid Quality, and Evaluation Aid flows increased markedly between 1945 and 1960, but subsequently slowed and from 1990, when it averaged 0.34 percent of the gross national income (GNI) of the donor countries, declined to around 0.22 percent of the GNI of high-income countries in 2001, as shown in figure 2. The recommitment to aid at the Monterrey Conference in 2002 finally arrested this decline, with ODA reaching a record high in 2005. Subsequently, aid flows again slipped back, reflecting the fact that the inclusion of Iraq and Nigerian debt write-offs had temporarily inflated the numbers earlier. Going forward, the key uncer-

tainty is the extent to which donors will honor the pledges made at Monterrey and reiterated at the 2005 Gleneagles G8 Summit, where it was agreed to double aid to Africa and to achieve the 0.7 percent commitment.

In comparison with domestic investment and government expenditure, aid flows are small. Development aid to developing countries in 2005 was a record $107 billion, but even without taking account of the fact that most of this was not transferred to developing countries, aid remained less than one-third of foreign direct investment in developing countries ($334 billion), which itself was only a small fraction of total investment in developing countries (more than $2 trillion). Although increasing the volume of aid is vital, improving its quality is even more important.

Both the relatively small levels of aid and the instability of these flows for middle- and low-income countries are reflected in figure 3. Since aid is typically small compared to budget and private investment flows, and more unstable, the key challenge is to ensure that aid effects systemic changes such as introducing ideas and improving practices. These in turn have positive effects on growth and poverty reduction. Such indirect effects are difficult to measure and attribute, however, and, as indicated earlier, attribution risks undermining government leadership and harmonization. It is important that aid be provided not solely for short-term and relatively easily measurable objectives.

A growing body of literature had sought to use randomized techniques to provide improved rigor to the evaluation of aid. Impact evaluation and other evaluative methods may be expected to become a necessary part of the toolbox of aid agencies as they and the recipient governments seek to enhance the effectiveness of pubic expenditures. These techniques yield powerful insights when applied through carefully designed studies of projects or programs but typically they are less helpful at the macro policy level, where there is limited scope for randomization or associating single actions or actors with particular outcomes.

The complexity of social and economic change means that the impact of foreign aid cannot be easily separated from other factors. The most successful projects are ones in which recipients are strongly committed and in charge of the development process, and where there is good partnership among donors and with local leadership. Recipients are then particularly well placed to draw on foreign aid, with a view to both learning lessons from international experience and funding well-defined investments that can underpin growth and poverty reduction. For such recipients, the objective is to become self-sustaining and to turn from being net aid recipients to donors, as has been the experience of China.

The increasing focus of aid on countries with relatively sound policies has meant that the estimated

poverty-reduction productivity of ODA is significantly better than it was in the early 1990s. Countries with poor policies and poor institutional quality cannot simply be isolated, however. Some recent studies have found that the impact of aid on growth is strong regardless of institutions and policies, and it is necessary to be cautious about the evidence in this area.

Weak States If viable institutions and policies are conducive to effective use of aid, what should be done in weak or failed states where these do not exist? Such states usually lack the governance, institutions, and necessary leadership for successful reform. Each incompetent government has its own specific problems, and aid interventions must be tailored to addressing and overcoming these. A growing specialist literature has examined the lessons of interventions in weak states, and a number of pointers to supporting such countries have emerged. It has been shown that knowledge transfer and capacity building are more effective than large-scale financial transfers and that improving basic services such as health and education is also important. In such situations, the potential role for the United Nations, in particular in terms of coordination, is often underestimated and tends to be inadequately resourced in terms of personnel and funds. While Ethiopia, Mozambique, and Uganda are postconflict success stories, unfortunately many other countries have seen little significant progress in the past decade. The challenge for aid agencies is to remain engaged but not to throw good money after bad policies. Part of the response lies in attention to coherence between aid and other policies, especially in weak states and in countries beset by conflict, as emphasized by Collier (2007).

Global Public Goods Although much of the attention in the aid debate has been on support to countries and national projects, global initiatives are also significant beneficiaries of aid. An important step in development is supporting what are known as global public goods. These are public goods whose benefits are felt beyond the border of any one country, benefiting the poor in many countries and even all humanity. The pooling of resources and coordination across national boundaries, and between the public and private sectors, is vital in addressing such global issues. These include combating major infectious diseases such as HIV/AIDS and malaria, developing better crops, managing intellectual property, and dealing with climate change.

An example of a global aid initiative is the Consultative Group on International Agricultural Research (CGIAR). This is a partnership working toward sustainable food security and poverty reduction through scientific research in the fields of agriculture, forestry, fisheries, policy, and environment. The partnership includes countries, international and regional organizations, private foundations, national agricultural research systems, civil society, and the private sector, all of which support the work of 15 international research centers. The CGIAR significantly helped the Green Revolution, which began in South Asia in the 1970s and has led to impressive gains in production of basic food crops across the developing world. Between 1970 and 1997, yields of cereals in developing countries rose more than 75 percent, coarse grains 73 percent, root crops 24 percent, and pulses nearly 11 percent.

Private Initiatives and New Donors The Global Alliance for Vaccines is an example of aid in support of a global public good. It is also indicative of the rapidly growing contribution of private donors. The Bill and Melinda Gates Foundation and other relatively recently established private aid donors, as well as privately launched campaigns such as the Clinton Global Initiative, are adding to the contribution and in terms of financial flows overtaking the more traditional nongovernmental aid institutions such as the Ford and Rockefeller Foundations, civil society groups such as Oxfam and Save the Children, and religious foundations. Together, these nongovernmental flows are channeling aid that in many countries, and perhaps also in aggregate, now exceeds the public flows. This greatly increases the potential as well as the complexity of aid (see Klein and Harford 2005). In addition to the rapid growth of private flows, interesting experiments are under way that seek to build on public-private partnerships and leverage official flows. One such example is the pilot Innovative Funding Facility for Immunization. The

French-led actions to increase aid flows through a levy on airline travel and the British-led securitization of future aid flows to raise finance from capital markets are indicative of the way that innovation and partnership are beginning to change the shape and potential of the traditional aid architecture.

The transformation of traditional aid recipients, notably China, into highly significant aid donors has challenged the aid establishment. The thrust of the OECD official donors has been closer coordination and ensuring that the recipients conform to governance and other standards. China's and other new aid donors' perspectives and objectives are not necessarily aligned with those of the traditional donors, and these new donors have not been part of the OECD Development Aid Committee coordination process. The growth in these new aid flows, both from private foundations and from governments such as China and Venezuela, has meant that there have been significant increases in the volume of aid. The key questions concern the coordination and quality of this aid and the extent to which it will be able to avoid the dangers of tied aid and aid fragmentation that undermined previous surges in aid. The ending of the Cold War and the ability of countries to access aid together with a range of development ideas and technologies have made the biggest difference to development outcomes in recent years.

A New Way Forward The polarization of the aid debate between the strong advocates, such as Sachs (2005), and deep skeptics, such as Easterly (2006), reflects an oversimplification of the complexity of the development challenges and the need for strong domestic and international actions. Resources alone will not be sufficient to ensure that poverty goals are met. Level of commitment and quality of policies and institutions in recipient countries are the primary determinants of progress. It is also evident that, when a country is committed to reform and poverty reduction, external support (which may not be limited to aid) can have substantial payoffs. An important area in which rich countries can provide support is through reforms of their own trade and other policies. As important as robust global growth is reform of the protectionist policies of rich countries (such as

in agriculture and textiles), which are so damaging to poorer countries. As Goldin and Reinert have shown (2007), changes in trade, investment, migration, environment, security, and technology policies in rich countries would pull many out of poverty. The Commitment to Development Index and associated analysis by the Center for Global Development provides an indicative summary of the importance of coherence between aid and other policies.

Coherence between aid policies and other policies is vital. For example, aid donors' support for health and educational systems is undermined by the recruitment of teachers, doctors, and nurses to work in the rich countries. Similarly, support for agricultural programs is undermined by protectionism and subsidies that prevent developing countries from competing on world markets. With continued reform momentum and steady external support, past experience suggests that developing countries can extend and deepen the progress of the last half-century. Despite the progress made in the past 50 years, an immense poverty challenge remains. Approximately 1 billion people still live on less than one dollar per day. Aid has never been more effective in supporting growth and reducing poverty, and returns on aid have increased sharply. Raising the volume and the quality of aid is a moral, strategic, and economic imperative.

■ aid, international, and political economy

International donors provided more than U.S. $2.4 trillion in the form of foreign aid from 1960 to 2004. In many African countries, for example, the size of the official development assistance (ODA) divided by gross domestic product (GDP) exceeded 10 percent during that period. Despite this large amount of financial aid, the economic performance of the recipient countries has been disappointing. The poor macroeconomic impact of foreign aid raises questions about its efficiency. Political economy considerations can provide explanations for the scarce effectiveness of foreign aid. By the term *political economy* we mean the allocation of markets and other economic institutions subject to the political environment in which these institutions work. In particular, the process of decision and delivery of foreign aid present multiple agency problems, derived from the existence of asymmetric information (the donor and recipient do not have access to the same information) and moral hazard (receipt of aid causes the recipient to exert less effort to solve its own problems), and inappropriate institutional designs.

Most of the academic research finds that international aid is ineffective in fostering economic growth. For instance, Boone (1996) finds that aid does not significantly increase investment or any human development indicator, but it increases the size of the government. Burnside and Dollar (2000) find that aid works, but only when there are good fiscal, monetary, and trade policies. Easterly, Levine, and Roodman (2003) dispute these results, however, since they are sensitive to changes in the sample period or filling in the missing observations.

One of the basic reasons that development aid does not seem to work is the presence of perverse incentives and faulty institutional designs. The political economy perspective treats foreign aid as the result of the incentives and motivations of the donors, the response of country recipients, and the interaction between donors and recipients.

The Incentives of Donors and Aid Agencies

Efficient public programs are supported by the existence of sufficient (perfect) information and the accountability of the representatives. Households in developed countries are, at the same time, clients and citizens. As clients, they have information about the programs intended for their benefit and as citizens in democratic countries they can hold politicians accountable for their poor performance. In the case of foreign aid this feedback loop is absent: taxpayers in donor countries (citizens) are not the beneficiaries of the aid, and they do not have information about its effectiveness; and the intended beneficiaries (clients) do not have the right to vote in donors' countries and, therefore, cannot affect the politicians in charge of approving the aid programs. We can describe this situation as a broken information feedback loop (Martens et al. 2002). In the absence of effective feedback from the intended beneficiaries of aid, the interests of consultants and suppliers of goods shape many decisions of aid agencies: these groups are the direct beneficiaries (control the information about the programs) and have direct influence on the decision-makers of donor countries.

Donors and aid agencies also have multiple objectives and represent multiple principals that often do not share the same objectives. For these reasons the institutional design of official aid agencies is difficult even if donors have good intentions. First, the multiplicity of objectives and the difficulty of performance measurement make it complicated to link the salaries of workers in aid agencies to their performance. Therefore, aid bureaucracies tend to define their output in terms of money disbursed (or volume of loans) instead of the rate of poverty reduction or economic development of recipient countries (Easterly 2003). Second, aid bureaucracies tend to develop their own procedures and increase the complexity of tenders and contracts (see Easterly 2006). Finally, aid agencies will tend to choose projects that minimize the risk of bad publicity, not the ones that maximize, for instance, the reduction of poverty.

Donor countries may also have objectives that undermine the effectiveness of foreign aid. In fact, almost half of the foreign aid provided by the members of the Organisation for Economic Co-operation and Development does not have as basic objectives poverty alleviation and economic

development. Alesina and Dollar (2000) find that while some donors have the right incentives (raising income level, poverty reduction, institutional improvement), many others are driven by political and strategic considerations. The wrong incentives include targeting aid to inefficient and nondemocratic former colonies or developing countries that vote in favor of the proposals of the donor at the UN. The strategic interest in the Middle East explains why Egypt and Israel receive so much economic support from Western countries.

Another possible reason for the ineffectiveness of foreign aid is the so-called warm glow effect. Donor citizens may be interested only in the fact of giving itself and not in its effects on the recipient countries. Therefore, the utility of donors does not depend on the well-being of the citizen of recipient countries but rather on the satisfaction the donors derive from providing aid to developing countries. This interpretation is consistent with the evaluation of policies based on inputs (money disbursed) rather than on outcomes (effect of the aid on poverty and economic development). It is also consistent with voters who are worried about the total amount of money that is dedicated to foreign aid (say 0.7 percent of GDP) and not about the results that aid produces in recipient countries.

Finally, since there are multiple principals (donors and agencies), the effectiveness of foreign aid depends also on the degree of coordination among them. The need for coordination has increased over time because the level of fractionalization, or diversity, of donors (many donors with a small share of aid) has increased from 0.25 in 1960 to 0.68 in 2003. Fractionalization is measured as 1 minus the sum of the squares of the shares of different donors. Empirical evidence suggests that higher donor fragmentation is associated with a reduction in the bureaucratic quality in recipient countries.

The Interaction between Donors and Country Recipients The relationship between donors and country recipients is usually subject to principal-agent problems and moral hazard. The relationship between a principal (the donor) and an agent (the country recipient) can lead to problems when the interests of the principal and the agent do not coincide and the principal has less than perfect information about the actions of the agent. The usual game theoretical solution to these types of problems is to write a contract, or design an incentive mechanism, to force the agent to perform as the principal wants. This incentive mechanism usually takes the form of aid conditionality: the requests associated with the concession of some types of foreign aid. The credibility of the threat to retire aid if the conditions of development of the projects are not satisfied is critical for the effectiveness of the conditionality, however. Recipient countries realize that these threats are not credible because donors do not have strong commitment ability. Donors may want to punish countries that do not fulfill their promises but, at the same time, they are pressed by their own constituencies to continue helping poor countries. The problem is reinforced by the fact that the status of the managers within the aid agencies is determined by the size of their budget and the disbursement of funds. Empirical studies show this lack of commitment technology. For instance, Burnside and Dollar (2000) do not find evidence of a significant positive relationship between aid flows (ODA) and good policies. Other studies find that there is no relationship between the developing countries' score on quality of governance (corruption, democracy, service delivery, etc.) and who receives adjustment loans, for instance, from the World Bank.

Some authors have proposed alternative institutional designs to overcome the lack of credibility of donor threats. Svensson (2000) shows that, when there is no commitment technology available for donors, the delegation of the aid budget to an institution with less aversion to poverty (underdevelopment) than the donor will improve the welfare of the citizens of the recipient country since it makes the threat credible. This theoretical result has yet to be implemented, however. If the aid game implies a donor and several recipients' countries, or a pool of projects that are disbursed to each individual country depending on its relative performance, it is possible to design an aid tournament in which potential aid recipients compete for funds. In a bilateral relation-

ship the recipient country has more bargaining power and, therefore, the credibility of the donor's threats is weak. If the donor can choose between different recipients, however, then recipient countries have to commit to a high level of reform effort if they want to win the aid tournament. In fact, donors can impose a cost on the recipients (for instance, they may ask for a set of reforms even to get considered in the tournament). This is the traditional "stick and carrot" type of strategy. In addition, having alternative countries to receive the aid of a donor reduces the ability of one particular recipient country to use hold-up strategies.

Another problem associated with the moral hazard present in the relationship between donors and developing countries is the so-called Samaritan's dilemma (Gibson et al. 2005), which can be represented as a two-person game. The donor (Samaritan) wants to help a poor country to get out of poverty. Therefore, it gets a higher payoff from helping, or giving a large amount of help, than from not helping (or providing less aid). The recipient has to decide how much effort to exert. Obviously, the donor prefers the big-effort action. The recipient country, however, prefers to exert little effort. If the game is repeated, as happens in real interactions between donors and developing countries, then we get little effort and high levels of foreign aid. There are many examples of this situation. Donors give large amounts of food aid to developing countries with food crises. Recipient countries know this and, therefore, they have incentives to relocate their own resources away from agriculture. This action will increase the likelihood of food shortages in the recipient country, which will generate constant food aid from the donor. Then the recipient country produces less food than necessary, and the developed country sends food aid on a regular basis.

The solution to this principal-agent problem is to monitor the recipient country. However, the lack of information and the absence of accountability of the bureaucracies of recipient countries make monitoring a nonviable solution. Another possible solution for this type of problem is to threaten to withdraw the aid in the future. If this threat is credible

it can support the best outcome (high level of aid and high level of effort, which economists describe as a Pareto efficient equilibrium). In game theoretical terms the donor threatens the recipient country with ending in the worst situation for both agents (low level of aid and low level of effort, which economists call, in this case, Nash equilibrium). However, donors are usually unable to make this type of credible threat.

The Delivery of Aid in the Recipient Countries
The distribution of aid at the operational level is also subject to a principal-agent relationship and to a moral hazard problem. The moral hazard problem exists because the benefit of the contract to the donor depends on the actions taken by the recipient, and the recipient may not have incentives to behave properly after the donor has provided the funds. The recipient will take the action most beneficial to his own preferences. Therefore, the terms of the contract must be modified to provide the recipient enough motivation to behave properly. Bureaucracies are even more important in recipients' countries than in donors' agencies. The civil servants of the public bureaucracies of developing countries have a long-term contract with a low wage. Public regulation makes it difficult to fire government workers even if their performance is not appropriate. One particularly important consequence of this lack of incentives in the provision of education and health in developing countries is the so-called missing doctors and teachers. For example, Banerjee and Duflo (2006) report that, in India, the absence rate for teachers is more than 24 percent and for health providers is more than 40 percent. This is the usual shirking behavior predicted by the principal-agent theory.

In addition, since salaries for workers in the public bureaucracies of developing countries are low, they tend to run private moneymaking activities or extract side payments from citizens (extort payment for free health services, demand money for a license, etc.). Corruption and rent-seeking behavior are often the result of severe moral hazard problems combined with the absence of clearly defined property rights. One important explanation for the lack of effect of foreign aid on growth and social development is the

capture of aid by government officials and politicians. The measurement of the extent of corruption in the allocation of foreign aid in developing countries is difficult because accounting systems work poorly and local accountability is weak. The World Bank has used Public Expenditure Tracing Surveys (PETS) to calculate how much money is diverted from the time the central government receives the funds until they reach the final beneficiaries. The proportion of funds that reach the intended beneficiaries tends to be very low. For instance, Reinikka and Svensson (2004) analyze a large public educational program (a capitation grant to cover schools' nonwage expenditures) in Uganda financed by the central government using district offices for its distribution. They find that many schools received nothing. On average, schools got only 13 percent of the government spending in the program. In Tanzania the analysis of the Primary Education Development Plan launched in 2002 by the World Bank and bilateral donors shows that, on average, only 20 percent of the funds disbursed at the central level finally reached the schools.

Rent-seeking activities may even produce negative consequences in the recipient countries. Djankov, Montalvo, and Reynal-Querol (2006) provide empirical evidence that a sudden windfall of resources in the form of foreign aid can damage the political institutions of the receiving country by reducing checks and balances in government and democratic rules. They label this effect the curse of aid. Other authors provide evidence that Somalia's civil war was caused by the desire of different factions to control the large amount of food aid that the country received.

The Market for Aid Some authors have argued that a possible solution to the agency problems in the aid industry is to increase competition among aid agencies (Klein and Harford 2005) and recipient countries (Svensson 2003) and use competition to make the market work better. Aid agencies should compete to fund the best projects, enabling donors to channel funds through the agencies that produce the best results; and developing countries should compete to receive official aid. This increase in competition, if accompanied with improved monitoring and benchmarking of aid agencies and proper evaluation of outcomes for the projects, may alleviate some of the incentive problems originated by the multiple layers of delegation in the delivery of foreign aid.

Notice that this does not contradict the need for coordination among the donors. Competition is good in the sense that recipient countries will choose the most efficient project, and therefore will end up with the best donor for them. So, the existence of many donors competing for recipients does not imply that many donors will be delivering money to the same project, but only the most efficient one.

■ aid, military

Military aid can take many different forms, includ ing grants, loans, or credits to purchase defense equipment, services, and training. Often military aid is "tied," in that recipients must use the funds to buy defense goods and services from the donor. The aim of military aid is to assist recipients with a variety of security problems. The recipient countries may face a number of different security threats, such as inter national war, internal rebellion, or terrorism. Military assistance is often supplied to help not only with the recipient's national security but with regional and global security threats. These international consider ations make the study of military aid controversial.

Military aid may imply that this is part of a do nor's official development assistance (ODA). How ever, *aid* as defined by the Organisation for Eco nomic Co-operation and Development (OECD) explicitly excludes military aid. The OECD defini tion of ODA to developing countries includes grants or loans to countries that are undertaken by the of ficial sector in order to promote economic develop ment and welfare. Grants, loans, and credits for military purposes are excluded.

Rather than being part of a donor's aid budget, military aid is part of the defense budget. Defense expenditure is typically one of the least reliable components of a government's budget. The level and composition of military expenditures are often treated as state secrets and sizable portions are not open to public scrutiny. Generally, it is hard to study the effect of military aid since data are scarce and unreliable (Brzoska 1995).

Military and Development Aid Military and development aid are both targeted at foreign nations. An interesting question is how much of foreign assistance is allocated to the seemingly different purposes of overseas security on the one hand and development on the other. This analysis requires data on the different components of aid. Development aid data are available through national governments and the OECD. Few countries, however, make military aid data available, the United States being a notable exception. When one sums up U.S. military and development aid to "total aid," it is interesting to see how the composition of total aid changed over time. From 1970 until 1975 the share of military aid was larger than the share of development aid; it accounted for 53 percent of the total aid figure. After the end of the Vietnam War the composition of total aid changed, and by the early 2000s the share of military aid in total aid was only 23 percent.

Military aid data for the other major donors are not readily available but if the shares of military and development aid are similar to those of the United States, a rough estimate of global military aid can be calculated. In 2006 the sum of all development aid was U.S. $85 billion; therefore, globally military aid was probably around $26 billion. Not all of this military aid is provided to poor countries. Much of this military aid goes to developed countries such as Israel and Turkey. A large proportion of low-income countries' military expenditure is provided through foreign assistance, however. Since this is precisely the aim of military aid, there does not seem to be any problem with financing other countries' military budgets. But is all of the development aid used for the purpose of economic development for which it is intended or is some of it leaking into military spending, which is explicitly excluded from the definition of development aid?

A large number of studies examine what determines the allocation of aid to the different recipient countries (Alesina and Dollar 2000). The literature distinguishes between recipient need, recipient merit, and donor self-interest as motivations for development aid. It seems that, for example, U.S. aid allocation over the past few decades has been predominantly driven by geostrategic interests rather than by recipient needs (McKinley and Little 1979). In this sense donors use development aid for purposes other than assisting economic development in the recipient country. If donors do not always use development aid for its stated purposes, what about the recipient countries? In the development aid literature there is a large debate on fungibility   that is, there is concern that funds that are earmarked for a specific purpose are being used to finance projects and programs for which they were not originally intended (Feyzioglu, Swaroop, and Zhu 1998). It has been estimated that about 11 percent of development aid leaks into military expenditure (Collier and Hoeffler 2007). In 2006 this would have amounted to about $9 billion. Taking this leakage into consideration, we can state that the share of military aid in total aid is greater than the officially reported 23 percent; it is about 32 percent.

Military Spending in Low-Income Countries Is this explicit and implicit funding of military expenditure in low-income countries a problem? After all, these countries have security concerns, and without security no state can provide basic services to its citizens. Without security, economic development is not possible. Studies show that higher military expenditure in poor countries hinders their development (Deger and Smith 1983), suggesting that these countries should spend more on basic services such as infrastructure, health, and education rather than on the military. There is also evidence that higher military expenditure does not lower the risk of civil war, which is the most common form of large-scale violent conflict. It may even be the case that higher military expenditure in postconflict situations is particularly damaging because it increases the risk

of a recurrence of civil war. Rebels may not trust the government to stick to a peace settlement if they observe an increase in armament (Collier and Hoeffler 2006). They are then more likely to restart a rebellion. To summarize, many developing countries receive direct and indirect military aid, but the evidence so far suggests that it neither helps them to develop economically nor increases their security.

■ **air transportation**

Air transportation is part of a service supply chain that moves both passengers and cargo. Although commercial airlines offer the immediate form of transportation, they are tied to airports for their takeoffs and landings and to air navigation services for guidance and control in route. Passengers and cargo also need to move to and from the airport. Air transportation, therefore, is a sector that caters to the transportation of passengers overall but especially those going the shortest distances and to the movement of high-value, low-bulk freight.

Air transportation is a major industry in its own right and acts as a lubricant for many other economic activities. In broad terms, air transportation accounts for about 1 percent of the gross domestic product of the European Union and slightly less for the United States economy. Globally, in 2005 there were about 18,000 commercial aircraft, carrying 1.6 billion passengers and more than 43 million tons of freight annually, and serving more than 10,000 airports. These statistics, however, ignore the role that air transportation can play in stimulating economic growth and trade (it is estimated that between 35 and 40 percent of international trade by value is moved by air transportation), linking together diverse communities, and fostering particular types of industry

such as tourism and specialized agricultural sectors such as exotic fruits and flowers.

Although air transportation played a role in providing mail service, and some limited passenger and cargo service before 1939, it has gained significance only since the end of World War II with major technological advances in aircraft design and enhanced air traffic navigation systems. The advent of commercial jet aircraft in the 1950s provided faster and cheaper long-haul services, and in the 1960s the development of wide-bodied aircraft increased carrying capacity, which cut the costs of air travel considerably, reduced environmental concerns, and improved safety. Radar and improved communications, together with institutional changes and accompanying new management practices beginning in the late 1970s, resulted in further cost reductions and the expansion of airline service networks.

Modern scheduled air transportation networks take a variety of forms. To meet social or political objectives, governments stipulate certain types of service that must be supplied either by state-owned airlines or through financial support to private airlines from the taxpayer. Although government interventions in the market are considerable, they have diminished in many countries since the 1980s. As a consequence, profit is the motivating factor for an increasing portion of the air transportation system worldwide.

Where the market plays a dominant role, three broad types of scheduled service are common. Many services are essentially point-to-point with the airline serving a set of individual origins and destinations, often in a linear network akin to a bus service. This approach may be refined into radial networks with a carrier concentrating services from a base airport but offering no coordinated services involving a change of plane that allow passengers who want to continue on to another destination from that base. Finally, hub-and-spoke operations involve a major airport serving as an interchange facility (a little like a postal sorting office) that consolidates passengers or freight from diverse origins on flights to a range of destinations. This type of operation allows economies of scope (the ability to offer a range of services at lower costs than if they were provided individually) and density (the lowering of costs as larger flows can be channeled into each route), but suffers from potential congestion at the hub airports as traffic converges. From the airlines' revenue perspective, hub-and-spoke operations also allow them to enjoy economies of market presence   the ability to offer direct and indirect services between numerous airports.

These various network types overlap to a considerable extent with the types of commercial airlines that provide the bulk of services. The linear and radial services are features of low-cost or "no-frill" airlines such as Southwest in the United States and Ryanair in Europe. These carriers can standardize their fleets, fly from secondary airports, avoid scheduling difficulties by minimizing the number of connecting services they offer, and provide limited onboard and ground services because of the short duration of flights. In contrast, the "legacy," or full-service, carriers focus on channeling their traffic through hubs   for example, Delta Airlines through Atlanta and Northwest Airlines through Detroit   and deploy a mixed fleet to meet the needs of a more complex network, wide variations in flight lengths, and long-haul international services. To enhance the range and frequency of services, the legacy carriers often form global alliances. The Star Alliance, for example, includes United, Lufthansa, SAS, British Midlands, and other airlines. This allows for easier ticketing and fight connections as well as larger frequent flyer programs that reward passengers for loyalty to an airline or alliance.

Globally, the scheduled airline industry as a whole has not, at least since the 1980s, earned what would normally be seen as an economically viable return. Even in good years the operating margins of most airlines has been below the return offered by bank savings accounts. Excessive competition and, at least for a time, inflated costs account for this. This situation contrasts with most other elements in the air transportation value chain, with airports, air navigation systems, and global distribution systems all often making significant financial returns.

Besides scheduled airlines services, there are also charter services. These involve an entire aircraft's

capacity being sold usually to a tour operator who then sells these seats, often in conjunction with hotel rooms, rental cars, and the like, to leisure travelers. Until the 1990s, because their activities were less regulated than those of scheduled airlines, these operators were important in Europe, taking up to 20 percent of the air travel market. Regulatory reforms have reduced the importance of charter carriers and also their nature: many offer near scheduled services with regular flights, and seat-only sales, not requiring the addition of a hotel purchase, are common. There are also air taxis and business aircraft that offer personal air transportation, usually to business executives. In addition to civilian air services, the military in most countries operates large fleets of aircraft to move equipment and personnel, in addition to any direct combat-related activities, and these flights must be integrated into the overall air traffic control system.

Regulation Air transportation traditionally has been regulated very heavily. Economic regulation of fares, cargo rates, market access, and capacity became widespread after World War II, both internationally as countries tried to develop their own commercial air fleets, and domestically as air transportation became a mechanism for greater mobility and political cohesion within countries. Notions that airlines, airports, and air navigation services, if left unchecked, would become monopolies that would penalize users were used to justify economic regulation of fares and access. Social regulation was also widespread and often aimed at providing otherwise unremunerative services to remote regions as well as to ensure adequate safety.

Internationally, the UN International Civil Aviation Organization, established at the end of World War II at the Chicago Convention, regulates air transportation. The resultant agreements give sovereignty to countries regarding their own air space and set down the basis of negotiations between nations over international routes, called air service agreements. Until the late 20th century, most international traffic was severely controlled: often, only one carrier from each country could offer international services at a regulated fare, with a limited capacity, and with the revenues shared equally between

the two countries. Many domestic markets were also strictly controlled, and in some cases a state-owned airline was the only supplier of services at a regulated fare.

From the late 1970s on, there has been a global movement to introduce more market-based structures into the air transportation sector. This began when U.S. airlines removed rate and market entry controls (other than those retained for safety and security reasons) for domestic air cargo services in 1977 and from passenger services in 1978. The United States also initiated a large number of "Open Skies" agreements in the 1980s and 1990s that removed route access and fare controls from bilateral air service agreements with other countries but retained cabotage, the freedom of external airlines to operate within another country, and ownership controls. Parallel to this, by 1997 a gradual relaxation of international bilateral air service agreements within the European Union freed airlines services, both domestic and international, from economic regulation, including ownership rules within the EU.

The result of these changes has been an expansion in the number of commercial airlines and an increase in the diversity of services provided, not only by low-cost carriers on short-haul routes, but also by specialist airlines that offer only business class service on long-haul flights. In markets where regulatory reforms have been enacted, fares have been brought more closely into line with costs. At the same time, competition has lowered fares and forced airlines to become more efficient.

Airports The vast majority of the world's airports are either nationally owned or owned by a local (city or state) authority. The original reason for this was that airports, because of the large capital costs involved in establishing them, often are not commercially viable but nevertheless are important for strategic or local economic development reasons, and as a way to tie remote communities to larger cities. From the mid-1980s, airports have had to comply with strong regulations related to the noise, safety issues, and traffic congestion associated with them. Private sector involvement, however, has become more common under the state or local government

ownership umbrella, with airlines financing, leasing, or owning parts of airports (such as terminal buildings) or directly providing services (such as ticketing and ground handling). In some cases, airports have allowed private caterers, retailers, and the like to offer services on their sites.

Since the 1980s, many countries have moved to privatize entire airports, or to distance their ownership and operations from political processes. The British Airports Authority, which owns seven airports in the United Kingdom, including the three major airports serving London, was privatized with equity capital. Other airports have been bought out as going concerns by commercial companies with no equity holdings. Privatization, however, often brings with it challenges of regulating monopoly power; most cities only have one airport, or at most two. The approach pursued in many cases involves "price-capping," with a regulator controlling the ways in which prices charged by airports for take-offs and landings may change.

In South America and some parts of Africa, various forms of concessions have allowed states to retain their ownership of an airport but hand their entire management and investment strategy over to private companies for long periods. Such approaches are aimed at bringing private capital and expertise into airport development where public finance is limited and the local market does not have an adequate supply of skilled workers and managers.

Air Navigation Systems Providers Air transportation involves the movement of aircraft along corridors akin to three-dimensional railway tracks. In some cases the traffic flows freely with air navigation system providers (ANSPs) supplying navigation and weather advice. Most commercial aviation, especially in congested air space, is subjected to air traffic control to prevent accidents. These involve en route controls at higher altitudes and tower controls around airports.

Reforms in air transportation infrastructure have been slower to materialize than for airlines. Most ANSPs traditionally have been state owned but in recent years a number have been privatized or "corporatized" (turned into nonprofit entities either in-

dependent or government-owned but not managed). For example, NAV CANADA became a private not-for-profit corporation in 1996; Airservices Australia became a government corporation in 1988; and the UK air transportation system, NATS, became a public-private partnership in 2001. France retains state ownership of its ANSP but allows Direction des Services de la Navigation Aérienne access to private financial markets and to levy user fees. The Federal Aviation Administration in the United States outsources some activities but is financed by taxes. Because of the increase in international air transportation and the need for greater integration of systems, some countries are developing coordinated strategies for delivering air navigation systems (ANSs). Within Europe, for example, EUROCONTROL has the remit for creating a Single European Sky that ultimately links the various national ANSs.

The changes have come about as new ways are being sought to finance the modernization of facilities and to improve their efficiency. ANSs are highly capital intensive and are continually being improved, but adopting the new technology is expensive and often has to be tailored to the peculiarities of the existing system rather than using generic hard- and software.

One of the main difficulties in enhancing air traffic management performance through regulatory reform has been the concern with aviation safety. Academic studies show a greater aversion to being killed in a plane crash, for example, than in an automobile accident. The evidence to date is that, although there are some geographical areas where the record is poor, the overall safety of air transportation has continually improved over the years in terms of both mortalities and morbidity per passenger mile flown.

Overall, air transportation is the fastest-growing transportation mode in the world for both passenger and freight traffic. It has traditionally been highly regulated but since the late 1970s, the removal of economic regulation from many markets has led to improved efficiency, innovation, and lower costs and fares, without any reduction in safety standards. There is now diversity in the types of airlines that

offer services and also in the forms of infrastructure that is required to support flights.

■ **Andean Community**

The Andean Community (CAN), as this organization is currently known, is a regional integration agreement among Colombia, Ecuador, Peru, and Bolivia. The community was originally known as the Andean Pact and was created in 1969 to reverse the stagnation of the Latin American Association of Free Trade and address the integration and development needs of the Andean countries (Venezuela, Colombia, Chile, Ecuador, Peru, and Bolivia). Venezuela became part of the Andean Pact in 1973, and Chile withdrew from the pact in 1976 to pursue more liberal trade policies. Initially, the pact sought to harmonize policies, define a common external tariff, liberalize intraregional trade, regulate foreign direct investment in the region, and organize production across member Andean countries by encouraging the development of promising industries. Later on, the pact supported the agenda of becoming part of wider economic agreements such as Mercosur a

regional economic agreement among Argentina, Brazil, Paraguay, and Uruguay and the Free Trade Area of the Americas (FTAA) to be consistent with the General Agreement on Tariffs and Trade and the World Trade Organization principles.

The initial strategy of the Andean Pact was based on the import substitution, or closed regionalism, model that predominated in Latin America during the 1970s. According to this model, the government must coordinate economic policies and regional development plans in order to direct production toward the intraregional market. The consequence of this model is that protected rent activities (activities that generate rent because of government protection through tariffs or subsidies) develop, mainly in the industrial sector, which are financed in part by the revenues generated by primary-resource-intensive exports (agriculture, mining, and energy). Intraregional trade only increased from 1.7 percent of total exports in 1970 to 4.5 percent in 1979. This early stage of the Andean Pact failed for several reasons: many products were exempted from the tariff liberalization process; a clear consensus about the common external tariff was lacking due to significant differences in the level of protection of each Andean country; the production requirements established by the Andean Pact did not match the trade needs of each country, especially after the foreign debt crisis; the market was too small; and trade activity was directed mainly to the members of the Andean Pact. Therefore, the Andean countries were limited in their capacity to generate new foreign exchange, which became very important for paying the increasing foreign debt (Edwards 1993). The lack of coordination of macroeconomic policies led to exchange rate imbalances and to differences of protection among the Andean countries. (In 1980, about 25 percent of items included initially in the tariff list were exempted.)

These macroeconomic imbalances partially generated by the closed regionalism model contributed to the foreign debt crisis that exploded in the early 1980s. The adjustment policies applied to solve the crisis led to a contraction of the trade preferences among the Andean countries, thereby reducing the

trade during the mid-1980s. By 1985 the Andean Pact was practically moribund. Intraregional trade did not follow the initial industrial planning, and only about a third of the investment programs (machine tools, petrochemical, and automobile sectors) were approved. Nevertheless, the Andean Pact was revived with the Quito Protocol, which was signed in 1987 and later modified over the course of several presidential meetings. The most important modification, the Trujillo Protocol of 1996, resulted in the name change from the Andean Pact to the Andean Community of Nations, a new structural organization, and a shift in emphasis from closed regionalism (inward integration) to open regionalism (outward integration with the rest of the world) (Reynolds 1997; and ECLAC 1994). The establishment of the Andean Free Trade Zone (AFTZ) in 1993, and the Andean customs union in the form of an Andean common external tariff in 1995, spurred private initiatives and innovative rent-seeking activities (instead of protected rent activities) aimed at achieving an efficient allocation of resources and exploiting the competitive advantages of the region. This increased efficiency and innovation is the main reason behind the shift toward the open regionalism model. The AFTZ was completed in 2006 with the full incorporation of Peru.

Using CAN as an example, Creamer (2003) demonstrated that economic integration by stages into wider regional agreements may lead to an improvement of intraregional trade and total trade, and not to a contraction of extraregional trade as during the period 1980 97. Taking a simple indicator, the trade balance of CAN exports minus imports with the rest of the world increased from U.S. $1.196 trillion in 1969 to U.S. $31.435 trillion in 2005 (Andean Community 2006). However, this growth is mostly explained by the significant improvement of the trade balance of Venezuela. Venezuela accounts for 90 percent of CAN's trade surplus with the rest of the world. This trade balance may be substantially affected because of the withdrawal of Venezuela from CAN in 2006, although this effect may be partially compensated by the integration of CAN with Mercosur and the incorporation of Chile. The Andean Council of Foreign Affairs Ministers and the Andean Community Commission accepted Chile as an associate member in September 2006.

Governance During the 1990s, CAN changed its emphasis from a trade-oriented agreement into a political, social, and economic integration agreement in the spirit of the European Union. This transformation required the creation of the Andean Presidential Council and the conversion of the Cartagena Agreement into a General Secretariat in 1997. The set of all institutions that support the mission of CAN is the Andean Integration System (SAI). The political institutions that are part of SAI and have representatives of each member country are the Andean Presidential Council, composed of the presidents of member countries, which defines the strategic priorities of CAN; the Andean Council of Foreign Affairs Ministers, organized by the foreign affairs ministers of member countries, which is responsible for the foreign policy of CAN, agreements with third parties, and the election of the general secretary; the Andean Community Commission, in coordination with the Andean Council of Foreign Affairs Ministers, which is responsible for the intraregional policies of CAN; the Andean Community General Secretariat, which is the executive body of CAN; the Andean Community Court of Justice, which is the judicial body that interprets the Andean Community laws and solves internal disputes; the Andean Parliament, the legislative arm of CAN, which harmonizes member countries' laws; and the Business and Labor Consultative councils, which represent business and labor organizations, respectively, and advise the Andean Council of Foreign Affairs Ministers. Additionally, the Andean Development Corporation, which is responsible for promoting trade, investment, and economic growth in the region, and the Latin American Reserve Fund, which provides funds to the member countries to correct short-term macroeconomic imbalances and coordinates monetary and fiscal policies, also are part of the SAI. Finally, institutions of SAI responsible

for social policies are the Simón Rodríguez Agreement, which coordinates social and labor policies; the Andean Health Organization Hipólito Unanue Agreement, which coordinates health policies; and the Simón Bolívar Andean University, which promotes academic activities that are relevant to the integration and development of CAN.

Most of CAN's political institutions have not had a major impact on the internal policies of the Andean countries. These countries are still very much under the influence of the major financial multilateral organizations. Hence, CAN's political integration has been very limited. The Andean Development Corporation, however, has become a major source of funds to support the development policy of CAN. This organization has also had an impact in social areas, providing funds for projects that generate employment, support microentrepreneurs, and improve the productivity of the region. The Simón Rodríguez Agreement has helped to integrate educational systems in the Andean countries, and the Simón Bolívar Andean University has been invaluable in supporting the professional training of social scientists. However, major regional challenges include the development of human capital in technical areas and a significant increase in research and development investment to attract foreign capital and outsourcing opportunities to the region.

Andean Customs Union and Free Trade Zone
The Andean customs union, as it has functioned since 1995, establishes four basic tariff levels: 5 percent for raw material and industrial output, 10 percent for intermediate output, 15 percent for capital goods, and 20 percent for final goods. There are some exceptions to this common external tariff. For agricultural products, price bands help protect Andean agricultural products from subsidies and price variations in the international market. In 1997, Peru decided to join the Andean customs union and started a program of tariff reduction with Columbia and Ecuador. The Andean common external tariff covers about 90 percent of imports. The Declaration of Santa Cruz of the Andean Community, signed in

January 2002, introduced a new structure of the common external tariff that includes Peru. However, the new common external tariff had not been implemented and was still under review by a high level advisory group since August 2007.

CAN represented the Andean countries in the FTAA negotiations and lobbied the U.S. government for the extension of the Andean Trade Preference Act of 1991 into the Andean Trade Promotion and Drug Eradication Act of 2002. Also, CAN renewed the Generalized System of Preferences with the European Union for the period 2006 15 and at the time of this writing was negotiating a trade association agreement. In April 1998, CAN signed an agreement with Mercosur to create a free trade zone. As a result of this agreement, 80 percent of the trade between Mercosur and CAN was freed in January 2005. The remaining 20 percent will be liberated during the next 14 years. Additionally, the members of Mercosur became associate members of CAN, and Mercosur reciprocally conferred associate membership on the members of CAN.

The withdrawal of Venezuela in 2006, the potential signing of free trade agreements between the United States and Columbia, Ecuador, and Peru, and the formation of a South American free trade zone as agreed during the South American presidential meeting of 2004 are signs of the difficulties facing CAN. As long as CAN maintains its own identity, free trade agreements with the United States or with the other South American countries may indicate the success of the open regionalism process that has characterized the Andean Group since the 1990s. In fact, a South American free trade zone will open a market of 377 million inhabitants with a gross domestic product of U.S. $1.493 trillion and exports of U.S. $305.3 billion for 2005.

CAN offers significant advantages to its members, especially once the Andean Common Market is established. This market will enable the free movement of goods, services, capital, and people. CAN envisions that, in this way, it gradually will integrate itself into the world market, either through its participation as a subregion in a South American free trade

zone or in a free trade agreement with the United States.

■ anti-dumping

Many countries reserve the right to impose import taxes on foreign products that have been found to be "dumped" into their domestic economies (that is, sold at less than their "normal" prices). These tariffs, known as anti-dumping duties, have become a crit ical but controversial part of the multilateral trading system that has developed first under the General Agreement on Tariffs and Trade (GATT) and then under its successor, the World Trade Organization (WTO). Anti-dumping duties are one of the few ways consistent with international obligations by which governments may increase tariffs beyond levels negotiated in international trade talks.

WTO rules allow its members to impose these duties if the individual governments determine that foreign firms "dump" a product that damages a do mestic industry producing a similar product. In common usage, anti-dumping duties are used to counteract "unfair" import pricing practices by for eign competitors.

Dumping is defined in two principal ways within the WTO system. The first is when a foreign firm sells in a domestic market at a price below the price it sets for the same good in its home market, known as "price-based" dumping. In others words, interna tional price discrimination is an actionable practice under multilateral trade rules. The second basic definition, known as "cost-based" dumping, in volves a foreign firm selling its product in the do mestic market below its cost of production. In practice, this usually means that foreign firms are selling below the average total cost of producing the item. Anti-dumping duties may be imposed under WTO only if the dumping margin exceeds a de

minimis level of 2 percent (i.e. the percentage difference between the "normal" value and the price charged in the export market); dumping below this level is not subject to duties.

It is important to note that dumping is based on the pricing practices of individual firms in specific countries. Consequently, anti-dumping duties may vary across firms within a particular exporting country. This means that customs officials in a country that has imposed anti-dumping duties must pay very close attention to which particular foreign firm is exporting the product and from which country. This can impose important administrative burdens and in principle may provide incentives for foreign firms to try to circumvent the duties by mislabeling the product's country of origin.

Anti-dumping duties are a recognized exception to a number of core WTO principles. For example, the "most-favored-nation" (MFN) principle means that a member commits to impose the same tariff on the same product for all WTO member countries. Anti-dumping duties, in contrast, can vary across countries for the same product. WTO rules also normally require governments not to raise duties beyond the tariff levels agreed to through multilateral negotiations. Members are freed from this obligation, however, if foreign firms are found to be dumping. Finally, WTO rules require "national treatment" so that foreign firms and domestic firms are treated in similar ways. Under anti-dumping rules, foreign firms selling below average total cost (i.e., total revenue is below total cost) may be subject to sanction while a domestic firm that does not cover its costs will not face similar fines. The fact that anti-dumping is a WTO-allowed exception to these critical principles of the multilateral trading system suggests the importance that member governments place on discouraging this type of foreign pricing behavior.

Administration of Anti-dumping Rules Anti-dumping investigations are usually initiated by domestic firms concerned about foreign competition. The importing country's government then must undertake two separate investigations, one to determine whether there is evidence of dumping and the other to find out whether the imported products are harming the domestic industry. The former requires information about foreign firm pricing and the latter data on the competing domestic firms' economic conditions.

A domestic administering agency responsible for calculating dumping margins requires different detailed information about foreign firm behavior. For example, it must collect pricing data in the foreign firm's home market if it uses price-based methods. If it uses cost-based methods, it must obtain information about the foreign firm's production costs. Both methods require foreign firm cooperation if precise dumping margins are to be calculated. Some foreign firms may be reluctant to open their books to another country's investigating agencies and may decide not to cooperate. WTO rules allow for an administering agency to use other sources of information, including allegations of the domestic import-competing firms, to complete the investigation. The threat of using domestic allegations serves as an inducement to the foreign firm to cooperate by providing needed data.

Calculating dumping margins can also be complicated if there is pervasive involvement of the government in the economic life of a country. For example, before the demise of the Soviet Union, an agency investigating a charge of dumping by a Soviet firm would not be able to use any information based on administratively determined prices. The multilateral trade system consequently recognizes different anti-dumping procedures in cases of "nonmarket economies" (with the People's Republic of China as the most prominent current example). In order to conduct an investigation involving such an economy the domestic agency may collect information about the quantities of inputs used by the Chinese firm. The agency will then apply the input prices of a third country deemed to be at a similar stage of development (e.g., Bangladesh or India) to calculate a proxy cost of production. This can then be used to determine the dumping margin by comparing the constructed value with the price charged in the export market.

The second part of an anti-dumping investigation requires that a domestic agency determine whether

the dumped import causes "material injury" to a domestic industry producing the "like product." This requires that the domestic industry provide critical information about its current condition. Various indicators of material injury are used, including declines in domestic sales, employment, and profits, or the degree to which the dumped import prices are below domestic prices. In addition, the "threat" of material injury can also be a basis of imposing anti-dumping duties. Such a threat might be found if a firm found to be dumping has recently added significant export capacity.

According to WTO rules, anti-dumping duties finally imposed can be calculated in two distinct ways. One is that the import duties are equal to the dumping margins (i.e., difference between the "normal value" and the export price). This procedure is used in many jurisdictions, most notably in the United States. Those favoring this approach argue that anti-dumping duties are allowed because dumping itself is the ultimate problem, so the policy response must eliminate any dumping. The other approach is that the anti-dumping duties can be limited to the lesser of the dumping margin or the minimum duty required to eliminate injury to the domestic industry. This second version, the so-called "lesser-duty rule," is used in the European Union. Supporters of the latter approach often argue that the main goal of the anti-dumping process is to eliminate injury, not dumping itself.

WTO rules also allow alternatives to increased duties in anti-dumping cases. "Price undertakings" involve a settlement between the foreign firms accused of dumping and the importing country government. Typically, foreign firms offer to raise their export prices to eliminate any dumping in order to avoid duties placed on their products. If the investigating domestic government agrees to the offer, it will suspend the anti-dumping investigation as long as the foreign firms keep their exports prices sufficiently high. Price undertakings are particularly common in the European Union.

Anti-dumping orders may be in place for long periods. There is no specific time frame for their removal as there is with safeguard measures, which have an eight-year maximum. WTO members did agree in the Uruguay Round to require governments to review anti-dumping orders every five years after the original imposition of duties. In particular, duties must be taken off unless an investigation determines that their removal likely would lead to lead to a resumption of dumping and material injury to the domestic industry.

Anti-dumping actions, like other aspects of the multilateral trading system, are subject to the WTO review. This means that member governments can ask the WTO dispute settlement bodies to rule whether countries imposing anti-dumping duties have lived up to their obligations. This setup allows WTO signatories to develop and use their own systems and procedures to protect their domestic industries against imports found to be dumped and causing injury but allows exporting countries some recourse if they believe that the anti-dumping duties are unjustified or implemented inappropriately.

WTO rules give governments the right to impose duties on injurious dumped imports but do not require it. WTO obligations allow governments to impose anti-dumping tariffs only if doing so would be in the "public interest." This provision reflects the fact that import taxes raise the price paid by domestic consumers, including industrial users that import intermediate inputs. For example, the European Union's procedures require that national representatives evaluate the impact of anti-dumping duties on broader EU interests. In sharp contrast, other countries such as the United States prohibit administrators from considering consumer interests when making the decision of whether to impose anti-dumping duties.

Anti-dumping procedures are similar to another WTO-consistent method to impose import restrictions. Countervailing duties (CVDs) are allowed by WTO rules if exports have been subsidized by a foreign government and those exports cause material injury to a domestic industry. Such subsidies are deemed to be unfair to domestic competitors since it involves competition with a government, not just with a private company. Thus, CVDs procedures have a structure similar to anti-dumping duty sys-

tems (i.e., "unfair" competition plus material injury) but involve foreign government actions rather than private firm pricing decisions as in the case of anti-dumping.

Supporters and Critics Anti-dumping duties are a controversial part of the WTO. Many supporters argue that anti-dumping is a necessary response to unfair trade. Critics regard it as simple protection with a rhetorical flourish.

Many of those who support anti-dumping's role in the international trading system argue that it counteracts foreign predatory pricing practices. *Predatory pricing* refers to a strategy under which a firm charges very low prices in order to drive out competitors so that it can later increase prices after achieving a monopoly position. Domestic antitrust and competition policy are at least partially built on these ideas. In the case of international competition, supporters of anti-dumping argue that international price discrimination or pricing below average total cost is akin to predatory pricing by foreign firms.

Supporters also argue that anti-dumping duties are necessary to counteract foreign firms operating from a "sanctuary market." This refers to the possibility that formal and informal trade barriers allow foreign firms to receive higher-than-normal profits in their own market, which they then use to offset losses in the export market as they try to drive out domestic competition. This also is sometimes seen as a part of a predatory pricing strategy.

Anti-dumping is often criticized by those favoring trade liberalization. One of the most important criticisms is that anti-dumping is a just another form of protectionism since it involves an increase in duties on imports. In this view, anti-dumping duties reduce access of domestic consumers to foreign goods and result in greater damage to consumers than any benefits accruing to the domestic producing industry. Critics also note that anti-dumping investigations are extremely complicated, especially regarding the calculation of dumping margins. Domestic agencies must make a myriad of decisions about how to treat transactions of an individual foreign firm and how to calculate foreign costs of production. Uncertainty about how the investigating agency will calculate those margins means that it is difficult for foreign firms to know what margin they will finally face. One reaction by foreign firms is to raise their prices even in the absence of an anti-dumping allegation; the mere presence of an anti-dumping system may result in higher prices for consumers. Critics also point out that there is no requirement to determine whether or not there is any evidence of a sanctuary market or predatory intent by foreign firms before imposing anti-dumping duties. Finally, they note that domestic firms that sell their goods for different prices in different cities domestically (i.e., engage in domestic price discrimination) or sell domestically below average total cost (i.e., losing money on domestic sales) are not subject to sanction by the domestic government. In other words, anti-dumping duties punish foreign firms for undertaking practices acceptable if done by domestic firms.

Some observers, even among those who doubt whether international predatory pricing is an important threat, believe that the presence of anti-dumping rules may allow politicians to engage in broader trade liberalization than would otherwise be possible. This view holds that anti-dumping rules can act as a kind of safety valve; governments may be able to deflect pressures for broader protectionist measures by giving domestic industries an administrative process under which they can petition for import restrictions. This could allow governments to raise duties on only a small number of narrowly defined products even as restrictions are lifted on a whole array of other imports.

Anti-dumping in Practice Anti-dumping has a long history, especially in the English-speaking world, but it has spread across much of the world in recent years. The world's first anti-dumping law came into effect in Canada in 1904, followed shortly by New Zealand (1905) and Australia (1906). The United States implemented its first anti-dumping law in 1916. The countries that would eventually make up the European Union were also early users of anti-dumping provisions. This group of countries constitutes the traditional users of anti-dumping; up until 1986, worldwide use of anti-dumping was almost exclusively restricted to this group. Beginning

in the mid-1980s, countries such as Mexico, Argentina, and Brazil began to use the procedure more frequently. After the establishment of the World Trade Organization in 1995, many other countries began to use anti-dumping, including most notably India, the Republic of Korea, South Africa, and Turkey. Japan, though frequently a target of anti-dumping actions by importing countries, has only rarely used anti-dumping to restrict imports. The People's Republic of China has used anti-dumping more frequently in the post-2002 period but that country's involvement principally has been as the most frequent target of anti-dumping actions.

Anti-dumping duties have been imposed on a wide variety of manufactured, agricultural, and commodity products. The steel and chemical industries have been the most frequent users of the anti-dumping process. For the period between 1980 and 2002, approximately 50 percent of all anti-dumping petitions involved these two industries. This may reflect the very high fixed costs of both industries, which make them vulnerable to downturns in their industries and create incentives to expand production through exports to try to lower average production costs. The steel industry has been particularly active in the United States in supporting the role of anti-dumping in the multilateral trading system.

In short, the anti-dumping system receives strong support among some important members of the World Trade Organization but is controversial among nations especially reliant on exports.

■ anti-globalization

The spectacular growth in the intensity, scope, and visibility of globalization (understood here as the increasing interconnectedness of individuals, groups, companies, and countries) since 1990 has been accompanied by a parallel growth in anti-globalization a broad term used to characterize a public debate over the shaping, slowing, or rejecting of globalization.

Driven by the growth of international economic integration and international institutional arrangements and the spread of ever-denser networks of global communications, a debate has arisen since the 1990s around concerns regarding the distributional benefits of globalization, the desirability and impact of different types of policy, and the nature and representativeness of the political institutions that decide on global policy issues. The public face of this debate has been notable for the high-profile role of nonstate actors and for its focus on perceived shortcomings in current systems of global governance.

The terms most commonly used for this global debate, particularly with the involvement of nonstate actors *anti-globalization* and *the anti-globalization movement* were used most frequently between the failed World Trade Organization (WTO) Ministerial in Seattle in 1999 and the Group of Eight (G8) Summit held in Genoa in 2001 amidst violence by both police and demonstrators. These terms are misleading, as participants in this debate are neither solidly "anti-globalization," nor a single movement. Under the umbrella of these labels is a wide variety of actors with often sharply differing philosophies, objectives, and assumptions. Yet since the late 1990s they have proved a useful if contested and in large part inaccurate shorthand to describe what many

identify as a new and important force in global politics.

In order to understand the nature of the current debate about globalization as well as what might happen next to the "anti-globalization movement" and its actors there is a need for disaggregation and a reflection on the context in which it exists.

Origins Although its political and social origins are diverse, anti-globalization in its broadest sense can be seen as a response to the economic and political events of the period since the early 1970s and their most visible symbols, the institutions of global economic governance. In the North, the oil crisis and the suspension of dollar convertibility in 1971 marked the end of the "long boom" of post-1945 Keynesianism. They also triggered the meteoric rise of global capital markets, which made earning and keeping "market confidence" an increasingly important determinant of government policies. In the South, the Mexican government's near-default on its foreign debt in 1982 marked the end of the postwar era of import-substituting industrialization and began a long and painful period for developing countries, characterized by the burden of massive foreign indebtedness and the rise in political influence of the International Monetary Fund (IMF), the World Bank, and international capital markets, all three of which ushered policymakers away from development policies focused on the domestic market and toward a strategy of export-led growth.

These developments helped drive the rapid expansion of trade and investment flows, as large parts of Latin America and Asia adopted export-led growth strategies, and the countries of the former Soviet empire were rapidly, if partially, absorbed into an increasingly integrated global economy. The term *globalization* quickly became the shorthand for this model of expansion a heady and complex mix of technological, economic, political, and cultural change.

Globalization was accompanied and underpinned by a set of interlocking institutional developments at international and national levels. First, the existing structures of global economic governance were overhauled. The World Bank and the IMF redefined their roles, moving swiftly away from Keynesian operating principles to become bastions of neoliberalism. A web of bilateral, regional, and global international trade and investment agreements, culminating in the creation of the WTO in 1995, bound the new system in place. These economic and political trends unified in opposition a diverse array of actors, however. Downsizing and corporate restructuring, privatization, the erosion of workers' rights, and the changing nature of production and supply chains activated opposition from the labor movement in both the North and the South. Global warming, unsustainable growth, and the depletion of resources created hostility from environmentalists, who were further outraged over the perceived threat to environmental legislation from trade rules in the WTO for example, when four Asian nations successfully challenged provisions of the U.S. Endangered Species Act forbidding the sale in the United States of prawns caught in ways that kill endangered sea turtles. The erosion of the nation-state and of democratic institutions antagonized proponents of state-led development, democrats, and some on the political right. Increasing corporate power and social inequality galvanized the traditional left and a whole host of other left-of-center actors. Structural adjustment programs and growing Southern marginalization and inequality radicalized civil society (the term for nonstate civic and social organizations) and some political parties in the developing world.

The changed international institutional landscape also aided the growth of this opposition. This shift of power to international institutions and the growth in the range and reach of their activities were not well linked into the traditional accountability mechanisms of states. These inadequacies in global governance have raised the profile of attempts by nonstate actors to make these institutions more accountable. The increasing global reach of the World Bank and the IMF has provided common rallying points for protest, and the founding of the WTO in 1995 in particular put an institutional face on what had

previously been an amorphous process   a gift to the protest movement.

Who's Who? At first glance, anti-globalization seems an incongruous political mix of contradictions, colors, and cultures, in part vocal and aggressive, in part quiet and conciliatory. Although it defies firm categorizations, the movement can be roughly divided into three strands: statists, alternatives, and reformists.

The statists believe the current process of globalization has been a disaster and seek to defend and rebuild the role of the state in economic management after the neoliberal assault that began in the 1980s. This group is dominated by the traditional left, some sections of the labor movement, and a large proportion of Southern activists. Through this group runs a strong sense of rejectionism and even conservatism. Some, such as a few of the U.S. labor unions protesting at the WTO Ministerial in Seattle, want to retain the state's ability to protect domestic industries from cheap imports. Others, such as the prominent Filipino activist Walden Bello, reject the terms of globalization outright, feeling that any alternative, including the abolition of the IMF and WTO, could not fail to be an improvement on present realities. Despite its focus on the nation-state, this group retains a strong sense of internationalism.

The alternatives are both highly visible and the hardest to define, though often labeled "anarchist." This element of the movement is strongly driven by cultural concerns and best understood in cultural terms. Its members   be they ecologists running organic businesses, followers of the *Small Is Beautiful* author E. F. Schumacher, activists seeking to "deconstruct" corporate power and global brands, or Zapatistas who wish to gain rights and land and make a statement about globalization's marginalizing effects   reject globalization in passing but concentrate more on building small-scale alternatives. These groups oppose the encroachment of the market or the market's power relations on their cultural or political spaces. Most are also small, decentralized, and strongly anticorporate.

The reformists make up the majority of formally structured groups involved in the movement, or at

least dominate the thinking of the movement's leadership. Their aim is partial change to offset current injustices and inequalities. The reformists act within current political systems and advocate gradualism and peaceful change. Most accept a role for the market but believe it must be better regulated and managed in order to achieve socially just and sustainable outcomes. This group includes some trade unions, faith groups, charities and development organizations (such as Oxfam), and most mainstream environmental groups (including Friends of the Earth), as well as issue-specific campaigns such as Drop the Debt and the Tobin tax.

The reformist current has also made strong inroads into global and national politics, going far beyond "the usual suspects." The *Financial Times*, Gordon Brown, Nobel Prize winning economists such as Amartya Sen and Joseph Stiglitz, Kofi Annan, the corporate social responsibility movement, Jeffrey Sachs, and George Soros could all be called reformists. As the economist Meghnad Desai puts it, "The reformists view themselves as the only true defenders of globalization. They believe that both isolationist calls to reverse the process and supporters' insistence on 'ultra-liberal' forms of global capitalism are bound to de-rail globalization, with tragic consequences" (Desai and Said 2001, 68).

This attempt to disaggregate the movement warrants several caveats, however. Many nongovernmental organizations (NGOs) and even individuals span more than one current: for example, Friends of the Earth is both reformist and alternative. Author Naomi Klein, one of the movement's most prominent figures since the publication of her book *No Logo*, may base her critique of globalization primarily in cultural terms and is a source of inspiration to the anticorporate wing of the movement, but is herself essentially a progressive reformist. Within mainstream NGOs, supporters and Southern partners often espouse more radical options than the full-time staff and leaders.

Nor does this picture do justice to the depth and breadth of the movement in the South. The largest protests against the WTO have been in India. Brazil is rapidly becoming a center of the movement, as

evidenced by the huge gatherings of activists in Porto Alegre since January 2001 as part of the World Social Forum, held as a "people's response" to the World Economic Forum business summits in Davos. The movement in the North draws inspiration and guidance from a number of prominent Southern intellectuals such as Vandana Shiva (India), Martin Kohr (Malaysia), and Walden Bello (Philippines, but based in Bangkok) and the work of the NGOs to which they belong. Finally, none of these categories describes the nihilist currents, few in number in Seattle but significant at the G8 summit in Genoa in 2001, which used the protests as a platform for street violence rather than political debate.

Global institutions also play a key unifying role, both in providing focus to the movement and in creating the backdrop against which the movement has thrived. The movement is seen by some to be an important international player in its own right, helping to redefine public notions of democracy, accountability, and collective mobilization. The *Financial Times* identifies it as a "fifth estate," a valuable global counterbalance in a world of aging and often inadequate global institutions. The movement's reformist currents in particular have played an increasing role in what some academics have called "postsovereign governance."

But attitudes toward global institutions also mark a significant cleavage in the anti-globalization movement. For reformists, engagement is vital if change is to be achieved. Engagement has provided a small measure of greater transparency, participation, and popular pressure as NGOs enter policymaking channels and new mechanisms are created in an attempt to bridge gaps within highly imperfect existing structures. For rejectionists, by contrast, global institutions (in particular the WTO, IMF, and World Bank) are fundamentally illegitimate and unreformable, to be abolished rather than improved.

Main Concerns In general, the concerns of NGOs and civil society stem from an assertion that although globalization has led to benefits for some, it has not led to benefits for all. The benefits appear to have gone to those who already have the most, while many of the poorest have failed to benefit fully and some have even been made poorer. A linked concern of NGOs is that the drive for liberalization is based too much on dogma and ideology rather than on careful examination of the evidence and assessment of likely impact.

Equity and redistribution are seen as the missing link between globalization and poverty reduction. NGOs argue that improved equity within states leads not only to faster poverty reduction for a given amount of growth but also to faster growth. What is good for poor people is good for the economy as a whole. Yet up to now, globalization is seen to be frequently linked to increasing inequality, at both the national and the international levels. NGOs also argue for redistribution of wealth between developed and developing countries through debt relief and increased aid flows.

NGOs highlight research that points to the importance of national differences. The same policy reforms have different outcomes in different countries, depending on the structure of the economy, the initial distribution of assets, and the nature of economic and political institutions. Policy responses to globalization should be appropriate to particular cases in terms of the instruments used, the sequencing of reforms, and the combination of policies implemented.

Even though the evidence points to the importance of diversity, however, developing country governments are pushed by international rule-making, whether under the auspices of the WTO, through the pressures exerted by structural adjustment packages, or by the need to reassure the markets, toward greater homogeneity of policy response. The challenge for policymakers is to find ways of ensuring that national and international rule-making accommodate appropriate diversity of policy rather than reduce diversity to a minimum.

One of the lessons of recent years is held to be that liberalization and deregulation have very different costs and benefits when applied to the three areas of financial flows, direct investment, and trade. There has been concern that the frequency and severity of financial crises in recent years demonstrate the need for serious reforms of the global financial

architecture. Crises are seen to hurt the poor disproportionately and increase inequality, making the achievement of growth favorable to the poor harder thereafter.

One of the most high-profile areas of public concern (demonstrated by the impact and worldwide sales of Naomi Klein's *No Logo*) is that the increasing size and dominance of transnational corporations is making them more influential and less accountable. Public concern over excessive corporate power has led to calls for increased international regulation and has put pressure on companies to regulate themselves through the introduction of codes of conduct for themselves and their suppliers. In financial circles, this pressure has been accompanied by a greater awareness that successful companies must take into account a range of nonfinancial risks, including social, environmental, and ethical issues.

There are also fears that competition between countries wishing to attract foreign investment and technology could lead to a "race to the bottom" in terms of tax incentives and labor market suppression, thereby minimizing the potential social benefits offered by the private sector. Critics argue that the impact of foreign direct investment on employment, export performance, and domestic industry is not guaranteed, and that governments must be able to provide a regulatory framework to maximize the benefits and minimize the costs.

Finally, although most mainstream NGOs believe strongly that it is essential to have rules governing international trade, they severely criticize the particular set of rules established in the WTO. They see a multilateral trading system as necessary to ensure that weaker nations are not discriminated against by the strong in both North-South and South-South relations, but they argue that rule-making must proceed at a pace that is appropriate for the weakest members of the system, and the rules made in the WTO must be the right rules for development and poverty reduction. Current rules expose Northern governments to well-founded accusations of double standards on issues such as protection for domestic industries and support for domestic farmers, and are seen to provide insufficient

flexibility to enable Southern governments to pursue their development goals. The agenda being pushed by Northern countries is seen by many to militate against development and to be incompatible with the historical experience of the industrialized North.

Hegemonic Shifts In general terms, it is clear that significant changes have occurred in the thinking of policymakers since the mid-1980s. In part this has been a response to some of the more catastrophic results of gung-ho liberalization: the debacle of free market reforms in Russia, the Mexican crisis of 1994, and the Asian financial crisis of 1997 98 led to some serious soul-searching and admissions of mistakes, deflating the excessive self-confidence of the 1980s.

The growth of the anti-globalization movement fed off and accelerated this rethinking. Politicians recognized a need to respond to public disquiet, for example in the G8's decision to put debt on the agenda at its 1998 Birmingham summit, or when British prime minister Tony Blair used the 2005 Gleneagles G8 summit as a platform to gain further commitments for increased aid flows to Africa.

The emergence of a group of more economically powerful developing countries has also increased the political pressure for greater reform. For example, the creation of the G20 alliance of developing countries (including China, India, Brazil, and South Africa) at the WTO has shifted the balance of power within global trade relations and put greater pressure on the members of the Organisation for Economic Cooperation and Development to reform their agricultural sectors.

In recent years the movement has achieved some notable successes:

Jubilee 2000: This largely church-based coalition was credited by the British government with putting debt back on the international agenda. Initially started in the United Kingdom, Jubilee groups were set up in dozens of countries, North and South. Many, especially in the South, rapidly moved to campaign on wider globalization-related issues such as the impact of transnational corporations and structural adjustment programs.

Attac: This French-based network of intellectuals and activists has taken the lead in promoting the introduction of the Tobin tax (a small tax on currency transactions designed to curb speculative capital flows) and was influential in persuading the French government to support a study of the tax and oppose the Multilateral Agreement on Investment.

Corporate social responsibility: Public criticism and campaigning directed at corporate misconduct for example, pollution or abusive labor practices backed by increasing pressure from institutional investors, have prompted numerous initiatives to improve corporations' social and environmental performance. In the United States, student-led, grassroots, antisweatshop campaigns galvanized political life on campuses to a degree not seen since the Vietnam War.

These partial successes have strengthened the reformists within the movement and endangered its unity by heightening the points of difference between them and the rejectionists. The difficulties posed by partial victories were most clearly demonstrated in the Jubilee 2000 movement, when at the height of its policy successes at the Cologne G8 summit in 1999 the more radical "Jubilee South" wing, based in countries such as South Africa and Nicaragua, condemned the Northern Jubilee organizations for their reformist acceptance of the status quo.

Underlying the political debate has been a steady shift in public opinion, with messages on several fronts press exposés of poor working conditions, public protest, and the growing availability and prominence of "fair trade" products combining to make the public increasingly aware of the social impact of globalization.

It is easy to lose sight of how much has changed since the early 1980s in policy debates about globalization. There is now a much more nuanced understanding among decision-makers of the differences between liberalization of finance, direct investment, and trade; at the very least, most wings of the private sector pay lip service to notions of corporate social responsibility, and some of the most notorious excesses of free market zeal have been curbed.

The Future of Anti-globalization Understanding what may happen to this movement means exploring deeper questions about its political and social origins, the economic issues that it addresses, and the future of the international system to which it is a response. It also means looking at its component parts and their likely, and possibly differing, reactions to changing circumstances.

This brief overview suggests that much of this movement's coherence is contingent on external conditions. The strongest force in shaping its future development is therefore likely to be external, notably stemming from the pace and depth of change in the institutions of global governance and of the international system in which these institutions are based.

The success of the movement and in particular its reformist current in achieving change has been helped greatly by the multilateralism of the current international system. It has provided focus and coherence to otherwise disparate groups and allowed small gains in attempts to create a more balanced form of international governance.

Threats to multilateralism, however either from a turn toward unilateralism by the most powerful states or from the increased strain put on the long-term effectiveness of global governance by the exclusion of the world's weakest nations would strengthen the rejectionists and undermine the reformists, as well as the unity of the movement as a whole, and possibly the usefulness of the term itself.

■ applied general equilibrium models

In their single-country form, applied general equi librium (AGE) models simulate the variety of markets that compose entire economies. In their regional or global forms, these models also simulate the market transactions among economies or groups of economies. In all these cases, AGE models ac count for the interactions in markets for goods, services, labor, physical capital, and other produc tive inputs. A large and growing body of evidence suggests that the indirect and economywide effects of policy changes captured in this framework are indeed important, and there is a well-established theoretical foundation for the approach. Economy-wide effects include upstream and downstream pro duction linkages through input-output relation ships; intersectoral competition for basic resources such as labor, physical capital, and land; realloca tion of rents from quantitative restrictions; distri butional effects across household types; and ex change rate changes. AGE models provide a means of explicitly accounting for these effects in a com prehensive and consistent manner.

The Notion of "Applied" What is meant by the notion of "applied" in AGE models? Francois and Reinert (1997) give the following four-part characterization:

Detailed policy orientation. Applied models use a broader set of policies than just ad valorem tariffs. The models involve an analytical commitment to the sectoral and institutional details of a policy, including the role of data nomenclatures and concordances among nomenclatures, as well as a commitment to the policymaking process itself and sensitivity to the kinds of results that are of interest to policymakers.

Nonlocal changes form distorted base equilibria. In most theoretical analyses of trade and other economic policies, the economy begins in a non-distorted state with no tariffs, quotas, or other taxes

present. To this initial nondistorted equilibrium an infinitesimal tariff or tax is introduced, and a new, counterfactual equilibrium is solved for using the linear approximation of differential calculus. In applied policy models, by contrast, the initial or base equilibrium reflects the relevant set of policy distortions. Since the policy changes introduced into the model are those actually under consideration rather than infinitesimal, the resultant changes are nonlocal. Consequently, functional forms prove to be crucial to model results, and what economists term "second-best effects" play a role in these outcomes.

Accurate and current data. Given the close link between modeling and policymaking, both the accuracy and the currency of data are important. Unfortunately, there can be a trade-off between accuracy and currency; the most recent data may be only estimates or not entirely survey based. Consequently, professional judgment is needed, and there needs to be a willingness to revise published results as new and better information becomes available.

Model structure determined by the data. The functional forms used to construct applied models must be chosen to allow for important regularities observed in the data. For example, the classical structures of theoretical trade models assume that imports and domestic competing goods are perfect substitutes and that there are no barriers to trade. In this case, the model describes interindustry trade only, cannot support a number of goods that exceed the number of factors of production, and cannot explain *bilateral* patterns of international trade. To avoid this in applied work, steps are taken to specify alternative model structures that allow for bilateral patterns of intraindustry trade and numbers of goods in excess of numbers of factors of production.

As an illustration of the complexities of applied policy modeling in general and the role of AGE models in particular, consider the case of multilateral Doha Round trade negotiations as described by Francois, van Meijl, and van Tongeren (2005):

Judging the economic impact of a WTO agreement is massively complex, even when it comes to issues as straightforward as tariff cutting. The eventual Doha Round agreement should lower thousands of individual tariffs in each WTO member country and there are about 150 members. The result would be important shifts of resources among sectors in most nations in the world, along with attendant changes in the prices of goods and productive factors. Due to international trade, the supply and demand factors in each nation affect resource allocations in all other nations. How can economists evaluate the impact of these choices? The most practical way of proceeding is to employ a large-scale computable general equilibrium model that allows simultaneous consideration of all the effects. (352)

This speaks to the utility of AGE models and explains why the methodology has evolved from an obscure exercise in applied econometrics to being a key tool for applied policy analysis. Indeed, many national governments use single-country models to assess policy changes, and both national governments and multilateral financial institutions use global models (e.g., the GTAP model described in Hertel 1997 or variants of the linkage model described in van der Mensbrugghe 2006) to assess a large variety of international policy issues.

Overview of Model Structure In AGE models, it is generally the case that an equation system is solved for prices that equate supply and demand in all markets simultaneously and satisfy the accounting identities governing economic behavior. Exceptions to this approach exist that allow for disequilibria in some markets (e.g., labor markets). Once the equation system has been specified, the equilibrium is calibrated to a base-year data set (often in the form of a social accounting matrix, or SAM), and the model reproduces the base-year economy in the absence of any policy changes. The calibration ensures that subsequent policy simulations move from an initial position that describes the economy (be it national, regional, or global) and its accounting identities as accurately as possible.

After calibration, the AGE model is used to simulate the effects of alternative policy changes

on the economy with reference to the base year (static) or a baseline scenario (dynamic). The model fully captures the flow of income from firms to labor, capital, and other inputs, from each of these inputs to households, and from households back to final demand of various types (household, government, investment, and rest of world or exports). Hence, it remains internally consistent even after introducing policy changes of various kinds.

The policy parameters of an AGE model include tariff rates, quotas, various domestic taxes and subsidies, and a number of behavioral elasticities. The behavioral elasticities play a central role in model results, and this represents an area of inquiry in which there is not always complete agreement with regard to appropriate values. Consequently, this is one aspect of AGE modeling that needs to be well documented and handled with care, including the analysis of the sensitivity of model outcomes to assumed elasticity values. Critical in this regard is what is known as the Armington (1969) elasticity, the elasticity of substitution between imports and domestic competing goods.

With a calibrated model in hand, an analyst can simulate the effects of proposed policy changes by comparing the base-year or baseline model solution with a counterfactual solution in which one or more of the policy parameters have been changed. A comparison of the base-year/baseline and counterfactual equilibria can reveal (depending on model specification) the effects of the policy changes on imports, exports, domestic production, employment, wages, aggregate economic welfare, disaggregated household welfare, and poverty and human development outcomes.

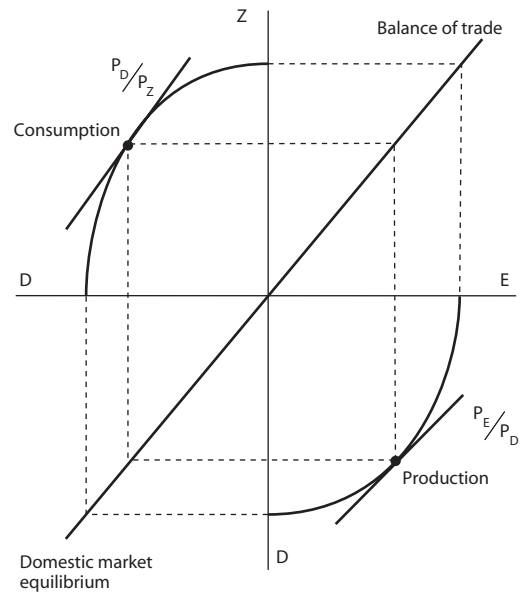
Standard Framework A standard framework of applied general equilibrium modes is that described by de Melo and Robinson (1989) and related to the previous contribution of Hazari, Sgro, and Suh (1980) on nontraded goods. In this framework, there are three varieties of goods: an export good (E), an import good (Z), and a nontraded, domestic good (D). Corresponding to these three goods, there are three different prices, P_E, P_Z, and P_D, and three dif-


Figure 1
A graphical representation of a simple applied general equilibrium model

ferent quantities, E, Z, and D. The graphical representation of this framework is provided in the four quadrants of figure 1. In the southeast quadrant, the country produces two goods, E and D. The concave curve in this quadrant is the country's production possibilities frontier (PPF) and indicates that there are no economies of scale sufficient to outweigh the increasing opportunity costs of production. In practice, this part of AGE models is actually implemented in two stages, with a constant elasticity of substitution PPF and a constant elasticity of transformation allocation between exports and domestic supply, the latter following Powell and Gruen (1968). Under perfect competition, profit maximization, and full employment of resources, the country produces at a point on the PPF that is tangent to the relative price line P_E/P_D.

In the northeast quadrant of figure 1, we have a balance of trade line, which relates E and Z. This line tells us what level of imports can exist given the level of exports. As drawn, this balance of trade line is a 45-degree line, but changes in the terms of trade P_E/P_D will rotate the line either up or down. Capital inflows

or outflows will shift the line up or down, respectively, without changing its slope.

In the southwest quadrant of figure 1, the vertical axis plots the supply of the domestic good from the PPF, while the horizontal axis plots the demand for the domestic good. The 45-degree line in this quadrant is simply a domestic market equilibrium condition.

Finally, the northwest quadrant of figure 1 addresses the consumption of goods Z and D. The concave curve in this quadrant is a consumption possibilities frontier (CPF). The consumption possibilities are determined by the PPF, the balance of trade constraint, and domestic market equilibrium. The choice of the point on the CPF will reflect utility maximization in the form of tangency with an indifference curve of a representative household based on product differentiation by country of origin and is typically modeled using a constant elasticity of substitution frameworks as in Armington (1969).

In standard trade theory with incomplete specialization and no transportation costs, bilateral trade patterns remain indeterminate. However, in the framework of figure 1, intraindustry trade is fully captured. In multicountry versions of the model, actual patterns of bilateral, intraindustry trade will be effectively described in both base and counterfactual equilibria. Finally, nontradability in the framework of figure 1 depends on the price line P_E/P_D. The higher is this ratio, the more of domestic output will enter into trade. Therefore, nontradability in the AGE framework is not fixed by sector but depends on relative prices. Further, unlike Salter (1959), the two traded goods, E and Z, are not aggregated into a single good, and this is more satisfactory for empirical implementation.

Dynamics The policy changes considered in AGE models have the potential to change both overall income levels and the returns to factors of production. As noted by Francois, McDonald, and Nordström, "To the extent that investment hinges on income levels and expected returns, the medium- and long-term results of changes in trading conditions will include induced shifts in the capital stock" (1997,

365). Incorporating these considerations into AGE models shifts the analysis from *static* to *dynamic* considerations. Dynamic specifications of AGE models can vary in a number of respects, but the research on these specifications is now fairly well developed.

When allowed for, dynamic effects show up in model results through a number of paths, including the following: increases in incomes due to trade liberalization and other policy changes raising savings rates, declines in the prices of capital goods increasing real investment, and increasing trade openness (typically measured by sectoral export-to-output ratios) causing sectoral productivity increases. The first and second of these dynamic gains are often referred to as "medium-run growth effects" as identified by Baldwin (1992) and do not depend on any dynamic externalities as emphasized in New Growth Theory. Therefore, they are best viewed as reflecting "classical" or "old" growth theory. In this respect, the first and second paths for dynamic gains are quite firmly reflective of received economic theory.

The third type of dynamic effect is often referred to as the "procompetitive effects of exporting" and can reflect economies of scale in production and trade, learning by doing, standards achievement, and network effects. These potentialities are less standard than the medium-run growth effects, and it is not clear whether they are as automatic as suggested by some model specifications. In addition, there is little empirical evidence with regard to the behavioral elasticities used to model these effects. For these reasons, it is prudent to separate out simulations based on these procompetitive effects as indicative of *potential* rather than as actual, realized gains.

Other Extensions The standard AGE model considered here has been extended in a number of relevant directions. These include environmental and natural resource issues (including climate change), industry structure (including imperfect competition), migration, capital flows (including foreign direct investment), financial crises, commodity prices, foreign aid, natural disasters, poverty, and human development. Given this broad coverage of issues that are paramount in assessing the world economy, as well as the more standard applications

to trade policies, it is clear that AGE models will continue to be an important methodology to help us understand the role of national and multilateral policies in the world economy.

KENNETH A. REINERT

■ appropriate technology and foreign direct investment

Appropriate technology generally refers to technology that is suitable for local conditions. Although the term has sometimes been used very broadly to refer to technologies that support goals such as the preservation of nature, local culture, or life in small villages, economists typically speak of technological "appropriateness" in the context of technologies adapted for local conditions such as factor abundance for example, capital-intensive technologies in capital-abundant countries and labor-intensive technologies in labor-abundant countries.

The discussion of appropriate technology in the context of foreign direct investment (FDI) arose from concerns that technologies developed under the economic conditions of developed countries could have harmful effects in developing countries in particular, that multinational enterprises (MNEs) would not create enough jobs. This possibility is particularly likely if innovations are "induced" by cost-saving possibilities in the markets where they are first used (Kennedy 1964). Because developed countries are capital-abundant, the technologies developed there tend to be capital-intensive, labor-saving technologies, and thus tend to generate less employment in a developing country than do technologies tailored to the conditions of abundant, cheap labor present there. Similar arguments apply to other features of technology: for example, technologies requiring a steady supply of electric power may be inappropriate for countries that experience fre-

quent power outages. Thus there has been a general concern whether MNEs bring in the right type of technologies whether the technologies that are in the best interest of MNEs to transfer are those that are in the best interest of the local economy.

Adaptation and Technology Transfer In simple models of the behavior of MNEs, the technology developed in the home market is often assumed to be reproduced identically in other countries, which is how the firm exploits its advantage of technological ownership. In fact, reproducing technology abroad is not easy; technology often must be adapted to local conditions for it to work. If the existing technology is not appropriate for local conditions in the host country, the MNE may have an incentive to adapt the technology.

Actual technology transfer is not simply a matter of shipping blueprints to another country, but involves a costly process of experimentation and trial and error (Teece 1977), during which the specifications of the technology adapt somewhat to local conditions. Some technologies may be more easily adaptable than others, such as ones where different techniques using different mixes of capital and labor are feasible. In some cases the costs of adaptation may be large enough that adaptation is not worthwhile to the MNE. The practical questions thus become a matter of how adaptable MNEs' technologies are to local conditions, how much adapting MNEs in fact decide to do, and whether local firms would in fact do a better job of adaptation (Lall 1978).

The degree to which MNEs adapt their technologies to local conditions has been widely studied. Since adapting technology is costly, and since the competitive advantage of MNEs lies in large part in their ability to replicate technologies they own in different countries, there can be a strong incentive to minimize adaptations to local conditions. For example, the basic type of machinery is likely to stay the same from country to country. Thus technologies initially created for local conditions may well be better suited for the local conditions than technologies created elsewhere and then adapted. However, the situations where technologies are ill adapted are

apt to be those where adaptation is difficult, and hence local firms may be unable to do better than MNEs.

Empirical results on the observed degree of technological adaptation often defy easy generalization. Large statistical studies often include firms in different industries, and therefore the differences in capital intensity may be due to the industry rather than to individual firm choice. The effect of foreign firms' technological choices on domestic firms in developing countries depends in part on whether the local firms are suppliers, are competitors, or have some other relationship to foreign firms. It has been reported that MNEs impose particular technologies on their suppliers in developing countries, at least partially in an attempt to maintain quality control. There are many possibilities for developing country firms to learn and imitate the technology of MNEs, through reverse engineering, social networking among employees, or employees who leave to become entrepreneurs or are hired away by competitors. Sometimes, domestic imitators have been more successful adaptors than MNEs and have been rewarded by rising market shares. At the same time, one can observe cases in which managers in developing-country subsidiaries of MNEs from developed countries adapt technologies in the labor-intensive direction (Pack 1976; Lecraw 1977).

Multinationals from Developing Countries In the 1960s and 1970s, an increasing number of firms based in countries such as India, Hong Kong, Korea, Brazil, and Argentina became direct investors. These "third-world multinationals" tended to place the bulk of their investments in other developing countries. Since economists were accustomed to think of MNEs transferring capital and technology from the North to the South, new explanations seemed necessary for the phenomenon of South-South FDI. A widely offered idea was that developing-country firms had acquired "appropriate" technologies in their home markets, which gave their affiliates in other countries a competitive advantage.

The types of intangible firm advantages that could arise from operating in a developing-country environment are widespread. These could include managerial skills in dealing with severe bottlenecks in acquisition of materials and power, local labor conditions, and developing-country bureaucracies, and superior information about local product and factor markets in certain trading partners. Also, in some countries such as Korea and India, the largest domestic firms were organized as multiproduct conglomerates, and the managerial skills needed for such organization readily adapt to the multinational form.

The motivations for South-South FDI need not be limited to intangible appropriate-technology advantages. Informational advantages gained from a past history of exporting or migration suggest a transactions cost explanation rather than a technological one. Even in developing countries, firm-level efforts to promote efficiency might encourage capital intensity rather than labor intensity (Ferrantino 1992). By the early 21st century, some investors from developing countries were seeking to acquire developed-country technologies through mergers and acquisitions (e.g., Chinese investors in the United States), showing that home-country production experience need not be the only determinant of technological development in developing-country MNEs.

Appropriate Technology, Efficiency, and Spillovers From a policy standpoint, part of the idea of appropriate technology is that the technology chosen by markets might not be optimal for either economic growth or employment generation. This imperfection suggests a role for government either in technology choice or at least in undoing distortions such as those that might make labor artificially expensive. In the 1980s the skepticism about the benefits of FDI for developing countries began to wane, and the promarket ideas collectively called the Washington consensus tended to see FDI as enhancing productivity and growth rather than being an original source of distortions. Under this view, the most important feature of technologies bundled with FDI is their potential for enhancement of overall productivity, rather than their bias toward either capital or labor.

Nonetheless, the question of the conditions under which the activities of developed-country MNEs influence technological conditions in developing

countries, and whether and under what conditions adaptation takes place, remains open. Much of the current research on technological spillovers from FDI is informed by the issues raised in the analysis of appropriate technology.

■ Asia Pacific Economic Cooperation (APEC)

The Asia Pacific Economic Cooperation (APEC) process was the first structured forum for intergovernmental cooperation among the economies of East Asia and their main trading partners in North America, Australasia, and Russia. It was launched in Canberra, Australia, in 1989 to promote closer communications to help seize the opportunities for trade and investment among a diverse group of economies with different resources and comparative advantages, as well as to anticipate the inevitable tensions when comparative advantage changed as economies developed. APEC's central objective is to sustain the growth and development of the region by promoting mutually beneficial economic integration and by encouraging international flows of goods, services, capital, and technology. APEC has adopted the principle of open regionalism, seeking to reduce impediments to international economic transactions among participants without diverting economic activity away from other economies.

APEC was built on foundations laid during the preceding decades. Since the 1960s, the Association of Southeast Asian Nations (ASEAN) has demonstrated that a voluntary association of diverse nations with diverse economies can be valuable and effective. Since those years policy-oriented analysis by researchers and business people with a broad international outlook noted the growing, market-driven interdependence of Asia Pacific economies. This included the work of the Pacific Forum for Trade and Development, a group of policy-oriented researchers that has met annually since 1967 to assess the changing environment for economic development

in the Pacific and its policy implications; the Pacific Basin Economic Council, a group of senior business people with a broad international outlook that also began to meet in the late 1960s; and the Pacific Economic Cooperation Council, established in 1980. APEC has also set up its own private-sector advisory group, the APEC Business Advisory Council.

In a January 1989 speech in Seoul, Australian prime minister Bob Hawke advocated the creation of a new intergovernmental vehicle of regional cooperation. The first ministerial-level meeting brought together representatives from twelve Asia Pacific economies. The initial participants were the then six members of ASEAN (Brunei, Indonesia, Malaysia, the Philippines, Singapore, and Thailand) together with Australia, Canada, Japan, the Republic of Korea, New Zealand, and the United States. Subsequently, APEC developed a comprehensive work program to promote economic integration and agreed on its main objectives and principles set out in the 1991 Seoul APEC Declaration.

APEC further distinguished itself from the legally binding and preferential arrangements adopted by the European Union (EU) and others by agreeing that Asia Pacific cooperation should be voluntary. APEC would not be a negotiating forum: instead it would seek to identify opportunities to promote mutual economic benefit through consultation, building consensus around a widening range of shared interests. APEC's nonformal structure made it possible to include all three Chinese economies. Taiwan participates as the economy of Chinese Taipei, and since 1997 Hong Kong has participated as Hong Kong, China. Membership has since expanded to 21: Chile, Mexico, Papua New Guinea, Peru, Russia, and Vietnam joined between 1993 and 1997. A subsequent moratorium on expanded membership was set to end in 2007.

Free and Open Trade and Investment APEC leaders met for the first time in 1993. At their 1994 meeting, in Bogor, Indonesia, they were able to make a political commitment to eliminating barriers to trade and investment by no later than 2010 for de-

veloped economies and 2020 for developing economies. A midterm stocktaking, conducted in 2005, showed considerable progress toward this goal. Average tariffs were considerably lower than in 1989 and border barriers to trade in most goods and many services were already set at zero or negligible levels. People and capital were moving much more freely around the region.

By harmonizing customs procedures, increasing the scope of mutual recognition of standards, adopting agreed principles for more transparent and competitive government procurement, and reducing impediments to international business travel, APEC made substantial progress in reducing other costs and risks of international commerce. This progress has led to the emergence of the Asia Pacific region as the engine of global economic growth, outpacing the rest of the world in terms of opening itself to international trade and investment and increasing its share of global output, trade, and investment (APEC 2005; Elek 2005).

Strengths and Weaknesses APEC's experience has also revealed some of the weaknesses as well as the strengths of voluntary cooperation among widely diverse economies. Coordinated unilateral actions have helped to bring down many impediments to trade and investment, but voluntary cooperation has not proved adequate to liberalize "sensitive sectors," such as agriculture, textiles, and clothing. APEC's limited ability to respond to the serious financial crises in East Asia in the late 1990s also demonstrated the value of attending to all of the foundations of sustained economic growth, not just the reduction of obstacles to international trade and investment.

By 2007, it was evident that one dimension of the vision of free and open trade and investment, the elimination of all traditional border barriers to trade, would not be achieved according to the 2010/2020 timetable. At the same time, there was growing realization that the removal of tariffs or quantitative restrictions on trade in goods, or even in services, would not be enough to promote deep economic integration. The experience of the EU had shown the value of a comprehensive program to reduce reg-

ulatory impediments to international movement, not only of products, but also of factors of production.

Facilitating economic integration by closer coordination or harmonization of policies on matters such as customs procedures or standards, adoption of compatible policies to encourage e-commerce, and reduction of the cost of international transportation have become relatively more important means of promoting economic integration. In these areas, the effective constraint on cooperation is not the short-term political cost of overcoming narrow vested interests but the capacity to implement more efficient policies. Facilitating trade by dealing with logistic or regulatory obstacles to trade is largely a matter of enhancing human, institutional, and infrastructure capacity.

The Busan roadmap for promoting progress toward free and open trade and investment, based on the 2005 midterm evaluation, takes account of these issues. Accordingly, the focus of attention is shifting from the remaining traditional border barriers to trade toward the sharing of information, experience, expertise, and technology to help all Asia Pacific economies build the capacity for designing and implementing better policies, which strengthen domestic as well as just international markets. At the same time, APEC economies would support traditional trade liberalization through the WTO. This could bring about a practical division of effort between APEC and the WTO, based on the comparative advantages of institutions for voluntary, rather than negotiated, cooperation.

Especially since 2000, APEC has needed to define its role alongside many other bilateral and subregional forms of economic cooperation. In response to the inability to make further significant progress on sensitive issues, such as agriculture, in either the WTO or APEC, combined with the need to address many new issues that influence international economic transactions, there has been a proliferation of mostly bilateral preferential trading arrangements. Yet bilateral preferential trading arrangements have also been unable to achieve significant liberalization of trade in sensitive products, while complicating all

international trade due to complex, and often overtly discriminatory, rules of origin. It remains to be seen whether that problem can be overcome by preferential trading arrangements among larger groups of economies.

Concurrently, reflecting the growing share of international production and trade in East Asia, several East Asia centered forums have emerged. As in APEC, members of the wider networks of cooperation in East Asia will resist ceding powers to any supranational authority. This suggests that they might best focus on issues of perceived shared interests, rather than the negotiation and imposition of binding constraints on one another.

In summary, APEC members have moved toward their original goals but their institution has been redefining its own goals and operation. At the same time, other institutional developments in the region now create the prospect of competition and overlap with APEC (Soesastro and Findlay 2005). Progress on economic integration may prove easier in an East Asian, rather than in a wider trans-Pacific, forum. On the other hand, East Asia is itself a very diverse grouping and will face constraints quite similar to those encountered by APEC while the United States will seek to sustain trans-Pacific cooperation. One outcome may be "variable geometry," with APEC-wide consultations encouraging different groups of economies to pioneer cooperation on issues of shared interest, not necessarily in the institutional context of the APEC process itself.

■ **assignment problem**

The assignment problem concerns the allocation of policy instruments to policy targets in order to im prove policy effectiveness. Policy instruments are the variables or procedures that policy authorities di rectly control. Policymakers' use of these instruments to achieve objectives (i.e., policy targets) directly af fects the welfare of their constituents. For example, government spending is an instrument that can be used to reduce unemployment. Assignment is im portant because in actual policymaking, competing government agencies can be given different instru ments. The question then becomes which is the appropriate allocation?

Trevor Swan (1960) noted the problem in the context of an open economy where the two objectives were full employment with price stability and a rea sonable current account deficit (CAD) of the balance of payments. The first is the objective of internal balance and the second that of external balance, which is an essential part of participating in the world economy. External imbalances in one country can lead to imbalances for others with which it transacts. One country's delays and inefficiencies in achieving balance impinge on others, and when the country is large, can have repercussions for the global financial system.

The Tinbergen Rule In 1952, Jan Tinbergen demonstrated that to achieve policy objectives, gov ernments must have policy instruments equal in number to the objectives. According to what is known as the Tinbergen rule, a government cannot achieve two objectives with just one instrument. If a country has unemployment and a CAD, for exam ple, and the only instrument available is government spending, it can fix only one problem (Meade 1951). If the government spends more to stimulate the economy, it will lower unemployment but worsen the disequilibrium in the balance of payments as overall output and imports rise. If it reduces spend ing, the balance of trade improves, but unemploy ment rises. One objective is attained at the expense of the other. If the government uses two instruments government spending and exchange rate policy to achieve its objectives, the question is one of appro priate assignment: which instrument should it assign to control demand, output, and employment, and which to achieve trade balance?

Adjustment in the Swan Diagram Swan (1960) showed that an incorrect assignment can move the economy away from full equilibrium. Figure 1 shows a simple Swan diagram where the internal balance, or domestic market equilibrium schedule, IB_f is downward sloping in the space of real exchange rate
Figure 1
Assignment in the Swan diagram

Z and absorption, or domestic demand, A. Z is the ratio of external to domestic costs of production. Currency appreciation reduces demand for domestic goods so that government spending, a component of absorption, has to rise to maintain output unchanged. The external balance, or balance of payments equilibrium schedule, EB, is upward sloping. The current account will improve with real depreciation as imports fall and exports rise, so government spending must be raised to restore imports and prevent the balance of payments going into surplus. The four quadrants denote different types of disequilibria. Only at the point of intersection of the two schedules are the two instruments such that both the targets are achieved. Output is demand determined below the full employment IB_f schedule and otherwise limited by the factor of production labor.

Consider an economy at point 1 with a current account surplus and a recession. Policymakers assign the real exchange rate to achieve internal balance and government spending to achieve external balance, and sequentially adjust the two instruments. Depreciation at point 1 will lead to internal equilibrium at point 2 as exports raise demand. A rise in government spending raising imports to match will bring the economy to external equilibrium at point 3, and so on through points 3, 4, 5. . . . But instead of converging to the full equilibrium point, the economy diverges away from it. The opposite assignment leads to equilibrium. Reversing the arrows before point 8 shows the convergence to full equilibrium where the starting point is a recession and a CAD. Government spending then is raised to reach internal balance at point 8, and then the exchange rate depreciated to reach external balance at point 7, the process converging finally to the full equilibrium. Thus this is the correct assignment of instruments.

Note that the result depends on the relative steepness of the two schedules. Convergence to a stable equilibrium occurs because the internal balance schedule is steeper than the external balance. Depreciation has more of an effect on the current account than it does on aggregate demand since changes in imports and exports act in the same direction on the CAD, but imports are a leakage from demand for domestic goods, and only the rise in exports raises output. Since a larger change in absorption is required to compensate for the relatively greater impact of depreciation on external balance, the EB schedule is flatter than the IB_f. That is, the exchange rate has a relatively greater impact on the external balance than it does on the internal balance. And government spending has a greater impact on internal balance than it does on external balance. It follows that exchange rate policy should be assigned to external balance, and government spending to internal balance.

Effective Market Classification Each policy instrument should be assigned to the target variable on which its relative effect is higher. Robert Mundell first formally stated this in 1962 as the principle of effective market classification. Consider a case where the two policy instruments are the interest rate and the budget deficit, with a fixed exchange rate. If the rate of interest has a larger effect on external balance, Mundell showed that the interest rate must be assigned to external balance and the budget deficit to internal balance in sequential adjustment; otherwise the economy will diverge from full equilibrium. The interest rate affects both the current and the capital account. Suppose government expenditure and interest rates rise, moving away from the unique equilibrium, but with internal balance satisfied. The rise in government expenditure tends to raise income, but the rise in interest rate reduces it, so that income remains at the full employment level. Since output is unchanged, the trade balance is unchanged as well, assuming exports are constant and imports depend only on income. But the rise in interest rates improves the capital account of the balance of payments, so that the balance of payments is now in surplus. Therefore the internal balance schedule must be steeper than the external balance schedule.

Starting from a position with recession and a CAD, if the government reduces spending to reduce the CAD, it will improve the CAD but worsen the recession. If it then decreases the interest rate to stimulate output, it will worsen the capital account as

capital flows out, resulting in cumulative movements away from equilibrium. Adjustment converges to the full equilibrium if the opposite assignment is made. That is, the interest rate is directed to achieve external equilibrium and government spending to achieve internal equilibrium each policy instrument is assigned to the target on which it has the greatest effect, or which it has a comparative advantage in achieving. In this simple model with fixed exchange rates, the implication is that monetary policy or the central bank should target external balance, while fiscal tax-expenditure decisions target full employment.

In practice, sequential policy adjustment is difficult since the economic system is simultaneous. In both models, since the full equilibrium is stable, it is attained with simultaneous adjustment of both instruments. Markets themselves also generate adjustment in response to disequilibrium. But optimal assignment is a useful feature to keep in mind when making a complex policy decision, especially if the two instruments are the responsibility of different institutions. The correct allocation of separate instruments to separate authorities may allow more efficient adjustment. In addition, since all models are a simplification of a complex reality, as international and domestic institutions change, the relevant model also changes or must be suitably adapted.

Allowing for Shocks In the simple deterministic models considered so far, there were no random shocks. Poole (1970) has an interesting variant of the assignment problem regarding the choice of the appropriate instrument for monetary policy. He showed that if aggregate demand was subject to more random shocks compared to the demand for money, money supply should be the operating instrument. Output fluctuations would then be lower, since procyclical interest rate movements would moderate the shocks. If the intensity of shocks to money demand was greater, interest rates should be the instrument, since automatic adjustment of money supply would smooth interest rates, reducing output fluctuations. The opposite assignment would magnify the impact of fluctuations.

■ Association of Southeast Asian Nations (ASEAN)

The Association of Southeast Asian Nations (ASEAN) is an intergovernmental association that was formed to enhance cooperation among countries in the Southeast Asian region. Since its formation in August 1967, this association has grown in size to include 10 countries: Brunei, Cambodia, Indonesia, the Lao People's Democratic Republic (PDR), Malaysia, Myanmar, the Philippines, Singapore, Thailand, and Vietnam.

The formation of ASEAN was officially opened at the signing of the Bangkok Declaration on August 8, 1967, by five countries: Indonesia, Malaysia, the Philippines, Singapore, and Thailand. Brunei in 1984, Vietnam in 1995, the Lao PDR and Myanmar in 1997, and Cambodia in 1999 joined the grouping. Political and economic considerations have influenced these countries to form a regional cooperation. The original five signatory countries saw the need to foster their economic development and promote regional security in the face of a growing communist threat in Southeast Asia, precipitated by the fall of Indochina to communism and the declared intention of the West to withdraw its military forces from the region. Their common objectives could be best achieved through mutual cooperation in the economic, social, and cultural areas.

Political Cooperation During its early stages of development, ASEAN was mainly concerned with political cooperation to promote political stability and harmony in the region. Since 1976, however, the economic objective has grown in importance as economic development has become its main priority in view of, among other things, the increasing need to maintain economic competitiveness in the midst of growing international competition and sustain member countries' pace of economic development in light of rising expectations.

Economic Cooperation There have been two types of economic cooperation in ASEAN: market sharing and resource pooling. These types of economic cooperation have developed since the Bali Summit of 1976. At this summit, the ASEAN leaders signed a Declaration of ASEAN Concord that laid out a program of action for regional cooperation in political, economic, social, cultural, and security matters. But ASEAN economic cooperation of a market-sharing type has generally been unsuccessful mainly due to the significant differences in members' economic development levels and different economic priorities.

Economic Cooperation in Trade The most important form of market-sharing cooperation envisaged in the Bali Summit was the establishment of preferential trading arrangements to promote intra-ASEAN trade. The agreement on ASEAN Preferential Trading Arrangement, signed in February 1977, was the first attempt by ASEAN member countries to promote a higher level of intra-ASEAN trade. Five measures have been identified to achieve the objective of greater intra-ASEAN trade: exchange of tariff preferences, purchase of finance support at preferential rates for selected products of ASEAN domestic origin, long-term (three to five years) quantity contracts for basic commodities such as fuels and agricultural products, preference in procurement by government agencies, and liberalization of nontariff barriers on a preferential basis.

Economic Cooperation in Industry ASEAN countries have resolved that industrialization and economic development of their members can be largely facilitated through industrial cooperation. There is also a common realization that a significant increase in intra-ASEAN trade can occur only if the supply side of the market is also increased. Thus since 1976 five major schemes of ASEAN industrial cooperation (ASEAN Industrial Projects Scheme, ASEAN Industrial Complementation Scheme, Brand-to-Brand Complementation Scheme, ASEAN Industrial Joint Venture Scheme, and ASEAN Industrial Cooperation Scheme) have been established to create new industrial capacity jointly owned by member countries serving the regional market. Unlike trade liberalization, which raises apprehensions of uncontrolled trade flows and market disruption, industrial cooperation is linked to the creation of specific new production facilities, giving rise to much more predictable trade flows. Except for the ASEAN

Industrial Cooperation Scheme, the success of these initiatives was quite limited.

Economic Cooperation in Agriculture Given the importance of the agricultural sector in ASEAN, cooperation in this area has been one of the priority issues. All the cooperative undertakings in agriculture have so far been technical and developmental in nature, however. The Committee on Food, Agriculture, and Forestry (COFAF) is responsible for the identification and implementation of cooperative undertakings in the agricultural sector. Formed in March 1977, it (a) coordinates, reviews, and prepares studies on the prospects of the agricultural sector; (b) develops efficient methods for the exchange of information on agriculture; (c) identifies areas for cooperation; (d) maintains close ties with related committees in ASEAN and with other related organizations inside and outside the region; and (e) reports its progress to the ASEAN Economic Ministers.

Between 1978 and 1988, COFAF had identified 46 cooperative projects—7 in food, 10 in agriculture, 15 in forestry, 8 in livestock, and 6 in fisheries. By 1985, 13 of them were ongoing, 4 completed, and 29 not yet implemented. The largest number of projects was located in the Philippines, followed by Malaysia, Thailand, and Indonesia in descending order. Most of the funding for these projects came from sources outside the region and only a few projects were pursued on a long-term basis. One of them was the ASEAN Food Security Project, which established in 1979 an ASEAN Emergency Rice Reserve to be contributed to by each of the member countries. The objective was to create a stockpile of 50,000 metric tons of rice to meet shortfalls in domestic supply. This program is periodically reviewed for the purpose of creating a more dynamic food security arrangement to enhance intra-ASEAN trade and promote food production under the principle of comparative advantage. Others included the Food Handling and the Seed Technology projects. ASEAN cooperation in agriculture has also been fostered in the association's dealings with developed countries on matters of market access for member countries' primary exports, better terms of trade, stabilization

of export earnings, and other nonsensitive areas of cooperation.

ASEAN Free Trade Area The 1992 ASEAN Free Trade Agreement (AFTA) was a watershed in the history of ASEAN economic cooperation, as it represents a significant step in the economic policy orientation of the ASEAN countries. The main objective of AFTA is to increase the international competitiveness of ASEAN industries and the ASEAN region as an investment location. Specifically, the objectives are to increase intra-ASEAN trade by abolishing intraregional trade barriers while allowing member countries to keep their respective trade policies toward the rest of the world, attract local and foreign investors to invest in the region, and make their manufacturing sector more efficient and internationally competitive within a liberalizing global market. An integrated regional market is expected to produce economic benefits from greater consumer welfare, exploitation of economies of scale, competition-induced efficiency, industrial rationalization, interindustry linkages, and intraindustry trade.

To realize these benefits, AFTA seeks to reduce tariffs on all commodities traded within the member countries to no more than 5 percent ad valorem and remove all other trade restrictions by the year 2002 under the Common Effective Preferential tariff, the main instrument of AFTA. The agreement also lays down the rules for fair competition and identifies a number of measures to enhance economic cooperation such as harmonization of standards, macroeconomic consultations, improved reciprocal recognition of product testing and certification, coordination of foreign investment policies to enhance more investment flows, joint investment promotion strategies, and cooperation in transportation systems. Further, it contains measures of contingent protection and allows the reintroduction of trade barriers in case of balance of payments difficulties.

ASEAN Economic Community The Asian financial crisis of 1997 and 1998, the terrorist attacks of September 11, 2001, the Iraq war, and the SARS outbreak all dampened the outlook for greater trade liberalization and economic integration as envi-

sioned under AFTA. Despite these unfavorable external events, the ASEAN countries have remained politically committed to the vision of transforming ASEAN into an economically integrated grouping within the framework of an ASEAN Economic Community (AEC). This AEC concept, which was first agreed on at the November 2002 ASEAN summit held in Phnom Penh, Cambodia, is based on the ASEAN Vision 2020, which foresees a more economically integrated ASEAN. The ASEAN Vision 2020 envisioned "a stable, prosperous and highly competitive ASEAN economic region in which there is a free flow of goods, services and investments, a freer flow of capital, equitable economic development and reduced poverty and socio-economic disparities" (ASEAN Vision 2020).

The AEC is built on the current initiatives under the ASEAN Free Trade Agreement, the ASEAN Framework Agreement on Services, and the ASEAN Investment Area, with clear timelines specified for removal of nontariff barriers, harmonization of product standards and technical regulations, and conclusion of mutual recognition arrangements for priority sectors.

Prospects for ASEAN Economic Cooperation ASEAN faces a number of challenges in its journey toward greater economic integration. One major challenge is the widening economic gap within the grouping as ASEAN membership increased to 10 countries with significantly diverse economies and political regimes, and as the grouping is establishing more extra-ASEAN free trade agreements. The widening gap and the proliferation of extra-ASEAN free trade agreements, if not managed correctly, could lead to the weakening or marginalization of the ASEAN integration and, worse, to the irrelevance of ASEAN to the individual member countries' economic development.

■ **asymmetric information**

An asymmetric information problem exists in a market if it is costly for some parties to observe the

characteristics or behavior of other parties, and an inefficient outcome results. One problem that arises due to asymmetric information is moral hazard, which exists when an arrangement that relieves a party of some risk causes the party to engage in riskier behavior. In credit markets, for example, use of a loan to finance a project means that the gains to the borrower are reduced if the project succeeds, because the principal must be repaid with interest. If the project fails, however, the creditor absorbs the loss of principal and interest, net of any collateral provided by the borrower. Risks are thus shifted from the borrower to the creditor, much as would occur with an insurance contract. If the creditor could costlessly observe how the borrower used the loan, then it might be possible to give the borrower contractual incentives to work hard and avoid risky projects, in order to hold down the risk of default on the loan. For example, future disbursements of the loan could be conditioned on the borrower's using the loan responsibly. However, if it is costly to observe the borrower's behavior, then moral hazard may arise, particularly if the loan is not fully collateralized or it is costly to take legal action against a borrower in default.

Adverse selection occurs in a market if it is difficult to distinguish parties that are good risks from those that are bad risks, and the parties that represent bad risks are particularly attracted to the market. For example, consider a set of borrowers that wish to finance projects that are identical in all respects, including offering identical expected returns, except that the projects vary in their riskiness. It can be shown that borrowers with riskier projects will have higher expected profits than other borrowers, and thus will have stronger incentives to borrow, while the expected rate of return to banks from these borrowers is lower than it is from other borrowers (Stiglitz and Weiss 1981). Thus the borrowers that tend to select themselves into the market cause problems for it.

If it were obvious which parties were the bad risks, those parties could be offered more stringent terms or even avoided altogether. Absent such information, in markets subject to adverse selection, the normal function that prices play in determining who participates in the market can result in a perverse outcome. In credit markets, higher interest rates limit who will want to borrow by making borrowing more burdensome, but those with the least risky projects will be the ones driven out of the market first, all else being equal. Those who are less likely to pay back the loan will be less concerned about paying higher interest. Because the average quality of the loans actually made can then deteriorate, the adverse selection problem can be worsened. A higher interest rate will also exacerbate the moral hazard problem for a given borrower, because the higher interest rate is burdensome only in the event that the borrower actually repays the loan.

Given these drawbacks of raising interest rates to limit access to credit, banks may choose to ration credit, so that borrowers are not allowed to borrow as much as they want at a given interest rate (Stiglitz and Weiss 1981). It is also possible that credit rationing may not occur, in which case a small increase in interest rates can lead to collapse of the loan market (Mankiw 1986).

Asymmetric Information and Financial Crises
Problems related to asymmetric information can contribute to, and be exacerbated by, financial crises, such as those experienced by South Korea, Thailand, and Indonesia in 1997 98. Financial crises that lead to bank failures can have real economic costs because of the loss of the customer relationships that these banks had cultivated. In the course of repeated interactions with their loan customers, banks gain a considerable amount of information on the customers' creditworthiness and other characteristics. This information is lost in a bank failure, which can worsen the moral hazard and adverse selection problems (Mishkin 1999). Thus financial intermediation becomes less effective, and real economic activity can be harmed.

Currency depreciation can exacerbate a banking crisis because it tends to worsen the balance sheets of individuals and corporations within the country that have borrowed in foreign currencies. This reduces the value of the collateral that can be obtained from these borrowers in the event of default and thus exacerbates

the moral hazard problem inherent in credit markets: borrowers with less to lose have weaker incentives to avoid default. Moreover, problems related to asymmetric information also limit how countries can respond to financial crises. For example, the higher interest rates required to combat inflation or stabilize the currency can aggravate adverse selection and moral hazard, as discussed earlier.

Information asymmetries can also exacerbate a tendency toward investor panic manifested by bank runs, capital flight, or asset price downturns, and can contribute to financial contagion between unrelated financial institutions or countries during crises.

Models of these phenomena typically posit that uninformed investors try to infer how asset prices will move based on the information revealed by these prices. Informed investors directly observe the fundamental determinants of asset prices, but the prices are also influenced by exogenous random factors. Moreover, informed investors are unable to drive asset prices directly to their equilibrium values dictated by the fundamentals because of various impediments to asset trading (such as trading costs, short-sale constraints, or borrowing constraints).

Now consider a negative shock to an asset price. Knowing that informed investors are limited in their ability to make trades, uninformed investors are uncertain whether the fundamental asset value is even lower, and therefore demand an additional risk premium to hold the risky asset, which forces its price down further. Thus asymmetric information exacerbates asset price movement.

For contagion between markets to occur, the simplest scenario is that the fundamental determinants of asset prices in two markets are correlated. Informed investors observe a shock to the fundamentals in one market, and in response reallocate their portfolios in the market that has experienced the shock and in other markets. The uninformed investor is uncertain whether asset price movements in either market are due to transactions by informed investors or due to random noise; given the greater uncertainties, uninformed investors demand a larger risk premium in both markets, which causes asset prices to move together.

Borrowing constraints can also trigger contagion, as shrinkage of investor assets in one country means that investors may be forced to sell their assets in other countries, as collateral requirements become binding (Yuan 2005). This contagion will also be exacerbated by the actions of uninformed investors. It will be stronger during asset price downturns than upturns and does not require that macroeconomic fundamentals in the countries be correlated. These findings are generally consistent with empirical evidence to date. Thus this model offers one explanation of why asset price shocks spread among East Asia, Latin America, and other parts of the world in 1998.

Lender of Last Resort Moral hazard becomes a policy issue in credit markets because of the lender-of-last-resort role played by various institutions. For example, central banks and other financial regulators are concerned about the possibility of a run on banks, which in turn could arise in part because it is difficult to distinguish solvent banks from insolvent ones. In order to lessen the risk of a run on banks, the central bank or other governmental institution usually provides implicit or explicit insurance to bank depositors. Bank liabilities may even be fully guaranteed on the grounds that the banks are too big or too politically important to be allowed to fail. The consequential moral hazard can give banks little reason to be cautious in their lending, or depositors little incentive to take the trouble to examine the financial soundness of one bank versus others. These problems can set the stage for a banking crisis.

Whether it is necessary or desirable for an international lender of last resort to assist countries in financial crises is a matter of some controversy. An argument in favor of such an institution is that the central bank of a country in crisis may have a limited capacity to restore the economy to health. For example, the provision of extra liquidity through monetary expansion could lead to currency depreciation and increases in inflationary expectations and interest rates (Mishkin 1999). Thus there may be an argument for an institution such as the International Monetary Fund (IMF) to lend foreign exchange to a country so that it can pay for imported inputs and

intervene to support its currency, say, to alleviate the real economic harms that a financial crisis can cause. As critics have observed, however, IMF bailouts of countries in financial distress can also cause moral hazard by relieving the governments of those countries of the painful effects of the inadequacies of their economic policies and by relieving international investors of the adverse consequences of investing in inherently risky environments such as emerging markets.

Following the IMF decision not to bail out Russia in 1998, the amount by which interest rates on bonds in developing countries exceeded those in industrial countries increased, particularly for countries with weaker economic fundamentals, indicating that investors were increasingly taking into account the risks of lending to developing countries (Dell'Ariccia et al. 2002). It cannot be concluded, however, that this change was for the better, even if it indicated that moral hazard was reduced: IMF lending that reduces risks could be a good thing on balance, and its positive effects would also be reflected in interest differentials across countries. For example, an IMF intervention in a developing country could alleviate market failures such as coordination problems among creditors to the country, by acting as a catalyst that restores confidence and induces creditors to resume lending rather than waiting for other creditors to take the first step.

Measures to Limit Moral Hazard At all the levels at which moral hazard exists in financial markets, measures can be taken to lessen its impact. Individual loan contracts can include provisions that make it harder for the borrower to take excessive risks or to shirk repayment of the loan. For example, loans can be disbursed in increments, conditional on performance to date. One reason for the existence of financial intermediaries like banks is that they can perform these disciplining functions at lower cost than can individuals, such as by threatening to withdraw future business from recalcitrant borrowers.

At the level of the banking system, the dilemma for policymakers is how to contain moral hazard and yet prevent or at least mitigate financial crises. Most

governments provide some form of implicit or explicit insurance for bank deposits. New Zealand does not, on the grounds that it eliminates depositors' incentives to monitor the riskiness of their banks, and because providing the deposit insurance at the same price to all banks implicitly subsidizes banks with riskier loan portfolios at the expense of those with more responsible ones. New Zealand instead tries to ensure that the public has complete and accurate information on banks' financial conditions. Some countries that provide deposit insurance, such as the United States, seek to lessen moral hazard by limiting deposit insurance to relatively small deposits, in order to provide larger depositors or other bank creditors with stronger incentives to monitor and price the risks embodied in banks' loan portfolios. In principle, the moral hazard from deposit guarantees can also be reduced through appropriate ongoing bank supervision and regulation. In practice, in many developing countries in particular, bank regulation remains problematic.

One approach to lessening the economic damage in the event of a crisis is for a lender of last resort to inject capital into financial markets. There may be merit in providing liquidity to the market in general rather than to particular distressed institutions, so that market forces can ultimately determine which institutions survive. If individual financial institutions are to be provided credit by the lender of last resort, Bagehot (1873) suggested that the terms should not be too attractive: the rate of interest should be higher than during normal times. Limiting moral hazard in this way is not without its own costs. Imposing a higher penalty rate can weaken the condition of the bank, signal to the market that the bank is in trouble, or induce bank managers to pursue a riskier strategy. However, Bagehot allowed that credit should be provided on collateral that would be marketable in normal times, so that a crisis-induced collapse of asset prices that caused collateral to shrink would not in itself limit the amount that could be lent.

If the crisis is due to a coordination failure, such as a panic-induced run on a bank, a lender of last resort may be able to suspend the obligations of the bank

temporarily, in a way that the bank could not do on its own due to credibility problems. This approach would not diminish the risk to which creditors of the bank are exposed, and thus could limit moral hazard. The lender of last resort could also coordinate a private bailout of the bank, in an effort to limit moral hazard. If the coordination of private institutions is at all coercive, however, it will in effect provide a subsidy to the distressed institution, in which case moral hazard reappears in an alternative form. Indeed, the bailout of the Long-Term Capital Management (LTCM) hedge fund in 1998 raised questions about whether private investors were coerced by the central bank. The LTCM bailout under the guidance of the Federal Reserve has been criticized for causing moral hazard.

Parallel issues have arisen for the IMF as an international lender of last resort that has bailed out countries in financial crisis. For example, IMF loans of foreign exchange to countries in crisis are disbursed over time, and the institution monitors whether the recipient country is complying with the performance and policy conditions negotiated as part of the loan agreement.

To avoid the moral hazard that IMF bailouts can cause, an alternative approach is to rely more on private-sector solutions. Along these lines, Mexico, Brazil, and other countries have introduced collective action clauses into their sovereign bond contracts since 2003. Such clauses are intended to facilitate debt restructuring in the event of a crisis, primarily by making it harder for a small minority of bondholders to block debt restructurings endorsed by a large majority. Inclusion of these clauses appears to have lowered borrowing costs for these countries, despite concerns that the clauses might make it easier for some countries, particularly those that are less creditworthy, to avoid repaying their debts.

A degree of deliberate ambiguity in the actions of the lender of last resort may also limit moral hazard. If it remains unclear whether the lender of last resort will provide a bailout in all situations, the parties who might or might not be bailed out will have incentives to act more responsibly. The decision

by the IMF not to bail out Russia in 1998, on the heels of its bailouts of South Korea, Thailand, and Indonesia in 1997 98, could be seen as creating such ambiguity.

A final restraint on moral hazard is for managers and owners of failed institutions to be punished: managers should lose their jobs and shareholders their capital. The argument may be applicable to national economies in crisis as well: a change of government tends to have a salutary effect in the recovery from a financial crisis, particular if mismanagement by the government was partly responsible for the crisis.

■ bail-ins

A bail-in is an agreement by creditors to roll over their short-term claims or to engage in a formal debt restructuring with a troubled country. Bail-ins are usually done in conjunction with a broader program of International Monetary Fund (IMF) lending and policy changes to help restore a country's economic and financial health. In a bail-in, creditors with claims coming due are asked to defer repayment deadlines and in some cases to agree to reduce their claims. In a bailout, by contrast, a country borrows hard currency reserves from the IMF, enabling it to pay off its maturing debt.

Academic models usually try to posit a clear choice between lender-of-last-resort financing and a standstill on all payments. In practice, though, policymakers rarely confront a binary choice between a complete standstill and lender-of-last-resort financing. Sources of existing or potential financial pressure on a crisis country are usually diverse: it is possible to bail in some creditors and bail out others. A strategy that combines a bailout (of some) and bail-in (of others) consequently can make sense. A successful bail-in of some creditors eliminates one potential source of financial strain. The benefits of securing additional financing from a set of private creditors, however, have to be balanced against the risk that attempting to bail-in some creditors will only prompt other creditors to run.

A bail-in is usually initiated when a country in financial trouble asks a set of its creditors to agree to roll over or reschedule their maturing claims. The debts coming due can be the obligations of the crisis country's government — for example, a maturing international sovereign bond — or they can be obligations of private borrowers (most often cross-border loans to the country's banks) in the crisis country. Convincing the country's creditors to defer payments, whether through a bond exchange or an agreement to roll over maturing bank loans, requires at least the implicit threat that the country will halt payments if the creditors do not agree on a restructuring. But the nature of the country's negotiations with its creditors can nonetheless vary. A country that tries to negotiate an agreement with its creditors to defer payments is acting quite differently from a country that just stops payments and demands that its creditors agree to reduce their claims.

Debt Restructuring and Burden Sharing Debt restructurings are a part of borrowing and lending; they would occur in the absence of any official-sector intervention. The trigger for a bail-in, however, is often a policy decision by the official sector not to provide a country with sufficient emergency financing to allow it to avoid a debt restructuring. The IMF, the Group of Seven (G7), and others can condition their lending on a requirement that a country keep its foreign exchange reserves above a designated level (effectively requiring the country to initiate a restructuring if it cannot find private sources of financing), refuse to lend in the absence of a restructuring, offer to provide financing to facilitate a consensual restructuring, or even help the country organize a rollover of its maturing loans. The Paris Club — a group of bilateral lenders — can also condition its willingness to restructure the debts a

country owes to bilateral creditors on a country's willingness to seek a comparable restructuring of the debt the country's government owes to private creditors. (The official sector generally has leverage over the debtor, not the debtor's creditors. The official sector sometimes can, however, exert leverage directly on certain types of creditors particularly banks. The official sector usually stops short of telling banks what to do. Nonetheless, major governments can make clear that it is in the banks' collective interest to cooperate to avoid default by agreeing to roll over their exposures.)

The line between a normal, voluntary market transaction issuing a new bond, a voluntary debt exchange and an involuntary concession to avert a crisis is not always clear. Some IMF programs rely on the expectation that the combination of financial support and policy adjustment will catalyze new private financial flows. Some debt exchanges done in the context of an IMF program occur at market rates and are altogether voluntary the creditors who do not participate can expect to be treated as well as creditors who do participate. Because these exchanges must be done at market rates, they are often expensive. The most famous example is Argentina's megaswap in the summer of 2001: the swap extended the maturity of Argentina's bonds, but at an implied annual interest rate of close to 15 percent. This transaction allowed Argentina to avoid default only for six months, however. These voluntary exchanges are not a true bail-in: private creditors are extending credit at a market rate in the expectation of earning a commercial profit, not making a concession to help the country through a crisis.

Other debt exchanges are done at below-market rates to avoid an imminent default. These transactions are also voluntary in some loose sense. Creditors often are willing to defer payments at an interest rate lower than the prevailing market interest rate at the time of the exchange as in Uruguay's 2003 exchange or even accept a deep "haircut" as in Argentina's 2005 exchange rather than hold debt that the sovereign debtor is not willing (or able) to pay. A haircut typically involves a reduction in the

face value, a reduction in the coupon (the amount to be paid at fixed intervals), or a reduction in both the face value and the coupon of the bond. The actual losses experienced by creditors who mark to market (that is, value the bond as an asset at its open-market price) depend on the price at which they bought the bond and the discount rate the market assigns to the payment stream on the restructured bonds. The decision to voluntarily agree to these kind of terms reflects the fact that the alternative to a restructuring is often default and creditors lack the legal ability to force a sovereign debtor that is in default to resume payments.

Throughout the 1990s, the G7 and the IMF had trouble reaching agreement on the right term to use to describe efforts to secure the coordinated provision of emergency financing from a country's existing private creditors. Calls for more "burden sharing" were considered too heavy handed: no private creditor happily takes on a burden. Talk of "constructive engagement" with private creditors was considered a bit too diplomatic: private creditors generally preferred other forms of engagement. The relatively informal term *bail-in* drew attention to the bailouts that sometimes were provided to avoid bail-ins. The most widely used term *private-sector involvement in crisis resolution* suited the international bureaucracy well: it was easy to reduce to an acronym (PSI).

Acronyms can still generate impassioned debate. "Market fundamentalists" opposed all forms of official intervention. They wanted to scale back IMF lending. But they also opposed the official sector's efforts to facilitate the coordinated provision of emergency financing by private creditors. This group wanted both fewer bailouts and fewer officially organized bail-ins. A more pragmatic group including many in the G7 and the IMF hoped to combine official financing with attempts to involve private creditors. This group argued that commitments by prominent creditors not to take their money out would help to limit the distortions introduced by official crisis support. Many Europeans viewed efforts to involve private creditors as a direct substitute for large-scale official financing they

wanted more bail-ins to reduce the need for financial bailouts. They emphasized the need to change the institutions for debt restructuring in order to make restructurings less disruptive whether through the introduction of collective action clauses in international sovereign bonds or the development of an international bankruptcy regime. Many emerging economies sometimes with support from those in the U.S. Treasury who believed recent emerging market crises were overwhelmingly the product of an international analogue to bank runs wanted to banish all talk of combining bailouts with bail-ins, arguing that any effort to bail in some groups of creditors would scare market participants and keep IMF financial support from generating the desired improvement in creditor confidence.

Bail-ins were rarely part of the official sector's initial response to market turmoil. Most countries approached their private creditors to seek emergency financing only after an initial (and sometimes limited) round of official financing failed to end their financial trouble. There have, nonetheless, been important successes. Korea convinced the international banks that had lent to Korean banks first not to demand payment on their maturing loans and then to reschedule these loans. The rollover agreement eliminated the immediate threat of default and along with continued financing from the IMF helped to pave the way for Korea's financial recovery. Uruguay successfully combined a very large credit line from the IMF with a bond restructuring. The credit line stopped Uruguay's bank run and provided Uruguay the time needed to execute the bond exchange; the exchange assured that the IMF's funds were not used to finance a reduction in the country's bond exposure. Pakistan and the Dominican Republic also restructured their international bonds without stopping payments.

Other bond restructurings came only after the country had fallen into general default. Such restructurings sought to clean up an existing financial mess rather than avert a deeper financial crisis. Russia's 2000 restructuring of its "London Club" debt was technically a restructuring of syndicated bank

loans, but since most of these loans had been securitized and sold into the market, it resembled a bond exchange. Both the Ukraine and Ecuador restructured their international sovereign bonds in 2000. Argentina's restructuring, though, dwarfs the others in size and complexity: in 2005 Argentina sought to restructure 152 separate bond issues with a face value of more than $80 billion.

The legal challenges associated with a bond restructuring, though significant, have to date proved to be smaller than many initially feared. The difficulty in keeping a bond restructuring from leading to broader financial collapse and specifically a domestic bank run proved larger than expected, however. In practice, many "international" sovereign bonds (bonds governed by a foreign law) are held not by international investors, but by the domestic banking system.

Crisis Management: Finding the Right Balance
No single measure can gauge the success of efforts to obtain crisis financing from the country's private creditors. Success requires convincing private creditors to contribute, whether by deferring payments or by agreeing to reduce their claims on the crisis country. But success also requires that the private creditors' contribution not come at the expense of other goals including preventing a sharp fall in output or triggering a broader run that leaves the country in a deep financial hole. Finding strategies that strike the right balance between these sometimes conflicting goals has been a constant challenge.

■ bailouts

Bailouts broadly refer to large loans from the official sector usually the International Monetary Fund (IMF) to a country facing difficulties repaying its maturing debts or needing to intervene in the foreign exchange market to defend its exchange rate in the face of the withdrawal of foreign investment or domestic capital flight. These loans are provided directly to the crisis country to augment its reserves in the face of acute balance of payments difficulties. Augmenting a crisis country's hard currency (international) reserves often allows the country to avoid what otherwise would have been an almost certain default on its private debts and, in some cases, to intervene in the currency market to maintain an exchange rate peg at a level that would otherwise be unsustainable. Consequently, large loans that help a country try to avoid economic and financial collapse also help external and domestic creditors with foreign-currency debts coming due, as well as those looking to exchange local currency for dollars, euros, or another currency.

The term *bailout* could be applied to all loans provided for balance of payments support by the official sector. In practice, the policy debate over these loans focused primarily on the largest of these loans, and specifically those loans whose size exceeded the IMF's traditional lending limits of 100 percent of quota in a year, or 300 percent of quota over three years. (A country's quota determines the size of a country's contribution to the IMF as well as its voting and borrowing rights.) The first prominent loan to breach these limits was provided in 1995 to Mexico. By the end of 2007, the IMF had provided "exceptional" levels of IMF financing to an additional eight emerging market economies facing acute balance of payments difficulties. Indeed, "exceptional" financing that is, financing in excess of the IMF's normal lending norms effectively became the new norm for large emerging market economies that encountered balance of payments difficulties.

Using the size of an IMF loan relative to quota to distinguish between small and often uncontroversial IMF loans and those exceptionally large IMF loans creates some difficulties. First, the size of a country's

IMF quota maps only imperfectly to other relevant economic criteria Korea in 1997 and Turkey in 2001 and 2002 got exceptionally large IMF loans relative to their quotas, in part because their quotas were quite small relative to their current gross domestic product (GDP). Second, in several prominent cases, the multilateral development banks and the Group of 10 countries (a group of economically advanced countries) provided large amounts of financing alongside the IMF, so looking only at IMF financing may understate the scale of official support. For example, the United States provided Mexico almost as much financing from its Exchange Stabilization Fund as the IMF and a group of bilateral creditors coordinated by the Bank for International Settlements (BIS) disbursed alongside the IMF in 1999. The World Bank and the Asian Development Bank pushed by the United States provided a large amount of emergency financing to Korea, and Japan provided additional bilateral funds to Thailand (the bilateral "second-line" commitments included in the initial packages for Korea and Indonesia were never disbursed). Loans that breached the IMF's own access limits also tended to be the largest loans when measured by other criteria. Those countries that got large amounts of financing from other official sources also tended to get large amounts of financing from the IMF.

How Does the IMF Differ from Domestic Lender of Last Resort? An IMF loan to a country is in some ways similar to emergency financing from a domestic lender of last resort (typically, the country's central bank). Both provide liquidity cash to those in need of it. Just as a loan from a domestic lender of last resort lets a troubled bank pay off its depositors, an IMF loan also lets some of the crisis country's creditors "off the hook" by financing the repayment of the debt. Just as support from a domestic lender of last resort can convince a troubled bank's creditors its depositors to give the bank time to try to work through its difficulties, international crisis financing can convince the country's creditors to give it time to work through its problems.

But there are also important differences between the IMF and a domestic lender of last resort. First, the IMF's lending capacity is constrained by the amounts members have placed on deposit with the fund. A domestic lender of last resort has no similar constraints, at least as long as it lends in the country's own currency. Second, IMF loans are usually tied to policy changes, and in order to encourage the country to implement those changes, IMF lending is rarely disbursed all at once; instead, IMF loans are usually disbursed in a series of tranches. A domestic lender of last resort can provide all necessary funds up front. Third, the IMF does not lend against collateral; rather, crisis countries, by long-standing convention, pay the IMF even if they are not paying their other creditors. This allows the IMF to lend to crisis countries at modest rates without taking losses. Finally, many domestic bank "bailouts" do more than just provide a cash-strapped domestic bank with emergency liquidity. They also typically require giving a troubled bank a government bond a new financial asset to prevent depositors (and sometimes even the shareholders) in the bad bank from taking financial losses. International bailouts, by contrast, do not increase the net assets of a troubled emerging economy. The country's external reserves rise, but so do its external debts. The international taxpayers who put up the money needed to make an IMF loan expect to get repaid in full.

Consequently the term *bailout* is perhaps too negative a term for emergency crisis financing, as it suggests that the crisis lender is picking up losses that otherwise would have been borne by the country and its creditors. The term *rescue loan* is probably too positive, however, as not all "rescues" have succeeded. Most neutral terms such as *large-scale official crisis lending* sound bureaucratic. The lack of an agreed term itself may be indicative of the ongoing debate about the wisdom of large-scale lending to crisis countries.

Debate Surrounding IMF Crisis Lending Proponents of large-scale IMF lending argue that financial integration is generally beneficial. But they also recognize that it can increase the risk that a country with correctable policy problems can be forced into a disruptive default by a self-fulfilling crisis of confidence. Concerns that other external creditors will not

roll over their short-term debts as they come due can lead all external creditors to demand payment as soon as possible. A country's own citizens can also decide that they want to shift their savings abroad before the country runs out of reserves. Such a shift from domestic to foreign assets puts enormous pressure on the country's reserves if it has a fixed exchange rate regime, on its exchange rate if it has a floating exchange rate regime, or on both reserves and the exchange rate if it has a managed float. Sergei Dubinin, the chairman of Russia's central bank during the 1998 crisis, observed, "We can play games against the market, against the banks even, but we can't do anything if the entire population wants to change rubles into dollars" (Blustein 2001, 266–67).

Such crises of confidence have usually stemmed at least in part from doubts about a country's ability to put in place needed corrective policies, not just doubts about the willingness of other creditors to maintain their exposure. But as the run intensifies, a country can be pushed toward default well before it has time to show whether it can make the policy changes to ensure its long-run solvency.

Critics of large-scale lending have raised a host of objections. Some object to all official intervention in private markets. Official action that insulates a country and its creditors from paying the full price for their mistakes only encourages more bad policies and additional risk-taking—so called moral hazard. Others object to the conditions attached to IMF loans,

Sources: IMF and bilateral first line lending data from IMF, U.S. Treasury; debt data from Moody's (apart from Mexico's precrisis debt data, which is from the IMF). Moody's debt numbers for Brazil are higher than other sources. The IMF has Brazil's 1997 (precrisis) debt to GDP at 35% rather than 40%; and Brazil's 2000 (precrisis) debt to GDP at 49% rather 65%.

[a] Thailand's IMF exposure peaked after 9 quarters, and it repaid half of that exposure after 17 quarters. At that point in time, it had not repaid ½ its bilateral lending. However, we do not have data indicating Thailand's bilateral repayments after the end of 2001.

whether fiscal austerity, monetary tightening, or domestic financial and corporate reform. This criticism was particularly vociferous after the Asian crisis; many argued that the IMF's conditions themselves contributed to the cascading loss of confidence. Many argued that the large bailouts of the 1990s and the first few years of the new millennium were a marked change from the 1980s, when the typical IMF loan was smaller (in relation to quota, though quotas were larger in relation to GDP) and was combined with commitments by the country's largest creditors   the commercial banks   to roll over their claims.

Finally, some argued that the real problem was not that the IMF was lending too much, but rather that the IMF was not able to lend enough. The IMF risked providing enough money to allow a lucky few to exit, but not enough to assure that the run would stop and the country would have time to put in place corrective policies.

This highlights a key point: in practice, even the largest IMF loans typically fell short of providing sufficient funds to cover all potential drains on the country's hard currency liquidity. For example, Mexico received enough money to cover payments on the government's maturing short-term dollar-linked debt, the famous *tesobonos*, but not enough to cover all potential sources of capital flight. Even a loan large enough to cover the most obvious sources of payment difficulties works only if additional sources of financial pressure do not also materialize.

Has IMF Crisis Lending Been Successful? Several large IMF bailouts achieved most of their intended goals. Mexico, Korea, and Brazil (in 1999) all avoided default, recovered market access relatively quickly, and paid back their official creditors quite rapidly. Eight quarters after the onset of their crises, all had paid back more than one-half of their initial loans (see table 1). Brazil, however, is less obviously a success than Mexico and Korea, as the rise in its debt levels during the 1998 99 crisis laid the foundation for its 2002 crisis. Brazil did not pay its 2002 bailout loan back in eight quarters   in part because the large loan in 2002 came on top of an earlier loan in 2001. But it otherwise resembles the "success" stories: it fully repaid the IMF at the end of 2005, and its debt

levels were coming down through the end of 2007. Other rescues achieved their goals, but not as quickly. Thailand (1997), Turkey, and Uruguay all avoided default, regained market access, resumed growth, and eventually made significant payments back to the IMF. All these countries entered into their crises with higher debt levels and generally have taken longer to repay the IMF than Mexico, Korea, and Brazil (particularly in 1999).

Three bailouts clearly failed to achieve their initial goals, however: Russia, Argentina, and Indonesia   whether because the country failed to carry out its commitments to the IMF or because the IMF backed a flawed strategy. In 1998, Russia was cut off quite quickly, after one $5 billion disbursement from the IMF's new program   a decision prompted in part by the IMF's substantial exposure from its previous lending programs. Indonesia received only $4 billion in the early stages of its crisis. Most of the funds it received from the IMF came later on, after its corporate sector had fallen into general default. Argentina, in contrast, received almost $15 billion in an unsuccessful attempt to ward off default.

By the end of 2007, the IMF had not approved a new large loan   setting aside those loans extended to refinance existing IMF loans   since 2002. In retrospect, the period of large-scale IMF lending that followed Mexico's crisis may be viewed as facilitating the transition of many emerging economies from a point where they held too few reserves to navigate periods of financial volatility to a point where most emerging economies held more reserves than they needed. During the turbulent period between 1995 and 2003, the size of IMF lending was striking. By 2005, though, the size of even the largest IMF loans seemed fairly small relative to the reserves of the typical emerging economies. For all the criticisms leveled at the IMF, most emerging markets concluded that they needed to hold far more reserves than the IMF was ever willing to make available.

balance of payments

A balance of payments is an international accounting record. It records the economic transactions of the residents of one country with the residents of other countries during a fixed period (month, quarter, year). The payments are usually measured in a country's home currency, although the accounts are sometimes expressed in U.S. dollars to facilitate cross-country comparisons. The payments are broken down into categories goods, services, transfers, investments, and official reserves. Inflows and outflows in each category are measured and a net figure for each is calculated. Strictly speaking, each category has a balance and, as a matter of practice, several balances are regularly reported by government agencies and the financial press. *The balance of payments* is a generic term that refers to payment flows in some or all of the different categories.

Although balance of payments accounts are constructed using sophisticated accounting principles, including double-entry bookkeeping, a country's cross-border transactions are not measured with the accuracy of a corporation's accounts. Balance of payments figures are statistically estimated based on sampling data gathered by government agencies. In the United States, business firms are required by law to provide information on international transactions. The Office of Management and Budget, the Customs Service, the Department of Commerce, and the Treasury Department gather or compile such information. Although these agencies do their utmost to provide reliable estimates, of necessity the accounts contain errors; the statistical estimates are based on data that are incomplete and otherwise imperfect.

Uses Business firms, labor unions, academics, lawyers, investors, and government officials take an interest in the balance of payments. Firms base financial and competitive decisions on the balance of payments. Firms and labor unions use balance of payments figures to argue for favorable tariffs or subsidies. Lawyers use information from the balance of payments to initiate cases in national courts or before the dispute resolution bodies of the World Trade Organization (WTO). Economists develop principles to explain the movement of goods and investments across borders, and they recommend policies based on those principles. Government officials are responsible for the policies that govern cross-border economic transactions. Some government policies, such as the trade restrictions imposed during the Cold War, discourage international transactions, while other policies, such as free trade agreements, encourage them. The balance of pay-

ments also helps us to understand how the world trading system is evolving. The flow of foreign aid from the United States to Europe in the 1950s, the increase in the exchange of services in the 1980s, and the rise of foreign direct investment in the 1990s all show up in the balance of payments accounts.

History The interest in international transactions goes back to at least the 14th century. The mercantilists, a group of British writers, urged government policies that encouraged exports and discouraged imports. They argued that a surplus of exports over imports would preserve the country's specie (metallic money supply) and enhance the wealth of the country. Borrowing the idea of an accounting balance from the double-entry bookkeeping of Italian merchants, the mercantilists introduced the term *balance of trade* into economic discussion in the 1600s. In the 18th century, David Hume pointed out that a country cannot run a permanent trade surplus (his famous price-specie flow mechanism), and Adam Smith roundly criticized the mercantilists for conflating money and wealth. The balance of payments received a great deal of theoretical attention in Britain's 19th-century monetary debates; the effects of fiduciary media (paper money) on the trade balance were especially controversial. European and U.S. governments collected international trade statistics in the 19th and early 20th centuries, but the modern system of payments accounting was not established until the end of World War II, when agreements at Bretton Woods empowered the International Monetary Fund (IMF) to gather and organize international trade data. World leaders recognized that the breakdown of the international trading system during the 1930s had exacerbated the Great Depression. They hoped that systematic gathering and presentation of trade data would enhance international cooperation.

Accounts All international economic transactions are divided into two main accounts the current account and the awkwardly named capital and financial account.

Current Account The current account is broken down into four categories goods, services, income, and transfers. Goods are the tangible items agricultural products, manufactured goods, and commodities such as copper and crude oil that are traded across borders. For most countries, goods are the main component of the current account. In 2004, the United States exported slightly more than $800 billion in goods, about 50 percent of current account credits for the year. Japan exported $539 billion in goods, about 70 percent of its current account credits (see table 1). Services are the exchange of intangibles across borders. Travel, transportation, royalties and license fees, and financial (banking, investment, insurance) and military services are the main ones traded across borders. In 2004, the United States exported $340 billion in services, Japan $98 billion. Business and personal travel is an important component of services in many countries; $74 billion, or 21 percent, of U.S. service export revenue came from travel in 2004. Income in the current account is primarily the dividends and interest paid to residents of a country from their investments abroad. The income can result from a resident in one country holding securities in foreign companies or governments, or from interest earned on loans to residents of other countries. For a country that invests large sums abroad but discourages foreign investment into the country, inflows of income outweigh the outflows by a large margin in Japan's case, $113 billion to $27 billion in 2004. Besides income from investments abroad, the income account also includes compensation to temporary workers, such as seasonal farmworkers and short-term business consultants. Compared to investment income, employee compensation is small for most countries; in 2004, the United States, for example, paid $9 billion to temporary workers from other countries, but $340 billion in interest and dividends to foreign investors.

The final item in the current account is unilateral transfers. The main items in this account are foreign aid (government grants of cash, food, clothing, etc. to the residents of other countries), charity (private donations to residents of other countries), and worker remittances (money sent home by workers employed abroad). Residents of wealthy economies usually spend considerable sums on government aid and charitable activities aimed at helping residents of

other countries. In 2004, the residents of the United States disbursed foreign aid of $30 billion, private charitable contributions of $39 billion, and worker remittances of $30 billion to other countries. Residents of developing countries are usually net recipients of aid, charity, and remittances.

Financial Account Like the current account, the financial account is divided into four main kinds of transactions. The first of these is direct investment. Whenever residents in one country make an investment abroad that gives them a "substantial voice" in management, the investment is considered direct. A firm may do this by investing in plant and equipment or by purchasing enough stock (10 percent or more of outstanding shares) to influence the managerial decisions of an existing firm. In 2004, U.S. investors spent $252 billion on direct investments abroad, $176 billion of which was reinvested earnings. Foreign investors spent $106 billion on direct investment in the United States, $56 billion of which was reinvested earnings.

The second kind of investment transaction is portfolio investment, which is the purchase of bonds and equities in one country by residents of another. Although equities are issued mainly by private firms, bonds are issued by both firms and governments, so portfolio investment includes the purchase of government bonds by residents of other countries. In 2004, foreign residents invested $62 billion in U.S. equities and $701 billion in U.S. bonds, $458 billion of which was government bonds. By way of contrast, foreign residents invested $197 billion in Japan. The investment was split evenly, with $98 billion going into equities and $98 billion into bonds, of which $53 billion was government bonds. The government absorbed 60 percent of portfolio investment in the United States, compared to 27 percent absorbed by the Japanese government.

A third category of investment is a residual, named "other" in the accounts, which includes trade credit, bank loans and deposits, and currency exchanges. In 2004, foreign residents increased their residual investments in the United States by $570 billion, $407 billion of which represented an increase in the holdings of U.S. currency and bank deposits.

In Japan, the pattern was rather different. Foreign residents increased borrowing from Japanese firms and government agencies by $81 billion but reduced their holdings of the yen by $13 billion, so residual investment increased by $68 billion.

The fourth category of investment in the financial account is reserve assets, which are funds available to monetary authorities to finance payment deficits. Central banks and treasuries use gold, holdings with the IMF, and foreign exchange (currencies and deposits) for such financing. In 2004, monetary authorities in the United States financed an overall deficit of $2.8 billion, mainly by altering its reserve position within the IMF. Japan had an overall surplus of $161 billion, with which it acquired foreign exchange (i.e., international reserves).

Double-Entry Bookkeeping Every economic transaction entered into a country's balance of payments accounts contains both a debit and a credit. On the current account, debits and credits are apparent. When a country exports, the account shows a credit; when a country imports, the account shows a debit. On the capital account, the debits and credits can be somewhat confusing. When a company receives payment for its exports, it is recorded as a debit in the capital account; when a company makes a payment for an import, it shows up as a credit in the capital account. One way to make sense of credits and debits is to view them as sources and uses of funds, where *funds* means financial assets used in international transactions. Currencies, deposits in banks, trade credits and other forms of loans are examples of funds. In the balance of payments accounts, a source of funds is a credit; a use of funds is a debit. When a firm sells a bond to a foreign resident, the sale will show up as a credit (a source of funds) in the capital account of the home country. By selling a bond to a foreign resident, a firm has also increased its liabilities. An increase in liabilities is a source of funds and therefore a credit in the capital accounts. Conversely, when a firm redeems a bond, it reduces its liabilities by using funds. A decrease in liabilities is therefore a debit in the capital account. The opposite is true of assets. When a resident of one country purchases equity shares in a foreign firm, she uses funds; an

increase in assets appears as a debit in the financial account. When this investor sells her shares, she decreases her assets and increases her funds. A decrease in assets appears as a credit in the capital accounts.

Balances If we accurately record all of the flows of payments between countries, they will always balance. Yet policymakers and others are often concerned with payment imbalances. Imbalances occur when we consider only particular types of transactions within the accounts, rather than all transactions. For example, if we consider only merchandise transactions, the resulting balance is officially called the balance on goods and is reported in the press as the trade balance. The trade balance for the United States, shown in line 4, was a negative $662 billion in 2004, while Japan's was a positive $132 billion. Although goods are usually the biggest item in a country's current account, services have become increasingly important. In 2004, the United States exported $340 billion and imported $296 billion in services. The United States' balance in services was a positive $44 billion, while Japan's was a negative $38 billion. The press does not usually report the services balance by itself, however. Instead, it reports the balance on goods and services, which for 2004 was negative $618 billion for the United States and positive $94 billion for Japan. This balance is particularly important, because it enters the national income accounts of each nation.

The gross domestic product of a country, measured in expenditures, equals consumption plus investment plus government expenditures plus exports minus imports, or $Y = C + I + G + (X - M)$. In this equation, $X - M$ is the balance on goods and services. Since U.S. residents spent more on imports than foreign residents spent on U.S. exports in 2004, the balance on goods and services subtracted from the gross domestic output of the United States. If we add to the balance on goods and services the balance on income and the balance on unilateral transfers, neither of which is widely reported, we get the current account balance, which is closely watched by policymakers. If this balance is negative, it means that a country's current transactions are being financed by investment from abroad (or from official reserves).

There is nothing wrong or even worrisome in this, as long as the investment is being used for productive purposes. If the investment does not produce a higher future income, however, then its repayment will lower a country's future standard of living.

Another balance closely watched is the overall balance. This is the sum of all current and financial account transactions, adjusted for errors and omissions, except for official reserve transactions, and is shown on line 41 of table 1. A negative overall balance means that a country is balancing its payments by draining its official reserves. If a country does not balance its current account deficit with a financial account surplus, or if it does not balance a financial account deficit with a current account surplus, then it must make up the difference by using its accumulated reserves. Governments will often use their reserves to balance the overall account over short periods, but they can do so only until their reserves are depleted. A large and persistent deficit in the overall balance indicates that a country's trade and financial policies are not sustainable.

The Effects of Monetary and Fiscal Policies on the Balance of Payments A country's balance of payments results from a large number of diverse transactions, conditions, events, and policies. Natural resources (copper in Zambia, oil in Saudi Arabia), comparative advantage (automobiles in Japan), entrepreneurial discovery (the computer industry in the United States), as well as exchange rates, interest rates, income levels and growth, savings rates, political stability, wars, tariffs, and subsidies all affect a country's balance of payments. Moreover, these influences affect different accounts in different ways, and they can operate at different speeds. Typically, economists and policymakers focus on only a few of the more important influences, among which are monetary and fiscal policies. Even within this restricted set of policies, the effects on the balance of payments are complicated. The effects of fiscal and monetary policies on a country's balance of payments will depend on its other policies   especially toward exchange rates and capital flows   and on the size and wealth of the country and the extent to which it trades with others.

balance sheet approach/effects

National authorities, market analysts, and the International Monetary Fund (IMF) traditionally have assessed the financial health of a country on the basis of *flow* variables, such as annual gross domestic product (GDP), the current account, and fiscal balances. Sudden and disruptive capital account crises in Mexico (1994 5), Southeast Asia (1997 8), Russia (1998), Turkey (2001), and Latin America (2001 2), however, called into question the capacity of such metrics to provide a full picture of an economy's vulnerabilities. Signs of impending trouble in these countries might have been spotted earlier through a more careful look at mismatches between the *stocks* of a country's assets and its liabilities; that is, by looking at imbalances within and between a country's sectoral balance sheets. Additionally, once a capital account crisis has begun, changes in the exchange rate, interest rate, and other asset prices can propagate the crisis through their effects on the relative valuations of assets and liabilities within and between sectors.

The balance sheet approach (BSA) represents a framework for identifying stock-based vulnerabilities and the transmission mechanisms between sectors that can turn these weaknesses into full-blown capital account crises. Knowledge of sectoral balance sheet mismatches can aid policymakers in reducing vulnerabilities and identifying appropriate policy responses once a financial crisis unfolds.

Key Balance Sheet Concepts The BSA is principally concerned with providing a comprehensive assessment of the currency and maturity mismatches in a country's assets and liabilities that can trigger large adjustments in capital flows. Whereas traditional flow-based analyses of an economy have focused on the gradual buildup of unsustainable fiscal and current account positions over a defined period, the BSA looks at imbalances in the stocks of assets and liabilities, such as debt, foreign reserves, and loans outstanding at a certain point in time. Although the two approaches are obviously interrelated, since stocks are the product of both flows and valuation changes, the BSA focuses on how misalignments in stocks can lead to the sudden changes in flows that presage liquidity and even solvency problems.

An application of the BSA begins by looking at a country's consolidated external balance sheet; that is, its position vis-à-vis nonresidents. This consolidated balance sheet summarizes the external debts of a country's public and private sectors relative to their external assets. The consolidated balance sheet's level of aggregation can, however, mask considerable imbalances between and within sectors that could trigger disorderly adjustments. For instance, a country's consolidated balance sheet does not show foreign currency debt between residents, but such debt can trigger an external balance of payments crisis if the country's government needs to draw on its reserves to roll over its domestically held hard currency debt. In fact, one of the key insights of the BSA is that cross-holdings of assets between residents can create internal balance sheet mismatches that leave a country vulnerable to an external balance of payments crisis.

In order to implement the BSA, an economy can be disaggregated into a set of interlinked sectoral balance sheets. The exact disaggregation used should

depend on the issues under analysis and the data available. A basic matrix of interrelated balance sheets would break down assets and liabilities by maturity and currency, and would include the public sector (i.e., central bank, government, and public corporations), the private financial sector (i.e., principally banks), and the nonfinancial private sector (i.e., companies and households), as well as an external (nonresident) sector to which all three of these domestic sectors are linked. Sectoral balance sheets are interrelated in that one sector's liabilities are by definition the assets of another sector (see figure 1).

Real assets, such as plants and materiel, which are often a major element of public assets, are not included in a BSA matrix since they are not sufficiently liquid to be called on in a crisis. Consequently, a BSA-style analysis provides a snapshot of an entity's net financial position and its capacity to draw on liquid assets in response to pressure for repayment of its liabilities. It is not intended as a method for calculating the net worth or solvency of an economy or sector, nor does it serve as a precise early warning system. Rather, the BSA reveals vulnerability to a sudden rebalancing of stocks without necessarily pro-

viding an indication of the probability that such an event could occur. In this regard, even partial data can provide useful insights into potential vulnerabilities.

Balance-sheet mismatches do not in and of themselves lead to crises. They simply create the conditions under which a random shock is likely to inflict damage on an economy. Maturity mismatches in Russia in 1998 left its balance sheets vulnerable to rollover and interest rate risks, but commodity price shocks and contagion from the Asian crisis were the actual triggers of the country's crisis. Conversely, Lebanon managed to avoid a financial crisis through 2007 despite years of marked exchange rate, rollover, and interest rate risks connected to gross public debt levels in excess of 180 percent of GDP. Unwavering investor confidence proved an effective shield against real shocks.

The particular vulnerability of emerging markets to sudden capital flow reversals has dictated an early BSA focus on these countries by the IMF and market analysts. The approach is increasingly used, however, to examine specific vulnerabilities, such as asset bubbles and unfunded pension schemes, in both emerging and more mature market economies.

Taxonomy of Balance Sheet Risks At least three major types of mismatch characterize the bulk of balance sheet risks:

1. Maturity mismatches. Mismatches between long-term, illiquid assets and shorter-term liabilities expose a balance sheet to risks related to both debt rollover and changes in interest rates. If liquid assets do not cover maturing debts, an economy or sector may be shut out of capital markets and unable to cover its debt-service liabilities. Similarly, a sharp change in interest rates can dramatically alter the cost of rolling over short-term liabilities, leading to a rapid increase in the cost of servicing debt.

2. Currency mismatches. A currency mismatch most often arises when a borrower's assets are mainly denominated in domestic currency, but its liabilities are denominated in foreign currency, leaving the borrower's balance sheet vulnerable to a depreciation or devaluation of the domestic currency. In many emerging markets, debtors have been motivated to borrow in foreign currency because it is often cheaper than borrowing in local currency. The choice to borrow in foreign currency is sometimes related to deposit dollarization: banks need to match deposits in foreign denominations with loans in the same currency, increasing their incentive to lend to unhedged local borrowers. Following Argentina's crisis and default in 2001 2, many other highly dollarized countries in Latin America also experienced severe crises as a result of the pervasive currency mismatches created by their financial sectors' need to match dollar deposits with dollar loans.

3. Capital structure mismatches. In the context of the BSA, capital structure refers to the balance between debt and equity in an entity's financing. Compared with debt, equity provides a natural buffer during times of balance sheet stress since dividends can be reduced along with earnings, whereas debt payments remain unchanged regardless of circumstances. Capital structure mismatches can arise when a country finances current account deficits through external borrowing (including from official sources, some of which can be difficult to restructure in the event of a crisis) rather than through foreign direct investment or portfolio equity flows.

These mismatches often combine to increase vulnerabilities. For instance, maturity mismatches in foreign currency can create difficulties if market conditions change and domestic borrowers do not have enough liquid foreign currency reserves to cover short-term foreign currency debt. This is what happened in Uruguay in 2002, when domestic banks had difficulties meeting a run on foreign-exchange-denominated deposits. Similarly, financial entities that borrow short-term funds to invest in longer-term debt instruments would suffer from a rise in interest rates brought about, for example, by an exchange-rate defense or cyclical developments, as occurred in Turkey during 2001. Maturity, currency, and capital structure mismatches combined in the Asian crises of 1997 8. Prior to these crises, the Korean government had severely restricted foreign direct investment, and most capital inflows were financed through foreign-currency, shorter-maturity external debt. Similarly, Thailand's tax regime favored corporate debt over equity, which, combined with an implicit nominal exchange rate peg, also led

the Thai nonfinancial private sector to build up foreign-currency denominated debt with nonresident creditors.

When current and expected liabilities exceed assets, a country, sector, or individual entity may face insolvency. Public-sector solvency is often assessed by looking at the ratio of sovereign debt to GDP or to revenue (as a proxy for the government's ability to service its debt). Similarly, a country's overall solvency is usually measured by the ratio of total debt to GDP or to exports. But such measures can indicate vulnerabilities only when combined with other measures of risk exposure and an assessment of related mismatches.

No single debt-to-GDP ratio indicates that a sovereign or balance of payments crisis is imminent. For instance, countries with identical debt-to-GDP ratios, but different currency and maturity mismatches, often face distinct balance sheet weaknesses. The recent literature on debt intolerance draws heavily on the BSA to explain why developing and emerging markets have tended to run into trouble at much lower debt-to-GDP ratios than advanced countries. On the asset side of the public balance sheet, this research has focused on weak revenue bases and poor expenditure control as probable explanations for such low sustainable public debt thresholds. On the liability side, the literature on "original sin" the inability to borrow long term in local currency highlights the vulnerabilities created by the predominance of foreign-currency debt in emerging markets' public borrowing.

Policy Implications The BSA can aid policymakers in preventing and resolving capital account crises. In support of crisis prevention, the approach systematically identifies balance sheet vulnerabilities and highlights sectors in which liquidity buffers may be wearing thin. The Brazilian authorities, for example, were able to head off a recession following the devaluation of the real in 1998 by shifting balance sheet risks away from the corporate and financial sectors, which were exposed to currency risks, and toward the public sector, which was relatively stronger at that time. They did so by issuing foreign-currency-denominated, interest-rate-indexed sovereign debt.

As overnight rates were hiked to defend the real, private domestic holders of these bonds stood to gain. The Brazilian operation also highlights the cost of such risk transfers: although it helped unhedged firms to weather the devaluation of the real, it burdened the public balance sheet for many years to come.

More generally, the BSA has guided policies to reduce vulnerabilities, such as building asset buffers (official reserves), promoting private-sector hedging instruments, strengthening banking supervision, conducting sound liability management operations, and where appropriate instituting flexible exchange rate regimes to reduce incentives for unhedged exposures. Once a country is in a capital account crisis, an awareness of balance sheet mismatches can help the authorities choose an appropriate policy response. The BSA can be useful in comparing, for example, the costs and benefits of letting a currency depreciate or of defending it with changes to interest rates.

Operationalizing and Extending the BSA Ideally, an application of the BSA begins with the compilation of the data needed to complete the basic 4×4 matrix shown in figure 1. Central banks in some OECD countries currently prepare and publish such balance sheet analyses of their economies. In emerging markets, data for the public and private financial sectors are usually easy to obtain, while data for the nonfinancial private sector are often harder to pin down. When national statistics are lacking, information from the Bank for International Settlements and the IMF on a country's international investment position can sometimes help in compiling the external position and deriving the rest of the matrix. In the context of its surveillance and program work, IMF staff has so far completed BSA-style analyses on more than 20 country cases. Furthermore, balance-sheet-related concepts underpin the IMF's frameworks for debt sustainability analysis and the Financial Sector Assessment Program, a key tool for identifying vulnerabilities in countries' banking sectors.

The basic BSA matrix can be further augmented by including off-balance-sheet items such as contingent claims and derivatives in the assessment of

vulnerabilities. Additionally, a full assessment of the risks arising from balance sheet mismatches should factor in attempts to identify the likelihood of future shocks.

■ Balassa-Samuelson effect

It has become conventional wisdom in economics that richer countries tend to have higher overall costs of living than poorer countries. Typically this is measured in terms of the real exchange rate, which compares the consumer price indexes of two coun tries converted to a common currency using the nominal exchange rate. This empirical observation has been referred to as the Penn effect, after the Penn World Tables data used to measure it, or alternatively as the Balassa-Samuelson effect, after the economists who wrote about the observation and endeavored to explain it. One important implication of this obser vation is that it indicates a systematic deviation from the theory of purchasing power parity, which is a building block in exchange rate theory. It indicates that there is a role for economic fundamentals such as relative income levels in explaining long-run real exchange rate behavior.

Although numerous theories have been proposed over time to explain this systematic relationship be tween the real exchange rate and income levels, by far the most influential is that proposed in 1964 in two separate papers by Bela Balassa and Paul A. Sa muelson. The theory is based on the divergence of productivity levels in a world of traded and

nontraded goods, explaining that rich countries specialize in and produce goods that are characterized by higher productivity and that are easily traded internationally. (Because this basic idea is also found in an earlier book by Roy F. Harrod in 1933, the theory is sometimes referred to as the Harrod-Balassa-Samuelson effect. This entry will follow the convention of referring to the empirical observation and the theoretical explanation jointly as the Balassa-Samuelson effect.)

Many early empirical studies failed to find statistical support for the connection between relative prices and income levels. It was even more difficult to find statistical evidence of a linkage to the underlying causal factors that the Balassa-Samuelson hypothesis said should be at work, such as between exchange rates and relative productivity levels (see Officer 1982). It appears, however, that the strength of the Balassa-Samuelson effect has grown steadily over time. Recent statistical studies of the second half of the 20th century find that for a large sample of countries the relationship between relative national price levels and income levels became positive as well as statistically significant only in the 1960s, thus validating the Balassa-Samuelson hypothesis (for instance, see Bergin, Glick, and Taylor 2006). It may not be a coincidence that Balassa and Samuelson began writing on the subject at this time. Further, the correlation between these two variables appears to have quadrupled over the half-century since then, and it is very strongly significant statistically in current data.

The Theory of Balassa-Samuelson How exactly are positive correlations between national price levels and income levels related to the Balassa-Samuelson effect? There is a specific way of explaining these correlations, based on differences in productivity levels across countries and goods. Here is a simple version of the theory with an intuitive example to follow.

Consider two countries, home and foreign, where foreign variables are denoted with an asterisk (*). Let there be two goods produced in these countries, where one good (T) can be traded internationally, and the other is a nontraded good (N). Traditional,

albeit imprecise, examples of this distinction would be manufactured goods as traded and services as nontraded. For simplicity, suppose these goods are produced competitively in each country, using only labor as an input, with wages W and W^* in each country. Denote the labor productivity in each sector as A_T and A_N at home, and A_T^* and A_N^* in the foreign country.

If one assumes that trade is costless for the traded good, its price will be equalized in the two countries. Conveniently, this also pins down the relative wage levels in the two countries, since $W/A_T = P_T = P_T^* = W^*/A_T^*$. The wage levels, in turn, pin down the nontraded goods prices with $W/A_N = P_N$ and $W^*/A_N^* = P_N^*$. Now construct a simple consumer price index, say, where the share of expenditure on nontraded goods in consumption is constant at the value θ in both countries. Then the relationship between the price levels of the two countries is given by

$$\frac{P}{P^*} = \frac{(P_N)^\theta (P_T)^{1-\theta}}{(P_N^*)^\theta (P_T^*)^{1-\theta}} = \left(\frac{P_N}{P_N^*}\right)^\theta = \left(\frac{A_T/A_N}{A_T^*/A_N^*}\right)^\theta.$$

This equation predicts that a country will have a higher overall price level if it is highly productive in traded goods, relative to its own nontraded goods, and relative to the traded goods of the foreign country. If one country is richer than the other, this higher income level can be due to higher productivity in the nontraded goods, the traded goods, or some combination of the two. The theory says that the larger the role of productivity growth specifically in the traded sector, the more likely it will be that high relative income levels will be associated with high relative price levels. On the other hand, if a country is richer due to higher productivity in the nontraded sector, or high productivity equally over both sectors, then the model will not predict that the rich country will have a higher overall price level.

As an intuitive and commonly invoked example of the Balassa-Samuelson effect at work, suppose that the home country is rich because it is very good at producing a manufactured good like automobiles, but it has no productivity advantage relative to the

foreign country in terms of a nontraded service like haircuts. The high productivity of home workers in the auto industry affords them a high wage. But it also requires that the wage be high for haircuts, or else no worker would be willing to provide this service, preferring instead to work in the auto industry. Given that a haircut requires the same amount of labor time in each country, but the wage rate paid to the haircutter is higher at home, it is clear that the price of haircuts will be higher at home. Since the purchase price of autos is the same across countries due to arbitrage through trade, the higher price of haircuts makes the overall cost of living higher in the home country.

Implications and Assessment of the Theory
The Balassa-Samuelson theory is used regularly by economists and policymakers to interpret a range of applied issues. Note that a straightforward extension of the theory from levels to changes would imply that countries with faster growth rates in the traded sector would have real exchange rates that are appreciating over time. For example, it predicts that China or other rapidly developing countries might expect pressure for their real exchange rates to appreciate as a natural counterpart to their rapid growth in productivity. Similarly, the theory predicts that if new accession countries joining the European Monetary Union experience a period of accelerated growth as they catch up to richer European countries, they likewise should expect pressure for real appreciation. Since a monetary union effectively implies that the exchange rate is fixed, this pressure should be expressed in this case as a higher inflation rate for countries with higher growth rates. The principle remains the same: higher rates of growth are associated with a rise in the relative cost of living.

The prevalence of the theory behind the Balassa-Samuelson effect in economics owes much to its elegant explanation of the basic price-income relationship. But it has received criticism for the assumptions needed to derive it. There is evidence that productivity gains, especially recently, are not limited to manufactured goods, but that the wealth of relatively rich countries is in part attributable to signifi-

cant productivity gains in many services, such as information technology and retail. Furthermore, it also appears to be true that many services, especially information services, are becoming more tradable due to new telecommunications technologies. As changes in technology and transportation costs lead to significant changes in the volume of trade and even the types of goods and services that are most traded, it is not entirely clear what the future holds for the Balassa-Samuelson effect.

■ band, basket, and crawl (BBC)

BBC (basket, band, and crawl) constitute the three pillars of an intermediate exchange-rate regime. A currency that uses all three pillars has its central rate (and margins) defined in terms of a basket of currencies rather than a single currency such as the

dollar. It has a wide band around the central rate, perhaps plus or minus 5, 10, or 15 percent, within which the currency floats, but at the edge of which the central bank is obligated to intervene to prevent the market rate going outside the band. Its central rate crawls rather than jumps; when it needs to move, it does so in a series of small, periodic steps rather than occasional abrupt changes. The three component elements were developed by different economists and were driven by different considerations, so they can be analyzed separately even though they tend to appeal to the same group of economists and to be used by the same set of countries. Although in practice there may be a strong complementarity among the three components, it is possible and helpful to consider them separately.

Baskets Before the break-up of the Bretton Woods system in the early 1970s there was no need to consider pegging to a basket of currencies since the major currencies were stable in relation to one another. It became clear that this was not going to continue after the advent of generalized floating in March 1973. Shortly thereafter the International Monetary Fund (IMF) redefined the value of its artificial reserve asset, the special drawing right (SDR), in terms of a basket of the 16 currencies of countries with more than 1 percent of world exports in the base period. When Jordan began to peg to the SDR, it was therefore indirectly pegging to a basket of currencies. This was the first instance of a peg to a basket.

The theoretical basis of the basket peg evolved shortly thereafter, in a number of papers that sought to develop rules for how developing countries should conduct their exchange-rate policies in a world where the major currencies were floating and therefore moving randomly against one another. The first major paper along these lines was that of Stanley Black (1976). He argued that in a context of generalized floating the strategic variable that affected a country's macroeconomic position was not its bilateral exchange rate with any single currency, but its effective (i.e., trade-weighted) exchange rate. According to Black, the weights in the effective exchange rate (EER) should reflect trade, both exports and imports, in goods and services — in other words,

the EER should be a concept broader than just commodity trade but narrower than all transactions that go through the foreign exchange market, in that it should not include capital flows. He also discussed whether the weights should reflect the currency of denomination or the direction of trade, preferring the latter on the ground that this was more relevant in the longer run. He recognized that there would be institutional costs in pegging to a basket, stemming from the fact that one could not intervene in a basket. (One can argue that the main cost of pegging to a basket accrues not — as Black assumed — because of the enhanced calculation costs of the monetary authority, but because it deprives traders of the possibility under normal circumstances of covering forward by utilizing the forward markets of the country's intervention currency.) If, but only if, a country decided that those institutional costs outweighed the macroeconomic benefits of pegging to a basket, then a country should peg to that single currency which minimizes the variance of its EER.

Several subsequent writers entered the debate. The possibility of a number of developing countries all pegging to the SDR was considered, the advantage being that this would avoid arbitrary changes in their cross-rates. Williamson (1982) argued that there was widespread agreement among the authors surveyed in the article that the peg should be chosen with a view to stabilizing something rather than optimizing anything. Specifically, the peg should be picked so as to minimize the instability in real income and inflation imposed by movements in third currencies that are noise to the domestic economy. This is the philosophy that lies behind the first B of BBC. It is perhaps best exemplified by the policy pursued for many years by the Monetary Authority of Singapore.

In recent years proposals for basket pegs have been advanced primarily in the context of East Asia. Several writers (e.g., Williamson 2005) have argued that the motivation to tie the region's currencies to the dollar arises not out of a mercantilist desire for export surpluses but as a response to the fear of losing competitiveness vis-à-vis one another. The way to overcome this collective action problem while avoiding wasting resources on large current account

surpluses as a by-product of dollar depreciation is for all the countries of the region to use a *common* basket peg. (In the case of floating currencies, countries might treat the common basket as a *numéraire*, the unit in terms of which the value of the currency is defined, though this gives less assurance that the market exchange rate would move in parallel to the basket.)

Band Discussion of a wide band for the exchange rate (then called a widening of the gold points) can be traced back to some of John Maynard Keynes's writings in the interwar period, but in the postwar period it was revived by a Brookings Institution report (Salant et al. 1963) and an influential paper of George Halm (1965). Halm looked to a wide band with permanently fixed central rates to enable exchange rate movements to make a worthwhile contribution to the adjustment of balance of payments positions, while decreasing the need for identical monetary policies in different countries and therefore increasing the ability of monetary policy to achieve internal balance. It was this latter aspect on which most subsequent attention focused.

Later authors have differed sharply from Halm in viewing a wide band as complementary to, rather than competitive with, a crawl of the central rate. Few recent analysts have agreed with him in thinking that variations in the exchange rate within the band could be expected to make a worthwhile contribution to payments adjustment; it is changes in the central rate that were expected to do the heavy lifting in that regard. However, the freedom to vary monetary policy has been emphasized by many writers (McKinnon 1971). Williamson (2000) emphasized that this is one of four reasons for favoring a wide zone. A second reason is the difficulty in identifying the equilibrium exchange rate (a rate that is usually conceived as consistent with a sustainable balance of payments outcome) with any precision; there is no point in distorting macroeconomic policy in order to defend an exchange rate target if there is a chance that the rate is not misaligned in the first place. A third reason for a wide zone is to permit nontraumatic changes in the central rate. The analysis here goes back to Harry Johnson (1970), who showed that there would be no incentive to speculate if the change

in the central rate were sufficiently small that the new and old bands overlapped; the wider the band, the easier it is to satisfy this condition. The fourth reason is the desirability of being able to accommodate strong capital flows in part by changes in the exchange rate rather than compelling them to be met entirely by reserve changes.

In 1988 Paul Krugman showed that a credible band would help the authorities to enlist support from speculators in stabilizing the exchange rate (the definitive version was published as Krugman 1991). The intuitive argument was that as the exchange rate approached the margin, speculators would understand that it was increasingly likely to move back toward the central rate, because if it tried to move beyond the edge of the band this would merely provoke the central bank into intervention rather than lead to a further change in the rate. Speculators would therefore be induced to enter the market and help stabilize the rate. The mere promise of official intervention at the margin would suffice to stabilize the rate, without any need for the central bank to actually intervene. First tests of the experience of the European Exchange Rate Mechanism (ERM) were reassuring: it did indeed seem that expectations within the ERM were mean-reverting, in contrast to those that hold in a floating system. But further tests created doubts: Krugman's model predicted that exchange rates would spend most of their time close to the edges of the band, but this did not seem to have happened in the ERM (Svensson 1992). One could reconcile the findings, for example, by intramarginal intervention, but that cast doubt on whether the target zone was really fulfilling its key purpose of making expectations stabilizing. And the ERM was not altogether credible, as is required for Krugman's theorem to apply.

Crawl A central rate is said to be adjusted according to a crawl if its changes are "small." Just how small is best answered by the Johnson analysis cited earlier: a rate is crawling if the old band (prior to the change in central rate) overlaps with the new band. By that test one would count the pre-1987 ERM central rates as mostly crawling, since, although there was no legal obligation for the bands to overlap, in

practice changes in the central rate were usually small enough to produce such an overlap.

A crawl may have several motivations. Probably the principal aim in practice has been to neutralize differential inflation and prevent a country that is inflating faster than the international norm from eroding its competitiveness. This is what led several Latin American countries (first Chile in 1965, then Colombia in 1967, and Brazil in 1968) to institute a crawl in the 1960s. Nowadays we tend to think that there is not much to be gained by running a high rate of inflation, but countries caught up in high inflation found difficulty in reducing it quickly and were acutely interested in preventing it from undermining their trade performance.

A much less common but surely more constructive purpose has been to neutralize biased productivity growth, for example, the bias in favor of tradables that typically comes as a by-product of rapid productivity growth (the so-called Balassa-Samuelson effect). Chile's crawl allowed 2 percent a year in real appreciation for this effect from 1995 until Chile floated in 1998.

Changes in the central rate may also be motivated by the desire to contribute to balance of payments adjustment. A country that wishes to improve its underlying balance of payments position will usually be advised to seek a more competitive exchange rate as one incentive for adjustment. Unless a government chooses to float its currency, it will have to accept a gradual adjustment, so that the incentive for capital flows can be offset by the interest differential. It was the desire to maintain a reasonable balance in international payments that motivated most of the parity adjustments in the early-phase ERM.

Why a BBC System? Perhaps the most basic argument in favor of the BBC regime is that this is the system best calculated to limit misalignments (defined as deviations of the market exchange rate from its equilibrium value), and that misalignments are the principal drawback of both of the alternative regimes. Fixed rates can become inappropriate through differential inflation, Balassa-Samuelson productivity bias, or a real shock that creates a need for balance of payments adjustment. Fixed rates are appropriate

only where there is reasonable certainty that none of these dangers will materialize: where the economy is small and open so as to satisfy the optimum currency area conditions; where it trades predominantly with the currency area to which it plans to peg; where it is comfortable with the inflation policy of that area; and where it is content to adopt institutional arrangements that will guarantee perpetuation of the fixed rate. Flexible rates follow a random walk: they are frequently pushed away from the level that would support a satisfactory evolution of the real economy. A BBC regime provides guidance as to what is considered the longer-run equilibrium rate and mandates action to bring the rate back to that vicinity when it deviates significantly from it. It is true that one advantage of a float, in comparison to the BBC regime, is that this permits a needed adjustment to be made instantaneously, rather than being strung out over time, with the need to retain an offsetting interest differential. There is no guarantee, however, that the private market will choose to make an adjustment at the right time or in the right direction. It is this fear that unguided markets will lead to misalignments that motivates support for the BBC regime.

■ **Bank for International Settlements (BIS)**
The Bank for International Settlements (BIS) was established in 1929, when representatives of the World War I reparations conference set up a com mittee of experts to provide a definitive financial framework for German war reparations. The BIS was chartered the following year in Switzerland under an international convention. The new institution ap pealed to different constituencies with different in terests. The Germans wanted to increase their exports and link the size of their obligations to capacity to pay; the French sought to replace a debt of the German government to private investors with a debt owed directly to the French government and, ulti mately, to thwart German industrial development; the British were keen to secure enough payments to settle their debt with the United States; and the United States aimed to separate reparations from war debts. But war reparations were only one part of the BIS mission; the other involved extending and deepening cooperation among central banks.

From the beginning, the BIS was a club of central bankers interested in preserving their independence from finance ministries and governments in general. Emblematic of the distinction between central bankers and governments was the decision of the U.S. government not to allow the Federal Reserve System to join the BIS because membership was believed to conflict with the official U.S. position on reparations. Over time, the distinction between central bankers and governments became less sharp, although it still exists; for example, the chair of the Basel Committee on Banking Supervision must be a central bank governor.

The launching of the new institution suffered from poor timing, with much of the industrialized world sliding into economic depression. German war reparations certainly did not help the international economy. In 1931, the Credit-Anstalt, a large bank based in Vienna, went bankrupt, sparking a banking crisis that spread to Germany, Britain, the United States, and most of the countries on the gold stan dard. The BIS acted as a crisis manager and lent to the central banks of Austria, Hungary, Germany, and Yugoslavia, but the treatment was too feeble for the disease. At the core of the problem was an inability of policymakers to understand that feasible cooperation was inadequate to sustain the combination of a gold standard and high employment. The BIS remained a staunch supporter of the gold standard. This posi tion, in addition to allegations that the institution had been too much under (Nazi) German influence before and during World War II, almost brought the BIS to extinction at the Bretton Woods conference in July 1944; it was saved by the Europeans (Toniolo 2005, chap. 8).

The BIS after World War II After World War II, the surviving BIS was out of step with the prevailing economic paradigm and policy prescriptions. The

institution emphasized budget discipline, sound money, free trade, and international monetary cooperation, and had little sympathy for mechanical applications of the standard Keynesian model. Furthermore, central bankers, the BIS's clientele, had lost much of their luster and prestige because of their support of the gold standard in the interwar period. Inevitably, power shifted to finance ministers, who made central banks subordinate to government. Yet, despite this decline in power and prestige, the BIS remained an important forum for central bankers and the international financial community to discuss and find agreement on critical issues of monetary policy and financial stability.

The terms of reference for cooperation have changed over time. In the interwar period, cooperation meant to sustain and "lubricate" the mechanisms of the gold standard. In the 1950s, the focus was on the mechanism of the European Payments Union, in which member countries offset debits and credits in inconvertible European currencies on the books of the BIS and settled balances in convertible currencies. In the 1960s, the BIS became a central point for the discussion of the tensions that were developing in the gold-dollar exchange standard.

Arrangements were made by central banks and among central banks, sometimes using the BIS as the organizer. Central bankers were searching for ways to defend themselves against speculative attacks. The defense arsenal included mutual guarantees all the way to the prohibition of converting funds placed by foreign speculators. Guarantees were implemented by means of swap agreements among central banks and the stipulation that a central bank would repay borrowed funds at the original exchange rate. The techniques evolved over the years. In the mid-1960s, the BIS began to provide regular reviews and analysis of the Eurodollar and Eurocurrencies markets, as well as quarterly statistics on bank lending in the G10 group of countries (Belgium, Canada, France, Germany, Italy, Japan, the Netherlands, Sweden, the United Kingdom, and the United States) and Switzerland to approximately 100 individual countries.

The demise of the Bretton Woods system in 1973 did not spell the end of international financial crises and the role played by the BIS club. On the contrary, financial liberalization in many nations and the abolition of capital and exchange controls exposed the international financial community to more and bigger crises; large currency, debt, and banking crises occurred in Mexico in 1982 and 1994, Southeast Asia in 1997, Russia in 1998, Brazil in 1999, and Argentina in 2001.

The BIS after Bretton Woods The end of Bretton Woods rejuvenated the BIS through a different agenda: European monetary integration and financial regulation. European monetary integration was the natural extension of the European Payments Union. As to financial regulation, the BIS became involved in it after the failure of a German bank, Bankhaus Herstatt, in 1974. Before this date the fixed exchange-rate regime was buttressed by exchange controls and domestic regulation that reduced the risk of financial crises.

Some central banks are also bank regulators and supervisors (e.g., the Bank of Italy); others share this responsibility with other financial regulatory agencies (e.g., the Federal Reserve System); others retain some responsibilities but the bulk of these lies with other government agencies (e.g., Deutsche Bundesbank); and some have no regulatory role aside from that pertaining to the payments system (e.g., Bank of Canada). In practice, however, it is difficult to separate "narrow" central banking from regulation. Even a "narrow" central bank needs credit information on financial participants to prevent losses to either itself or participants in the payments system. Thus it is not surprising that central bank governors considered financial regulation as part of their mandate (Fratianni and Pattison 2001, 205 6).

The BIS acts as a host and secretariat for various committees on financial regulation, of which the best known is the Basel Committee on Banking Supervision (BCBS), which promulgates international standards and "best practices." The BCBS works with national banking regulators, among others, and also participates more broadly, where required, with

securities regulators and insurance regulators. In 1988, a new regime, the Basel Capital Accord, or Basel I, went into effect: internationally active banks were subject to a somewhat common regime for minimum capital requirements. Basel I linked banks' capital requirements to their credit risk through mandated weights for different categories of bank credit. Basel I was ultimately adopted by more than 100 countries and was deemed a success, despite criticism of the crudeness and political bias of the mandated weights: for example, the preferential treatment given to government debtors and to industrial countries that were members of the Organization for Economic Cooperation and Development (OECD).

For several years now, the financial and prudential regulatory committees meeting in Basel have been working on Basel II, a new international agreement on bank capital measurement and minimum capital requirements (BCBS 2004). The main innovation of Basel II is to assess credit risk as the markets would, in contrast to mandated fixed weights. Market-sensitive credit risk assessment, however, requires expensive investments in sophisticated risk management systems and, in practice, can best be implemented by large and internationally active banks. These systems would pay off in terms of lower capital requirements. Smaller banks, instead, would rely on the cheaper and mechanistic formulas of Basel I. Basel II, which has yet to go into effect, got stuck because of U.S. opposition. Small U.S. banks perceive that large banks will gain a competitive advantage, through lower capital requirements, by the implementation of Basel II and have pushed for changes in it. The proposed changes, in turn, would make investment in sophisticated risk management systems cost ineffective and consequently would frustrate one of the main objectives of the new accord.

In sum, the BIS was created with two initial objectives: handling German war reparations payments and promoting and extending central bank cooperation. The first objective is long gone; the second remains central to the current activities of the BIS. The effectiveness of this institution rests on the confidence and commitments that can be made by a

relatively small number of players who meet frequently and in relative seclusion to ensure a high degree of confidentiality. The geographical expansion of the BIS in Asia and Latin America, in the early part of the 21st century, suggests a strategy of enlarging the size of the club.

■ Bank of Japan

The Bank of Japan was established in 1882, under the direction of the Ministry of Finance, to be the sole issuer of convertible notes in Japan. The first substantial revision of the Bank of Japan Law occurred in 1942, when the central bank was given the broad objective to conduct its operations "solely for the achievement of national aims" (article 2). There was no mention of financial or price stability, and the law

was designed to support Japan's wartime military effort (Cargill, Hutchison, and Ito 1997 and 2000). In response to the triple-digit inflation in Japan immediately after World War II, in part due to monetization of government deficits, a change in the Finance Law was made in 1947 that provided the Bank of Japan a degree of independence from government deficit financing (e.g., prohibiting the bank from underwriting government bonds or making loans to the government except under some conditions).

In 1949 the Bank of Japan Law was again amended, mainly to provide an overall management structure to the bank by establishing a Policy Board consisting of five voting and two nonvoting members. The Policy Board was given primary authority for almost every aspect of monetary and financial policy operations of the Bank of Japan. Although the Ministry of Finance held a nonvoting position on the Policy Board, the Bank of Japan Law gave the ministry overall control over the bank and the ability to influence policy decisions, if not to determine them outright. For example, the cabinet had the authority to dismiss the governor and vice governor, and the minister of finance could dismiss executive directors, auditors, and advisors of the Bank of Japan "whenever it is deemed particularly necessary for the attainment of the objective of the Bank" (article 47).

New Bank of Japan Law The basic institutional and legal framework governing the Bank of Japan was unchanged during most of the postwar period until creation of the "new" central bank under the changes of the law in 1998 (Cargill, Hutchison, and Ito 2000). A number of economic and political events prompted the change in the law, including widespread dissatisfaction with the Ministry of Finance's handling of the serious banking problem. In particular, the Ministry of Finance was slow to address the bank's nonperforming loan problem (brought on by the collapse of the bubble economy, recession, and poor lending practices), the liquidation of the *jusen* industry (subsidiaries of financial institutions specializing in real estate loans), and other aspects of its response to the financial crisis that had burdened Japan since the early 1990s.

The 1998 Bank of Japan Law fundamentally changed the formal operating objectives of the central bank, its formal relationship to the government, its role in banking supervision, and other functions. Two elements are central to the reform. First, unlike the 1942 law, the new law specified two operating principles for currency and monetary control: the pursuit of price stability (article 2) and the maintenance of an orderly financial system (article 1). The law clearly states that the Bank of Japan is responsible for price stability and shares responsibility for financial stability with other parts of the government. Second, the bank was given much more autonomy from the government and in particular from the minister of finance. The new law states, for example, that autonomy for monetary and currency control shall be respected, and the Ministry of Finance's power to remove Bank of Japan officers was significantly limited. A number of other important changes were also made in the new law, including in the areas of governance and policy formulation, transparency and accountability, budgeting, lender-of-last-resort functions, exchange rate intervention, and government financing.

Conduct of Monetary Policy The conduct of monetary policy has gone through a number of distinct changes during the postwar period. The years immediately following the war were characterized by a chaotic environment and triple-digit inflation during 1946 48. From the mid-1950s to the early 1970s, Japanese monetary policy operated under the constraints of the Bretton Woods fixed exchange system, a period of very high growth, economic progress, and moderate inflation. The early 1970s were again a chaotic period: buffeted by the first oil-price shock and double-digit inflation (called "wild" inflation), Japan struggled to recover a nominal anchor following the breakdown of the Bretton Woods fixed exchange rate system.

The Bank of Japan then introduced a "money-focused" monetary policy in the mid-1970s that served to gradually lower inflation and then keep it at low levels, combined with very strong economic performance through the 1980s (Hutchison 1986). The Bank of Japan, despite its legal dependence on

the Ministry of Finance, and facing the constraints imposed by the wartime conditions of the 1942 law, achieved an extremely successful policy record from 1975 to 1990. The price stabilization record of the Bank of Japan, combined with sustained real growth of the Japanese economy during this period, attracted international attention. The Bank of Japan appeared to be a stark exception to the conventional wisdom that the legal independence of central banks is necessary to generate good inflation records (Cargill, Hutchison, and Ito 1997). The biggest dilemma the Bank of Japan faced at the end of this period the latter part of the 1980s was how to respond to sharp increases in asset price inflation (in retrospect identifiable as an asset price bubble) without affecting other aspects of the economy, which otherwise seemed to be performing well, with strong economic growth and low price inflation overall.

The 1990s brought a completely new set of challenges for the Bank of Japan. The country faced a period of stagnation from 1991 to 2003, with real gross domestic product growth averaging only 1.5 percent, about half that of the rest of the members of the Organisation for Economic Co-operation and Development and much less than Japan's historical norm. During much of the stagnation Japan experienced prolonged deflation, or essentially zero price changes, and a sustained period of near-zero short-term interest rates when the central bank seemed unable to provide additional stimulus to the economy (Hutchison, Ito, and Westermann 2006). During this latter period, much of it when the Bank of Japan was operating independently under the new law, the bank came under severe criticism for not preventing price deflation and not doing more to stimulate the economy. Whether the Bank of Japan could have, or should have, operated differently during this period remains an open question.

■ banking crisis

In modern economies, banks play an important role in mediating between borrowers and lenders. Lenders, which are usually households, often do not have profitable investment opportunities on their own and seek high-quality borrowers from whom they can secure a higher rate of return. Households have difficulty finding high-quality borrowers because the financing needs of borrowers are such that the savings of numerous lenders must be aggregated. The coordination costs are simply too high for households to carry out this aggregation. Also, households usually

do not have expertise in evaluating the quality of borrowers, so the lender-borrower relationship can be plagued by adverse selection problems (that is, lenders who lack sufficient information to make wise selections may be apt to select "bad" borrowers). Collecting the information on borrowers necessary for evaluating their quality is costly. Modern banks can aggregate the individual savings of lenders and, by developing expertise in evaluation of borrowers, can mitigate adverse selection problems, thereby smoothing the transfer of funds from households to borrowers.

Banks can play other important roles, such as lengthening the maturity structure of loans by borrowing short-term and lending long-term. Banks do this by taking short-term deposits of say, 1 month, and making loans of say 3 years. Moreover, financial markets such as stock and equity markets are volatile and expose households that invest their savings in them to market risk. By accumulating reserves, which are not typically linked to the stock market, banks can lessen the market risk for households that instead deposit their savings in banks.

There are times, however, when the banks' ability to serve this intermediary role is curtailed and banks actually raise the risk level in the financial system. Because banks have a mismatch between short-term liabilities (e.g., demand deposits) and long-term assets (e.g., loans), they are vulnerable to liquidity crises. Such vulnerabilities can lead to bank runs, as a critical mass of depositors suddenly withdraws funds, leaving the bank without liquid assets to carry on their normal business, which in turn may cause more depositors to panic and withdraw their funds.

In addition, when banks are improperly regulated, they are prone to excessive lending and loan creation, leading to a "bubble" in asset prices. The collapse of the bubble can result in defaults, which can lead to serious dislocation of the economy, as happened to Japan in the 1990s. Excessive loan creation abetted by improper regulation is also the root cause of the emerging market crisis of the late 1990s.

Causes of Banking Crises A banking crisis occurs when many depositors attempt to withdraw their funds all at once. In the past, banking crises happened with some frequency in Europe and the United States, particularly during the Depression in the 1930s. Banking crises occur with some frequency in emerging markets. For example, during the turbulent decade of the 1990s, many emerging markets   including Mexico, Thailand, Indonesia, Korea, Argentina, Russia, and Turkey   faced simultaneous banking and currency crises.

There are two traditional views of banking crises: the "fundamentals" view and the "random shocks" view (Allen and Gale 2000). The fundamentals view is that banking crises are a natural phenomenon of the business cycle. A recession will typically increase loan delinquencies and reduce bank equity, sharply lowering the value of bank assets. As depositors receive information about banking-sector weaknesses, they will withdraw their funds, leading to banking-sector insolvencies. According to this view, bank runs are not random events, but a result of the ups and downs of the business cycle.

The random shocks view is that banking crises are a result of herding or mob psychology. According to this view, bank runs are largely self-fulfilling prophecies (Diamond and Dybvig 1983). If depositors believe that a bank run is about to happen, they will withdraw their funds all at once and a bank run will occur. If depositors believe that bank runs will *not* happen, then they will stay put and a bank run will not occur. A good rendition of the random shocks view is a scene in the movie *It's a Wonderful Life*, in which depositors hear rumors about a failing savings and loan and mob its window. The depositors calm down and stay put when the character played by Jimmy Stewart confidently stresses that the savings and loan is actually doing fine.

In well-supervised jurisdictions, banking regulators promulgate rules and conduct inspections of banks to ensure that they are prudent in their lending, so that when a downturn inevitably comes, banks' balance sheets are not unduly impaired. A bank with an impaired balance sheet has many loans for which the collection of principal and interest is difficult. Thus, the loans will probably have to be written off as

a loss. Should bank balance sheets become impaired, the country's central bank usually serves as the lender of last resort to banks, so that bank runs will not occur. Deposit insurance can serve the same role as "blanket insurance" by the central bank, since the government will "bail out" depositors at a failing bank.

The Late 1990s Banking Crisis in Japan Japan in the late 1990s had a fundamentals-driven banking crisis in which a crash in Japan's equity and real estate markets led to deterioration in bank balance sheets. Dekle and Kletzer (2006) explore the late-1990s crisis in the Japanese banking system and emphasize three key facts about the Japanese financial system at the time: (1) domestic investment was financed primarily by bank loans; (2) the government provided deposit insurance guarantees to the holders of domestic bank deposits; and (3) prudential regulation and enforcement were weak.

Weak prudential regulation in Dekle and Kletzer's model is interpreted as a failure of the government to enforce loan-loss reserve accumulations by banks against nonperforming corporate loans. Banks thus still make dividend payments to their shareholders against the interest collected on their performing and nonperforming loans, when banks should be foreclosing on firms that are in default on their loans. That is, the banks are paying dividends on even the loan repayments they have not yet received. Nonperforming borrowers are kept afloat by further borrowing from banks. Although the public is aware of the mounting nonperforming assets of the banks, they do not withdraw their deposits because of deposit insurance. In effect, deposit insurance allows the banks to transfer resources from the government to their shareholders. Deposit insurance makes the depositors feel safe, so they will keep their deposits even in a failing bank. In the eventuality that a bank fails, the depositors will be bailed out by the government.

If the government fails to intervene by closing banks before a critical date, then the banks' nonperforming loans will exceed the government's ability to borrow. At that point, there is a bank run by depositors, leading to a banking crisis. This appears to be the story of the Japanese banking crisis, from which Japan began to emerge only in 2006.

Twin Crisis in Emerging Markets Another example of a fundamentals-driven banking crisis is the emerging market crisis of the late 1990s. At that time, many emerging market countries were hit not only with a banking crisis but also with a currency crisis, which is characterized by a rapidly depreciating currency, a sharp outflow of foreign exchange, and a slowdown in fact, almost a depression in the domestic economy. The phenomenon of a banking crisis occurring simultaneously with a currency crisis is called a "twin" crisis.

Perhaps the best description of a twin crisis is by Diaz-Alejandro (1985), who discussed the Chilean crisis of the early 1980s. Like many emerging markets, Chile had a nationalized banking system. In the 1970s, Chile's banking system was privatized, even to the extent that authorities repeatedly warned the public that deposits were not guaranteed. In early 1981, however, following the cessation of credit payments by a troubled Chilean sugar company, the central bank bailed out several private banks to stem incipient bank runs. Realizing that the Chilean Central Bank stood ready to protect domestic bank deposits, foreign capital rushed in to take advantage of high Chilean interest rates.

By January 1983 the value of the peso fell as the official Chilean exchange rate rose from 39 pesos per U.S. dollar to 75 pesos. Chilean companies and banks with dollar-denominated debt came under great stress. Nonperforming loans of banks rose from 11 percent of their capital at the end of 1980 to 113 percent by May 1983. Foreign depositors became worried and started to withdraw their funds, rapidly depreciating the Chilean peso. The Chilean Central Bank had no choice but to intervene again, formally guaranteeing all deposits to stem the bank runs and injecting massive liquidity into the banking system to recapitalize the banks.

The Chilean experience illustrates the dangers of capital market liberalization with blanket government deposit guarantees. Such blanket guarantees can lead to moral hazard (in which a party insulated from risk engages in riskier behavior), with too much

capital flowing in, excessive bank lending, a rise in nonperforming loans, bank failures, and finally, a currency crisis.

■ Basel Convention

The Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal is an international agreement that governs cross-border shipments of toxic waste. Adopted in 1989 and entering into force in 1992, the agreement was a direct response to the growing problem of unregulated waste shipments in the 1980s, particularly between rich and poor countries. Waste exports to developing countries emerged at that time as a result of rising disposal fees in rich countries, the need for foreign exchange in poor countries, and an increasingly fluid global economy that facilitated the trade in waste.

The United Nations Environment Program sponsored negotiations on the Basel Convention in the late 1980s following public outcry in response to waste export scandals involving poor countries. The agreement covers toxic, poisonous, explosive, corrosive, flammable, eco-toxic, and infectious wastes. As of October 2007, there were 170 parties to the Basel Convention.

The objectives of the Basel Convention are to reduce the transboundary movement of hazardous wastes, encourage the treatment and disposal of hazardous wastes as close as possible to their generation, and minimize the generation of hazardous wastes.

The agreement governs the international trade in hazardous waste through a system of informed notification and consent. Exporting states must notify the importing country in writing before they ship hazardous waste and must receive consent in writing from the importing state before the shipment can be made. This system allows states to decide case by case whether they wish to accept a particular shipment. Parties to the agreement are prohibited from exporting hazardous waste to states that have banned its import. They are also prohibited from exporting waste to nonparties unless a bilateral or regional agreement allows such trade, provided it is disposed of in no less environmentally sound a manner than that called for in the Basel Convention. Parties to the agreement are encouraged to export hazardous wastes to other countries only if they themselves lack the capacity to dispose of it in an environmentally sound manner, or if the importing country considers the waste a raw material.

Immediately after the Basel Convention was adopted, a number of developing countries and nongovernmental organizations (NGOs) criticized it for having a weak control mechanism. Critics had wanted the agreement to place an outright ban on the trade in hazardous waste between rich and poor countries, but the adopted agreement only regulated exports of waste between these groups of countries. In addition, some countries continued to export hazardous wastes

to developing countries for the purpose of recycling, thereby evading the Basel Convention's control mechanism because the material was not identified as hazardous. Throughout the early 1990s environmental NGOs documented a significant number of toxic waste exports to developing countries for recycling purposes. Most of these exports were recycled in environmentally unsound ways, or were in fact not recycled at all and were simply disposed of.

Basel Ban In response to these concerns, developing countries and NGOs worked to strengthen the convention in the early 1990s. In 1995, at the second conference of the parties to the agreement, the parties adopted an amendment to the convention that bans outright the export of hazardous waste destined for either disposal or recycling from Annex VII countries (parties that are members of the European Union or the Organisation for Economic Co-operation and Development, and Lichtenstein) to non Annex VII countries. This amendment, which has come to be known as the Basel Ban, required ratification by three-fourths of the parties in order to come into force. Many assumed that this number would be 62, as there were 82 parties to the Basel Convention when the Basel Ban amendment was adopted. Uncertainty emerged, however, over ratification procedures when the number of ratifications approached 62: whether the amendment required ratification by three-fourths of the parties at the time it was adopted, three-fourths of the parties present when it was adopted, or three-fourths of the current number of parties. It is expected that the 2008 Conference of the Parties to the Basel Convention will adopt a decision that will resolve this ambiguity. As of October 2007 there were 63 ratifications of the Basel Ban amendment.

In the late 1990s, the parties to the Basel Convention also adopted a classification system for hazardous wastes that delineates more clearly which wastes the treaty covers, including those destined for recycling operations. This system has clarified the scope of the convention considerably.

Challenges for Enforcement The Basel Convention has curtailed some types of hazardous waste exports to developing countries, but two major challenges have emerged that illustrate the difficulty of full enforcement.

The first of these challenges concerns the export of ships containing toxic materials to developing countries for scrapping. Since the mid-1990s, industrial countries have exported a number of ships to scrap yards in developing countries, most commonly India and Bangladesh, for decommissioning. These ships often contain highly toxic materials such as polychlorinated biphenyls (PCBs) and asbestos. In developing countries, ships are commonly dismantled in dangerous and environmentally unsound conditions. Because the ships are technically in use when exported and often not designated as waste material until on the high seas or until they reach their final destination, many have escaped control under the rules of the Basel Convention. Environmental NGOs such as the Basel Action Network (BAN) and Greenpeace have launched campaigns to halt this practice by exposing the failure of exporting states to enforce the Basel Convention when toxic ships are exported from their ports. These efforts have had some success, such as the 2006 decision of the French government to halt the export of the *Clemenceau*, which had been destined for scrapping in India.

The second challenge has to do with the export of electronic waste (e-waste), including discarded computers, mobile phones, and other electronic equipment. E-waste, which contains numerous toxic components, including heavy metals and polyvinyl chloride (PVC), is an especially fast-growing waste stream in industrial countries. Much of this waste has been exported to developing countries, such as China and Nigeria, without being subjected to the Basel Convention rules on notification and consent, and despite bans in those countries on the import of toxic waste. Often these wastes are exported under the pretense of reuse, when in practice they are recycled or simply land-filled. The conditions under which these wastes are recycled and disposed of in these locations are dangerous and environmentally unsound. Several factors have contributed to the continued export of e-waste to developing countries, including the facts that it can escape control when it is

exported for reuse even if most of it is broken and beyond repair, and that customs officials lack knowledge about the hazardous nature of second-hand electronic components. Environmental groups such as BAN have called for pretesting of secondhand electronics before shipment to determine whether they are suitable for reuse or are simply hazardous wastes that would then be bound by the rules of the Basel Convention.

At the same time that the parties to the Basel Convention are considering ways to address these continuing problems with the transboundary movement of hazardous wastes, they have broadened the emphasis of the treaty for its second decade. Environmentally sound management of hazardous waste, as well as the prevention or minimization of such waste, has received more attention. Much of the work of the Basel Convention Secretariat now focuses on enhancing technical and administrative capacity to minimize waste generation and manage hazardous waste safely, especially in developing countries.

The Basel Convention has served an important role in the global economy by regulating the trade in what many consider to be "bads" as opposed to "goods." The parties to the agreement have taken considerable steps toward banning the export of toxic wastes from rich to poor countries. Although the difficulties of monitoring and enforcement allow certain types of toxic waste exports to continue, without the Basel Convention it is likely that the problem of unwanted hazardous waste exports to poor countries would be far worse.

■ beggar-thy-neighbor policies

Beggar-thy-neighbor policies are those that seek to increase domestic economic welfare at the expense of other countries' welfare. What might be called the classic case of beggar-thy-neighbor policies occurs when one country devalues its currency in order to boost its domestic output and employment but, by so doing, shifts the output and employment problem onto other countries. This occurred in the 1930s when, faced with a worldwide recession, countries sought to increase their own output and employment by devaluing their currencies, a policy that would boost domestic output by reducing the demand for imports and increasing the demand for exports. This exacerbated the recessions in other countries, however, and invited the

response of devaluations by other countries and countries became locked into a series of competitive devaluations.

The experience of the 1930s played a significant part in the design of the Bretton Woods system. This system, by restricting the flow of capital internationally, provided countries with sufficient policy autonomy to target domestic output and employment levels without having to resort to changing the exchange rate. One of the aims of the Bretton Woods system in introducing fixed exchange rates was therefore to obviate the need for competitive devaluations and remove the temptation of beggar-thy-neighbor policies.

With the move to flexible exchange rate regimes since 1973 after the collapse of the Bretton Woods system, beggar-thy-neighbor policies or the possibility of them have occasionally resurfaced. For instance, following the Asian crisis of 1997, when the currencies of Thailand, Indonesia, Malaysia, and South Korea all plummeted, China came under considerable international pressure not to devalue the renminbi, which would likely have further destabilized the crisis-affected countries and led to a new round of currency depreciations. China maintained the value of the renminbi. Similarly, one of the arguments made for trading rivals adopting dollar or euro pegs is that it removes the possibility of beggar-thy-neighbor exchange rate policies. The creation of the euro provided similar benefits to its European members.

Historically, the classic term *beggar-thy-neighbor* has been associated with countries devaluing their currencies to increase domestic output and employment at the expense of other countries. More recently, however, the term has been used more generically to describe policies pursued by one country (or jurisdiction within one country) to increase its economic welfare at the expense of other countries (or jurisdictions), whether the mechanism is exchange rate policy, tax policy, competition policy, or foreign investment policy. Any policies that may have negative spillovers for other jurisdictions are now often referred to as beggar-thy-neighbor policies (Guha 2006).

The solution to the use of beggar-thy-neighbor policies in the 1930s was found in the international policy coordination instituted under the auspices of the Bretton Woods system. In the post Bretton Woods period, the International Monetary Fund and the World Trade Organization face the challenge of providing of such coordination.

■ black market premium

Black market premium refers to the amount in excess of the official exchange rate that must be paid to purchase foreign exchange on an illegal ("black") market. A black market premium typically arises in two different cases: when the official exchange rate is not the rate that would prevail in the commercial market; and when a nation prohibits access to foreign exchange for specified purposes. In the first case, excess demand at the official exchange rate leads to the development of a parallel, unofficial ("black") market in foreign exchange to meet the demand, with

the market rate exceeding the official rate. The difference between this rate and the official rate represents the black market premium, and it may exceed the difference between the official rate and the rate that would clear a legal market, because of the risks to sellers from participating in the unofficial ("black") market. In the second case, demand for foreign exchange for the prohibited activity induces the supply of foreign exchange in an illegal ("black") market, provided those seeking it will pay a sufficiently high price. Because of the risk involved in supplying foreign exchange for the illegal activity, sellers will demand a price higher than the official rate. The difference between this rate and the official rate will again represent a black market premium.

A black market premium has arisen most often in the context of fixed exchange rate regimes. The premium typically arises when a country fixes the value of its exchange rate in relation to another currency irrespective of the rate that would prevail in the commercial market. It is akin to the authorities' fixing a price for a commodity at a non-market-clearing level. Figure 1 depicts the situation.

In figure 1, schedule DD reflects demand for foreign exchange, while schedule SS reflects the supply. Under normal circumstances DD will be downward sloping, meaning that demand for foreign

exchange will be greater as the price (in units of domestic currency) declines. Similarly, SS will slope upward, since additional foreign currency will be supplied to the market only as the price (in units of local currency per unit of foreign currency) increases. Provided normal economic conditions prevail, the market can be expected to clear at price P^*, where the supply and demand schedules intersect. At this price, quantity Q^* of foreign exchange will be bought and sold.

When a nation fixes its exchange rate at a non-market-clearing rate, the normal market mechanism is disrupted. At the official exchange rate, P^{OFF}, demand for foreign exchange, Q^{DO}, exceeds the available supply, Q^{SO}. Those wishing to purchase foreign exchange cannot obtain it at the official price in the commercial market. If they seek to obtain foreign exchange from a private source, rather than using the queuing mechanism established by the authorities, they will need to pay more than the official price. The margin will reflect the scarcity value of the foreign exchange, plus a premium to compensate sellers for participating in an illegal ("black") market. This risk can be depicted by a leftward (upward) shift in the supply curve to $S'S'$, making the market-clearing exchange rate, P^B, likely to exceed the clearing rate in a legal market. The difference between the clearing rate in the illegal market, P^B, and the official exchange rate, P^{OFF}, is the black market premium.

In the second case, represented by figure 2, the premium arises because sales and purchases of foreign exchange for the specific activity are illegal. In this case, shadow demand and supply schedules, depicted by the lines DD and SS, occur. The difference between the clearing price in this market, again called P^B, and the official exchange rate will represent a black market premium. The size of this premium may differ from that in the previous case, depending on how the law affects the demand for and supply of foreign exchange for the restricted purpose. If the activity itself is illegal for example, seeking foreign exchange to buy illegal drugs risks for the buyer may drive down the price somewhat relative to the case where only the seller faces risks. If the restriction exists alongside a market-clearing exchange
Figure 1

regime for legal transactions, however, the opportunities for sellers to earn normal profits in the legal market may reduce the supply, and thus raise the price and the size of the black market premium, relative to what would prevail in the previous case of an official rate that is not market-clearing (figure 1).

Whichever situation applies, a black market premium signals a significant imperfection in the exchange market. This, in turn, typically has adverse implications for economic performance. Research has shown that countries with significant black market premiums tend, on average, to have lower rates of economic growth (Fischer 1993). Exchange market imperfections make it hard for foreign exchange to flow to the most productive activities, thus impairing the allocation of resources. In addition, when an overvalued exchange rate is the cause of the problem, firms and individuals must expend additional resources in obtaining foreign exchange. Thus economists typically advocate removing whatever restrictions may be leading to the emergence of black markets in foreign exchange.

■ Bonn Summit

During the Bretton Woods era (1944 72), the proportion of dollars in world reserves rose steadily. As a result, it was in the countries with a persistent tendency to run balance of payments deficits (the United States and the United Kingdom) that the shortage of world liquidity was observed. In surplus countries (Germany, Italy, and the Netherlands), there was a widespread suspicion that deficit countries were all too ready to accept inflation rather than reduce growth and undergo the discipline needed to restrain their external trade to a position without deficits. In reality, however, world trade growth was not noticeably impeded by reserve shortages when the United States had run more conservative or restrictive policies. But the system was put under significant strain after 1967, when the United States followed policies that greatly increased the supply of dollars and necessitated devaluations. The expansionary policies of the United States, and the inflationary finance of the Vietnam War, are now generally credited with undermining the Bretton Woods system.

In this context, many governments responded to the oil price rise of 1973 by cutting taxes to maintain the level of demand. Governments did this to differing extents, and the industries of different

countries also showed differing abilities to adapt to a new pattern of demand in world trade. This combination of policies led to large current account imbalances and, in particular, a weakness in the dollar. But despite those policies, unemployment rose generally largely because profits bore the brunt of the adverse terms of trade shock, while wages did not adjust. At this point policymakers regarded unemployment as the more serious problem, and the view that potential growth had been permanently reduced was not widely accepted. Meanwhile, inflation, though subsiding from its 1974 peak, remained high in many countries.

Several years of discussion among governments in this climate led to the Bonn Summit agreement of 1978, which epitomized the period. Long discussions and careful staff work finally led to a wide-ranging agreement that embraced, but went beyond, macroeconomic policy. In an effort to offset what was seen as flagging growth, while contributing to better-balanced international payments, Japan and Germany were asked to take stimulative fiscal policy actions. In return, the United States agreed to liberalize its energy prices so that they would rise to world levels, dampen U.S. energy demand, and reduce prices for all oil importers.

This agreement has been extensively criticized. It has been viewed by many as the imposition of American power, pressuring Germany and Japan to accept inflationary policies in order to assist the United States. It was also widely criticized as an example of inappropriate and procyclical fine-tuning of aggregate demand. In fact, the Bonn Summit agreement helped each country to achieve the domestic policies it favored but had been unable to achieve because of political opposition at home (Putnam and Henning 1989). The summit may therefore have been necessary to bring about the policies at the time that they were implemented, but the governing groups in each country favored them anyway. Coordinated policies were not imposed on reluctant governments.

Indeed, given the priorities of the time, the summit measures were not mistaken. Policy preferences did change soon afterward, however. In 1978, the

German government wanted faster growth when faced with forecasts of 3.5 percent real growth and 3.5 percent inflation while unemployment was only 4 percent. Moreover, a strong but temporary surge of inflation, caused by the second oil shock, and the replacement of the governments of the United States and Germany in 1980 and 1982 by Republican and Christian Democratic administrations respectively, led to a substantial reordering of priorities (Holtham 1989).

In practice, the expansionary effects of the fiscal policy changes in Germany and Japan were modest at best. In Germany, they barely offset the automatic claw back through the tax system, and they were accompanied by a tightening of monetary policy. This was acceptable because the summit agreement did not cover monetary policy, although it was clear that any German expansions would have to be bond financed. The fiscal measures therefore had a negligible impact on inflation and a very small effect on the current account. As a result, the main effect of the summit was the deregulation of American oil prices which most commentators now agree was beneficial.

The aftermath of the Bonn agreement looked rather different from the circumstances that brought it about. Unlike the first oil shock, it is implausible to ascribe the second oil shock (1979 80) to monetary expansions or loose policies in the industrial countries. Instead it was triggered by the fall of the shah of Iran. Although this did not lead to a substantial reduction in oil supplies, it caused a surge of speculative buying that drove up the oil price.

Nonetheless, by 1980 popular tolerance of inflation was exhausted, and the threat that a new surge in inflation could again ratchet up the trend inflation rate made for considerable uniformity of view in all countries. This reflected several changes of government, and resulted in a lack of interest in policy coordination plus a perception that each country should concentrate on putting its own house in order.

At this point, there was general agreement among governments on the need to reduce inflation and a much greater readiness to bear the costs in unemployment and recession a readiness that had dem-

ocratic endorsement. In part this readiness was disguised behind an assertion that there would be no lasting output or unemployment costs of eliminating inflation. Indeed, some analysts even suggested that there would be no costs at all so long as the authorities showed enough commitment to their policies, since the private sector would then adjust its expectations to the new regime. There was also some concern, however, that the Bonn Summit's attempt at coordination had failed because governments had failed to carry through their part of the bargain, preferring to free-ride on the stimulus provided by other governments. There is little evidence that this in fact happened. But it is a good example of the potential difficulties in negotiating and then sustaining a program of coordinated policies among sovereign governments.

■ brain drain

Brain drain is the emigration of skilled and professional workers (such as engineers, scientists, doctors, nurses, and university professors) from a country. These people emigrate legally, become residents or even citizens of a new country (the host or destination country), and stay there with no intention of returning to the source (sending) country. There are two main legal ways for skilled workers to move to another country permanently: direct immigration through official channels, and indirect migration through overseas education. Direct migration refers to obtaining permanent residency directly because the worker possesses a particular skill or is reuniting with family. Indirect, education migration occurs when a university graduate (or graduate of higher education or a training program that qualifies the worker as skilled) goes to another country to pursue further education, but later chooses to stay in the host country and apply for permanent residency after graduation.

One important feature of the current system of direct and indirect migration (except for family reunion) is that the governments of the host countries usually accept those workers with great skills and talent, because usually only those who are smart and perform well will be able to find new jobs in the host country to support their applications for permanent residency.

Brain drain is usually associated with developing countries, since most of the movement of skilled workers is from developing to developed countries. Many countries in Asia and Africa experience substantial outflow of skilled workers, both in absolute numbers and as a percentage of the initial stock of skilled workers, and this can have an adverse impact on the source countries. Furthermore, the big gaps between the wage rates of skilled workers in developed countries and those in developing countries make brain drain difficult to control.

It is not quite correct to regard brain drain as a problem only for developing countries. Many developed countries also experience outflow of some of their skilled workers. Canada, for example, has suffered a net loss of skilled workers and professionals to the United States, and some people have urged the Canadian government to do something to stem the loss. For developed countries such as Canada, however, while some local skilled workers are moving out, skilled workers from other countries, especially from developing countries, are moving in.

Both government policymakers and economists are interested in the impacts of brain drain on the local economy. A simple analysis of these impacts involves three steps: (1) determining the benefits that brain drain may bring, (2) determining the costs that brain drain may cause, and (3) comparing the benefits and costs of brain drain. This approach applies to both the host country and the source country.

Impacts on the Host Country Brain drain, as a form of permanent immigration, is usually not considered a problem by the host country, and in many cases it is regarded as a positive thing for the local economy. First, it gains workers, which contribute to the gross domestic product (GDP) and gross national product. Second, more skilled workers coming in usually drive down the marginal product of these workers, a phenomenon called the Law of Diminishing Returns. This phenomenon will lead to a drop in the market wage rates of these workers. At any point in time, each additional worker moving in will receive a wage rate equal to the value of his/her marginal product. However, the associated drop in the wage rate will mean that all the workers who moved in before will receive a new wage rate lower than their marginal products measured at the time they moved in. This means that the economy benefits from the gap between what these workers have contributed (their marginal products) and what they receive (the wage rate). Third, skilled workers could generate positive externalities for the society (such as increases in productivity and overall employment), and these immigrants can bring benefits to other parts of the economy not measured by the wage rates they earn.

Externalities (that is, the unintended effects of immigration of skilled workers) take two primary forms. By working with other skilled workers, new immigrants can raise the productivity of local workers through friendly competition and interactions. Also, there is usually some kind of complementarity between skilled workers and unskilled workers so that when a firm hires a skilled worker (such as a doctor or engineer) it also hires a certain number of less skilled workers (such as nurses or technicians) to work with

the skilled worker. This means that the employment of skilled workers could generate demand for unskilled workers. This type of externality is especially helpful in solving the problem of unemployment of unskilled workers.

Brain drain, like other types of permanent migration, involves inflow of people, and thus it can have social and political effects. For example, the government may be concerned about any possible impacts of the inflow of foreign workers on crime, social order, and local education, or about cultural and language differences and conflicts between the new immigrants and local residents. Furthermore, the demographic distribution, the income levels, and the political views of the new immigrants may also have impacts on the local society.

Impacts on the Source Country The impacts of brain drain on the source country could be very different from those on the host country. Consider first the special case in which only one skilled worker moves out so that the local wage rate is not much affected. If before the move the worker is paid his/her value of marginal product, then the impact on *those left behind* (TLB, or the rest of the local economy) will be negligibly small because while the economy loses the contribution of the worker, it saves the payment to the worker. The nonharmful effect of brain drain will no longer hold if (1) the outgoing worker received a wage rate less than what he/she has contributed, or (2) more similar workers move out so that the wage rate rises.

If the outgoing worker received a wage rate less than his/her contribution, the emigration is harmful to TLB because the worker takes with him/her his/her previous contribution, which is bigger than what the rest of the economy is able to save. A worker receives less than his/her (value of) marginal product if there are distortions in the labor market. Two main types of distortion are monopsony (in which a single buyer has disproportionate influence in a market) and externality. A monopsonistic firm will tend to underemploy workers and underpay each worker. The existence of (positive) externality can lead to a wage rate less than the marginal product of labor. As explained earlier, a skilled worker can generate two

types of externality: positive impacts on his/her co-workers through friendly competition and interactions, and complementarity between skilled workers and unskilled workers.

Brain drain can hurt TLB even if there are no distortions (such as monopsony or externality) in the economy. Suppose that a sufficient number of skilled workers move out so that the marginal product of labor increases, and thus the wage rate of the remaining workers increases. The gap between the new, higher marginal product and the original wage implies that TLB have experienced a net loss between the contribution of the emigrating workers and the wages saved by no longer paying them.

The impacts of brain drain on TLB in the source country are not all negative; some of them could be positive. For example, skilled workers working abroad may remit part of their income to their family, relatives, and friends back in the source country. They also serve as examples to younger generations of the benefits of acquiring high-level skills. Some of them may even bring back technologies and investment to the source country.

Brain drain can also have dynamic effects on the source country's economy. First, brain drain means that the country is losing human capital. Since human capital is an important growth factor, brain drain can adversely affect economic growth. Moreover, because skilled workers tend to earn high wages before their departure, they usually have saving rates higher than the average rate in the economy. Thus the outflow of some of these high-income workers could pull down the average saving rate of the remaining population, and this means that the local investment rate and thus economic growth will be hurt.

Emigration of these workers could have other impacts on the rest of the economy. One very important impact is that on education, especially higher education. The prospect of moving to other countries where higher wage rates are offered will increase the incentive of local students to seek higher education and in-depth training. This will in general raise the skill level of workers in the economy, and they could help the economy grow. There are,

however, some problems associated with this increase in the demand for higher education, sometimes referred to as a *brain gain*. First, the demand for higher education could be biased toward technical subjects such as engineering, medicine, science, and computer science, and away from other subjects such as the humanities. Second, there is always an excess demand for education, especially higher education. When there is an increase in the demand for higher education, it is not likely that the government will respond with an increase in the supply. As a result, brain drain may not imply an increase in higher education graduates although it may lead to an improvement in the quality of the graduates because talented children will have bigger incentives to get education.

Brain Drain as a Serious Issue for Developing Countries There are several reasons that the governments of developing countries regard brain drain as a serious problem for their economies. First, the wage gaps between developing countries and developed countries are wide, implying big incentives for the skilled workers in the developing countries to emigrate. Second, the externality associated with skilled workers could be high in these developing countries, mainly because there is usually widespread unemployment of unskilled workers. The complementarity between skilled workers and unskilled workers means that the loss of a skilled worker to another country could lead to a drop in the economy's demand for unskilled workers. Thus large outflow of skilled workers could substantially raise the unemployment rate of unskilled workers. Third, the outflow of different types of skilled workers may not be balanced, and the developing countries could very well be losing more of the types of skilled workers that they need the most   for example, doctors, engineers, and nurses, who can easily apply for immigrant visas to developed countries but also are in very short supply in the source countries. Fourth, most developing countries are in an early stage of development, and skilled workers are needed for the economy to take off. Losing some of these workers could seriously hinder the growth of the economy.

Policy Recommendations In view of the impacts of brain drain on local economies, many economists have suggested policies to protect the welfare of TLB.

Exit Tax One suggestion is that those who want to emigrate would have to pay a tax before leaving the country, and that the tax revenue collected would be distributed to the remaining population in some way. The amount of the tax could be set at a level so that TLB would be adequately compensated, and might include an amount to cover the subsidy on education the government provided to these emigrants. It has been argued in economic theory that the increase in the income of the emigrants should be big enough to cover the compensatory tax. For the emigrants the tax payment could come from their own funds, or loans from relatives, friends, and banks. For example, the former Soviet Union imposed exit taxes on some Jews who immigrated to Israel (although in this case the main reason for the tax may have been political deterrence of emigration rather than economic recovery of investment in the emigrants). China had a policy closer in essence to the exit tax suggested here: it required people who went abroad for education to put down deposits before they were allowed to go, and the deposits would be forfeited if after graduation they did not return to China.

Exit taxation is not common in developing countries, partly because it is difficult to calculate the right tax rate. Another reason is that the amount required to adequately compensate TLB could be big, and people who want to move out may not be able to raise that sum of money. Even though it is argued that the future earnings of the emigrants are big enough to cover whatever is required to compensate TLB, banks will not accept these future earnings to guarantee loans. Thus exit taxes, when implemented fully, could turn out to be prohibitive.

Host Countries to Collect Taxes for the Source Countries Since it is difficult to collect taxes before the emigrants actually earn the new wages, some economists have suggested that the host countries, notably the United States and other developed countries, could impose taxes on the new immigrants. The collected taxes would be returned to the source countries on a regular basis, with the purpose of compensating the remaining population. The merit of this argument is that taxes are collected only after the new immigrants have received income. However, it has a number of practical difficulties.

First, the administration of the tax scheme could be very costly, as a lot of information has to be collected in order to calculate the rates for immigrants from different countries. Second, strictly speaking, the tax scheme requires that people from different countries be subject to different rates. The problem of this requirement is that it could create a lot of administration problems, and it may generate feelings of unfairness among the immigrants. To respond to this point, it has been suggested that the source countries impose only one tax rate on the new immigrants, no matter where they came from. The required rate will be the one that is based on the average amount of compensation needed for all important source countries. The tax revenue collected will then be handed over to some international organization such as the United Nations to spend on programs that promote economic growth and development of developing countries.

Even if the high costs associated with administrating the scheme and the difficulty of implementing the scheme can be overcome, the tax scheme may be against the constitution of most developed countries: it requires that the initial residents in the host countries and new immigrants be subject to two different income tax rates, the higher being on the new immigrants. These developed countries are prohibited from imposing such a two-tier tax system, based on whether people emigrated from another country recently.

Other Policy Recommendations The fundamental way to solve the brain drain problem is to raise the local wage rates, so that skilled workers will have less incentive to emigrate. There are at least three possible ways to raise the local wage rates. First, the government can provide a general wage subsidy to all

skilled workers to close the gap between what they may be able to get elsewhere and what they receive locally. This policy could be more effective in dampening brain drain, but it is costly because substantial subsidies will be needed. That could be beyond the budget capacity of the governments. Furthermore, the main reason why these skilled workers are able to earn higher wage rates is because they have higher marginal products in the host countries because of, for example, the availability of more and better capital and facilities. These can hardly be provided by the source country governments in the near future.

The second way is to substantially promote the growth of the economy so that the income levels of the population are raised. Economic growth of the country will boost not only the GDP and national income of the economy but also the wage rates of the skilled workers. The growth of the economy will substantially diminish the incentive of the skilled workers to move out.

This policy is only part of a long-term solution, as it takes a long time for the economy to have a substantial growth. Furthermore, brain drain has a negative impact on economic growth, as brain drain lowers the stock of human capital in the economy. To promote economic growth while skilled workers are moving out is not an easy task. To do that, the government can invest more in education and/or invest more in infrastructure. The first strategy seeks to slow the rate of depletion of the stock of human capital or even to increase the stock. The second one seeks to promote other growth factors, such as the infrastructure needed to attract foreign direct investment or support high-tech development.

The third policy is to implement a two-tier wage system for skilled workers: one at the prevailing rate in the economy, and a second, higher one for those who choose to come back from abroad, usually after graduation from a training program or higher education. The higher wage scale for the returning skilled workers is to attract them to come back. To carry out this policy successfully, either there must be a sub-stantially large public sector or the government must be willing to use widespread subsidies on the employment of these returning graduates. Many countries such as China have been using this policy to lure students who went abroad for education to come back after graduation.

The use of a two-tier wage system, however, has its own costs. This system requires subsidy payments to these returning workers, and the gap between the two wage scales could alienate those workers who were trained locally and are working with those returning skilled workers.

Another policy to slow the rate of brain drain and to encourage returning immigrants is to attract foreign direct investment. There are three channels through which the domestic demand for skilled workers can be raised. First, attract foreign firms to invest and produce locally. Because foreign firms usually have more advanced technologies than what local firms have, foreign direct investment could substantially raise the demand for skilled workers. Second, recent development of technologies allows local skilled workers (such as telephone operators, computer programmers, and accountants) to be employed by firms located in other countries, without having these workers moving out of the country   a phenomenon called offshoring. Third, local production of products to be exported can increase through a process called fragmentation and outsourcing. As firms in developed countries are able to fragment their production processes, they may move the production of some of the components and intermediate inputs of the final products to developing countries where labor costs are much lower. This will raise the demand for skilled workers in the developing countries.

■ brain gain

Brain gain refers to the hypothesis that the emigra tion of advanced students and highly skilled workers may produce domestic incentives for investment in education and skills that offset the human capital losses resulting from the departures. This hypothesis poses a challenge to the more widely held view that such emigration results in a net loss of human capital, or brain drain.

A brain gain may be realized only if several con ditions are met. First, many emigrants must receive substantially higher returns on their education and skills than they would have done had they stayed home. Second, these gains must be perceived by in dividuals in the sending countries who have the in terest and potential to acquire more education and skills, thereby inducing a demand for them. Third, domestic institutions must be able to respond effec tively to this demand. Fourth, some of those who have been induced to acquire more education and skills, and thus add to their human capital stock, by the prospect of emigration, must be unable to emi grate. Finally, this group must be able to put their newly gained education and skills to good use at home.

The first condition is likely to be met quite often. Large international differences in compensation are a driving factor in many migration decisions. Al though not all emigrants are able to put their edu cation and skills to work in the receiving countries, many do. A quarter of all college-educated workers in science and engineering occupations in the United States in 2003, for instance, were born outside the country.

When emigrants experience employment success, reports are likely to filter back to interested com munities in the sending countries, fulfilling the second condition. (Indeed, if these reports are exag gerated, so much the better for the brain gain hy pothesis.) Electronic mail and the World Wide Web have expanded and accelerated the communication channels for such information. A case in point is the close association in the late 1990s and early 2000s between salaries in the U.S. information technology industry and foreign student enrollments at the graduate level in related fields.

The third condition may be the most difficult to fulfill. Effective institutions for education and training tend to be rigid. They require highly skilled teachers who may be difficult to recruit and retain. They may need substantial capital inputs for facilities

and equipment. They may be burdened by red tape and political demands. Even when it is possible to expand such institutions, their quality may decline so significantly that their net contributions to human capital formation are far less than hoped for. New higher education franchises in India, for example, are a far cry from the Indian Institutes of Technology that have shaped high expectations among foreign employers.

If the educational bottleneck is surmounted by a large number of prospective emigrants, it does seem probable that a substantial fraction of them will be frustrated in their attempt to secure a better return on their investment in themselves by seeking skilled work abroad. This condition, the fourth for realizing a brain gain, is enacted through immigration quotas, labor market regulations, and other forms of protection for skilled workers in the receiving countries. Applicants for an employment-based "green card" for permanent residence in the United States, for instance, must typically wait several years for a decision.

The final question is whether these would-be emigrants can put their hard-won knowledge to effective use in the domestic economy. This condition, like the third one, is not necessarily easily met. The profile of the demand for skills, especially highly specialized skills, may be different at home than abroad. Nurses and doctors whose training prepared them to treat middle-class patients in comfortable surroundings provide an illustration; they may choose not to practice their professions rather than serve poor villages where the medical needs are greatest.

The data available for assessing the brain gain hypothesis, although they are improving, are still too poor to allow for anything other than tentative conclusions. The firmest of these conclusions is that a brain gain is more likely in countries with large populations than small ones. Beine et al. (2003), for example, find that China and India benefit from current levels of emigration of college-educated individuals and would benefit even more if outflows were to rise. At the other extreme, Guyana, Haiti, and Jamaica, which have lost more than 80 percent of

their college-educated to emigration, have been made worse off. Although more of the 50 developing countries in Beine et al.'s sample are "losers," the winners contain some 80 percent of the total population.

These tentative findings are intuitively appealing, given the conditions required to realize a brain gain. Large countries seem likely to more easily achieve the economies of scale required to support expansion of and new entry into higher education. They may also benefit more from competition among provinces and localities to provide public education and among private educational institutions as well. National quotas in receiving countries amount to a smaller fraction of the populations of large sending countries than small ones. (Citizens of Jamaica, for instance, are more than a hundred times more likely to be admitted as legal immigrants to the United States than those of India.) Finally, the more diversified economies of large countries may provide more opportunities for "surplus" human capital to be used productively.

Although the conditions for a brain gain may be more likely to be fulfilled in large countries, there are many policies that sending countries of all sizes might undertake to raise the odds of such an outcome. Chief among these are educational policies that provide general skills and economic policies that foster investment and entrepreneurship. Receiving countries, too, have a potential role to play, for instance, by linking their immigration policies to labor market conditions at home and abroad. Neither brain gain nor brain drain is, in the final analysis, an outcome of immutable laws of economics, but rather a construction of policy decision-making within institutional constraints.

■ brain waste

Brain waste refers to the underuse of migrant knowledge within a host country. In contrast, *brain use* refers to a situation in which migrants obtain jobs commensurate with their educational level and are in a position to make use of their knowledge and skills in the host-country labor market. Greater incidence of brain waste translates into lower levels of brain use and vice versa.

The 1990s were characterized by major geopolitical change and state reconfiguration. These changes put in motion new patterns in the movement of people across boundaries and gave rise to several new trends in international migration (International Organization for Migration 2005). An important new trend is that contemporary migration is concentrated in a few developed countries. In 1970, the developed world received 47 percent of all international migrants whereas 53 percent of migrants moved to developing countries. By 2000, the proportion of international migrants to developed countries had risen to 63 percent. The sharpest increase was in the United States, but Australia, Canada, France, Germany, and the United Kingdom also experienced substantial increases in their migrant populations (International Organization for Migration 2005).

In many of these receiving countries, family reunification has been an important vehicle of admission. In recent years, however, admission of skilled workers has gained prominence. In 2000, more than a half million skilled migrants were selected for admission to the United States, along with more than 100,000 in Australia and the United Kingdom, fewer than 100,000 in Canada, nearly 50,000 in New Zealand, and fewer than 10,000 in France (International Organization for Migration 2005). The growing use of skill level as an admission criterion in destination countries is important to the effective use of labor resources in the world economy.

National Origin and Brain Waste Migrants to Europe and especially the United States tend to be highly educated (Özden 2006). Those who migrate to the United States from Africa, the Middle East, Asia, and Eastern Europe are more educated than their counterparts that set out for Western Europe. In contrast, the United States is by far the destination of preference for Latin American migrants, and their educational levels tend to be lower than the average levels in their home countries (Özden 2006).

A key issue in brain waste research is the extent to which migrants' knowledge and skills are employed in destination countries. Some researchers have indicated that, despite the same level of educational attainment, migrants from different regions show significant differences in job placements in the U.S. labor market. One can discern three categories relating to the incidence of brain waste low, moderate, and high from Özden's (2006) study.

The first category is composed of professional migrants from Asia and Western Europe. It also includes migrants from Japan and Australia. Using 2000 U.S. Census data, Özden (2006) concluded that, in general, migrants from Asia tend to do better in terms of brain use than those from Western Europe. Brain use is lowest (and thus the incidence of brain waste is highest) among migrants from the Republic of Korea (33 percent) and Pakistan (38 percent); comparatively moderate for migrants from the Philippines (40 percent), Taiwan (46 percent), and China (51 percent); and highest among those from India (76 percent). For migrants from Western Europe, Japan, and Australia, brain use is estimated at between 38 percent for migrants from Italy to 69 percent for migrants from Ireland. Migrants from

Japan, the United Kingdom, Germany, Canada, and Australia also do relatively well, with between 59 percent (Japan) and 65 percent (United Kingdom). In this study, brain waste and brain use were measured by assessing the gap between educational attainment and job description in the destination country.

The second category of migrants, characterized by moderate brain waste, is composed of those from various African countries. The incidence of brain use is lowest among professional migrants from Ethiopia (37 percent), and highest among those from South Africa (62 percent). For immigrants from countries such as Nigeria, Ghana, and Kenya, brain waste is in the middle of this range, between 40 percent and 52 percent.

The third category of migrants, characterized by a high degree of brain waste, is composed of professional migrants from Eastern Europe, Latin America, and the Middle East. Although the incidence of brain waste is highest in this category, important differences between regions can be discerned. For migrants from Eastern Europe, brain use is estimated at between 31 percent (former Yugoslavia) and 57 percent (Hungary). For migrants from Latin America, brain use is estimated at between 32 percent (Guatemala) and 51 percent (Brazil). Of all groups, migrants from the Middle East experience the greatest incidence of brain waste, with brain use estimated at between 25 percent (migrants from Morocco) and 46 percent (migrants from Lebanon).

Factors Contributing to Differences in Brain Waste What explains the pattern of brain use among migrants from different regions of the world who possess the same educational credentials? Some brain waste researchers attribute the differences to quality and selection variables (Özden 2006; Matto, Neagu, and Özden 2005). *Quality variables* affect the extent to which an immigrant's human capital is valued within the host country. Two such variables are the source country's expenditure on tertiary education and whether the English language is used in the host country. The greater the expenditure on tertiary education, the better the schools and therefore the better the knowledge and skill level of the migrant. Proficiency in the English language can facilitate

migrant communication in the United States since it is the primary language of business.

Selection variables relate to differences in the abilities of immigrants from different countries. Selection variables predict whether immigrants from a particular country represent the highly educated and therefore professionally competitive, or the minimally educated and therefore professionally uncompetitive, members of their own society. Özden (2006) considers three selection variables (gross domestic product GDP per capita, distance, and conflict) that relate to the source country and one selection variable (migration policy) that relates to the destination country.

The higher the GDP per capita of the source country, the higher the opportunity cost of migration. Therefore, those who might wish to migrate are those who expect to get higher monetary returns on their knowledge and skills overseas. Less-educated individuals from high GDP per capita countries are unlikely to migrate because the costs of migration are greater than the expected returns. In contrast, both highly educated and less-well-educated individuals from low GDP per capita countries may want to migrate to high GDP per capita countries because of the expected economic rewards. Migration from low GDP per capita countries tends to favor the highly educated, however, because they are likely to possess the financial resources required to make a move. The implication of this for differentiating the abilities of migrants from different source countries is that we can expect migrants from high GDP per capita countries to be educated and skilled, while, in general, there is greater uncertainty about the abilities of those from low GDP per capita countries since they represent an education and skill mixture that has to be sorted out in the host country labor market. Further, the process of sorting between skilled and unskilled migrants can be costly for organizations.

Distance between source and destination countries can also have an impact on migrant ability through a self-selection process. Migrants are likely to select a distant destination over a closer one if they believe that they will obtain higher returns on their knowledge and skills in the former. Thus highly

skilled migrants from Africa and the Middle East who expect higher rewards in the U.S. labor market are likely to migrate to the United States rather than to the closer destination of Western Europe. Even in Western Europe, where migration policy has favored family reunification and political asylum seekers, there is a trend toward policies that favor economic migration, making the distance explanation more widely applicable.

Military conflict can have at least two impacts on differences in abilities among migrants. The presence of political instability and military conflict creates an incentive for people with varying educational levels to migrate. This, in turn, contributes to a migrant population with a varying skill and knowledge composition. Military conflicts also affect the allocation of scarce resources from education to military efforts in source countries. This, in turn, diminishes the quality of education and the abilities of migrants from affected countries.

The only selection variable that relates to the destination country is migration policy (Özden 2006). This relates to the openness of immigration policies to migrants from particular countries. The more open the migration policies of destination countries, the more varied the skill composition of migrants. In contrast, migration policies can range from being open to migrants from countries perceived to have highly educated migrants in targeted industries, to being relatively restrictive toward migrants from countries perceived to have a low level of educational attainment among their populations.

Destination Country Labor Markets Although quality and selection variables may play an important role in brain waste, they mask destination-country labor market characteristics that may play an even greater role in explaining the differential patterns of brain waste among migrant professionals. The presumed efficiency of the labor market can hold only if employers in the destination country have perfect information relating to the quality and selection variables pertaining to the source countries of each immigrant. Furthermore, they would also have to use this information rationally to assess the value of identical educational credentials of migrants from different source countries. Research in organizational studies, migration, and cross-cultural adaptation, however, suggest that both structural and cognitive biases on the part of employers and migrants alike play a significant role in shaping perceptions of migrants from different parts of the world and affecting hiring decisions.

Research on diversity in organizations in the U.S. context identifies a wide range of structural barriers faced by nonmajority group members. These include discrimination and prejudice based on a variety of differences (Cox 1993), institutional barriers such as the organizational history in relation to diversity practice, formal hiring practices, and informal organizational processes (Nkomo 1992; Cox 1993). There are reasons to believe that these barriers would also be relevant to other destination countries (de Beijl 1996). Although diversity research has provided significant insight into the impact of these types of barriers on minority members in general, it has generally ignored the unique circumstances of migrants. Research on migration and cross-cultural adjustment suggests that many of the barriers identified in the diversity literature are important in understanding migrant work adjustment. There are other barriers faced by migrants, however, such as language, culture clash, lack of information and knowledge about the labor market, and the inability of potential employers to assess migrant credentials (de Beijl 1996). These barriers affect migrants' ability to adapt and become effectively integrated into the work context as well as the employment and promotion decisions of employers. Most important, these employment decisions on the part of employers fly in the face of any rational calculation regarding the migrants' qualifications. Thus exploring the cognitive and structural biases that play a role in migrant work adjustment would give us greater insight into the factors that may contribute to the differential pattern of brain waste among migrants from different parts of the world identified by Özden (2006).

■ Bretton Woods system

The Bretton Woods agreements negotiated at the United Nations Monetary and Financial Conference held in Bretton Woods, New Hampshire, in 1944 laid the groundwork for the creation of the International Monetary Fund (IMF) and the International Bank for Reconstruction and Development, now known as the World Bank. These institutions provided the framework for the postwar international trade and financial system that came to be known as the Bretton Woods system.

In the early 1940s the Allied powers started to consider the shape of the post World War II international financial and trading system. Influencing their decision on measures to be taken was the assessment of why the trading system had broken down in the 1920s and the causes of the economic depression that had plagued the United States and the United Kingdom in the 1930s. The period had been characterized by record levels of unemployment, excessively onerous war reparations payments imposed in the Treaty of Versailles, and volatile international capital flows, as well as the collapse in the prices of primary commodities.

The response to these problems had been the introduction of policies to protect domestic producers by restricting imports, placing controls on the access to foreign exchange used to purchase imports, introducing preferential tariffs on imports from selected countries, and bilateral clearing and payments arrangements to ensure that imports balanced exports. Other measures included international schemes restricting supplies of primary commodities, as well as national import restrictions, export subsidies, and agricultural price supports. The objective of these policies was to defend domestic income and employment and the stability of domestic financial institutions. Instead, the attempted return to the gold standard was thwarted by sustained financial crises.

Postwar planners recognized the need to coordinate national policy objectives in an interdependent international system and concluded that multilateral institutional structures could eliminate the financial factors that had caused international trade

to be viewed as a threat to national economic welfare. It was generally agreed that a stable international financial and exchange rate system was a prerequisite to successful restoration of free international trade.

The United States and the United Kingdom played the major role in the discussions of the shape of the new system, and both governments contributed proposals of what was to be the first step in this process. The UK proposal, authored by John Maynard Keynes, called for an international clearing union based on an internationally created and managed unit of account. The U.S. proposal, devised by U.S. Treasury official Harry Dexter White, proposed an international stabilization fund, similar to the U.S. Federal Reserve System on an international scale, that would hold reserves of the currencies of all members, from which countries could borrow to support their exchange rates.

The difference in the two proposals reflected the different motivations of the two countries. The United Kingdom was concerned that large payments imbalances under the gold standard had required debtor countries to reverse their balance of payments deficits and protect their declining gold stocks by reductions in domestic income and employment. Surplus countries, on the other hand, were accumulating gold and could easily postpone any action to reduce their surpluses through policies to expand their imports from the deficit countries. The goal of the United Kingdom, as a postwar debtor country, was thus to eliminate this asymmetric adjustment to trade imbalances by ensuring full participation of creditors in the international adjustment process.

The United States, on the other hand, was more concerned by the breakdown in free trade and the manipulation of exchange rates that had occurred in the interwar period as countries attempted to protect themselves from the exchange rate instability caused by large payments imbalances and the instability of international financial flows. The U.S. concern, as the major creditor country, was to prevent deficit countries from resolving their debt positions by using protection and exchange rate manipulation to create trade surpluses.

Article VII of the Atlantic Charter, negotiated by Winston Churchill and Franklin D. Roosevelt at the Atlantic Conference in August 1941 during a secret shipboard meeting, set out the conditions for U.S. support of the British war effort. It reflected U.S. concerns that the postwar trade and financial system be built on a rules-based system of relatively free multilateral trade as opposed to the British approach of trade preferences. The differences were worked out at the Bretton Woods Conference in 1944. The trade and commercial policy aspects of the new system were the subject of discussions at the UN Conference on Trade and Employment held in Havana in 1947.

Creation of the Bretton Woods Institutions
The Bretton Woods Conference created the IMF, largely on the lines proposed in the White plan. On a proposal from the United States, concerned to separate the financing of the postwar reconstruction of Europe from the financing of exchange rate stability, an International Bank for Reconstruction and Development (IBRD) was also created to deal with the longer-term problem of development finance for postwar reconstruction in Europe. The unanimously adopted Havana Charter, proposing the creation of an International Trade Organization (ITO) that would deal with the regulations on commercial policy, create a Commodity Stabilization Fund, and meet the British concerns for symmetric balance of payments adjustments, was never ratified by member states. Instead, a single chapter, the General Agreements on Tariffs and Trade (GATT), which dealt with commercial policy, was the only part of the charter that survived as a series of bilateral treaties to eliminate subsidies and reduce tariffs in support of world trade.

The role of these multilateral institutions with complementary mandates to ensure favorable international trade and financial conditions to support rapid income growth and employment is reflected in their stated objectives. The IMF was created "to facilitate the expansion and balanced growth of international trade, and to contribute thereby to the promotion and maintenance of high levels of employment and real income and to the development of the productive resources of all members as the pri-

mary objectives of economic policy." The ITO charter (Chapter 2, Article II) was even more explicit: "The Members recognize that the avoidance of unemployment or underemployment, through the achievement and maintenance in each country of useful employment opportunities for those able and willing to work and of a large and steadily growing volume of production and effective demand for goods and services, is not of domestic concern alone, but is also a necessary condition for the achievement of . . . the expansion of international trade, and thus for the well being of all other countries." Finally, the role of the IBRD was "to promote the long range balanced growth of international trade and the maintenance of equilibrium in balances of payments by encouraging international investment for the development of the productive resources of members, thereby assisting in raising productivity, the standard of living and conditions of labor in their territories."

This ambitious project of negotiating a new, coherent, and coordinated set of international institutions for the postwar period was never completed, however. The IMF and the IBRD became specialized agencies within the UN system, which allowed them to maintain independent governance mechanisms with representation based on each country's economic weight and financial contribution instead of on the UN General Assembly's rule of one country, one vote. In 1996 the GATT was transformed into the World Trade Organization, an ad hoc international body outside the UN system and without the wider mandate to eliminate discriminatory bilateral agreements as the third pillar of Bretton Woods originally intended for the ITO.

As a result, no multilateral institution was created to deal with the stabilization of primary commodity prices or to oversee trade in agriculture. Instead, official intervention in support of the prices of primary commodities continued in the form of ad hoc agreements dependent on controls over supply, and national and (in the case of European Union countries) regional schemes for the support of agricultural prices and incomes. The most important and most costly examples of the latter were found in industrial countries, and, as in the earlier period, they were generally supported by tariffs and other restrictions on imports, as well as by subsidies and other methods of export promotion. The responsibility for the consequences of fluctuations in developing country export earnings caused by volatility in commodity prices was left to the IMF.

The IBRD, although it was commonly referred to as a "world bank," was not a "bank" because it could not create money, and the majority of the financing for European reconstruction effort was provided by the Marshall Plan. As a result most European countries delayed full observance of their obligations in the international trading system, while the need for finance for reconstruction and trade was met by official aid or through regional multilateral monetary arrangements such as the European Payments Union. The financing problems facing the growing number of newly created democratic developing countries were addressed by the creation of special institutions in the World Bank such as the International Development Association and regional development banks. In addition, the UN Conference on Trade and Development, which had no financing capabilities, provided a forum for the formulation of financing policies designed to benefit developing countries.

Membership in the IMF required a country to maintain a fixed parity for its national currency relative to gold or the dollar. If necessary, countries were to maintain these rates by borrowing reserves temporarily from the IMF and by implementing policies to ensure external equilibrium. Only in the case of a "fundamental disequilibrium," where such adjustment would have meant insupportable domestic hardship, could a country contemplate a change in exchange rates, and such a change was to be negotiated with the other members of the IMF.

Dollar Standard Since most countries did not have the requisite gold stocks after World War II, they chose to fix their exchange rates to the dollar. The United States, with most of the global gold stocks, fixed its parity relative to gold. Nonetheless, the weak external positions of most European countries meant that convertibility at fixed parity for imbalances created by commercial account transactions was not

implemented until the end of the 1950s. By 1960 the Bretton Woods fixed exchange rate system came under pressure when gold traded above its official dollar peg of $35 an ounce on the London gold market. Several years earlier, Yale economist Robert Triffin had suggested that this was the inevitable result of the decision made at Bretton Woods to require members to fix their exchange rates relative to gold or the U.S. dollar. Since all countries except the United States had fixed their currencies relative to the dollar, this created a system that resembled the prewar gold standard that the Bretton Wood system was supposed to replace, as the dollar had simply taken the place of gold.

When U.S. external deficits created a stock of international claims on the dollar that exceeded the U.S. gold stock, the United States could no longer ensure the exchange of dollars for gold at the rate of $35 per ounce. This is precisely what occurred in 1960 when the value of U.S. gold stocks at the official parity of $17.8 billion fell short of the $18.7 billion of outstanding liquid foreign dollar claims. To avoid changing the dollar parity, a series of ad hoc measures to prevent dollar conversion into gold and to increase foreign demand for dollars were introduced during the decade of the 1960s. These included a two-tier gold market separating official and private conversions of currencies into gold; an interest equalization tax on borrowing in the U.S. capital market; Operation Twist, which attempted to produce an increase in short-term rates while keeping long-term rates low in order to support U.S. growth prospects; and new methods of calculating the U.S. balance of payments on the basis of liquidity balances.

In 1966, to provide a supplement to the dwindling U.S. gold stocks and an alternative to the dollar in countries' reserves, the Group of 10 (composed of the ministers of finance of the 10 major industrialized countries) proposed a "special reserve drawing right," which was implemented by the IMF in 1967 with the creation of a facility based on "special drawing rights" (SDRs) in the fund. The SDRs, also known as "paper gold," were simple credit entries in the IMF accounts, distributed to members in proportion to their existing membership quotas in the IMF. They could be used in place of dollars or gold to settle payments imbalances. The value of the SDR was initially defined as the gold equivalent of the dollar (0.888671 grams of fine gold), but after the collapse of the Bretton Woods system the SDR was initially redefined as a basket of 16 currencies. In 1981 it was reduced to 5 currencies, with a revision of the weights and currencies that comprise the basket conducted every five years. Rather than a transaction currency that can be used to finance purchase and sale, it is a unit of account to be used by deficit countries losing foreign exchange reserves in defense of their parity to acquire currencies of other members.

Despite all these attempts to shore up the system, U.S. gold stocks by 1971 had fallen to just over $10 billion against outstanding claims of more than $60 billion. In August of that year the United States suspended convertibility of the dollar to gold at the fixed $35-an-ounce parity and introduced an import surcharge. This represented the de facto confirmation of Triffin's prediction and the end of the Bretton Woods system.

From 1971 to 1974 an ad hoc Committee of the Board of Governors on Reform of the International Monetary System and Related Issues (composed of the 20 executive directors of the IMF and known as the Group of 20) worked on proposals for the resurrection and reform of the Bretton Woods system. This attempt was abandoned, however, after the outbreak of the oil crisis in 1973, and negotiations focused instead on interim arrangements such as a quota increase, the creation of a new governance structure in the form of an "Interim Committee" and a "Development Committee," abolition of an official price of gold, and regulations for the valuation of gold held by the IMF on behalf of its members. The changes were finally completed at a special meeting held in Jamaica in 1976 that eliminated the formal obligation under Article IV for members to fix a parity relative to gold or the dollar. Under the new arrangement each member was bound to "collaborate with the Fund and other members to assure orderly exchange arrangements and to promote a stable system of exchange rates." In particular, each mem-

ber was encouraged to "avoid manipulating exchange rates or the international monetary system in order to prevent effective balance of payments adjustment or to gain an unfair competitive advantage over other members"

Changing Roles of the Bretton Woods Institutions After the reform there was no longer a need for countries to borrow from the IMF in order to support their exchange rates. In theory, under flexible exchange rates countries no longer needed to hold exchange reserves since adjustment to external imbalances would take place through the changes in the relative prices of tradable and nontradable goods produced by exchange rate adjustment. IMF operations were thus concentrated on orderly adjustment by ensuring that flexible currency exchange rates reflected underlying economic forces.

The World Bank's mandate has also changed. As the need for European reconstruction finance disappeared, attention shifted to the financing of large economic infrastructure projects to support developing countries. The bank is an active borrower in private capital markets to finance its projects in developing countries. Dissatisfaction with the development impact of these projects, however, and criticism of widespread corruption in their implementation during the 1980s, led the bank to focus on supporting the creation of markets and institutions in developing countries that would eliminate poverty and support their more active participation in the international trading system.

Thus the two Bretton Woods institutions have lived on beyond their original mandates negotiated in 1944 to become complementary and sometimes conflicting institutions that aim to finance development and eliminate poverty in developing countries.

■ bubbles

Bubbles are situations in which asset prices persistently deviate from their fundamental values that is, the prices warranted by the true earning potential of firms. Until recently, economists believed that asset prices as a rule reflected fundamental values, and that bubbles were highly implausible. This view relied on an argument of backward induction: the worth of any asset in the period before the final payoff

date would simply be equal to the discounted value of its face value in the period it expired — that is, terminal value. Extending this argument backward, the value of an asset at any period would be equal to the discounted present value of its future stream of revenue. Otherwise, it was argued, an arbitrage opportunity would arise and the price would be pushed back to its fundamental value by the exploitation of this opportunity by informed traders.

Both the rise of rational expectations theory in economics and the idea that assets prices (such as shares and exchange rate) always incorporate all available public information (efficient market hypothesis in its most widely accepted *semistrong* form) went hand in hand with the backward induction argument, underpinning the view that the best way to understand asset prices changes was by focusing on information about fundamental values.

With the rise of behavioral finance theory since the mid-1980s, however, the view that asset prices equal discounted present value of future streams of revenue has come under critical scrutiny (Shiller 2003). In fact, with the growing skepticism about the efficient market hypothesis, much of the theoretical literature on asset pricing has been in a "vibrant flux" (Hirshleifer 2001). Given this change of paradigm in finance theory, it is hardly surprising that conceptual understanding of bubbles has been changing as well. In fact, in many of the new models with risk-averse traders that have asymmetric expectations it has become next to impossible to define what "fundamental value" is (Allen et al. 1993).

The older, standard view argued that all major asset price variations, including famous historical episodes of bubbles such as the Dutch Tulip Mania (1634–37), the Mississippi Bubble (1719–20), and the South Sea Bubble (1720), were not really "bubbles" in the sense that they were caused by changes in fundamental values (Garber 1990). Although it was always recognized that less than fully rational behavioral traders exist in financial markets, defenders of the standard view have held that informed arbitrageurs would undo any mispricing caused by them even when they did not cancel out each other's effect

(Fama 1970; Malkiel 2003). In this setting, bubbles could arise only in assets that had an infinite horizon (and thus lack a terminal value) because in this instance the backward induction argument did not apply. This case has largely defined the limits of initial theoretical interest in bubbles, going back to the economist Paul Samuelson (1958), and is the foundation of more recent work that now goes under the name of "rational" bubbles (also see the comprehensive survey by Santos and Woodford 1997).

With the rise of behavioral theory, however, the effectiveness of arbitrage became a central issue of contention. Behavioral theorists have produced numerous examples where arbitrage is severely limited in its ability to prevent persistent deviations of asset prices from their fundamental values, bolstering the view that major asset price variations are caused by mispricing as opposed to changes in fundamental values (De Long et al. 1990a, 1990b; Shleifer and Vishny 1997; Allen and Gorton 1993).

Contrary to what is often argued, bubbles are not necessarily the result of irrational trading behavior. A body of more recent work suggests that the main cause of bubbles is the uncertainty about higher-order beliefs, that is, rational agents not knowing what other rational agents will do, where irrationality is not a necessary ingredient (Allen et al. 2006). For instance, in Abreu and Brunnermeier (2003) fully rational traders know that the bubble will eventually burst, but in the meantime generate profits by riding it. They cannot individually bring down the price for lack of sufficient funds, but collectively can if they act in tandem. They all know that a common arbitrage opportunity exists, yet they are uncertain when other traders will begin to act on it. Thus each trader has to determine the right time to exit the market without knowing the exit strategies of other traders, and the varied opinions about the right time to exit cause the bubble to persist. In this setting, some news events can have a disproportionately strong effect beyond what their intrinsic information value would warrant by having the effect of causing traders to synchronize their exit strategies, and thus lead to a precipitous fall in price.

The idea that a bubble bursts only when rational traders' subjective expectations begin to coalesce provides an interesting connection to some of the currency crisis models with self-fulfilling expectations. But the linkages between the new body of work on bubbles by behavioral theorists and international finance so far remain few, despite the rich potential for fruitful connections between the two literatures. Such linkages are made in many economic models (e.g., Allen and Gale 1999; Morris and Shin 1999; Shin 2005), where it is argued that financial liberalization has led to asset price bubbles in numerous countries around the world, and the banking crises that usually accompany currency crises are seen to result from the bursting of the asset price bubble.

■ **capital accumulation in open economies**
Capital accumulation increases the amount of machinery, equipment, and structures available to workers in the economy, thus raising their productivity. Moreover, new capital often embodies technological progress. Hence capital accumulation can be viewed as the most direct way of raising the standard of living.

An open economy enjoys opportunities for capital accumulation that are not available in the absence of international transactions. For one, it does not have to produce all the equipment employed in that country. Importing capital equipment allows a country to take advantage of international specialization in the manufacture of capital goods. For example, East and Southeast Asia produce the bulk of semiconductors and computers, while North America and Europe make most of the airplanes. More generally, a country does not have to specialize in capital goods at all, as trade gives it opportunities to acquire machinery and equipment in exchange for commodities or consumption goods. China is perhaps the most prominent current example of the latter case. Although some researchers have suggested that specialization according to comparative advantage in, say, agriculture, may deprive an economy of the benefits associated with learning by doing, it should be noted that importing capital goods gives a country access to sophisticated technologies, helping it to advance its own technological frontier and learn by imitation.

In addition to the classical static gains from trade, opportunities for trade over time are also important. In a closed economy capital goods have to be manufactured domestically, and resources for their production have to be diverted from other uses, in particular from making consumption goods. This constraint is relaxed in an open economy, where first, capital goods can be purchased from abroad, and second, current consumption does not necessarily have to be sacrificed to make room for investment, since foreign borrowing can partially finance both.

Canonical View Traditionally, the relaxation of the intertemporal budget constraint has been viewed as a great benefit of openness. This is particularly true of emerging markets. A prototypical emerging market country is one where current output per worker is relatively low because there is not enough capital. The diminishing marginal productivity of capital means that if such a country has access to the same technology as industrial countries, the rates of return on investment in the emerging market will be high. The country will be poised for growth, but it faces a dilemma. On the one hand, investment today would raise productivity and therefore the standard of living tomorrow. On the other hand, impatience and intergenerational equity considerations create pressures to bring some of that future prosperity into the present, generating high consumption demand today. Since both consumption and investment goods

have to be produced from current resources, however, it is impossible to manufacture more of both, and hard choices have to be made.

The trade-off is much less stark in an open economy. Either consumption or investment goods or both can be imported. Moreover, the total value of everything that the country produces does not have to equal the value of its absorption (the sum of consumption and investment), as long as the country can finance its trade deficit by borrowing or selling its assets abroad. Of course, debts have to be serviced, and opportunities offered by openness are not unlimited. What happens is that the autarkic requirement that domestic output equal absorption at every point in time is replaced with just one intertemporal constraint that the present discounted value of output equal that of absorption. Hence when new investment opportunities arise and the future looks bright, it is possible to increase both investment and consumption, thus laying the foundation of future prosperity and at the same time enjoying some of its fruits in the present.

Foreign financing of trade deficits can take many forms, all of which, being manifestations of intertemporal trade, involve a gain today for a loss tomorrow. The country's residents can take out foreign loans. They can also sell bonds or shares in their enterprises to foreign portfolio investors. A form of foreign financing particularly important for capital accumulation is foreign direct investment, whereby a foreign investor either builds a new plant in the host country or purchases a substantial enough share in a host country enterprise to participate in its management. In any case, some degree of openness in the capital account is required to realize this benefit, which relies on exchanging not only different goods, but also goods delivered at different points in time and thus can be viewed as a generalization of gains from trade.

Of course, intertemporal trade requires the existence of willing partners. In the canonical view, the counterparts of capital-hungry emerging market countries are advanced economies, where capital-labor ratios are high and, because of diminishing returns, the marginal product of capital may be low. These countries (Japan being one example) may not have enough profitable investment opportunities at home, and they may seek opportunities for investment abroad, particularly as aging residents of these countries save for retirement.

To recapitulate, in the canonical view, when a low-income country has in place conditions for high return on investment and rapid growth and opens up to international trade and capital flows, it will experience an investment boom while also increasing consumption. This is possible because the country is able to finance the resulting trade deficit by borrowing abroad or selling its assets to foreigners. Over time, as its productivity catches up with that in advanced countries and returns to investment decline, its growth decelerates, and trade surpluses replace trade deficits. This description fits broadly the experiences of many countries that experienced rapid growth, including Japan and continental Europe after World War II, South Korea from the mid-1960s through the mid-1980s, and the Central European economies during postcommunism transition.

Dynamics of Growth and Capital Accumulation in an Open Economy Abstracting from technological progress, the rate of growth of output per worker is determined by the pace of "capital deepening," or increases in capital per worker. In a closed economy, that rate depends on available investment opportunities and the residents' preferences regarding the choice between investing and consuming their income. Capital accumulation is gradual, and the standard of living, measured by consumption per capita, converges slowly to a steady-state value determined by available technology. Greater impatience an unwillingness to sacrifice current consumption for the sake of investment implies slower convergence. The presence of technological progress does not alter the essence of this progression, except that the economy converges to a steady-state growth rate rather than a steady-state level of output.

As discussed in the previous section, openness relaxes the budget constraint and could accelerate capital accumulation dramatically. Exactly how much is a contentious question in the open-economy macroeconomic literature. If one extends the classical growth

model the Ramsey-Cass-Koopmans model, where rational, forward-looking households and profit-maximizing firms operate in a perfectly competitive environment to an open-economy setting by assuming free trade and perfect capital mobility, the result will be instantaneous convergence. Perfect capital mobility implies unlimited borrowing at a constant interest rate, so domestic residents will immediately borrow enough money and install enough capital equipment to equalize the domestic rate of return on new investment with that available in the advanced economies they are borrowing from. Assuming they have access to the same technology, output per worker would immediately jump to its steady-state level, equal to that in the most advanced countries. Consumption per capita would permanently remain below the level of advanced countries, reflecting the need to service the debt, but it would also stay constant after a momentary upward transition (or grow at a constant rate in the presence of technological progress).

Needless to say, instantaneous income convergence is not observed in practice. In reality, countries cannot borrow unlimited amounts at a constant interest rate, purchase unlimited amounts of capital equipment, and install it costlessly and instantaneously. Many things get in the way. Borrowing over a certain limit may raise the probability of default or result in too much concentration in the lender's portfolio. Lenders may respond by charging the borrowing country a higher interest rate or by cutting off additional funding. Poor legal systems and the risk of government intervention give rise to doubt about the enforcement of contracts and make lending institutions in advanced economies hesitant to commit overly large sums to emerging market borrowers. Lack of information about local investment opportunities also hinders flows of external finance, and underdeveloped financial systems in emerging markets have a limited capacity to process these flows. In addition, some types of capital, such as buildings, may not be tradable internationally, or at least require some local nontradable inputs, such as construction labor, for their installation. Therefore, if some items in the consumption basket (e.g., services) are also nontradable, the trade-off between

consumption and investment is still relaxed by openness, but less than a model with a single tradable good would imply.

These and other obstacles have been incorporated into open-economy macroeconomic models to moderate the rate of convergence. Details of these frictions and other model assumptions have implications for the evolution of other macroeconomic variables, such as domestic interest rates and the exchange rate. For example, combined with the assumption that production in the tradable sector is more capital intensive than in the nontradable sector, friction in the financial markets such that the interest rate charged on foreign borrowing increases with the amount borrowed in a given period results in gradual convergence of interest rates in emerging and advanced countries and in gradual real exchange rate appreciation in the former, a phenomenon known as the Balassa-Samuelson effect.

Recent Experience The canonical view suggests that capital should flow from advanced countries to emerging markets, where returns are higher. Over the first decade of the 21st century, however, a new pattern has emerged, where trade surpluses in China and some other fast-growing emerging economies are financing trade deficits in a number of advanced economies, most notably the United States. The investment rates are very high in the surplus economies, exceeding 40 percent of gross domestic product (GDP) in China, but national saving is even higher, reflecting the relatively low share of consumption in GDP. While China has attracted a lot of foreign direct investment, it has been purchasing foreign financial assets on a grand scale.

Several explanations have been offered for this reversal of the traditional pattern. Among the factors cited are the relatively weak social safety net in China and some other emerging economies, creating the need for high precautionary private saving; the relatively underdeveloped financial systems in these countries, resulting in the flow of these savings abroad, particularly to the United States, whose innovative financial system has been able to generate attractive assets; and government policy of preventing the exchange rate from appreciating despite the

trade surpluses in order to promote exports and to accumulate international reserves as insurance against external shocks.

The canonical view still holds in many instances. Many advanced economies, for example Germany and Japan, are running current account surpluses, and many emerging market countries, including Central and Eastern European economies and many Latin American economies, are running deficits. High commodity prices, which boost the incomes of many developing countries and reduce their reliance on external finance, may have disrupted the traditional pattern, although this explanation clearly does not pertain to China. On the other hand, the fact that capital does not flow to the poorest developing countries does not really contradict the canonical view, as these countries, for many reasons, do not promise high return on investment despite having little capital.

■ capital controls

Capital controls are public policies that aim to curb or redirect flows of financial assets (e.g., bonds, loans, stocks, and foreign direct investments) across international borders, through taxes or various types of quantity restrictions. Governments use these policies as a means to generate fiscal revenues and for other economic and/or political reasons.

From an economic efficiency perspective, an important economic rationale for capital controls usually revolves around a "second-best" argument, that is, a distortion of the operation of free markets that cannot be eliminated. These distortions may be due to asymmetric information (when the two sides of a transaction do not have access to the same information), externalities (unaccounted for consequences of agents' decisions), financial sector problems, or other market pathologies. In such cases when the distortion cannot easily be eliminated, a policy that would have been clearly inferior to free markets (such as capital controls) can be used to counter the cost of the initial distortion.

The first modern era that was to a large extent free of capital controls and in which international financial markets became highly integrated occurred prior to World War I (1880 1914). During the war, and during most of the interwar period that followed, numerous countries, including all of the major participants in the international economy, relied on the heavy use of capital controls. During the post World War II era of 1945 72, capital controls were also

used, based on a set of agreements signed at Bretton Woods in 1944. This usage was supported by the International Monetary Fund (IMF). Under the Bretton Woods system, fixed exchange rates and capital controls protected countries from destabilizing external shocks. The IMF Articles of Agreement allowed countries to retain capital controls, stipulating that countries could not draw on IMF resources to meet a "large or sustained outflow of capital" (IMF Articles of Agreement, Article VI, Section 1a).

The countermovement, which began with the breakdown of the Bretton Woods system in the 1970s, sought to remove government controls and allow markets to operate freely. Most developed countries removed the bulk of their restrictions on capital flows in the 1970s and 1980s, with the United States removing its main capital controls in 1974. A number of countries in Asia moved in the same direction during this period and were followed in turn by several South American economies at the end of the 1980s. The majority of African and Middle Eastern countries did not progress as far in liberalizing their capital accounts at the time. This process gained momentum in the early 1990s, with many developing countries removing most of their control on international capital flows. In the developing economies, this trend was seen as part of the neoliberal "Washington consensus," a set of liberalizing policies that included the decontrol of foreign direct investment.

The Asian financial crisis of 1997–98 fostered a wave of analyses that sought to determine its causes. Many analysts charged that the Asian countries that were hit the hardest had liberalized their capital accounts prematurely under pressure from the IMF. This criticism gave rise to intense skepticism about the wholesale removal of capital controls. This debate has spawned an extensive literature striving to evaluate the economic impact of the various types of capital controls.

Classifying Restraints on Capital Movements Restraints on capital flows may broadly be divided into those that focus on capital account transactions (*capital controls*) and those that focus on foreign currency transactions (*exchange controls*).

Capital Controls These involve constraining one or more elements of the balance-of-payments capital account. In principle they can cover foreign direct investment (FDI), portfolio investment, borrowing and lending by residents and nonresidents, transactions making use of deposit accounts, and other miscellaneous transactions. Within each of these categories, there may be a wide range of possible controls. For example:

FDI by residents abroad or nonresidents domestically can be directly restricted, or restrictions can influence the repatriation of profits and initial capital, and the structure of ownership.

Portfolio investment restrictions can take the form of regulations on the issuance or acquisition of securities by residents overseas or by nonresidents domestically. Limitations on the repatriation of dividends and capital gains and transfers of funds between residents and nonresidents may also exist, as may "market-oriented" tax measures.

Regulations on external debt transactions largely take the form of ceilings or taxes on external debt accumulation by residents and firms (financial and nonfinancial institutions). Special exemptions are often provided in the case of trade-oriented enterprises or on a case-by-case basis, as determined by the regulatory authorities.

Restrictions on deposit accounts may be imposed on foreign currency deposits held locally by residents and nonresidents, or deposits held in local currency by residents abroad or by nonresidents overseas or locally.

Other capital controls entail restrictions on real estate, emigration allowances, and other forms of capital transfers.

Some Key Distinctions Mechanisms for seeking to restrain international capital flows may be applied on a *selective* or *comprehensive* basis; they can be based on *outflows* or *inflows*; they can be either *temporary* or *permanent*; and they can focus on direct *quantitative* controls or on using the *price mechanism* via explicit or implicit taxation.

Selective versus Comprehensive Curbs on capital movements may be more or less extensive. At one end of the range, the capital account could be virtually inconvertible (i.e., comprehensive capital controls). India and China are notable examples in Asia. This being said, it is more typical for a country to impose controls selectively, on one or more items within the capital account. Of the 155 countries surveyed in an IMF study, 119 were reported to have imposed some type of restrictions on certain capital account transactions (Ariyoshi et al. 2000). Of the 119 countries with some controls, 67 were reported to use comprehensive controls. The distinction between selective and comprehensive controls may not be precise, however. For instance, even India and China have relative freedom in some forms of capital movements (such as FDI). The distinction is therefore more of degree than of kind. A generally illiberal regime, that is, one with comprehensive controls, typically has a "positive list" of exceptions to the controls. A generally liberal regime, that is, one that imposes controls selectively, is likely to have a "negative list" of items to be controlled.

Outflows versus Inflows What is the purpose of restraints on capital outflows? First, restraints can slow the speed of capital outflows when a country is faced with the possibility of a sudden and destabilizing withdrawal of capital during a time of uncertainty. Second, they are supposed to break the link between domestic and foreign interest rates, recognizing that a country cannot maintain a flexible exchange rate regime, monetary policy autonomy, and an open capital account all at once (i.e., "impossible trinity"). Thus, crisis-hit economies could conceivably pursue expansionary monetary and credit policies as a means of growing their way out of debt or a recession without having to worry about possible capital flight and the weakening of the currency.

Controls on capital inflows have become more common since the mid-1990s and are meant to minimize the chances of an abrupt and sharp capital reversal (bust) in the future. These are sometimes referred to as "speed bumps" or "sand in the wheels" of the international financial system. Empirical studies have indicated that capital controls have been more effective at preventing "excessive" capital inflows than at stemming capital flight (Mathieson and Rojas-Suarez 1993).

The most prominent example of these controls is the Chilean *encaje*, implemented between 1991 and 1998. The *encaje* was the requirement that a fixed percentage (initially 20 percent) of any short-term capital inflow be deposited in a non-interest-bearing account at the Chilean Central Bank for at least three years. The *encaje*'s aim was to slow down capital inflows, prevent an appreciation of the Chilean peso, and discourage short-term flows and shift more flows into less destabilizing inflows with longer maturities.

Temporary versus Permanent Restraints Temporary restraints are seen as a deterrent to excessive outflows or inflows during an "extraordinary" period. When a country is facing the possibility of capital flight, for example, temporary restraints give policymakers time to make appropriate changes in economic policy. Conversely, temporary restraints may be imposed when an economy experiences unsustainably large capital inflows, due to excessive confidence in the growth prospects of the economy (i.e., "irrational exuberance").

The rationale behind temporary restraints arises from the fear that such capital surges could lead to a loss of competitiveness through a real exchange rate appreciation (sometimes referred to as the "financial Dutch disease phenomenon") (Calvo et al. 1996). In addition, the literature on optimal sequencing of economic liberalization has emphasized the need to reform the financial sector in conjunction with putting in place adequate prudential regulation so as to limit the possibility of systemic risks, before attempting to decontrol capital account transactions. As such, temporary controls may allow reforms to be phased (for instance, see Eichengreen et al. 1999).

Permanent controls are seen as necessary even during "normal" times. The rationale here is that even if all the microeconomic distortions are eliminated and macroeconomic policies are generally sound, certain inherent market failures will cause suboptimal decisions to be made in a decentralized

and free market economy. Insofar as these market failures are prevalent in a laissez-faire economy, they may provide a rationale for permanent, rather than event-specific or transitory, capital restraints.

Direct/Administrative versus Market/Price-Based Restraints Restraints can either directly control market movements or they can be a market-based mechanism that alters the structure of price incentives market participants face, thereby inducing them to modify their behavior. Direct controls can generate such problems as bribery and corruption, high enforcement costs, and the inevitable creation of a black market. These drawbacks have generally led economists to prefer cost-based levies, which also may generate tariff revenues, over quantitative restrictions.

Exchange Controls Exchange controls regulate the rights of residents to use foreign currencies and hold offshore or onshore foreign currency deposits. They also regulate the rights of nonresidents to hold domestic currency deposits onshore. In addition, they may be defined to include taxes on currency transactions and multiple exchange rate practices that are aimed at influencing the volume and composition of foreign currency transactions. Exchange controls are not necessarily aimed at restricting capital flows; they are occasionally intended only to restrict the current account (trade in goods and services). Yet, strictly speaking, currencies are simply another type of financial asset, and therefore these controls amount to restrictions on trade in assets. Furthermore, whatever their original intention, exchange controls generally have a significant impact on the capital account.

Data on Capital Controls The primary source for internationally comparable data on capital controls is the IMF *Annual Report on Exchange Arrangements and Exchange Restrictions* (AREAER). The publication contains a detailed description of the legal framework that governs the capital account and is published annually, providing data relating to a large number of countries. Prior to 1996 the IMF reported only whether the country had imposed restrictions; after 1996 the publication includes a much more detailed description of the legal regime governing the capital account.

A number of researchers have devised various numerical indicators of the degree of capital account openness/controls, using the IMF AREAER dataset in addition to primary country sources (e.g., Miniane 2004; Edwards 2006). Several researchers alternatively focus on stock markets and detail various aspects of their actual or de jure state, such as when stock markets are open to trading by foreigners, or when domestic companies are allowed to cross-list abroad (e.g., Henry 2003; Edison and Warnock 2003; Bekaert et al. 2005).

This research agenda is still in its infancy, with little agreement among researchers on the appropriate measures and wide agreement on their respective drawbacks. As data quality improves economists should be better able to analyze and distinguish among the effects of various types of controls.

■ capital flight

Today's world economy is characterized by large movements of capital across countries and regions. Cross-border financial movements include legal transactions that are duly recorded in national ac counts as well as the illicit smuggling of capital re ferred to as *capital flight*. Capital flight is the residual difference between capital inflows and recorded foreign-exchange outflows. Capital inflows consist of net external borrowing plus net foreign direct in vestment. Recorded foreign-exchange outflows comprise the current account deficit and net addi tions to reserves and related items. The difference between the two constitutes the measure of capital flight (Erbe 1985).

Measuring Capital Flight Capital flight (KF) for a country in a given year is calculated as:

$$KF = \Delta DEBT + FDI - (CA + \Delta RES)$$

where $\Delta DEBT$ is the change in total external debt outstanding, FDI is net direct foreign investment, CA is the current account deficit, and ΔRES is net additions to the stock of foreign reserves.

A number of refinements are made to the capital flight formula to obtain a measure of capital flight to take into account the various channels and factors that affect capital flight. First, as countries' debts are denominated in various currencies, the reported U.S. dollar value needs to be adjusted to take into account fluctuations in the exchange rates of these currencies against the dollar (Boyce and Ndikumana 2001). Second, trade misinvoicing constitutes an important channel of capital smuggling (Gulati 1987; Lessard and Williamson 1987). Export underinvoicing and import overinvoicing inflate the current account deficit recorded in the balance of payments, while import underinvoicing leads to understatement of the true deficit. Thus the capital flight estimate ob tained using balance of payments trade data is likely either to overstate or understate the actual volume of capital flight. The refined measure of capital flight is the following:

$$KF = \Delta ADJDEBT + FDI \\ - (CA + \Delta RES) + MISINV$$

where *ADJDEBT* is debt flows adjusted for exchange rate fluctuations and *MISINV* is net trade misinvoicing. Additionally, a measure of the opportunity cost of capital flight or the losses incurred by the country through capital flight is obtained by imputing interest earnings on capital that left the country in early years.

Significance of Capital Flight from Developing Countries The problem of capital flight from developing countries deserves serious attention for several reasons. First, capital flight reduces domestic investment directly by reducing the volume of savings channeled through the domestic financial system, hence retarding economic growth. Second, capital flight affects the government's budget balance indirectly by reducing the tax base through reduced domestic economic activity. Moreover, capital flight forces the government to increase its borrowing from abroad, which further increases the debt burden and worsens the fiscal balance. Third, capital flight is likely to have pronounced regressive effects on the distribution of wealth. The individuals who engage in capital flight generally are members of a country's economic and political elites. They take advantage of their privileged positions to acquire and channel funds abroad. The negative effects of the resulting shortages of revenue and foreign exchange, however, fall disproportionately on the shoulders of the less wealthy members of society. The regressive impact of capital flight is compounded when financial imbalances result in devaluation of the national currency because those wealthy individuals who hold the external assets are insulated from its negative effects, while the poor enjoy no such cushion. Fourth, capital flight exacerbates the resource gaps faced by developing countries and forces them to incur more debt, which worsens their international position and undermines overall economic performance.

What Causes Capital Flight? The empirical literature has identified a number of factors that are associated with high levels of capital flight (Ndikumana and Boyce 2003; Murinde, Hermes, and Lensink 1996). The single most consistent finding in empirical studies on capital flight is that the annual flows of external borrowing are strongly associated with capital flight. The causal relationship between capital flight and external debt can run both ways: that is, foreign borrowing can cause capital flight, and capital flight can lead to more foreign borrowing. Foreign borrowing causes capital flight by contributing to an increased likelihood of a debt crisis, worsening macroeconomic conditions, and causing a deterioration of the investment climate. This is referred to as *debt-driven capital flight*. Foreign borrowing may provide the resources as well as a motive for channeling private capital abroad, a phenomenon called *debt-fueled capital flight* (Boyce 1992). Capital flight also induces foreign borrowing by draining national foreign-exchange resources and forcing the government to borrow abroad.

Good economic performance, measured in terms of higher economic growth, and stable institutions are associated with lower capital flight. Strong economic growth, for example, is a signal of higher expected returns on domestic investment, which induces further domestic investment and thus reduces capital flight. High and sustained economic growth also gives confidence to domestic investors about the institutional and governance environment of the country, which encourages domestic investment while reducing incentives for capital flight. The political and institutional environment is also an important factor in capital flight. In particular, political instability and high levels of corruption encourage capital flight as savers seek to shield their wealth by investing in foreign assets.

Policy Responses to Capital Flight Private assets held abroad by residents of developing countries include both illicit and legally acquired assets. Different strategies are required to repatriate the two types of assets. Presumably, savers choose to hold legally acquired assets abroad to maximize risk-adjusted returns. These assets will be repatriated as domestic returns rise relative to foreign returns. In order to prevent further transfers of resources abroad and to entice repatriation of legally acquired assets, therefore, governments in developing countries must implement strategies to improve the domestic investment climate.

Illegally acquired assets are held abroad not so much to maximize the returns on assets as to evade the law. Owners of these assets will be enticed by higher domestic returns only if they have guarantees of immunity against prosecution for fraud and penalties for unpaid taxes. Such guarantees, however, would have perverse incentive effects by rewarding malfeasance. Alternatively, these assets could be impounded and repatriated by force. However, the identity of the owners of capital that has been illegally smuggled out of a country can be difficult to obtain from the major financial centers, which have strong customer privacy legislation. In order to recover the proceeds of capital flight, therefore, developing countries will need the cooperation of the international financial centers and their governments.

■ capital flows to developing countries

Since the 1970s, business cycles in many developing countries have been characterized by fluctuations in international capital flows. This has been particularly true for economies integrated into world financial markets. Fluctuations in capital flows lead to variations in the availability of financing (absence or presence of credit rationing) and in length of loans (maturities). This involves short-term volatility, such as the very intense upward movement of spreads (margin over basic interest rate that reflects perceived risk) and the interruption (rationing) of capital flows observed during the Mexican (1994 95), Asian (1997 98), and Russian (1998) crises. They also involve *medium-term* cycles, as the experience of the past few decades (since the last quarter of the 20th century) indicates.

The developing world experienced two full medium-term cycles between 1970 and 2000: a boom of external financing in the 1970s, followed by a major debt crisis, mainly in Latin America, in the 1980s; and a new boom in the 1990s, followed by a sharp reduction in net flows after the Asian and Russian crises of 1997 98. By 2007, international

capital flows to developing countries had recovered, but new sources of potential procyclicality had emerged, particularly related to the explosive growth of derivatives worldwide. Derivatives, at their simplest, allow two parties to agree on a future price for a given asset, for example, a purchase of foreign exchange. Derivative contracts have become increasingly important in developing economies as instruments for firms and others to hedge risk and for international hedge funds and investment banks to speculate. Large parts of these derivative markets are not regulated, nor have existing regulations fully incorporated the risks that derivatives pose in situations of stress, when they can add to systemic risk.

During booms, developing countries that markets view as success stories are almost inevitably drawn into a capital flows boom, inducing private-sector deficits and risky balance sheets (Ffrench-Davis 2001). For example, when Mexico joined both the North American Free Trade Agreement (NAFTA) and the Organisation for Economic Co-operation and Development (OECD) in the 1990s and was seen as a "successful reformer," it initially attracted huge inflows of capital. Even countries with weak macroeconomic fundamentals, such as low current account deficits, may be drawn into the boom, however, and all countries, again with some independence from their fundamentals, will suffer sudden stops of capital flows. There is also widespread evidence that ample private capital flows encourage expansionary macroeconomic policies during booms, such as excessive growth of government spending. Ample private capital flows encourage expansionary responses by individuals (who consume more) and companies (which invest more), as well as by macroeconomic authorities. When capital inflows fall sharply or turn into outflows, consumers, companies, and governments in developing countries have to reduce their spending. Thus unstable external financing distorts incentives that both private agents and authorities face *throughout* the business cycle, inducing a procyclical behavior of economic agents *and* macroeconomic policies (Kaminsky et al. 2004) .

Although procyclicality is inherent in capital markets, domestic financial and capital account liberalization in the developing world, as well as technological developments, such as very rapid communications, have accentuated its effects. A lag in developing adequate prudential regulation and supervision frameworks increases the risks associated with financial liberalization.

The costs of such financial volatility in the developing world in terms of economic growth are high. There is now significant evidence that capital flows have not encouraged growth and rather have increased growth volatility in emerging economies (Prasad et al. 2003). Whatever the efficiency gains from financial market integration, they seem compensated by the negative effects of growth volatility. During and after financial crises, major falls in output, employment, and investment have occurred (Eichengreen 2004). Volatility in financial markets is partly transmitted to developing countries through public-sector accounts, especially through effects of the availability of financing on government spending, and of interest rates on public sector debt service payments. In commodity-dependent developing countries, links between availability of financing and commodity prices reinforce the effects on public sector accounts. The most important effects of capital account fluctuations are on private spending and balance sheets. Capital account cycles, their domestic financial multipliers, and their reflection in asset prices (such as stock markets and property prices) became an important determinant of growth volatility.

Different types of capital flows show different volatility patterns. The higher volatility of short-term capital indicates that reliance on such financing is highly risky (Rodrik and Velasco 2000), whereas the smaller volatility of foreign direct investment (FDI) vis-à-vis all forms of financial flows is considered safer. FDI also can bring valuable benefits related to technology transfers and access to management expertise and to foreign markets. Use of risk management techniques by multinationals, via derivatives, may make FDI in critical moments as volatile as traditional financial flows, however (Griffith-Jones and Dodd 2006).

Countercyclical Prudential Regulation and Supervision Managing countercyclical policies for

developing countries in the current globalized financial world is no easy task. For this, it is essential that international cooperation in the macroeconomic policy area be designed to overcome incentives and constraints. This means that the first role of international financial institutions, from the point of view of developing countries, is to mitigate the procyclical effects of financial markets and open policy space for countercyclical macroeconomic policies, that is, policies that can attenuate the economic cycle, for example, by expanding government spending when the economy is slowing down so as to accelerate recovery and by contracting government spending in boom times, to avoid overheating of the economy. This can be achieved partly by smoothing out boom-bust cycles at the source through regulation.

One of the major problems seems to be the focus of prudential regulation on microeconomic risks and the tendency to underestimate risks that have a clear *macroeconomic* origin (see BIS 2001, chap. 7). For example, in times of rapid economic growth, a portfolio of bank loans may seem very safe; when the economy slows down or goes into recession, however, that same portfolio of bank loans may become highly problematic. This dimension of changing risk through time is not usually sufficiently perceived by individual banks or even by bank regulators. The basic problem in this regard is the inability of individual financial intermediaries to internalize collective risks assumed during boom periods.

Moreover, traditional regulatory tools, including both Basel I and Basel II international standards for bank regulation on capital adequacy, have a procyclical bias. The basic problem is a system in which loan-loss provisions are tied to loan default or to short-term expectations of future loan losses. Precautionary signals may be ineffective in hampering excessive risk-taking during booms, when expectations of loan losses are low, effectively underestimating risks and the counterpart provisions for loan losses. The sharp increase in loan delinquencies during crises reduces financial institutions' capital and, hence, their lending capacity, potentially triggering a credit squeeze; this would reinforce the downswing

in economic activity and asset prices and, thus, the quality of the portfolios of financial intermediaries.

Given the central role all of these processes play in the business cycles of developing countries, and the important influence of banking regulation on credit availability in the modern economy, the crucial issue is to introduce a countercyclical element into prudential regulation and supervision. The major innovation is the Spanish system of forward-looking provisions, introduced in 2000 and later adopted by Portugal and Uruguay. According to this system, provisions are made when loans are disbursed based on the expected ("latent") losses; such latent risks are estimated on the basis of a full business cycle.

Under this system, provisions build up during economic expansions and are drawn on during downturns. Moreover, many regulatory practices aimed at correcting risky practices shift underlying risks to nonfinancial agents (e.g., companies). This is why capital account regulations aimed at avoiding inadequate maturity structure of borrowing in external markets by all domestic agents, and at avoiding currency mismatches in the portfolios of those agents operating in nontradable sectors, may be the best available option (Ocampo 2003). Also, as long as there is no international central bank that could provide unconditional official liquidity in times of crisis, international rules should continue to provide room for the use of capital account regulation by developing countries.

More broadly, the Basel II Accord to regulate banks internationally has a number of problems that require attention: it is complex where it should be simple; it is implicitly procyclical when it should be explicitly countercyclical; and although it is supposed to more accurately align regulatory capital with the risks that banks face, in the case of lending to developing countries it ignores the proven benefits of diversification. In particular, by failing to take account of the benefits of international diversification of portfolios, capital requirements for loans to developing countries will be significantly higher than is justified on the basis of the actual risks attached to such lending. There are thus fears that Basel II creates the risk of a sharp reduction in bank lending to de-

veloping countries, particularly during crises (thus enhancing the stop-go pattern of such lending).

One clear way in which Basel II could be improved to reduce these problems would be to introduce the benefits of diversification. One of the major benefits of investing in developing and emerging economies is their relatively low correlation with mature markets. This has been tested empirically using a wide variety of financial, market, and macro variables. Different simulations that compared estimated losses of portfolios that were diversified across both developed and developing countries with the losses of portfolios in developed countries only indicate that the former were from 19 to 23 percent lower (Griffith-Jones, Segoviano, and Spratt 2002). If risks are measured precisely, this should be reflected in lower capital requirements.

An additional positive effect of taking account of the benefits of diversification is that this makes capital requirements far less procyclical than otherwise. Indeed, if the benefits of diversification are incorporated, simulations show that the variance over time of capital requirements will be significantly smaller than if they are not.

Adequate Official Liquidity for Crises At the country level, central banks have acted for many decades as lenders of last resort, providing liquidity automatically to prevent financial crises and avoid their deepening when they occur. Equivalent international mechanisms are still at an embryonic stage, with International Monetary Fund (IMF) arrangements, as of 2007, providing credit only with policy conditions attached and not automatically (Ocampo 2003). Despite some moderation in this area in the early 2000s, the general trend in IMF financing was toward increased conditionality, even in the face of external shocks, including those that involve financial contagion. Enhanced provision of emergency financing at the international level in response to external shocks is essential to lowering unnecessary reduction of economic growth or recession within a country and to avoiding the spread of crises to other countries.

Between the 1980s and the early 2000s, capital account liberalization and large capital account volatility greatly increased the need for official liquidity

to deal with large reversals in capital flows. There is increasing consensus that many of the crises in emerging markets in the late 1990s and early 2000s have been triggered by self-fulfilling liquidity runs (Hausmann and Velasco 2004). Indeed, capital outflows could be provoked by many factors not related to countries' policies. The enhanced provision of emergency financing in the face of capital account crises is thus important not only to manage crises when they occur but to prevent such crises and to avert contagion (Cordella and Yeyati 2005; Griffith-Jones and Ocampo 2003).

To address this obvious need, the IMF has made efforts to improve its lending policy during capital account crises. In 1997, the Supplemental Reserve Facility was established.

The evidence that even countries with good macroeconomic fundamentals might be subject to sudden stops of external financing also gave broad support to the idea that a precautionary financial arrangement, closer to the lender-of-last-resort functions of central banks, had to be added to existing IMF facilities. In 1999 the IMF introduced the Contingent Credit Line (CCL). The facility was never used and was discontinued in November 2003. Contrary to what was desired, the potential use of the CCL was seen as an announcement of vulnerability that could harm confidence.

After the expiration of the CCL, the IMF explored other ways to achieve its basic objectives. A move in that direction was proposed by the managing director of the IMF and approved by the International Monetary and Financial Committee in April 2006. Interestingly, as the IMF recognized, by offering instant liquidity, a well-designed facility of this sort "would place a ceiling on rollover costs thus avoiding debt crises triggered by unsustainable refinancing rates, much in the same way as central banks operate in their role of lenders of last resort" (IMF 2005). Approval of such a facility within the IMF, however, seems difficult to achieve.

Implications Volatility and contagion in international financial markets increased the incidence of financial crises and growth volatility in the developing world, and reduced policy space to adopt

countercyclical macroeconomic policies. Therefore, a major task of a development-friendly international financial architecture is to mitigate procyclical effects of capital flows and open a debate about countercyclical macroeconomic policies in the developing world. To achieve these objectives, a series of useful policy instruments can be developed, including explicit introduction of countercyclical criteria in the design of prudential regulatory frameworks; designing market mechanisms that better distribute the risk faced by developing countries throughout the business cycle; and better provision of countercyclical official liquidity to deal with external shocks. Such measures would make capital flows better support development.

■ **capital mobility**

Capital mobility refers to the ease with which fi nancial flows can occur across national borders. High capital mobility implies that funds are transferred relatively seamlessly from one country to another. Low capital mobility implies that financial capital does not flow as easily into or out of a particular country, and that there may be barriers hindering the capital flow. In the world of international finance there are many types of financial flows, including foreign direct investment (FDI), portfolio flows, and flows processed through the banking sector. In order to capture the mobility of such a broad range of financial flows, economists use many different ways to measure capital mobility. No single measure will capture all the essential characteristics of capital mobility. The best results are probably obtained by using several measures together. This entry groups

the many types of measures into four main cate gories: arbitrage measures (for debt flows), quantity based measures, measures of equity market integra tion, and regulatory/institutional measures (figure 1).

Arbitrage Measures The first category refers to arbitrage conditions, which involve returns on debt instruments. These are largely embodied in the in terest parity conditions: the covered interest parity (CIP), the uncovered interest parity (UIP), and the real interest parity (RIP). The basic idea behind parity conditions is that in a perfectly integrated fi nancial market, investors will detect any gaps be tween the domestic currency return on a domestic asset and the domestic currency return on a foreign asset and will seek to close that gap. In other words, arbitrage should equalize the prices of identical assets traded in different markets that is, the law of one price holds and participants in the market will behave in such a way as to remove any differences in the exchange rate adjusted returns on assets in dif ferent markets. There are important differences be tween these measures: the CIP is the narrowest of measures; the UIP is a somewhat broader measure; and the RIP is the broadest of arbitrage measures. The arbitrage conditions seek to equate rates of re turns of comparable assets across different markets/ economies. If capital mobility is high, then any dif ferences in (exchange rate adjusted) rates of return will be alleviated through arbitrage in those markets. Hence, high capital mobility implies that the various interest differentials will be low; perfect capital mo bility implies a zero differential; while nonzero dif ferentials suggest that there are barriers to capital flows.

Arbitrage conditions are probably a more appro priate way of measuring integration for certain sec tors, such as banking, than for the whole economy. The perennial problem with using such arbitrage measures, especially in developing economies, is the question of what interest rate to use, and to what extent the available interest rates are comparable across countries.

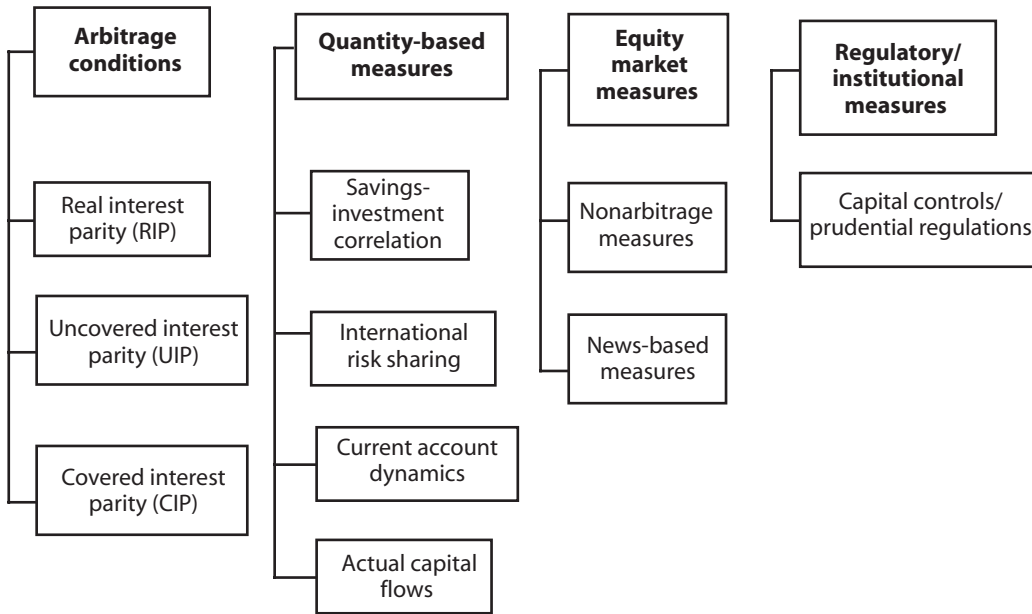
Quantity-Based Measures A growing body of literature has explored quantity-based measures of financial integration. These measures provide an


Figure 1

Categorizing measures of capital mobility: A simple framework

alternative to the traditional arbitrage conditions as a way of measuring capital mobility. Four such measures include savings-investment correlations, consumption correlations, current account dynamics, and actual capital flows.

Savings-Investment Correlations Feldstein and Horioka (1980) pioneered the use of savings-investment correlations as a measure of capital mobility. The argument regarding savings-investment correlations is that in a closed economy, by definition, savings must equal investment (i.e., the correlation between savings and investment should be very high). At the other extreme, with highly integrated capital markets and a single world interest rate, domestic investment should be largely independent of domestic savings since the former can be financed through foreign savings. There are significant empirical and theoretical shortcomings with the Feldstein-Horioka criterion and it remains a controversial measure of financial integration. The so-called Feldstein-Horioka puzzle is discussed in a separate entry.

International Risk Sharing Although savings-investment correlations are the most popular quantity measure of financial integration, a more theoretically elegant measure is examination of consumption patterns within and across economies (Obstfeld 1989). Essentially, agents access capital markets to save or dissave based on how they wish to smooth levels of consumption over time. If two agents in different countries have similar consumption patterns, this implies that they use the same capital markets and that the markets are equally accessible to both. More specifically, a high level of correlation of consumption between two economies is an indication that each country is accessing the same capital market to choose a time path for consumption that is outside the path implied by available domestic resources, thus implying access or openness to international capital flows.

The intuition behind tests of consumption correlations ("international risk sharing") is that financial openness ought to afford individuals the opportunity to smooth consumption over time as they can borrow and lend on international financial markets. Thus consumption in any one country should co-move less with income over time, and if their preferences over consumption are similar, consumption should be correlated across countries.

Conceptually, although consumption-based tests of capital mobility are attractive when attempting to discern whether a region is ready for monetary union (as the degree of business cycle synchronization may be less relevant as long as agents can share consumption risks across borders), they are based on a number of restrictive assumptions that limit their practical usefulness.

Current Account Dynamics A related strand of the literature has focused on current account dynamics and, in particular, whether the current account is stationary (i.e., its mean and variance do not change over time). Simply put, the argument here is that if savings and investment are cointegrated (i.e., a linear combination of the two is stationary), their difference, which is the current account, ought to be stationary (Ghosh 1995). The problem with this line of reasoning is that a finding of stationarity could imply either that an economy is not financially integrated (thus suggesting the existence of a long-run relationship between savings and investment) or that the open capital market is imposing a solvency constraint on the country in the sense that the financial market will penalize a country that is viewed as being profligate by persistently running current account deficits (i.e., spending more than it is producing).

Actual Capital Flows A fourth quantity-based measure of capital mobility is observation of the actual magnitude of capital flows (FDI, portfolio flows, bank flows). All other things being equal, the higher the levels of capital inflows and outflows, the greater the level of capital market integration. Although examination of cross-border capital flows is useful in examining the composition of flows, insofar as there is no yardstick by which to gauge high versus low capital mobility, it tends to be of limited use as a measure of financial integration.

Measures of Equity Market Integration Another measure of the integration of international capital markets involves examining equity market returns. This measure essentially refers to those nonarbitrage price-based measures that include stock market correlations (both direct correlations as well as the extent to which risky assets can be priced using the international capital asset pricing model), or news-based measures (i.e., the extent to which interest rates and other financial market variables are affected by common shocks versus country-specific ones).

Papers measuring nonarbitrage measures examine the bivariate properties of the data and how movements in the equity markets in one country influence the series in another country. In general, the methodological applications range from simple correlations and covariances to value-at-risk-based approaches such as Granger causality and variance decompositions for the short-run analysis and vector error correction models and cointegration tests for the long-run scenario. Essentially, these approaches examine the effect of changes in stock markets in major financial centers (the United States, Japan, the United Kingdom, etc.) on local stock markets. In addition, the use of test of asset pricing models has gained popularity. Asset pricing models allow for risk characteristics to be considered when evaluating market data for different countries. The variance of stock returns provides very useful information about the extent of capital mobility, in that a variance that decreases as the international portfolio increases would imply that correlations between markets are low enough for benefits to diversification to be realized. This is evidence against integration between these markets.

The news-based measures tend to be analyzed in a multivariate setting. The objective is to test for the existence of common trends and common sources of variation among a group of markets. A single common trend, for instance, implies a high level of integration. The existence of country-specific sources of variation would imply the opposite.

Regulatory, Institutional, and Other Measures The degree of capital mobility can also be measured by observing the extent to which a country has imposed capital controls. The types of controls that might be in place are numerous, including legislative control over deposit rates, restrictions on capital account transactions such as restrictions on term or currency, regulations relating to the entry and exit of foreign financial services, and exchange controls. An obvious limitation of these measures is the difficulty

of obtaining good proxies to measure such barriers or regulatory impediments that prevent financial integration. A fundamental assumption with all indexes of capital controls is that the removal of capital controls may, in some way, result in a more financially integrated economy. A situation could exist, however, in which a country has very few capital controls and yet is not regarded as being integrated with other economies. This could be due to legal or political factors, cultural variables, business practices, or the economy's simply not having been noticed by others as a potential place to export capital flow that is, it "escaped the radar" of the international financial community.

Going Forward It is generally believed that innovations in communications and market access, including reduction in barriers to capital flows, have increased the extent of international capital mobility worldwide. Obtaining empirical evidence of this is difficult, however. There is no single measure of capital mobility. Each measure offers only a partial indication of the extent of integration. Given the multiplicity of definitions of capital mobility, an important area for future research would be to develop a multivariate methodology to reduce the multidimensionality of the concept of capital mobility to an operational univariate measure. It is equally important to undertake more detailed studies on the legal, institutional, and other barriers that hinder the free movement of cross-border capital.

■ carry trade

The term *carry trade*, or *currency carry trade*, refers to trades in which funds are borrowed in a relatively low-yielding currency to invest in a higher-yielding currency. In the process, a "short" position is established in the low-yielding currency and a "long" position is created in the other currency. The degree of leverage depends on the amount of capital (or the required margins) put up against the borrowing in the relatively low-yielding currency. The borrower benefits not only from the difference in yields but, more important, from any favorable change in the exchange rate. In principle, carry trades can take place between any assets that offer different expected rates of return. This entry covers carry trades in currencies.

The considerable recent attention paid to carry trades reflects the judgment of some market analysts that these trades can significantly influence exchange rate dynamics. Surprisingly, however, there is little quantitative evidence on their importance. This, in large measure, reflects the opaqueness of the over-the-counter (OTC) markets in which the bulk of currency trading takes place, along with the difficulties of identifying the size of such trades from balance of payments data. Much of the evidence on carry trades tends to be anecdotal and based on the assessments of currency market analysts or participants.

The possibility of systematically earning higher-than-normal returns from carry trades is closely linked to whether foreign exchange markets are informationally efficient. In an efficient market, such trades would not be expected to systematically produce above-average returns (adjusted for risk), and any abnormal returns would be a matter of chance. Either because foreign exchange markets are not informationally efficient or on account of differences in view about the appropriate underlying equilibrium model of returns, the carry trade literature assumes that market players seek to systematically earn superior returns.

Market Efficiency The *informational efficiency* of financial markets refers to whether asset prices fully reflect all available information. The concepts of informational efficiency and rational expectations are closely related, and the term *rational expectations* is also used to characterize situations in which expectations (and markets) are informationally efficient.

Since the move toward generalized floating in the early 1970s there has been an extraordinary amount of empirical work on the efficiency of major foreign exchange markets. For the most part, the work has not been successful in unambiguously determining whether major foreign exchange markets are informationally efficient. Largely because efficiency tests are joint tests of both informational efficiency and an assumed underlying model of equilibrium returns, statistical findings invariably are open to different interpretations. As applied to the foreign exchange market, a common assumption in many tests has been that interest-earning assets denominated in different currencies are perfect substitutes and carry

the same expected rate of return (uncovered interest rate parity). Based on this assumption together with the assumption of covered interest rate parity, which allows the forward rate to be used as a proxy for the unobserved expected future spot rate many early tests considered whether forward exchange rates were biased predictors of future spot exchange rates (see equation [1]) or whether the difference between the realized spot rate and the lagged forward rate could be predicted on the basis of the available information set $I(t)$ (see equation [2]).

Under the null hypothesis of market efficiency, the parameter α in equation (1) should be equal to zero and the parameter β equal to unity, while the error term should be white noise. Alternatively, informational efficiency can be considered with relation to equations such as (2) where depending on the assumed content of the information set $I(t)$ the market is either weakly or strongly efficient when $\Gamma = 0$ and the error term is white noise. Here lower case s and f refer to the natural logarithms of the spot and forward rates, respectively, $I(t)$ is the information set at time t, υ and η are error terms, and Δ is the first difference operator. The term $f(t, k)$ refers to the period t forward rate for period k.

$$\Delta s(t + k, k) = \alpha + \beta(f(t, k) \\ - s(t)) + v(t + k) \qquad (1)$$
$$s(t + k) - f(t, k) = \Gamma I(t) + \eta(t + k) \qquad (2)$$

Almost without exception, tests based on equations such as (1) and (2) have rejected the informational efficiency of foreign exchange markets under the maintained assumption of interest rate parity. In particular, a relatively robust finding across many major currencies and time periods sometimes referred as to the negative forward bias puzzle is that β in equation (1) is closer to negative unity than to positive unity as implied under efficiency. In addition, it is not uncommon for available information including lagged values of forward and spot exchange rates to be found useful in helping predict the difference between forward and spot exchange rates in equations such as (2). In short, forward premiums appear to be biased predictors of future exchange rate changes and forecast errors tend to be predictable.

These findings are open to a number of different interpretations with regard to whether it is informational efficiency or uncovered interest rate parity that is rejected. Hence the underlying equilibrium model of returns is not conclusive. This issue has not been resolved, but recent tests of efficiency have increasingly moved beyond the assumption of uncovered interest rate parity to incorporate both constant and time-varying risk premiums. In addition, a number of studies have used survey data to measure exchange rate expectations in place of forward rate data.

Carry Trades and Exchange Rate Regimes The extent to which large carry trades can be built up is likely to be influenced importantly by the exchange rate regime. Under a pure floating regime, uniformity in exchange rate expectations across agents would be expected to exclude the possibility of a very large buildup in carry positions. Negative sentiment toward a currency would be expected under floating rates to be reflected relatively quickly in adjustments in interest rates and exchange rates as individuals sought to build up their short-long currency positions. As a result, risk-adjusted expected returns on assets denominated in different currencies would tend to be equalized. Any substantial buildup in carry positions under flexible exchange rates could arise when agents hold very different exchange rate expectations or there are differences in risk appetites. In such circumstances, one individual's "long" carry position on a currency would be matched by an equal and offsetting position on the part of other individuals.

When there is substantial exchange market intervention and sterilization, the emergence of large carry positions seems more plausible. Such positions would represent bets of the private sector vis-à-vis the official sector about the future time path of the exchange rate. The positions would be facilitated by the official sector intervening in the foreign exchange market and providing increased supplies of the currency in which the private sector sought to go "long." Of particular interest in this latter connection are situations in which the buildup in "long" positions in a currency is matched by the authorities' sterilization of their exchange market interventions. In these cases, the long carry position of the private sector would effectively be matched by the authorities assuming the short position in the currency.

Carry Trades and Asia Notwithstanding the large amount of attention paid to carry trades, the evidence of their importance in particular episodes is largely in the eye of the beholder. In analyzing the 1997 98 Asian financial crisis, international organizations such as the International Monetary Fund took the view (based largely on market intelligence) that carry trades had been important determinants of exchange market dynamics. Spurred by sterilized intervention that led to interest rates in many Asian emerging markets remaining well above those in the United States and Japan even as currencies were expected to appreciate, carry trades were seen as contributing importantly to the surge in short-term capital flows to the region before the crisis. Subsequently, the unwinding of these trades during the 1997 98 crisis was seen as contributing to significant downward pressure on many regional currencies. No attempt was made, however, to quantify the importance of these trades.

More recently, many market analysts expressed concern about a possible disorderly appreciation of the Japanese yen during 2006 related to a possible earlier buildup of large carry trades that had been funded in yen during the period when short-term interest rates in Japan were effectively zero. As the Bank of Japan began to raise interest rates in 2006, the possibility that these trades might be unwound led to concerns that the Japanese yen would appreciate sharply. In the event, the yen continued to remain weak even as short-term interest rates in Japan were increased modestly during the first half of 2006. Subsequently, there has been debate among private sector financial analysts as to how large the buildup in yen-funded carry trades during the zero interest-rate period had been and whether its importance had been exaggerated.

Carry trades can be viewed as one of a large number of ways in which individuals can speculate on currency movements. The absence of data on the quantitative significance of carry trades precludes a systematic evaluation of their potential importance, but many market analysts regard them as potentially

important influences on exchange markets dynamics during particular episodes.

CHARLES ADAMS

■ **Central American Common Market (CACM)**
The Central American Common Market (CACM) was established by the General Treaty of Central American Economic Integration signed on December 13, 1960, by Guatemala, Honduras, El Salvador,

and Nicaragua. Costa Rica joined on July 23, 1962. The treaty was the principal economic component of a series of measures adopted during the 1950s and early 1960s that were designed to facilitate the political and economic integration of the five nations of the Central American isthmus. The General Treaty also created two regional institutions: the Secretariat for Regional Economic Integration and the Central American Bank for Economic Integration. The political component of this integration process was to be carried out through the Organization of Central American States (ODECA), which was formed on October 14, 1951.

Integration Efforts in the 1950s and 1960s The notion of a unified isthmus has a long history in Central America. It dates back at least to 1821 and the formation of the Federation of Central American States shortly after the region's independence from Spain. The federation lasted only 15 years, but the ideal of unification continued to prevail throughout the next century and finally led to concrete unification measures in the 1950s. During this period, regional integration was driven in part by the example of the European Community and by the views of economists at the UN Economic Commission for Latin America (ECLA). According to their import-substitution industrialization (ISI) strategy, poor nations should eschew international trade and turn inward by closing their internal market to foreign products. The resulting boost to their domestic industry would lead to higher living standards. Since the ISI strategy does depend on the size of internal markets, however, ECLA economists believed that the strategy would be more effective in the region if the five nations formed a free trade area that expanded the market size for local firms but still protected them from international competition. Prompted by these ideas, the five nations signed the Multilateral Treaty on Free Trade and Economic Integration in Central America on June 10, 1958. That same day, they also signed the Regime for Central American Integration Industries (RII), which permitted member countries to identify firms that due to economies of scale would be granted monopoly right to supply the entire region. To

ensure balanced development, each nation would be allocated an equal number of these industries.

The ECLA approach led to opposition from the United States and other groups concerned with its protectionist bent. Responding to this pressure, the five nations reached a new agreement the General Treaty that altered the direction of the proposed common market from one focused on protection to one intended to be more encouraging of trade. For instance, whereas the Multilateral Treaty required that products eligible for free trade intraregionally be listed within the treaty, the General Treaty freed all products unless specifically exempted and identified by the treaty.

By most criteria, the CACM was considered a dramatic success, especially during its first decade of operation. According to Bulmer-Thomas (1998, 314 16), the elimination of duties on intraregional trade and the creation of a common external tariff (CET) was done rapidly and efficiently: 74 percent of goods listed on the tariff schedule traded freely immediately on the General Treaty's entry into force and, by the end of 1966, 94 percent of all listed products were assessed no duty when trading intraregionally. In addition, by 1967, 90 percent of traded goods were covered by the CET. As a consequence, intraregional trade expanded by a factor of nine, from $31.3 million in 1960 to $285.2 million in 1970, and the share of intraregional trade as a percentage of total exports rose from 7.0 percent in 1960 to 26 percent in 1970. For more details see Bulmer-Thomas (1998, table 1).

Despite these successes, deficiencies in the integration model soon became evident. The General Treaty was biased toward freeing up intraregional trade in consumer goods manufactured regionally and left in place barriers to intraregional agricultural trade. This contributed to sizable intraregional trade imbalances among the less-developed members such as Honduras and Nicaragua, which had small or nonexistent manufacturing sectors. It also led to sizable trade diversion as third-country manufactured consumer goods, which faced high protectionist CETs, were replaced by more expensive, lower-quality regional goods. Yet the mechanisms

established to address imbalances were either incapable of reaching a consensus or nonexistent. For instance, the RII was suspended when Costa Rica permitted the establishment of a tire factory to compete with an integration industry already operating in Guatemala. Finally, since the structure of the regional agreement still maintained elements of the ISI model, tariff revenues fell sharply as a percentage of total government revenues. Not only did consumer goods trade duty-free, since they were manufactured regionally, but also imports of intermediate and capital goods from outside the region entered duty-free to avoid harming these regional manufactures. To address this problem, the five nations agreed to a 30 percent increase in the CET under the San Jose Protocol of 1968.

Finally, regional integration collapsed when a dispute over the attempted expulsion by Honduras of Salvadoran immigrants during the summer of 1969 led to a four-day war between the two neighbors and the eventual withdrawal of Honduras from the CACM in December 1970. Relations between the two nations would remain suspended for a decade.

A Revival of Integration Efforts in the 1990s As a by-product of efforts to restore peace to Central America, the Central American presidents' meeting in Antigua, Guatemala, in 1990 called for reviving the integration process. In response, the five nations, including Panama as a new member, signed the Tegucigalpa Protocol to the ODECA Charter on September 13, 1991. The protocol amended the existing integration framework and established a new institution, the System of Central American Integration (SICA), which was to oversee the integration process. As an umbrella institution, SICA oversaw 4 thematic areas (economic, political, social, and environmental) and incorporated 27 other regional institutions, more than 200 treaties or protocols existing among the member nations, and 3 regional bodies: the Central American Court of Justice, the Central American Parliaments, and the Secretary General of SICA.

It is worth underscoring that the protocol called for the creation of an economic union and the positioning of the region within the global economy.

This was one of a number of important indicators that views within the region regarding the appropriate development model had shifted dramatically. The integration efforts were now to be guided by an export-led development model whose orientation was outward, as opposed to the inward-oriented, import-substitution framework that dominated the views of the early architects of the CACM. Regionalism was now to be open, not closed. Moreover, several of the member countries had adopted a neoliberal trade strategy that focused on lowering tariffs, eliminating quantitative trade barriers, and employing more market-friendly measures.

The next important step in the revival of economic integration was taken on October 29, 1993, when the six member nations of SICA signed the Guatemala Protocol to the General Treaty. This protocol focused on economic integration and committed the six nations to the formation of a customs union.

Since these steps were taken, the momentum toward integration has ebbed and flowed, buffeted by a host of factors internal (such as the election of presidential candidates opposed to further integration) and external to the region. For instance, Hurricane Mitch in 1998 dampened enthusiasm for integration, the prices of the region's commodity exports deteriorated sharply, and SICA was confronted with a severe funding crisis.

Nonetheless some progress has occurred and the enthusiasm for integration appeared to be on the rise by about 2005. By early 2007, all but a handful of regional goods traded freely within the region and, according to data provided by SICA, 94 percent (5,846 out of 6,198) of the products in the tariff schedule had been harmonized into a CET. Additionally, the CET was far less protectionist than during the earlier integration period and was applied as follows: 0 percent to capital goods and raw materials produced outside the region, 5 percent to raw materials produced regionally, 10 percent to intermediate goods produced regionally, and 15 percent to final goods. Moreover, the recent implementation of the Central American–Dominican Republic Free Trade Agreement (CAFTA-DR), which establishes a free trade area (FTA) that includes the United States, the five Central American countries, and the Dominican Republic, has great potential for deepening the region's integration.

Following a comprehensive comparison of the FTA with existing integration instruments, Gonzalez (2005) concludes that among the most important features of the new FTA is that the Central American countries opted to make its requirements apply in a plurilateral fashion, as opposed to only bilaterally between the United States and each country. This contrasts with the FTA agreements signed earlier by the region with Chile and with Mexico, which were hub-and-spoke in nature. A second important feature identified by Gonzalez is that the FTA agreement sets a "floor" on disciplines in a host of existing areas (e.g., trade in goods) and new areas (e.g., services, investment, intellectual property, dispute settlement, etc.). As a result, the new FTA essentially deepens and updates the regional integration instruments.

■ Central American–Dominican Republic Free Trade Area (CAFTA-DR)

On May 28, 2004, after a year and a half of intense negotiations, the United States and five Central American countries (Costa Rica, El Salvador, Guatemala, Honduras, and Nicaragua) signed the Central American Free Trade Agreement (CAFTA). The Dominican Republic joined the agreement on August 5, 2004, and to reflect this, the acronym was changed to CAFTA-DR. Like other recent free trade agreements (FTAs) signed by the United States, CAFTA-DR is a comprehensive agreement that goes far beyond traditional FTAs. Once fully implemented the agreement will bring about the elimination of barriers to virtually all trade and investment, and each member country will have implemented legal and regulatory reforms designed to protect intellectual property, raise and enforce labor and environmental standards, improve customs administration, and open up government procurement.

By December 2007, the treaty had been implemented between the United States and four countries and implementation with the Dominican Republic was imminent. Costa Rica had yet to submit the treaty to its congress for a vote, but ratification was certain following approval on October 7, 2007 by 51.6 percent of Costa Rican voters of a referendum supporting the treaty.

Challenges and Opportunities For the Central American (CA) countries, the FTA offered an opportunity to enhance their protrade, market-oriented development strategy by locking in the strategy with a trade agreement with the United States, their principal trading partner as well as the world's largest market. In 2004, the United States accounted for 56 percent of the region's exports and 44 percent of the region's imports. The agreement would also secure access on a reciprocal and more permanent basis. Eighty percent of the region's exports to the United States already entered duty free, but under the Caribbean Basin Initiative and General System of Preferences, tariff programs are one way, highly limited, and subject to periodic review and approval by the U.S. Congress.

U.S. policymakers saw an opportunity to improve national security because boosting regional prosperity would strengthen the region's ability to cooperate on security. They also saw an opportunity to pry open global markets for U.S. exporters and investors. The U.S. Trade Representative (USTR) notes that in 2004 the region represented the 2nd largest U.S. export market in Latin America behind Mexico and the 14th largest worldwide, ahead of India, Indonesia, and Russia combined.

The treaty posed two major challenges. First, it had to be perceived as balanced and not one in which the United States used its large economic size to gain the bulk of concessions. In 2004, the six countries had a combined population of about 45 million and a joint gross domestic product (GDP) of $90.7 billion, whereas the U.S. population stood at 294 million and GDP amounted to $11.7 trillion. Second, the treaty needed to balance the beneficial competitive pressures that come from freer trade with a recognition that the burden of adjustment would fall heaviest on the Central American countries since their economies were relatively more closed. Their average rate of protection was estimated to be more than three times that for the United States. Also, a high share of their economy was vulnerable. In 2004, the trade exposure index (the ratio of exports and imports to GDP) ranged from a low of 49.4 percent for Guatemala to a high of 94.3 and 95.8 percent, respectively, for the Dominican Republic and Costa Rica. Yet the Central American countries were least able to counteract the harmful adjustment effects. In 2004, per capita incomes (valued at purchasing power parity, or PPP) ranged from a high of $9,887 for Costa Rica to a low of $2,677 for Nicaragua, whereas the U.S. per capita GDP (valued at PPP) was $39,710.

Agreement Highlights The treaty commits the signatories to the elimination of import tariffs on nearly all goods traded among member countries. The only products exempted from tariff reductions are imports of sugar by the United States, white maize by El Salvador, Guatemala, Honduras, and Nicaragua, and potatoes and onions by Costa Rica.

The majority of products will receive zero-duty status immediately on the treaty's entry into force. According to estimates provided by USTR (2005), nearly 80 percent of U.S. exports of consumer and industrial goods to the region and 50 percent of its agricultural exports will receive immediate duty-free access. The tariffs on the remaining exports of industrial goods would be phased out in 10 years, whereas those facing U.S. agricultural products would be subject to tariff phase-out periods ranging from 5 to 20 years. For regional exporters, nearly 100 percent of their exports to the United States will receive immediate duty-free access, with only 19 products restricted to a 10-year phase-out period.

In addition to the lengthy transition provisions for duty reductions in order to lessen adjustment effects, the treaty permits tariff-rate quotas (TRQs) to be established for sensitive agricultural products. TRQs provide immediate zero-duty access to the quota amount of imports, but above-quota imports are assessed a higher, prohibitive rate. A special temporary safeguard rule was also established to prevent harm to domestic agriculture during the transition.

The United States made two important concessions in terms of market access. First, it agreed to double the region's sugar quota allocation over a 15-year period. Second, it relaxed the rules of origin pertaining to apparel, allowing certain apparel to enter duty-free even if the fabric was not produced in the United States. Eligible textile and apparel imports would also receive duty-free treatment retroactively to January 1, 2004.

In the services area, the treaty commitments go beyond those under the World Trade Organization's General Agreement on Trade in Services. Most industries receive broad market access. United States negotiators were also successful in opening access to sensitive sectors such as the telecommunications and insurance industries in Costa Rica. By late 2007 all that remained was passage of the necessary implementing legislation, considered a virtual certainty given the composition of the legislature. The related investment provision locks in rights for foreign investors that are already recognized in the region, such as the right to national treatment and nondiscrimination, fair compensation for expropriation, free transfer of profits, third-party arbitration, etc. A unique feature of this FTA is that it provides for a tribunal to review decisions by arbitration panels to ensure that foreign investors are not using them to circumvent domestic judiciaries (World Bank 2006).

The treaty includes detailed rules for improvement of customs procedures, enhancing transparency and access to government procurement bidding, and the monitoring and enforcement of labor and the environment standards. Unique aspects of the treaty related to the latter include: (1) establishing the right of citizens to request investigations if they believe environmental laws have been violated, (2) a commitment from the United States to strengthen the region's capacity to monitor labor and environment standards, and (3) the establishment of fines of up to $15 million for each instance of nonenforcement of labor laws.

Several studies have developed estimates of the likely economic effects on member countries of forming CAFTA-DR. Despite differences in techniques and scope, the conclusions are broadly similar. For the United States, they show that the aggregate economywide effect will be positive, but negligible. According to the largest estimate of the economic effects, by Brown et al. (2005), liberalizing trade in goods improves U.S. economic welfare by 0.04 percent of U.S. gross national product (GNP), while liberalization in services adds an additional 0.13 percent of U.S. GNP. The remaining studies, though limited to the effects of removing barriers to trade in goods, project a positive and even smaller impact on the U.S. economy. Two other studies (surveyed in Brown et al. 2005) project an improvement of GDP of 0.02 and 0.01 percent, whereas USITC (2004) obtains a positive impact on

U.S. welfare of $166 million which, when rounded, amounts to 0.00 percent of GDP.

The consequences for the regional economies are projected to be more significant. Brown et al. estimate an increase of 4.4 percent in Central American countries' GNP, whereas the other two studies calculate a rise of 2.4 and 1.5 percent in GDP.

It is important to note that the projections just cited for the Central American countries may be viewed as "minimum" estimates since they do not take into account the likely impact on foreign investment flows. Nor do they take into account the effects of locking in access to the U.S. market and providing a more stable regulatory environment. On the other hand, as underscored by the World Bank (2006), for these gains to be fully realized and spread equitably, the Central American countries will need to make complementary investments in areas such as infrastructure and create programs to assist the most vulnerable groups, that is, the poor, so they "have the means to take full advantage of the new opportunities."

■ child labor

There are an estimated 191 million economically active children ages 5 to 14 in the world today (ILO 2006). This corresponds to 16 percent of this age group. The images that pervade the popular press of children chained in factories, forced into prostitution, or coerced into a country's military do not represent the conditions of most working children around the world. Most working children are at their parents' sides, helping in the family farm or business. A 2000 UNICEF (United Nations Children's Fund) project surveyed working children in 36 developing countries. The data represent more than 120 million children ages 5 to 14. Although nearly 70 percent of children in these countries spend time in some form of economic activity or domestic chores, less than 3 percent work in the formal wage labor market. Most of this wage employment, like most employment overall in the world's poorest economies, is in agriculture.

What Is Child Labor? There is no universally accepted definition of child labor. Some researchers view the phrase as referencing all nonschool, non-

leisure activities of children. Others define "child labor" as referring to activities that harm the child in some sense.

Most quoted estimates of the incidence of child labor come from the International Labor Organization's (ILO) Statistical Information and Monitoring Program on Child Labor (SIMPOC). In their most recent global estimates of child labor, they define child labor as:

- An economically active child under 12 who works 1 or more hours per week;
- An economically active child 14 and under who works at least 14 hours per week or 1 or more hours per week in activities that are classified as a worst form of child labor;
- An economically active child 17 and under who works more than 43 hours per week or 1 or more hours per week in a worst form of child labor.

SIMPOC estimates that there are 218 million child laborers in 2004 under this definition (ILO 2006). This number is larger than the 191 million economically active children ages 5 to 14 because of older children in worst forms of child labor or working intensively.

This reference to *activities classified as a worst form of child labor* refers to activities that are considered either unconditional worst forms of child labor or hazardous work. *Unconditional worst forms of child labor* are activities that ILO convention C182 on the Worst Forms of Child Labor lists as inappropriate for children under 18: forced and bonded labor, prostitution, pornography, illicit activities, soldiering, and child trafficking. Each signatory country of C182 defines a set of industries and occupations that are classified as *hazardous work* and therefore a worst form of child labor. Hazardous work is defined as economic activity that, owing to the nature or circumstance of the work, is harmful to the child. There are an estimated 126 million children in hazardous work worldwide (ILO 2006), and 8.4 million children are involved in unconditional worst forms of child labor, 68 percent of whom are in forced or bonded labor (ILO 2002). A common bonded labor arrangement is when parents are paid an advance on the child's future

labor earnings, and the child is then committed to the employer until the advance is repaid.

The Child Labor Decision Poor families balance the child's potential economic contribution against alternative uses of child time. What is the child's potential economic contribution? Direct wage income paid to working children may be important in some contexts, but wage work is rare. In most contexts, working children's primary economic contribution comes through the help they offer their families. Most often, this help is providing domestic services that free up adult time for income-generating pursuits. When there is a family business or farm, the child and other family members often help, and working in the family business or farm is the most prevalent economic activity of children. The value of the child's economic contribution to family farms and businesses can be large. One recent study from Nepal estimates that children are responsible for nearly 9 percent of gross domestic product (GDP). Even when the net economic contribution of the working child is small, it may be important to the welfare of a poor family.

Schooling is typically viewed as the most important alternative use of a child's time outside of work. The net return to school will depend on how the family values future returns to schooling against the direct costs of schooling. Schooling is not the only alternative use of a child's time outside of work. Leisure and play are important components of how children spend their time and may be critically important for child development. In fact, the early Progressive-era arguments about child labor all focused on the value of leisure and play as reasons why children should not work.

Overall, children are most likely to work when the family's valuation of their net economic contribution is high or the perceived returns on alternative uses of the child's time are low. Empirically, poverty has stood out as a key factor influencing the allocation of children's time. Across countries, roughly three-fourths of differences in the economic activity rates of children can be explained by differences in GDP per capita. Within a country, some of the most compelling evidence is from Vietnam, which cut child labor nearly in half over a five-year period during its

economic boom in the 1990s. A majority of this decline in child labor can be explained by improvements in living standards alone.

It is not clear whether the strong poverty child labor connection that is generally observed reflects something about parental or child preferences, changes in the structure of household production, the weakening of credit constraints, a decline in insurance failures, or increases in the returns to activities outside of work such as schooling. All may play some role, and the importance of these factors should vary depending on country context.

Child Labor and International Trade One frequently hears anecdotes about children working in export industries. It is possible that if high-income countries increase labor demand for unskilled labor in low-income countries through international trade, then trade may increase the net economic contribution available to working children and thereby increase child labor. Also, trade can affect returns to education, prices of consumption goods, opportunities for household specialization, and the availability of substitutes for goods or activities involving children.

The cross-country data suggest that the most important connection between trade and child labor stems from the positive association between trade and family incomes. Child labor is lower in countries that trade more because incomes are higher in those countries. This income-driven positive association between trade and child labor holds when one considers all countries, only low-income countries, only trade between high- and low-income countries, and exports of unskilled labor intensive products from low-income countries (Edmonds and Pavcnik 2006). The cross-country data provide no support for the claim that trade perpetuates high levels of child labor in poor countries.

The microeconomic evidence also emphasizes the importance of the effect of trade on family incomes. When income effects are negligible or transitory, children may work more, as apparently occurred in response to coffee price booms in Nicaragua and Brazil (Kruger 2007). When the income effects are positive and long-lived, children work less even when labor demand has increased, as apparently happened with Vietnam's liberalization of its rice trade (Edmonds and Pavcnik 2005). Thus the microeconomic evidence illustrates both that child labor is primarily a facet of poverty and that ultimately decisions about child labor depend on the family's assessment of the relative value of the child's time in its alternative uses.

The End of Child Labor? There is no universally accepted definition of child labor. There is no consensus about how many of the world's 191 million working children are worse off because of their work. Evaluating whether work harms a child requires understanding what children would do in the absence of work. High-quality schooling is too rarely available as an alternative. Hence, it is not surprising that so many of the world's poor families choose to have their children help their families meet their basic needs. Most child work is not in the formal wage sector. In practice, international trade seems to have little influence on the propensity of children to work aside from trade's impact on living standards in low-income countries. Children will no longer work in today's poor countries when families can say that the returns to the child's time in other activities such as school or play are greater than the family's valuation of the child's potential economic contribution.

■ **commodity chains**

Commodity chain refers to the linked set of processes involved in the design, production, distribution, and consumption of goods and services in the world economy. Many commodity chains are, and have long been, geographically extensive, spanning multiple countries and regions of the world. They are also often organizationally complex, involving multiple firms and economic agents connected to one another by a range of contractual and noncontractual relationships, including ownership ties, joint ventures, subcontracting networks, and strategic alliances. Because of the analytical leverage that the commodity chain construct provides for understanding the organization of global industries and the dynamics of the capitalist world economy, it has attracted considerable interest among social scientists from a range of disciplines. There are several varieties of global chain analysis, but each focuses on the networks linking people, places, and processes to one another across space, and seeks to underscore the importance of these networks as a critical infrastructure of economic globalization.

History of the Concept The term *commodity chain*, first defined by Terrence Hopkins and Immanuel Wallerstein as a "network of labor and production processes whose end result is a finished commodity," originates in world-systems theory. Three features characterize the world-systems tradition of commodity chain research. First, the focus is on how the global division and integration of labor into the world economy has evolved over time. Although some scholars argue that globalization is a relatively novel process facilitated by advances in information technology and transportation, historical reconstruction of commodity chains suggests that trade and production networks have been international in scope since modern capitalism's emergence. Second, the commodity chain concept enables analysis of the distribution of wealth and power in the world system by focusing on the differential returns to various actors linked through particular chains. Some links in a chain tend to be located in core (i.e., developed) countries of the world system, and others in the less-developed zones of the semiperiphery and periphery, although the particular geography of any chain changes over time. Third, the spatial and social configurations of chains are linked to cyclical shifts in the world economy. World-systems theorists contend that during phases of economic contraction, chains tend to shrink in size (as production volumes or the numbers of producers decline) and/or scope (with production becoming more geographically concentrated). During such periods, the degree of vertical integration along the chain also increases (i.e., a greater number of links become consolidated into fewer). The reverse is true for expansionary periods.

The first book in this field, *Commodity Chains and Global Capitalism*, edited by Gary Gereffi and

Miguel Korzeniewicz, appeared in 1994. This volume featured papers presented at an annual conference of the Political Economy of the World-System section of the American Sociological Association. Most of the essays, with the exception of those on the shipbuilding and wheat flour commodity chains during the 16th and 17th centuries, focus on contemporary manufacturing industries and, in particular, on trade and production networks linking developing country exporters to world markets.

In retrospect, the 1994 volume can be seen as having inaugurated a distinct approach to chain analysis, the global commodity chain (GCC) framework, which diverges somewhat from the world-systems research program on commodity chains. The GCC framework was first developed by sociologist Gereffi, who identified four dimensions with respect to which all commodity chains can be analyzed: (1) an input-output structure, describing the process of transforming raw materials and other inputs into final products; (2) a territoriality, or geographical configuration; (3) a governance structure, referring to the processes by which particular players in the chain exert control over others and appropriate and/or distribute the value that is created along the chain; and (4) institutional context, or the "rules of the game" bearing on the organization and operation of the chain.

Over the course of the 1990s, a substantial empirical literature on commodity chains accumulated, featuring studies of products such as cars, computers, clothing, chocolate, and coffee, among others. By the end of that decade, some scholars were beginning to reappraise the original GCC approach. Specifically, they questioned the very description of these networks as *commodity* chains, since the term commodity is generally taken to denote either primary products (e.g., agricultural staples) or basic manufactures (e.g., T-shirts as "commodity" garments). Others criticized the insularity of the GCC approach, noting that there was relatively little exchange between researchers working within Gereffi's paradigm and those who, although similarly interested in the organizational dynamics of the world economy, were using different concepts to describe interfirm networks in global industries. Some argued that a common terminology would foster dialogue and promote a sense of intellectual community among scholars of international trade and production networks. With the aim of selecting a neutral term that would encompass these various network constructs, *global value chain* (GVC) was chosen "because it was perceived as being the most inclusive of the full range of possible chain activities and end products" (Gereffi et al. 2001).

Governance of Global Chains As Gereffi explained in his contribution to *Commodity Chains and Global Capitalism*, the governance structure of a commodity chain is the set of "authority and power relationships that determine how financial, material, and human resources are allocated and flow within the chain." Gereffi proceeded to make what has become a seminal distinction in the GCC literature between "producer-driven commodity chains" (PDCCs) in heavy manufacturing or more capital-intensive industries such as motor vehicles, and "buyer-driven commodity chains" (BDCCs) in light manufacturing industries such as footwear and apparel. While producer-driven industries tend to be characterized by hierarchy (i.e., links in the chain are vertically integrated within the ownership structure of a firm or, in the case of international production, foreign direct investment), network (i.e., nonequity) forms of governance are characteristic of buyer-driven chains.

Gereffi's BDCC construct was a key theoretical innovation because it pointed to the changing role of commercial capital in establishing and managing global production networks. The lead firms of BDCCs, mostly retailers and brand name marketers, are able to exert control over firms involved in their production networks, although they generally have no equity relationship with the manufacturers and/or contractors making goods on their behalf. One of Gereffi's main interests was to show that even chains with more "marketlike" governance structures require coordination, and that these coordinating tasks are assumed by lead firms that determine much of the division of labor along the chain and define the terms on which actors gain access to it. In this sense, the

distinction between PDCCs and BDCCs presented a new twist on the "markets versus hierarchies" formulation elaborated by Oliver Williamson and other contributors to the new institutional economics: lead firms in BDCCs are frequently connected to their suppliers by networks that differ from both arms-length, one-spot transactions (market) and ownership ties (hierarchy). Nevertheless, these networks are generally characterized by a power structure that gives the "buyers" in these chains leverage over other actors.

Although the analytical utility of these ideal types was confirmed by many studies using the PDCC/BDCC constructs as templates for analyzing various industries, the buyer-driven/producer-driven distinction was also faulted for being too narrow or overly abstract. Some critics suggested that these categories did not adequately capture the range of governance forms observed in actual chains. In his analysis of the electronics industry and the relationships between brand-name computer companies such as Dell and Compaq (so-called original equipment manufacturers, or OEMs) and their major component suppliers, Timothy Sturgeon identified a new governance structure, which he termed the *modular network*. Although modular value chains appear similar to BDCCs in the sense that OEMs typically have no equity tie to the companies manufacturing their components, Sturgeon argued that interfirm networks in the electronics industry are also different from the paradigmatic BDCCs characterizing industries such as apparel.

Sturgeon drew on transaction cost economics in elaborating his theory of value chain modularity. The question underlying transaction cost economics is, why are so many economic activities bundled within the firm instead of transacted on the market? For Williamson, the answer hinged largely on asset specificity; transactions are more likely to be internalized in the firm when they require particular, dedicated investments. This is because such investments foster mutual dependence between the actors in an exchange (for example, between buyer and supplier), which creates conditions for opportunistic behavior on the part of one or both parties to the transaction. To mitigate this risk, safeguards that are capable of guarding against malfeasance must be built into the exchange, and this process increases the cost of the transaction. One way to deal with this problem is through hierarchy that is, the acquisition and incorporation of asset-specific suppliers into the boundaries of a vertically integrated firm. But Sturgeon argues that modular value chains represent a different solution to the problem of transaction costs: in these networks, asset specificity remains relatively low because the codification of knowledge in industry standards allows a highly formalized link at the interfirm nexus between OEMs and their main suppliers.

Thus characteristics specific to the electronics industry particularly the development of industry-wide standards permitting a high degree of codification enable lead firms and highly competent "turnkey" suppliers to exchange rich information (such as detailed product or design specifications) without the kind of intense, face-to-face forms of communication associated with the interfirm networks documented by contributors to the "new economic sociology" literature. Economic sociologists, many influenced by Mark Granovetter's seminal statement regarding the embeddedness of economic activity in social life (1985), have tended to emphasize the "relational" feature of interfirm networks that is, their particular value orientation as open-ended and trust-based. Sturgeon's work implicitly contrasts the relational networks described by sociologists such as Granovetter and Uzzi (1977) with the modular networks found in the electronics industry.

Sturgeon's work on value chain modularity challenged the adequacy of the PDCC/BDCC distinction and underscored the need for a more differentiated understanding of governance structures in global chains. This challenge was taken up by Gereffi, Humphrey, and Sturgeon (2005), who developed a formal theory of global value chain governance that aims to explain and predict the way that exchanges at the interfirm boundary are coordinated. The authors propose a continuum of five governance structures that describe the type of transactional linkage connecting firms in a global

value chain. In addition to the poles of market and hierarchy, this continuum contains three distinct types of network linkages: (1) closest to the hierarchy pole is the captive network, which is characterized by a relatively large power differential between the stronger firm (usually the buyer) and the weaker firm (typically the supplier); (2) the relational network, which is in the middle of the continuum and characterized by complex interactions and greater mutual dependence; and (3) the modular network elaborated in Sturgeon's work on the electronics sector, which is closer to the market pole. Gereffi, Humphrey, and Sturgeon identify three independent variables which, they contend, explain a significant portion of the variation in governance structures across chains: the complexity of transactions, the codifiability of information to be exchanged, and the capabilities of the supply base.

Many GCC and GVC scholars focus on the governance dimension because they seek to understand how the dynamics of global chains can be leveraged into development outcomes, such as facilitating the shift of firms to more profitable links in the chain and fostering the creation of skills and competencies that would permit local producers to upgrade to higher-value-added activities within a chain (e.g., moving from assembly subcontracting to integrated manufacturing), or to switch to a new value chain (e.g., moving from apparel to electronics). For this reason, research on global chains has been supported by bodies such as the UN Commission for Latin America and the Caribbean as well as the U.S. Agency for International Development. The influence of the GCC and GVC literatures in the contemporary development field reflects an elective affinity between global chain frameworks, which analyze the way in which particular economic actors are inserted into international trade and production networks, and the paradigm of export-oriented development, which similarly focuses on the incorporation of local firms and workers into global markets. Chain-inspired development research also highlights, if not resolves, perennial units of analysis problems in development theory and policy: To what extent does increasing the participation of firms in global markets and their competitiveness in particular chains benefit local capital and labor? What is the relationship between firm-level upgrading at the micro level and the more macrolevel development of the regional or national economy?

Future Research and Complementary Approaches As analytical frameworks, the GCC and GVC approaches bring to the foreground the organizational dynamics of contemporary capitalism and their implications for local development in today's global economy. Some critics contend, however, that empirical analysis of commodity chains must pay greater attention to the historical and socio-institutional specificity of the contexts in which these networks are formed and operate. Although ideal types such as the producer-driven and buyer-driven constructs are useful abstractions, the study of commodity chains in situ reveals significant variation in the way that trade and production are organized across space and time, even within the same industry, thus reflecting the influence of the broader regulatory and political-economic frameworks which shape the linkages that emerge between places and processes in the world economy. The contingent and variable nature of international trade and production networks is underscored by recent contributions to an emerging subfield of historical research on commodity chains, with scholars describing and analyzing the centuries-old connections between geographically distant producers and consumers that world-systems theorists coined the term *commodity chain* to describe (Topik, Zephyr, and Marichal 2005).

In addition to the commodity chain concept, several related terms and frameworks have also been developed to analyze the geographical dispersion and organizational fragmentation of production in the global economy. These alternative but potentially complementary frameworks, such as global production networks, systems of provision, and the *filière* approach, draw inspiration from intellectual traditions that differ, to a greater or lesser extent, from those orienting GCC and GVC analysis. Furthermore, the GCC and GVC approaches are not identical to each other, as the former draws more from world-systems theory, organizational sociol-

ogy, and the comparative political economy of development, while the latter borrows from the fields of institutional economics and industrial organization. Despite the different methodological and theoretical emphases of these various approaches, greater dialogue among them may facilitate a richer understanding of how international trade and production networks are organized, as well as their implications for a range of economic and developmental outcomes at the global-local nexus. Similarly, commodity chain analysis might be strengthened by dialogue with the New Economic Geography, since the latter's emphasis on spatial and institutional specificity could enrich the former's understanding of the processes by which the organizational dynamics of global industries become manifest in particular locations.

commodity-price pegging

Pegging the price of a broadly defined commodity basket would be an almost perfect means to achieve price stability. An adjustable commodity-based dollar was formally laid out in 1920 by the American economist Irving Fisher, who suggested adjustments in the number of resource units in the dollar to achieve price stability. If prices fell below a specific target by 1 percent, for example, the dollar value of the resource unit would be raised by 1 percent   at the same time automatically lowering the number of resource units in the dollar. But the larger the number of commodities involved, the more difficult it is to assign their relative weights. A single commodity price target would be more feasible than Fisher's system; however, it would be desirable only if this single commodity price were well correlated with the aggregate price level.

The principle that governments should intervene in commodity markets to maintain supplies and stabilize prices was endorsed by Confucius in China during the sixth century B.C., and stabilization of grain prices became an important part of early imperial Chinese policy. Communist anti-inflation policy during and after the Chinese Civil War also involved the buying and selling of surplus stocks. In this case, the state established trading companies to undertake large-scale commodity sales in the cities and bring prices down. Later, these same state trading companies used commodity purchases to offset deflationary pressures in 1950 and 1952. On a smaller scale, President Clinton employed the U.S. Strategic Petroleum Reserve (SPR) in a similar fashion in 1996, ordering the sale of a portion of these reserves in an attempt to combat rapidly rising gasoline prices. The SPR was subsequently tapped for limited interventions by the George W. Bush administration as well.

More recently, the economist Jeffrey Frankel suggested that policymakers in smaller commodity-dependent nations use a more dominant form of commodity-price pegging: specifically, policymakers should undertake monetary expansion whenever they face declining demand for that nation's key commodity (Frankel 2003). Under a pure commodity peg, oil producers would simply tie their monetary policy to the price of oil, expanding when oil prices fall and contracting when oil prices rise. Such a strategy has strong intuitive appeal given that it is almost inevitable that an oil-dependent country will face deflationary pressures if oil prices plunge and inflationary pressures if oil prices surge upward. Less specialized producers might enjoy analogous benefits by fixing the price of a basket of export commodities in terms of local currency. Once a target price range has been set, open market operations involving purchases or sales of foreign exchange or domestic

securities could be used to keep the export price index within the band (Frankel 2005). Even larger economies could gain from a commodity-based strategy, at least in comparison to the more popular alternative of pegging to the U.S. dollar. For example, had Argentina adopted a wheat-peg rather than a dollar-peg during 1991 2001, the Argentine peso would have depreciated instead of appreciating as it did over the latter part of the period (Frankel 2003).

The dollar peg was deflationary for Argentina just as the gold peg was deflationary for the United States and many other countries in the late 19th century and during the Great Depression and the authorities in each case ended up maintaining a fixed single-asset price while almost all other prices declined. Faced with very low interest rates and persistent deflation on a global scale during the Great Depression of the 1930s, a number of economists laid out proposals for a "commodity reserve standard" and intervention that would pull commodity prices up from their depressed levels. Some proponents saw this as an alternative to the old gold standard but others saw intervention in commodity markets as simply a means of achieving the desired expansionary end as in, for example, the U.S. silver purchase program that began in 1934 under President Roosevelt.

Other Commodity-Based Proposals Although economists have argued that government warehousing of the commodities involved would not be necessary (see, e.g., Hall 1982), commodity-based proposals have more often been based on government stocks and direct government intervention in commodity markets. For example, one prominent proposal was for a commodity reserve currency to be established. Under this scheme, Federal Reserve banks would buy warehouse receipts for the chosen commodity units so as to "redeem their liabilities, on demand, in commodity units or gold at the option of the holder" (Graham 1941). The premise that a commodity reserve currency could be adopted as an alternative to the old gold standard received serious consideration in the 1930s and 1940s. Critics have pointed to the impracticality and cost of the proposed commodity-market interventions; the relatively narrow range of suitable standardized com-

modities, as well as high elasticity of supply, could force excessively large fluctuations in the stock of money under such a scheme (Friedman 1951).

Although few economists today would advocate an actual commodity-based monetary standard, commodity-price pegging may nonetheless merit consideration as a possible guide for monetary policy. Targeting commodity prices could provide for quantitative monetary easing in the face of deflation, for example, whereas pure interest-rate pegging soon runs out of room as interest rates cannot be driven below zero. In this case, implementation of commodity-price pegging could help secure an inflation or price-level target or, at the very least, offer a complementary policy goal.

■ Common Agricultural Policy

The Common Agricultural Policy (CAP) of the European Union (EU) is called "common" because the main agricultural policy decisions are made at the EU level, and these agricultural programs are financed for the most part from the EU's common budget. The functioning of the agricultural sectors in the member countries of the EU is widely determined by decisions at the Community level. Consequently, agriculture is perceived as one of the most integrated sectors in the EU and is sometimes viewed as a possible model for other sectors. Although the EU's agriculture sectors are politically integrated, however, they are less integrated economically than other sectors.

The creation of the CAP in 1962 was vital for the European Economic Community (EEC), the forerunner of the EU. The six founding countries Belgium, France, Germany, Luxembourg, the Netherlands, and Italy had their own national agricultural policies, which differed vastly. The individual countries were reluctant to remove their intervention in agricultural markets, or allow for free trade among member countries and to follow the rules of a customs union. It did not make sense to exclude one sector from market integration, however, and politically the stakes were high: France wanted access to the large German market for its agricultural products if it were to allow for German

industrial products to enter the French market. Hence, it became necessary to establish the organizational and institutional framework for agricultural policy at the Community level.

The institutional framework set up at the inception of the CAP was a compromise to satisfy the heterogeneous interests of the member countries. Under German pressure, the EEC decided on a common price level for agricultural products significantly higher than world market levels and introduced border regulations that completely disconnected EEC prices from those on the world market. The evolution of the CAP has proven that this initial framework constrained the CAP in adapting to changing conditions in the EEC and on the world market.

The Features of the CAP at the Time of Inception Common market organizations regulated the CAP for the main agricultural products. These market organizations are Community law and include the legal framework needed to administer the markets. The aim was to keep domestic farm prices above the level of world market prices. Variable levies were implemented as border measures to cover the gap between the domestic farm prices and the corresponding world market prices. The levies varied with the world price since the commonly agreed-upon prices were the lowest prices at which foreign supply was allowed to enter the European domestic market. From the start, the CAP provided for export subsidies in the event that domestic production was to surpass domestic use at domestic prices. The export subsidies were termed "export restitutions." Under the General Agreement on Tariffs and Trade (GATT) and later the World Trade Organization (WTO), export subsidies for industrial products were eliminated and import tariffs rates were bound by a ceiling rate negotiated by member countries. Thus the trading regime for agricultural products remained very different from that of industrial products.

In addition, market organizations included domestic measures of protection. The most important ones were guaranteed purchases by state agencies of selected products such as butter, skimmed milk

powder, grains, and sugar at intervention prices, and facultative purchases for some other products if some additional conditions prevailed. The protection regime for sugar was exceptional as it included intervention prices for sugar, minimum purchase prices for sugar beets, and production quotas. For quantities above their allocated quotas, farmers received the world market price. The sugar market regime was the least in line with free market principles; it was more comparable to instruments used in centrally planned economies.

The Evolution of the CAP The institutional prices were the main instruments of the market regimes that constituted the Community law. The Community law or any changes to the law were generally proposed by the European Commission; in the case of agricultural law the decisions were made by the Council of Ministers, which is composed of agricultural ministers from member countries. The most important decision by the Council of Ministers was to make the agreed changes to the institutional prices. These changes were made annually up to the 1990s. Since no objective criteria guided the setting or changing of institutional prices, political considerations dominated these decisions. National interests diverged widely between member countries, partly because of differences in their national conditions such as inflation, overall growth in the economy, and productivity changes in agriculture. Moreover, the framework that was instituted to finance these policies accentuated the differences in national interests among the member countries. The EU had adapted the principle of financial solidarity, which stipulated that policies implemented at the Community level should be financed from a common budget. As the EU did not generate revenues, the contribution to the common budget came either from the member countries' budgets or from import tariff revenues, that is, member countries would deliberately forgo their own tariff revenue in favor of the Community budget. Not all countries benefited from these policies. For example, the Netherlands was traditionally a huge exporter of dairy products so decisions that resulted in higher dairy prices increased the income of Dutch dairy farmers much

more than it taxed its consumers. For the United Kingdom (UK), which was a huge importer of dairy products, an increase in dairy prices had the reverse effect. Hence, it is understandable that national interests diverged significantly.

The voting procedure made it even more difficult for member countries to come to an agreement. The Treaty of Rome (1957), from which the Community emerged, provided for majority voting for most decisions. The six founding members agreed in 1966, before the first market organization came into existence in 1967/68, to apply unanimity voting whenever there were vital interests at stake for any individual country. Thus agreements could be reached only if member countries for which common policies conflicted with national interests were compensated. The result was that an increase in the domestic price level was decided year after year, even in times where world market prices for agricultural products declined and the exportable surplus of the EU rose. The increase in agricultural protection, the enlargement of the EU, and unprecedented technological progress in EU agriculture contributed to a faster growth in EU agricultural production than consumption. For the Community, which had started as an importer of agricultural products, the changes in supply and demand reduced the import gap gradually over time and by the end of the 1970s generated export surpluses. Increasing exports and falling world market prices put pressure on the EU budget as outlays for export restitutions rose strongly. A new phase of the CAP began with even more governmental interference in the market. The milk market presented the most urgent problem. Milk production in the EU grew strongly as imports of concentrated feed could be imported free of duties due to the GATT. At the inception of the CAP, the EU had set its bound tariffs at zero or a very low level at a time when imports of these products were negligible. In return, the EU was allowed to introduce the variable levy system. The import regulation for concentrated feed became the Achilles' heel of the CAP. Low prices for feed, which were partly due to significant declines in transatlantic transport costs, and high support prices for CAP products, led to high

effective rates of protection for meat and milk and increases of production. On the demand side, imported feed was substituted for domestically produced grain, and because of cheap imports of vegetable oil, margarine was substituted for butter. The consequence was the accumulation of stocks in the EU and accelerating budget outlays. The latter seemed to have been the main constraint for the CAP during this period.

In 1984, the council agreed on a quota system for milk. Farmers received a right to sell under the quota at guaranteed prices. Sales above the quota were taxed with a superlevy, which for many years was higher than the price paid for sales within the quota. Hence, production was curtailed and growth of production was stopped. Moreover, a set-aside program was offered to farmers in 1986. Grain farmers were offered a premium if they voluntarily took arable land out of production.

The first 25 years of the CAP were characterized by increases in border and domestic EU protection for agricultural products. The EU reacted to changes in the economic environment mainly by introducing new instruments to limit budgetary expenditure. The concerns of the trading partners were for the most part neglected.

1992 to 2003 The Uruguay Round (1986 94), the last round under the GATT, focused on agricultural trade. The EU had to reform the CAP in order to comply with the rules of the new round. The council decided to first reform the EU grain market in 1992. For the first time, the CAP prices of specific commodities were cut, some significantly: the council agreed to cut institutional prices for grain by 30 percent. Farmers were compensated entirely for their prospective income loss by direct payments. These payments were linked to the use of land for grain. In addition, farmers would qualify for payments if they set aside at least a politically determined percentage of their land. Although the effect on grain production was minimal, domestically produced grain became competitive against imported concentrated feed and, thus, the grain surplus vanished.

The decision on the grain sector contributed to a final agreement in the Uruguay Round. The agreement required further changes to the CAP, however. The EU's export subsidies were now constrained in two ways:

1. the quantity of well-defined products or product groups that was allowed to be subsidized was reduced by 21 percent (from their 1986–88 level); and
2. the amount of export subsidies had to be cut by 36 percent (from their 1986–88 level).

Moreover, like other GATT/WTO members, the EU had to accept concessions on the import side. Each country was to allow imports of specific products up to 5 percent of domestic consumption in the base period 1986 88; variable levies and other nontariff trade measures had to be converted to tariff equivalents (tariffication), and the tariff equivalents had to be reduced by 36 percent on average from the base period 1986 88, and by at least 15 percent for individual products. Thus, the EU was not allowed to apply the variable levy system anymore and had to take into account changes in world prices when setting domestic institutional prices. It was this international agreement that forced the EU to change its market organizations. Finally the EU reformed the CAP drastically in 2003, aiming at making a positive contribution to the Doha Round of trade negotiations, which was launched in November 2001. One of the reforms was of domestic support. The CAP direct payments were included in the "Blue Box." These are direct payments under production-limiting programs and hence they were exempted from reduction. This concession was given to the EU in return for price cuts and the realization that aid to the farmers was needed during the adjustment period. But the EU would have to give up these exemptions by the end of the Doha Round as adjustment compensations cannot be paid permanently, and the EU would have to look for alternatives for providing aid to farmers.

CAP Reform in 2003 and Thereafter The CAP reform of 2003 was a change in the paradigm of agricultural protection. Previously, support to agri-

culture took the form of price support to output and factors of production; and in the livestock sector, some kind of payments were made by head of animals. This support stimulated production and taxed consumption. Hence trading partners opposed this system and pressed for a change. The council decided in 2003 to reduce price support even more (for the main products from 2004 onward and for some products such as sugar, olive oil, tobacco, and cotton at a later time) and to decouple in principle all types of direct payments. The general proposal of the European Commission combined all income losses due to price cuts made until 2003 and all types of direct payments granted up to 2003 in one type of payment, the Single Farm Payment, to be made to individual farms based on historical levels. Entitlements to farm payments were made tradable and, thus, became decoupled completely from production, at least in principle. But the council allowed member countries a lot of flexibility. For example, countries were allowed to link part of the payments to production or to the use of factors of production during the transition period and to link them again to production in the future if regional or domestic production in a country fell too strongly. Payments could also be linked completely to land, either by granting a flat rate across the country or by differentiating between regions or between arable land and grassland. Finally, some payments were tied to environmental standards that farmers needed to meet, a process known as cross-compliance. Cross-compliance links payments to farmers to their respect of environmental and other requirements (such as animal and plant health and animal welfare) set at EU and national levels.

The 2003 reform also introduced a new classification of the CAP instruments: Pillar I for market and price support measures and Pillar II for rural development. In the reforms, a decline was imposed on Pillar I spending, while Pillar II spending was allowed to go up.

The distinction between the two types of measures may sound economically reasonable, but what justification could there be for increasing Pillar II's budget by about the same amount that Pillar I's decreases, given that in principle the two pillars have different purposes? Rural development should not focus mainly on agriculture. Rural development needs differ across regions and countries and they are not related to past agricultural support, so it is questionable that the changes in budget needs for rural development of each region and country (Pillar II) match widely the reduction made in agricultural support (Pillar I).

Hence critics suspect that Pillar II is a way for policymakers to continue providing support to farmers when they can no longer justify direct payments as adjustment compensation for price cuts that occurred more than a decade earlier. The framework of Pillar II seems suitable for hiding subsidies for agriculture. Pillar II measures require a higher quality of governance than Pillar I measures, but unfortunately, due to the enlargement of the EU from 15 to 25 member countries in 2004, and the further enlargement on the inclusion of Romania and Bulgaria in 2007, the competence to monitor and to enforce Pillar II measures has declined on average. The European Court of Auditors regularly finds irregularities and fraud in Pillar II measures.

The Future of the CAP The CAP has changed significantly over time. Changes have been driven by budgetary concerns rather than economic rationale, however. Up to the 1990s, budget constraints led to reforms, but they resulted in even more protective and trade-distorting policies. Finally, under the GATT/WTO multilateral trade negotiations, the CAP abandoned most of its border protection. Some products such as sugar and milk continue to be highly protected, however. Changes in the EU and other countries' policies and rising oil prices may result in higher world prices and may make further reforms of EU border measures unnecessary. But if these changes do not happen, the EU will need to cut its agricultural prices further in order to comply with the constraints imposed by the WTO.

The role of the CAP has become more important for the world food system over time as the EU has grown from 6 to 27 members as of 2007. The

reduction in the CAP's external rate of protection contributes to less distorted agriculture. Two major concerns remain, however: first, as long as EU prices for food products are not completely linked to world market prices, the CAP does not buffer fluctuations in world market prices to the maximum possible extent. Thus further complete coupling of EU and world market prices is needed. Second, Pillar II of the CAP allows for hidden farm subsidies and causes distortions across EU member countries and worldwide. Hence, Pillar II measures have to be reconsidered and scrutinized with respect to distortive effects.

■ common currency

In the modern world economy, a common currency shared by a number of countries has been a rare phenomenon. At least since the 19th century, the rule has been that independent countries have independent currencies. Territorial currencies were established in the 1815 1914 period, a result of important technical advances such as presses that could mint coins and print notes that were hard to counterfeit combined with economic factors, such as the spread of the monetized economy and the state taking on more functions and casting its revenue net more widely. As new nations such as Italy, Canada, and Germany formed in the second half of the 19th century, they adopted national currencies.

The pattern of one country one currency was reinforced with the decline of empires. Some former colonies were reluctant to discard shared currencies, but after a brief time lag, currencies became national. An example from the 1990s is the rapid introduction of national currencies following the dissolution of Yugoslavia, the USSR, and Czechoslovakia. The 12 Commonwealth of Independent States successors to the USSR recognized the increased transaction costs that would result from abandoning the common currency, but after less than two years the ruble zone had collapsed.

Most currencies are national, where N_m is the number of monies and N_c is the number of countries:

$$N_m \approx N_c \qquad (1)$$

In practice, however, the one country one currency rule is not always the case and sometimes $N_m < N_c$. The exceptions to the rule fall into two categories: carrots and ministates (Pomfret 2005).

Carrots and Ministates The principal examples of currency union driven by carrots (i.e., incentives offered by an interested party) are the CFA franc zone in central and West Africa and the rand zone in

southern Africa. The French Treasury, which acts as a guarantor of the fixed exchange rate, manages the CFA franc zone's reserves and settles the regional central banks' payments and receipts. The zone has existed for more than a half a century because of preferential French aid to zone members and balance of payments (BOP) support. In the rand zone, South Africa has formal arrangements to share seigniorage (i.e., the real resources obtained from printing money which can be spent on goods and services) with the countries in which the rand is legal tender (Lesotho and Namibia), and the South African central bank is prepared to act as lender of last resort in these countries. Similar carrots encouraged retention of the ruble zone in 1992 93, but Russia objected to the size of transfers to other members while some members opposed the political use of the levers. Ultimately, lack of agreement on monetary policy institutions made the ruble zone unstable. In the both the CFA franc zone and the rand zone, by contrast, members accept the institutions imposed by a dominant economic power. Even so, the membership of the CFA franc zone and the rand zone has not been entirely stable. Mali withdrew from the CFA franc zone in 1962 and rejoined in 1984; Mauritania withdrew in 1973; Equatorial Guinea, a former Spanish colony, joined in 1985; and Guinea-Bissau, a former Portuguese colony, joined in 1997. Botswana withdrew from the rand zone in 1976.

Other countries that lack independent currencies or those that participate in a shared currency arrangement are small and often special cases, known as ministates. Between 1970 and 1990, according to Rose (2000, 41), 82 countries were involved in currency unions, 15 of which were in the CFA zone and three in the rand zone. The remaining 64 countries were small economies using the currency of a neighboring or quasi-colonial power or ceding monetary policy control to a larger country. The Eastern Caribbean Currency Area (consisting of eight small island economies), the British Virgin Islands, Bahamas, Barbados, and Belize have tied their currencies' value to the U.S. dollar since 1976. Ireland-UK (pre-1979), Luxembourg-Belgium (pre-euro), and Brunei-Singapore are often described as

currency unions, but the second-named country in each pair had total control over monetary policy. The remainder of the 82 currency union members used another country's money for all or part of the twenty-year period. Most of these are tiny economies, such as Svalbard, Isle of Man, and Norfolk Island. The largest, Liberia, ceased using the U.S. dollar in the 1980s when a new government started issuing first coins and then paper currency. The next largest, Panama, has had a special status with the United States since it was created prior to construction of the Panama Canal.

Historically, some colonies have had separate currencies, although this typically involved large colonies of a kind that no longer exists. The status of some territories is not clear cut, because the ruler, occupier, or guardian is sensitive to the term *colony*, but territories such as Guam (and Panama, to a lesser extent), Northern Cyprus, or Western Sahara have a quasi-colonial relationship with the country whose currency they use. Other currency union members are integral parts of the larger nation. Scotland, for example, is part of the United Kingdom, not a member of a currency union, just as Christmas Island is part of Australia.

Apart from the CFA countries, Lesotho, Namibia, Swaziland, Ireland, Luxembourg, Brunei, Liberia, and Panama, all currency union members identified from 1970 to 1990 were small islands or territories without full sovereign status. An updated version of this list would include another exception: the eurozone. The euro, however, is a unique example of independent nation-states agreeing to use a common currency whose monetary policy is determined by a common institution.

Explaining Currency Domains The theoretical approach to explaining the use of a common currency has been dominated by the optimum currency area (OCA) literature initiated by the economists Robert Mundell and Ronald McKinnon in the early 1960s and continuing to Alberto Alesina and Robert Barro (2002). OCA theory, which emphasizes the trade-off between the macropolicy benefits of an independent currency and the microeconomic benefits from a common currency, is appealing in

principle but has a poor record of explaining the composition of existing currency areas or predicting changes in currency domains.

Independent countries want their own currency because they want to set their own monetary policy. Economic stability is not always a primary concern. Ukraine left the ruble zone in 1992, for example, so that the government could print money to support inefficient producers. In many newly independent countries in all eras, monetary policy independence enabled rulers to finance expenditures. Fixed exchange rate arrangements and currency unions both involve some level of constraint on independent monetary policy, but all exchange rate regimes involve an important element of choice (over instrument and peg) and leave an option of reversal. Fixed exchange rate systems enable countries to make their own macroeconomic policy choices, while a currency union definitively cedes control over monetary policy.

OCA theory takes the position that very small nations, or microstates, cannot afford to have a national currency because the transaction costs would be too high. The threshold for such transaction costs is not so high as to prohibit small countries like Malta or Iceland from having independent currencies, however. Neither are transaction costs the reason for membership in the CFA franc zone and rand zone; these members use common currencies because France and South Africa provide carrots for them to do so, and even then the carrots were insufficient to keep Mauritania in the franc zone or Botswana in the rand zone.

What explains the use of a common currency by independent countries, and especially the case of the euro? The OCA theory does not explain the timing or composition of the euro because it ignores the importance of a common currency for public finance. For governments, seigniorage is a benefit of a national currency, but the benefit tends to be small, especially as cash declines in significance. More important is the need to have a common unit of account for the public finances; the concept of legal tender allows the government to set tax rates, approve expenditures, and similar functions. The use of multiple currencies within one country would undermine political

agreement over the allocation of the central budget. Internal exchange rate changes would reduce the tax burden and increase the relative value of expenditures for the users of one currency over another.

The Adoption of the Euro The emergence of single-currency areas paralleled the consolidation of the nation-state. The major currency unions of the second half of the nineteenth century, including those in Germany, Italy, and Canada, were associated with political unions. In 1990, German monetary union accompanied the reunification of the country. Although debates took place at the time over acceptance of the deutschmark in the former East Germany and the rate at which old Ostmarks would be exchanged, a common budget in common units played a key role in German reunification. The euro, first adopted for noncash transactions in the late 1990s before it became a cash currency, is a 21st-century example of public finance driving adoption of a common currency.

The adoption of the euro was preceded by a lengthy transition period during the existence of the European Monetary System, which began in 1979, and especially after the Maastricht agreement of the early 1990s. The process did not follow the predictions of the OCA theory. Although the EU did become more integrated with more open national economies and greater movement of labor and capital across national borders, the pace of monetary integration did not follow these trends, and in the end, restrictions on capital movements were abolished as a step toward monetary union rather than monetary union being driven by greater factor (e.g., labor or capital) mobility.

How to explain these outcomes? The European Monetary System began operation in 1979, and an important driving force was the difficulty of managing the Common Agricultural Policy based on agreed common prices when exchange rates were market-driven (Pomfret 1991; Basevi and Grassi 1993). The problems of the EU's agricultural policy may be reduced by reform, but any common policies based on political negotiations about financial contributions and monetary benefits will be undermined by changes in bilateral exchange rates. The

more far-reaching the EU's common policies and the larger the EU's common budget became, the more severe the problems associated with lack of a common currency. Meanwhile, the desire for independent monetary policies was moderated by growing agreement on the primacy of price stability and on the desirability of central bank independence. In the 1990s, the crucial issues behind adoption of a common currency concerned who determines the conduct of monetary and fiscal policy, rather than the emphasis in OCA theory on private sector transaction costs and on whether macropolicy will be effective or not.

If the EU is becoming a territorial unit as Germany or Italy or Canada did in the 19th century, and this was a significant motive behind the introduction of the euro, then the euro as a common currency is sui generis in the current world economy. Apart from the euro, the only current examples of common currencies are the special cases of the CFA franc zone and the rand zone, where carrots encourage membership, and the extreme cases of ministates.

■ **common market**

A c*ommon market* differs from other preferential trading arrangements, such as a free trade area or a customs union, in that, in addition to free trade in goods and services among members, there also is free mobility of factors, that is, free mobility of labor, capital, and other inputs used in producing goods and services. The European Union (EU) is a prominent although imperfect example of this form of integration.

Global free trade and global factor mobility allow the most efficient allocation of resources and, therefore, yield the best situation. In contrast, a common market, which restricts trade and factor mobility between members and nonmembers, has to be seen in a *second-best* context. As in any preferential trading arrangement, a common market leads to welfare-reducing trade-diversion effects to go along with its welfare-enhancing trade-creation effects. Trade diversion occurs when an importing country buys a

good at a higher price from a member of the common market, while this same good was previously imported at a lower price from a nonmember nation. This can happen because of the tariff preference that is granted to the members. As a result, trade is diverted from a low-cost nonmember to a high-cost member, and this is efficiency reducing. These effects apply to factor mobility as well. To the extent that intrabloc capital movement or labor migration might improve factor allocation within the union, it is efficiency enhancing. On the other hand, if factor mobility within the union leads a country to replace factor inflows from nonmembers with less-efficient factors from members, it will be welfare reducing. Finally, as with goods, the prices for mobile factors might differ in a common market, thereby conferring terms-of-trade losses or gains to member nations.

In the presence of foreign factors of production, many of the conventional welfare results of international trade break down. Brecher and Bhagwati (1981) highlight the role of the *differential trade volume* phenomenon and the *differential trade pattern* phenomenon in leading to apparent paradoxes. The trade volume for the home nation as a whole will, in general, differ from the corresponding volume for the nationals (excluding the immigrant factors of production) only. This is referred to as the *differential trade volume*. It is also possible that, while the country is a net exporter of (say) a capital-intensive good, the nationals are net importers of the same good. Brecher and Bhagwati (1981) call this the *differential trade pattern*. A terms-of-trade improvement for the country can be an adverse movement for the nationals because of this effect. Similarly, even with the same trade pattern, an adverse terms-of-trade movement will be amplified if the nationals' volume of trade is disproportionately large (compared to the country's as a whole). This can reduce the income of the nationals, even if the aggregate income (including that of the immigrants) rises. Overall, they conclude that even if standard trade theory may suggest that a nation will gain (or lose) from a certain change, the effect on its citizens might be ambiguous in the presence of immigrant factors. In light of this discussion, we infer that factor mo-

bility can lead to conflicts between member-nation interests. Policies that might be good for the union need not raise the national income of each member. In such a situation, welfare-enhancing policies might be feasible only if members can coordinate and set up compensation mechanisms that allow for appropriate intrabloc transfers.

Wooton (1988) considers the effects of moving from a customs union to a common market. To the extent that factor mobility leads to superior resource allocation within the union, efficiency rises. However, given that trade taxes exist between the union and the rest of the world, factor mobility can amplify or reduce distortions. For example, consider a good that is subject to an import tariff by the union. When factors move within the bloc, production of the good will fall in some nations and rise in others through changes in their respective production possibility frontiers. If the net effect is such that production of the good falls at the union level, more will be imported by the union, thereby moving the outcome closer to the free-trade level. In such a situation, a common market will improve on a customs union. If not, then the opposite will occur. The welfare issue is more complicated at the national level: even if the union as a whole gains, some member nations might lose because of adverse terms-of-trade movements in product and/or factor markets. For an individual member nation, the extent of gains or losses from such movements will depend on its volume of trade. Furthermore, because a common external tariff restricts trade, a member nation will gain if factor mobility induces an expansion of trade with nonmembers. Kowalczyk (1993) focuses on related issues and, in addition to the terms-of-trade and volume-of-trade issues related to trade taxes, considers the role of nontariff barriers (NTBs). He points out that intraunion trade in goods or factors is often subject to NTBs that do not generate revenues. Consequently, the welfare gains related to NTB removal depend on the initial volume of trade and not the change in the volume, which is scaled by the tariff rate. Viewed in this context, a union that already has a large volume of trade in factors is likely to gain significantly from the removal of impediments to factor mobility.

Issues of tax competition and coordination also arise when there is factor mobility between union members (see Haufler 2001). Broadly speaking, as long as there are differences in national policies within a union, there will be incentives for labor and/or capital to move to take advantage of the differences. By the same token, nations can anticipate such movements and adjust their policies accordingly. In the absence of coordination at the union level, factor mobility can lead to tax competition between nations and to inefficient policy outcomes for an individual member and perhaps for the union as a whole. Competition for mobile capital is an example: Consider two nations that are competing to have capital locate within their borders. Assume also that capital-tax revenues go toward financing a public good. If one nation raises its tax rate on capital, the other nation will benefit as some of the capital will relocate to it. In other words, the tax imposed by one nation causes a positive externality on the other, which experiences an increase in tax revenue, and public-good provision, without increasing its tax rate. In a noncooperative Nash taxation equilibrium, this leads to tax rates and public-good provision that are too low from the perspective of a union of these two nations. At a noncooperative Nash taxation equilibrium, each country sets its capital tax unilaterally to maximize its objective function, assuming that the other country's tax rate is fixed at a certain level. In addition, at this equilibrium, the tax rates of the two nations (say A and B) must be such that, given A's tax rate, B's tax rate maximizes its objective function, and vice versa. Tax coordination between the nations will help to alleviate this problem. However, asymmetry between nations can make such coordination difficult. It is possible that the coordinated outcome is not superior for a nation that stands to benefit from tax competition. Therefore, for heterogeneous unions, coordination can be harder to achieve.

Although capital and labor mobility have been treated symmetrically in our discussion so far, there is evidence that actual movements of labor within a common market are relatively small compared to the movement of capital. Dustmann et al. (2003) note that the introduction of mobility between Greece, Portugal, and Spain and existing EU members did not lead to large migration flows from these nations to the rest of the EU. This is significant, because these acceding countries differed substantially in their economic conditions (for example, much lower per capita incomes) relative to the existing EU nations. Qualitatively similar conclusions are reached by Zaiceva (2004) regarding accession of East European nations to the EU. No major jumps were anticipated and, indeed, as income levels converge over the long run, migration flows are expected to fall. As an explanation for the low levels of labor migration following integration, Dustmann et al. suggest that it is not only current conditions but also expectation of future conditions that can determine such flows. To the extent that agreements such as that for EU expansion create optimism in a new member nation about its own economy, it may dampen the desire of a potential migrant to incur the costs associated with migration.

Harris and Schmitt (2005) contrast intra-EU mobility with the relatively high mobility between states in the United States and note that labor market shocks in the EU generate changes in the labor market participation rate without affecting migration significantly. The EU experience may not immediately generalize to other groupings of nations. For example, mobility between Canada and the United States has been high historically and is likely to strengthen with potentially deeper labor market integration under the North American Free Trade Agreement (NAFTA) (see Harris and Schmitt 2005). Similarly, labor market integration that includes Mexico might also lead to large flows. The migration pressure between Mexico and the United States is readily seen in the large existing stock (and flow) of legal and illegal immigration across the U.S.-Mexican border. At least in the context of NAFTA, however, the recent immigration reform proposals, and the debate surrounding them, suggest that a common market with full mobility of labor seems unlikely to be politically feasible in the near future.

■ **Common Market for Eastern and Southern Africa (COMESA)**

The Common Market for Eastern and Southern Africa (COMESA) is a regional trade organization consisting of 20 African states in the eastern and southern regions of Africa and a small number of countries in central and northern Africa. In 2007 its membership included Angola, Burundi, Comoros, Democratic Republic of Congo, Djibouti, Egypt, Eritrea, Ethiopia, Kenya, Libya (since June 2005), Madagascar, Malawi, Mauritius, Rwanda, Sey-chelles, Sudan, Swaziland, Uganda, Zambia, and Zimbabwe. Its objective is to strengthen the institu-tions of member states to help them achieve collective and sustained development.

Origin and Background COMESA, also known simply as the common market, traces its origin to the pan-African vision of economic integration of the African continent that gained prominence between the late 1950s and early 1960s. The consensus then was that the smallness and fragmentation of post-colonial African national markets would constitute a major obstacle to the development of the continent. Accordingly, it was agreed that the newly indepen-dent African states should promote economic co-operation among themselves. In the mid-1960s, the countries of eastern and southern Africa initiated the process toward the formation of an eastern and southern African cooperation arrangement. After the preparatory work had been finalized, the Preferential Trade Area (PTA) Treaty was signed in 1981 and ratified in 1982, giving birth to the Eastern and Southern African PTA.

COMESA was created by treaty in 1994 to re-place the PTA. Its formation was a fulfillment of the requirements of the PTA Treaty, which provided for the transformation of the PTA into a common market. The common market was intended to strengthen the progress of regional integration that had begun under the PTA. The COMESA Treaty had two notable provisions that the PTA Treaty lacked: (1) the concept of multiple speed or variable asymmetry, which allows some countries to progress faster in the regional economic integration process than other countries, and (2) the use of sanctions

(financial penalty, suspension, or expulsion) to discipline member states that fail to implement COMESA programs or to settle disputes arising from the interpretation or implementation of the treaty. These two innovations helped to expedite the process of economic integration in the region.

The affairs of the common market are managed by a number of institutions, including those organs (the Authority of Heads of States and Governments, the Council of Ministers, the Court of Justice, and the Committee of Governors of Central Banks) responsible for making decisions on behalf of the common market; the COMESA Trade and Development Bank, which provides capital for development; the COMESA Re-Insurance Company, which is responsible for providing insurance for trade, investment, and other productive activities, and for promoting trade in insurance and reinsurance business; the COMESA Association of Commercial Banks, which is responsible for promoting and strengthening links between banks in the region; the COMESA Clearing House, which is responsible for settling payments with respect to all transactions in commodities conducted within the common market; and the COMESA Leather Institute, which is responsible for promoting productivity, competitiveness, trade, and regional integration in the leather subsector.

Member countries of the common market are diverse in terms of socioeconomic development and resource endowments. According to 2004 data, gross domestic product (GDP) per capita ranged from as little as US $90 for Burundi to more than US $8,600 for Seychelles. The United Nations Development Program ranked only two countries (Seychelles, followed by Mauritius) as high-human-development countries, six as medium-human-development countries, and 12 as low-human-development countries. The population levels range from less than a million in Comoros to more than 70 million each in Egypt and Ethiopia, with a total of 380 million people in the entire region. Resource endowments vary from agricultural products to crude oil (in Libya) to mineral ores. COMESA was intended to take advantage of the larger market size, to share the region's

common heritage and destiny, and to allow greater social and economic cooperation with the ultimate goal of creating a regional economic community. This regional economic community would then form one of the building blocks on which the creation of the African Economic Community (AEC) would be erected, as envisaged by the Lagos Plan of Action of 1980 and the Abuja Treaty of 1991.

Key Elements and Procedures The COMESA integration strategy comprises the following four phases: (1) the establishment of a free trade area (FTA) through the abolition of all tariff and nontariff barriers on commodities imported from member countries by 2000; (2) the establishment of a customs union with a common external tariff structure by 2004; (3) the adoptions of common investment practices and visa arrangements, and the establishment of a payments union; and (4) the establishment of a common monetary union by 2025. The FTA phase was achieved in 2000 when Djibouti, Egypt, Eritrea, Ethiopia, Kenya, Madagascar, Malawi, Mauritius, Sudan, Zambia, and Zimbabwe eliminated tariffs and nontariff barriers on goods produced in the common market. Burundi and Rwanda eliminated theirs in 2004 and became FTA partners. At the end of 2007, the common market was still operating as an FTA.

The common market has five key provisions. First, there are no custom duties or charges of equivalent effect imposed on goods from one FTA member to another unless it is for protecting an infant industry or against dumping. Second, member states are allowed to impose full national tariff rates on goods from nonmember states. Third, there are no nontariff barriers against goods from one FTA member to another unless such goods are deemed to pose a health or security risk. Fourth, member states follow the COMESA rules of origin in determining whether or not a good is eligible for preferential treatment. Strict local content requirements have been established to prevent nonmember countries from establishing assembly operations in one member country in order to gain duty-free access to the common market. Fifth, member states that are not yet FTA partners but have met the 60 percent tariff

reduction target are granted trade preferences by the FTA partners on the basis of the tariff reductions they have attained. For instance, countries such as Comoros, Eritrea, and Uganda that have reduced their tariff rates on products originating from the common market by at least 80 percent qualify to receive an equivalent reciprocal preferential treatment from the FTA partners. Other COMESA member states that have not implemented the 60 percent minimum tariff reduction do not get any preferential rate from the FTA partners or from those that have reduced their tariffs by at least 60 percent.

Besides market integration, the COMESA integration strategy has been expanded to include transport and communications infrastructure development. More specifically, the focus is on development and implementation of transit traffic facilitation programs; identification and coordination of regional investments in the transportation, communications, and energy sectors; and the promotion and coordination of institutional and policy reforms in the transportation, telecommunication, postal, energy, and environment sectors.

Impact on Member States Economists separate the welfare effects of a regional economic integration into static and dynamic effects. Static effects are short-run effects that relate to productive efficiency and consumer welfare. Static effects are further delineated into trade creation and trade diversion effects, à la Jacob Viner (1950). Trade creation is associated with increase in trade among member states of a regional organization owing to the reduction in tariff and nontariff barriers. Trade diversion occurs when trade with nonmember countries declines as a result of the formation of a regional organization. A regional economic arrangement is welfare-increasing if the trade creation effects more than compensate for the trade diversion effects.

There is evidence of trade creation in the COMESA region. Trade among member countries (intra-COMESA trade) has expanded substantially since the creation of COMESA. Intra-COMESA trade increased from US $1.7 billion in 1994 to US $5.5 billion in 2003. The formation of the FTA has played a major role in facilitating this trade. More

specifically, trade among the FTA partners alone increased from US $1 billion in 2000 to more than US $5 billion in 2005. Jacob W. Musila (2005) investigated the static effects of the COMESA regional trade agreement and concluded that it is welfare-increasing. More specifically, Musila estimated the relative sizes of the trade diversion and trade creation effects for COMESA and found that the trade creation effects exceed the trade diversion effects.

The dynamic effects of regional economic integration relate to the long-run growth rates of the member countries due to increased efficiency as a result of market enlargement. It is believed that large markets permit economies of scale to be realized on certain export goods and, therefore, may lead to specialization in particular types of goods. The net impact of the dynamic effects, like that of the static effects, is not obvious, however. Whether or not regional economic integration increases welfare in the long run depends on the scope of liberalization in member countries and the type of goods in which countries specialize. Athanasios Vamvakidis (1999) shows that growth is faster in economies that liberalize broadly than in those that merely join regional trade agreements and do not liberalize. Augustin K. Fosu (1990) finds that primary commodity exports do not have a significant impact on long-run economic growth.

For COMESA, the approach to regional integration is open regionalism — that is, it liberalizes trade without crowding out the world economy. COMESA member countries specialize mainly in primary commodities, however. As a result, the trade commodity base among member states is narrow and similar. The trade pattern of the common market is such that manufactured goods are imported from outside the region (mainly from rich nations) while primary commodities dominate the exports of the region. And Antonio Spilimbergo (2000) has shown that the importation of manufactured goods may not necessarily result in dynamic gains for less-developed countries (the South). The learning-by-importing models suggest, however, that imports of high-technology goods lead to transfer of technology that

stimulates domestic innovation and economic growth in the importing country.

The experience for the common market region has been a slight improvement in economic growth since the creation of COMESA in 1994. The average growth rate of real GDP per capita per annum increased from about 0.01 percent during 1980 94 to 1.35 percent during 1995 2005. It is likely that the improvement in economic growth in the common market is partly due to the trade liberalization programs implemented under the auspices the CO-MESA Treaty. Together, the static and dynamic effects determine the overall welfare gains or losses associated with regional economic integration. The evidence appears to suggest that there are overall welfare gains in the case of COMESA.

Relation with External Actors COMESA and other African regional trade blocs seek to augment and deepen regional integration on the African continent with a view to creating an AEC. Accordingly, COMESA supports and has signed cooperation agreements with several other African regional undertakings such as the Intergovernmental Authority on Development and the Economic Community of West African States (ECOWAS) and allows overlapping memberships with other regional organizations. Robert Sharer (1999) has observed, however, that overlapping memberships with internal inconsistencies, conflicting regulations and rules, and different strategies and objectives work to impede market expansion and, thus, discourage domestic and foreign investment. Indeed, some of the countries with dual or more memberships, such as Namibia and Tanzania, have been reluctant to implement COMESA programs in full or have quit the common market.

Non-African regional trade blocs are often seen as impeding Africa's regional integration. Jeffrey D. Lewis, Sherman Robinson, and Karen Thierfelder (2003) have observed that North-South trade is more attractive to African countries than South-South trade. Indeed, a majority of the member states of COMESA trade with the European Union (EU) more than with one another. The trade with the EU and the United States was set to increase even further following the opening up of the EU and U.S. markets under the Everything-but-Arms and the African Growth and Opportunity Act initiatives, respectively. A 2001 WTO provision aiming at removing quotas and duties on a large number of goods originating from the world's poorest countries also promised to increase trade with non-African regional blocs and further reduce the advantages that the common market offers to its member states. Ironically, however, the very same processes of global trade liberalization and cooperation with non-African trade blocs have contributed to the evolution of COMESA. The EU directly encourages developing countries to form a group and speak with one voice. For the EU, dealing with a collective organization rather than with numerous individual countries reduces transaction costs. Indirectly, the success of the EU has inspired the hopes for creating the AEC, with COMESA being an intermediate step.

■ comparative advantage

The term *comparative advantage* was first used in England in the early 19th century by economists of the classical school, which dates from the publication of Adam Smith's *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776). Sometimes denoted by the synonymous term *comparative cost*, it expresses the principle by which a nation that opens to international trade is led to specialize in and export certain commodities and to import others. Whereas the former commodities are those in which it has a comparative advantage, the nation is said to have a comparative disadvantage in the latter. The concept of comparative advantage is vital for understanding the structure of world trade and how each country contributes to it. It underlies the whole field of international trade theory and policy, the earliest and arguably the most important of the applied fields of economics and of its predecessor, political economy. Textbooks of international trade devote successive chapters to exploring the reasons why nations have a comparative advantage in certain commodities, and the welfare implications of specialization in accordance with its dictates. Comparative advantage is also relevant to different regions of a country in studying the pattern of interregional trade.

Starting in England at the end of the 17th century with mercantilist writers such as Sir Dudley North and Henry Martyn, the sources of comparative advantage and the gains from the trade that it induces were explored by the luminaries of the nascent economics profession: Smith himself and the classical economists who followed him, such as David Ricardo, Robert Torrens, and John Stuart Mill. Ricardo (1817) enshrined comparative advantage as a key concept for economists by illustrating it with a numerical example relating to trade in wine and cloth between England and Portugal. In the first half of the 20th century the neoclassical school of thought added its own perspectives to the concept of Ricardian comparative advantage when it was generalized by Gottfried Haberler (1936) and critiqued by two Swedish economists, Eli Heckscher (1949) and Bertil Ohlin (1933). Heckscher and Ohlin postulated that the source of comparative advantage resides in the differential factor endowments of trading countries. The Heckscher-Ohlin theory became the mainstream theory of trade after World War II. Since the late 1970s, doubts that had been raised about the empirical validity of comparative advantage led some economists to formulate a New Trade Theory that harks back to another source of trade mentioned by Ohlin (1933), economies of scale, and explains why much of the trade between advanced economies consists of differentiated commodities produced under conditions of imperfect competition.

Despite the frequency with which the principle of comparative advantage is discussed, a precise defi-

nition is hard to find, and most authors cite particular economists or associate the concept with numerical examples, such as Ricardo's, based on two countries, two commodities, and a single input, labor. An algebraic definition along Ricardian lines can clarify the concept. Consider two commodities, 1 and 2, and two countries, A and B. Define L_i^C as the input of labor per unit of output of commodity i ($i = 1, 2$) in country C (C = A, B). Then country A has an *absolute advantage* in commodity 1 if $L_1^A < L_1^B$, and a *comparative advantage* in commodity 1 if

$$L_1^A/L_2^A < L_1^B/L_2^B. \qquad (1)$$

Inequality (1) is consistent with the possibility that $L_1^A < L_1^B$ and $L_2^A < L_2^B$, so that A has an absolute advantage in both commodities but a comparative advantage in the first. Absolute advantage in a commodity thus indicates a smaller absolute cost in terms of a factor such as labor, whereas comparative advantage implies that the ratio between the unit costs of production is lower in A than in B. What is being "compared" in comparative advantage are unit costs relating both to countries and to commodities: a double-barreled comparison. Since relative prices before trade conform to the ratios L_1^C/L_2^C in A and B according to the labor theory of value, the commodity whose relative cost of production is lower is exported in exchange for the other commodity. If $L_1^A < L_1^B$, $L_2^A < L_2^B$, and inequality (1) holds, specialization according to comparative advantage has important welfare implications for both countries: A is better off if it participates in international trade despite its greater efficiency in producing both goods, and B can participate gainfully in the international division of labor despite its absolute disadvantage in both commodities. If $L_1^A < L_1^B$, $L_2^A < L_2^B$, and (1) is changed to the equality $L_1^A/L_2^A = L_1^B/L_2^B$, A has an absolute advantage in both commodities and a comparative advantage in neither. Trade cannot take place since both countries face the same relative price. Comparative advantage clearly trumps absolute advantage as a cause of trade.

According to Jones and Neary (1984, 3), "While the principle of comparative advantage may thus be defended as a basic explanation of trade patterns, it is not a primitive explanation, since it assumes rather than explains inter-country differences in autarkic relative prices." Autarkic relative prices are those that prevail in a state of *autarky*, when a country is closed to trade. Successive models of international trade have been based on different "primitive explanations" for why relative prices differ in autarky, such as intercountry differences in technologies, factor endowments, or tastes. The specification of an autarky equilibrium is, for most countries, a thought experiment designed to ascertain the prices that would prevail in the unlikely event that an economy were isolated or self-sufficient. It is part of an exercise in "comparative statics," in which an economy's resource allocation and economic welfare in autarky are compared to their pattern under free trade. If transportation costs are neglected, free trade equates the prices of traded commodities across countries. Each country's export good rises in value while the import-competing good falls. Under free trade one can therefore no longer speak of a country being a "low-price" country for the goods in which it holds a comparative advantage.

18th-Century Views on the Causes of Specialization Before Ricardo, comparative advantage was interpreted in a looser way than that indicated earlier, namely, as the reason why particular economies show a tendency toward specialization in certain types of commodity. In 1752 the philosopher David Hume published a series of essays analyzing a variety of commercial issues including trade between more developed economies such as England and less developed ones such as his native Scotland. Lower wages give a competitive advantage to more backward economies, allowing them to compete successfully with more advanced ones in the simpler manufactures. In a similar vein the English pamphleteer Josiah Tucker argued that

> It may be laid down as a general Proposition, which very seldom fails, That *operose* or *complicated Manufactures* are cheapest in rich Countries; and *raw Materials* in poor ones: And therefore in Proportion as any Commodity approaches to one, or other of these *Extremes*, in that Proportion it will be found to be cheaper, or dearer in a rich, or a poor

Country. . . . [Moreover] there are certain *local* Advantages resulting either from the Climate, the Soil, the Productions, the Situation, or even the natural Turn and peculiar Genius of one People preferably to those of another, which no Nation can deprive another of. (Tucker 1774, 188, 193)

Tucker not only spoke of national "advantages," but traced them to climate, soil, and even "the natural turn and peculiar genius" of the people, factors that were often subsequently cited as explanations of economic specialization by the classical school of economists. He engaged with Hume in what became known as the "rich country poor country" debate, in which they argued whether poor countries could catch up with or even surpass the standard of living of richer ones. In opposition to Hume, Tucker maintained that the built-in advantages of rich countries are hard to reverse. Without citing Tucker, Adam Smith also anticipated the theory of comparative advantage by maintaining that "the most opulent nations . . . generally excel all their neighbours in agriculture as well as in manufactures; but they are commonly more distinguished by their superiority in the latter than in the former" (Smith 1776, 16). This notion of a "natural" territorial division of labor between rich and poor countries was adopted by most 19th-century economists.

Ricardo's Example of Comparative Advantage

The principle of comparative advantage is contained in chapter 7 of Ricardo's *Principles of Political Economy and Taxation* (1817), which is devoted to foreign trade:

The quantity of wine which she [Portugal] shall give in exchange for the cloth of England, is not determined by the respective quantities of labour devoted to the production of each, as it would be, if both commodities were manufactured in England, or both in Portugal.

England may be so circumstanced, that to produce the cloth may require the labour of 100 men for one year; and if she attempted to make the wine, it might require the labour of 120 men for the same time. England would

therefore find it her interest to import wine, and to purchase it by the exportation of cloth.

To produce the wine in Portugal, might require only the labour of 80 men for one year, and to produce the cloth in the same country, might require the labour of 90 men for the same time. It would therefore be advantageous for her to export wine in exchange for cloth. This exchange might even take place, notwithstanding that the commodity imported by Portugal could be produced there with less labour than in England. Though she could make the cloth with the labour of 90 men, she would import it from a country where it required the labour of 100 men to produce it, because it would be advantageous to her rather to employ her capital in the production of wine, for which she would obtain more cloth from England, than she could produce by diverting a portion of her capital from the cultivation of vines to the manufacture of cloth.

Thus England would give the produce of the labour of 100 men, for the produce of the labour of 80. (Ricardo 1817, 135)

These paragraphs contain four numbers denoting the amounts of labor needed to produce wine and cloth in England (120, 100) and Portugal (80, 90). International trade textbooks interpret them as constant labor coefficients per unit of output of wine and cloth, and deduce from them linear production possibility frontiers and complete specialization in both countries (unless one of them happens to be "large" and remains nonspecialized). Ruffin (2002) and Maneschi (2004) show that this interpretation is incorrect. A close reading of the first three paragraphs of the foregoing passage reveals that the two numbers relating to each country refer instead to the amount of labor embodied in its *total exports* and the amount it would require to produce its *total imports* of the other commodity. In the second paragraph, Ricardo is able to assert which commodity England exports before even mentioning the two numbers relating to Portugal. It is clear that Portugal has an absolute advantage in both commodities since it uses less labor

than England does to produce both traded amounts of wine and cloth. Ricardo did not justify the four numbers by referring to particular economic characteristics of the two countries. Economists have assumed that differences between them in the technology of production account for their respective comparative advantage.

Ricardo never specified the quantities exported by each country. If X is the amount of cloth exported by England and Y that of wine imported, the *terms of trade* (defined as the relative price of the export good) are Y/X units of wine per unit of cloth. Since England requires 100 units of labor to produce X and 120 units to produce Y, the unit labor coefficients are $100/X$ and $120/Y$ respectively, so that its opportunity cost of cloth in terms of wine is $(100/X)/(120/Y) = (5/6)Y/X$. The corresponding unit labor coefficients in Portugal are $80/Y$ for wine and $90/X$ for cloth, so that its opportunity cost of cloth in terms of wine is $(9/8)Y/X$. If these opportunity costs remain constant for all levels of output they are equal to the internal price ratios, so that Portugal has a comparative advantage in wine while England has it in cloth. Since $(9/8)Y/X > Y/X > (5/6)Y/X$, these opportunity costs lie on either side of the terms of trade Y/X, so that trade causes the price of the imported commodity to fall in each country.

Classical Perspectives on Comparative Advantage after Ricardo Another classical economist, Robert Torrens, is often mentioned with Ricardo as a codiscoverer of the comparative advantage principle. In his *Essay on the External Corn Trade* published two years before Ricardo's *Principles*, Torrens argued that even if England produces "corn" (grains) more efficiently than Poland, it may be to England's advantage to import it from Poland: "tracts of her territory, though they should be equal, nay, even though they should be superior, to the lands of Poland, will be neglected; and a part of her supply of corn will be imported from that country" (Torrens 1815, 264 65). Although England has an absolute advantage in corn, it has a comparative advantage in manufactures and specializes in them in order to import corn. Despite Torrens's two-year precedence in print with a passage that shows that he appreciated the dis-

tinction between absolute and comparative advantage, Ricardo deserves his reputation as the discoverer of the principle of comparative advantage since (unlike Torrens) he presented it in terms of a numerical example that allowed both the determination of the direction of trade and the gains from trade accruing to each country. Ruffin (2002) highlights other deficiencies in Torrens's formulation of this principle.

Torrens deserves to be remembered for another reason. In his comparative cost example, Ricardo postulated the existence of a trade equilibrium but never explained how the terms of trade, and hence the division of the gains from trade between the two countries, are determined. Torrens advanced the notion that they depend on the reciprocal demand of each country for the export goods of the other country. As O'Brien (2004) points out, Torrens was a pioneer in the theory of trade policy by proposing that a tariff can turn the terms of trade in a country's favor, and hence insisting on reciprocity with other countries in tariff policy. His argument for an aggressive trade policy was critiqued, and the theory of reciprocal demand developed more rigorously, by John Stuart Mill (1848), who among the classical economists ranks with Ricardo as a great innovator in international trade theory. Mill postulated that reciprocal demand determines the terms of trade in such a way that a country's exports match the value of its imports. He noted that the terms of trade are located between, and bounded by, the autarky price ratios of the two trading countries. The gap between the two countries' autarky price ratios, which indicate their respective comparative advantages, thus fixes the possible range of the terms of trade, while reciprocal demand determines their location in this range. Mill also analyzed how technical change in the export good of one of the countries alters the pattern of comparative advantage and turns the terms of trade against it.

The first professor of political economy in Ireland, Mountifort Longfield, took an important step in generalizing the Ricardian model to many commodities, observing that a commodity is exported by a country if and only if the productivity of the labor

producing it, relative to the other country's, exceeds their relative wages. In his words, "That kind of labour will succeed in each country which is more productive in proportion to its price" (Longfield 1835, 56). Longfield realized the importance of reciprocal demand in determining the range of commodities exported, noting that "if a nation enjoyed an immense superiority in the production of two or three articles of very general demand, the wages of her labourers might be, in consequence, so high that she could not compete with the rest of the world in any other manufacture, under a system of free trade" (69). In the two-commodity Ricardian world, comparative advantage is determined entirely by techniques of production that dictate that one good is exported and the other imported. In a multi-commodity world, a country's comparative advantage depends not only on technology but also on the reciprocal demand of each country for the other's commodities, such that commodities are exported (imported) when the ratios of their labor productivity are greater (smaller) than the ratio of their wage rates. As Longfield asserted, a country that enjoys a very high wage rate compared to its trading partner produces and exports very few commodities.

Neoclassical Perspectives on Comparative Advantage The classical school of thought gradually gave way to the marginalist economics of W. Stanley Jevons in England, Carl Menger in Austria, and Léon Walras in France and Switzerland, and then to the neoclassical school that originated with Alfred Marshall in England. Marshall achieved a "neoclassical" synthesis by combining insights derived from the marginalist economists on the important role played by demand in price determination with the supply-side view of the classical economists that price is determined by the cost of production. This spelled the end of the classical labor theory of value used to determine the autarky prices in the theory of comparative advantage of Ricardo and Mill. The prestige enjoyed by the theory of comparative advantage guaranteed its continued longevity for several more decades, as shown in Jacob Viner's (1937) scholarly *Studies in the Theory of International Trade*, which painstakingly analyzed and critiqued the achievements of the mercantilist, classical, and neoclassical writers in international trade theory and policy.

Marshall did not do much to advance the theory of international trade beyond graphically translating Mill's analysis of reciprocal demand and terms of trade determination by means of the two trading countries' offer curves. The latter show how much of the good in which each country holds a comparative advantage it is willing to export in exchange for alternative amounts of its import good. The slope of the ray joining the origin to the intersection of the offer curves yields the terms of trade. Offer curve analysis was developed in greater detail by Francis Edgeworth, who incorporated the two countries' comparative cost ratios in the offer curves and showed diagrammatically that they bound the terms of trade. Both Marshall and Edgeworth used offer curves to illustrate the impact of a tariff on the terms of trade and to investigate the stability of a trade equilibrium.

Considerably more progress was made by the Austrian-born economist Gottfried Haberler in a 1933 book that appeared in English translation three years later as *The Theory of International Trade with Its Application to Commercial Policy* (Haberler 1936), and by the Swedish economists Eli Heckscher (1949) and Bertil Ohlin (1933). Haberler generalized Ricardian comparative advantage to an economy in which price is defined by the opportunity cost of a commodity in terms of another, rather than by its constant "real cost" of production. He depicted by means of a transformation curve, or production possibilities frontier (PPF), the menu of outputs that can be produced with the economy's factors of production and the available technology. Whereas the PPF is linear in the textbook Ricardian case since real costs of production are constant for any level of output, the neoclassical PPF is concave to the origin. Its slope measures the opportunity cost of one commodity in terms of the other and increases with the level of output because of increasing unit costs. In autarky this slope differs for the two trading partners and signals their comparative advantage in the commodity that is cheaper there. Unlike in the Ri-

cardian case, this slope is no longer independent of demand considerations, and the mix of factors used changes along the PPF together with its slope. Haberler thus generalized the comparative cost model while accepting most of its welfare conclusions.

In an article published in Swedish in 1919 and translated into English in 1949 as "The Effect of Foreign Trade on the Distribution of Income," Eli Heckscher set out to discover for the Ricardian trade model the hitherto missing rationale for why comparative advantage differs across countries and, as the title of his paper suggests, to explore how trade affects income distribution. The clue lies in the difference in the relative abundance of factor endowments across countries combined with differences in the intensities with which commodities use factors in production. Under autarky these features yield differences in commodity prices across countries that in turn lead to trade between them. Making the additional assumption that techniques of production are identical across countries, Heckscher argued that trade causes factor prices to converge and even become equal if neither country becomes fully specialized, a result that later became known as factor price equalization. As in the case of Haberler's PPF, the difference between comparative costs responsible for trade in the first place is erased by the very trade it engenders. After trade is established, and unlike the Ricardian constant-cost case, the difference in comparative costs disappears since it is no longer needed to ensure continued trade.

Haberler's generalization of the Ricardian model and Heckscher's rationale for comparative costs in the context of that model did not go far enough for Heckscher's student Bertil Ohlin, who in 1933 published a book-length critique of the Ricardian model. Together with Heckscher's 1919 article, whose assumptions and conclusions were adopted by Ohlin, it laid the foundations for what became known as the Heckscher-Ohlin theory, the mainstream theory of international trade after World War II. According to Ohlin's critique, the Ricardian model could not be reformed or generalized, but must be rejected as based on false assumptions in order to reconstruct the theory of trade on the new foundations sketched by Heckscher and the neoclassical school. The association of the term *comparative advantage* with the theory of comparative costs that Ohlin wished to discredit explains why this term is hardly used in his 1933 book and disappears completely from the revised edition of 1967. When Paul Samuelson (1948) applied the Heckscher-Ohlin model to two countries, two commodities, and two factors of production and thereby made it more comprehensible and suitable for graphical representation, he was not deterred from using the term *comparative advantage* in connection with it. In fact, Samuelson formulated what became known as the Heckscher-Ohlin theorem: a land-abundant (labor-abundant) country has a comparative advantage in the land-intensive (labor-intensive) commodity and exchanges this commodity for the other since in autarky it is cheaper than in the other country. Its validity depends on numerous assumptions, including identical demands in the two countries such that at the same price ratio they consume goods in the same proportion. It is somewhat ironic that, following Heckscher's lead and despite Ohlin's objection to the term *comparative advantage*, Ohlin ultimately provided the first book-length explanation of the causes of comparative advantage based on international factor endowment differences and differential factor intensities for commodities.

Comparative Advantage and the New Trade Theory The Heckscher-Ohlin (H-O) theorem was tested empirically by Wassily Leontief (1953). Despite his surmise that the United States was then the world's most capital-abundant country, Leontief discovered that it exported labor-intensive and imported capital-intensive commodities! His finding became known as the Leontief paradox and gave rise to numerous articles that attempted to account for it. The underlying H-O theory was extended to more factors than the two (capital and labor) considered by Leontief, including natural resources and skilled labor. Later empirical tests that included these extensions sometimes reversed, sometimes reaffirmed the Leontief paradox. Moreover, contrary to what the H-O theory suggests, most trade flows were shown to occur between industrialized countries whose factor

endowments are fairly similar. Much of this trade is intraindustry in nature, meaning that the same types of commodity (such as automobiles) are both exported and imported. Dissatisfaction with the underlying H-O theory led in the 1970s to the formulation of a *new trade theory*, some of whose models dispense altogether with the notion of comparative advantage. They allow instead for increasing returns to scale, external economies, differentiated products, and the associated imperfectly competitive market structures. Trade can arise even between economies that are identical with respect to factor endowments and technical knowledge. The new trade theorists later realized that Ohlin himself had partly anticipated them in 1933. In chapter 3 of his book, titled "Another Condition of Interregional Trade," Ohlin argued that a powerful secondary reason for trade is economies of scale, due to the indivisibility of certain factors of production. Ohlin remarked that trade and specialization are partly determined by history and accident, factors also stressed by Paul Krugman (1990). Emphasizing increasing returns and monopolistic competition in economies in which comparative advantage plays no role, Krugman showed that the New Trade Theory can provide a satisfactory explanation for intraindustry trade. Other models of the New Trade theorists combine comparative advantage with economies of scale to produce a rich variety of possible trade outcomes.

Comparative Advantage: An Enduring Legacy

Comparative advantage has been attributed to many causes in the trade literature, such as different techniques of production in the Ricardian model and differential factor endowments in the writings of Heckscher and Ohlin. The strategy adopted by the innovators of each theory was to discover a factor that differs between countries, hold everything else in them the same, and build a theory based on this difference. As the French put it, *c'est la différence qui compte*.

Although comparative advantage plays no role in a few models of the New Trade Theory, where the industries that countries adopt are immaterial as long as they end up specializing and thus reaping economies of scale, some of its other models combine such increasing returns with traditional comparative ad-

vantage. Models of the Ricardian or Heckscher-Ohlin type thus endure as significant explanations of comparative advantage in the world economy. The drastic changes in the structure of world trade since the mid-20th century and the emergence of new major exporters such as China and the countries of the "East Asian miracle" present economists and policymakers with the task of analyzing and keeping up with the rapid evolution of comparative advantage in the presence of multinational corporations and of phenomena such as outsourcing and the instantaneous transmission of technological knowledge across frontiers.

■ competition policy
The term *competition policy* is typically taken to include all government policies that influence the degree of competition in a nation's markets, including trade policy. Competition law, in contrast, refers to a specific set of legal provisions concerning the manner in which firms collaborate and compete with one another. That set usually includes measures on cartels, other forms of interfirm collaboration (including so-called vertical restraints), mergers and acquisitions, and abuse of market power. Competition law, therefore, is an element of competition policy but not vice versa.

The appropriate relationship between national trade and competition policies and the merits of different international initiatives on competition law have long been controversial matters both in economic analysis and in international deliberations.

Indeed, if Adam Smith's critique in *The Wealth of Nations* of granting monopolies on trade with Britain's colonies is considered, then these debates are of very long standing. The spread of competition law and the strengthening of existing laws during the current era of international market integration accounts for the renewed interest in the relationship between trade and competition policies.

Many argue that open borders and competition laws are substitutes. Bhagwati (1968) was among the first to show that the pricing power of incumbent firms would be restrained by foreign firms that are prepared to supply domestic customers at world prices. In recent years empirical support for this contention was first provided by Levinsohn (1993) and Harrison (1994). Both showed that the markups of domestic firms declined as tariff rates fell. It should be pointed out, however, that such findings need not imply that setting zero tariffs eliminates market power.

The case for complementing trade reforms with active competition law has been made on several grounds. In the 1980s and 1990s the claim was frequently advanced that prior reductions in tariffs on imports into Japan had not led to greater foreign access to its markets because agreements among Japanese manufacturers, wholesalers, and retailers effectively blocked distribution channels to foreign suppliers (Lawrence 1993; Saxonhouse 1993). More generally, the argument has been made that tariff reductions provide incentives to import-competing firms to take steps, including engaging in anticompetitive practices, that frustrate imports. Private barriers to trade, according to this argument, replace state barriers. A related but distinct argument is that sometimes these anticompetitive practices are facilitated by national unfair trade laws, in particular antidumping measures. The policy implications of the last two arguments are different, however: the former calls for enforcement action against private anticompetitive acts; the latter for reform, if not outright abolition, of unfair trade legislation.

The resurgence of national enforcement actions against international cartels that has taken place since

1993, when the U.S. antitrust authorities offered more generous terms to cartel members to "defect" and turn state's evidence, revealed other complementarities between open borders and competition law (Evenett, Levenstein, and Suslow 2001). Underenforcement of national cartel law creates safe havens where international cartel members can hide evidence, thereby creating a negative cross-border spillover for trading partners. Successful prosecution of an international cartel in one jurisdiction has often prompted investigations in other jurisdictions, creating a positive cross-border spillover. The case for international discipline requiring nations to properly enforce a cartel law can be justified by reference to the first spillover. The case for promoting cross-border cooperation among national competition agencies, which would include the sharing of evidence on cartel investigations, can be made on the basis of the second spillover. Both forms of international collective action would enhance the deterrent effect of national cartel law enforcement.

Since 1995 there has been another wave of cross-border mergers and acquisitions (Evenett 2003). These combinations can involve commercial operations in many jurisdictions and, under current merger review legislation, are often subject to investigations by many national competition agencies. Decisions by national competition agencies to allow or refuse proposed combinations can have cross-border ramifications and from time to time have become the subject of commercial disputes between nations (Muris 2001; Neven and Röller 2000). The adverse reaction of certain U.S. commentators and policymakers to the European Commission's decision on July 3, 2001, to prevent the merger of General Electric and Honeywell is an example. Suboptimal resource allocation is not just a matter of potentially poor analysis of mergers by competition agencies or of different substantive welfare standards, but is also due to the generalized practice of competition agencies of taking into account only those effects of a merger that fall within its jurisdiction's borders. The absence of any compensation mechanism to take account of all relevant cross-

border spillovers, similar to the cross-sectoral bargaining in trade negotiations, is at the center of the inefficiency of simultaneous national merger enforcement. Economic analyses that endogenize the decision to engage in cross-border mergers and acquisitions (Horn and Persson 2001) and that examine the effects of such consolidation in a general equilibrium setting (Neary 2004) have also been developed.

Although considerable attention has been given to competition policy in international forums since the late 1990s, two significant international initiatives predate them. The first was the failed attempt to include binding disciplines on "restrictive business practices" in the postwar multilateral trading system. The chapter on such practices in the Havana Charter, elements of which subsequently provided much of the legal foundation for the General Agreement on Tariffs and Trade, was rejected by the U.S. Congress. Second, in 1980 the members of the United Nations (UN) adopted a nonbinding Set of Multilaterally Agreed Equitable Principles and Rules for the Control of Restrictive Business Practices. The latter remains the only multilateral instrument on competition law.

In July 2004, World Trade Organization (WTO) members decided not to act on proposals to negotiate a multilateral framework on competition policy. The proponents of such a multilateral framework advocated binding obligations to enact and enforce national anticartel law and to adhere to core WTO principles. In addition, provisions to promote both voluntary cooperation between competition agencies and technical assistance for developing countries were advanced (Clarke and Evenett 2003). Some of the strongest opponents to negotiating competition rules at the WTO were the leading competition agencies, fearful of a loss of discretion. These parties created the International Competition Network in 2001, and its numerous activities have contributed to the sharing of best practices in many aspects of competition law. The Organisation for Economic Co-operation and Development has developed a number of recommendations pertaining to competition law and its enforcement. Binding provisions

on competition law have been included in more than 80 free trade agreements, but the evidence to date on these provisions' effectiveness is too sparse to draw any broad policy conclusions.

■ competitive advantage

The concept of competitive advantage came into popular usage in the 1980s as an attempt to identify and define the strategic goals of the firm. In his now famous work *Competitive Advantage: Creating and Sustaining Superior Performance*, Michael Porter showed that the goal of all firms is to achieve a competitive advantage in relation to their rivals. This they do either by selling at a lower cost/price or by differentiating their product from those of their rivals (Porter 1985). Cost and differentiation advantages are frequently referred to as "positional advantages," as they determine the firm's position in an industry, such as whether it competes in the broad, mass market or a segment/niche. A competitive advantage enables a firm to earn profits that are higher than the average profit earned by competitors ("excess prof its"). A *sustainable* competitive advantage is one that cannot be duplicated or imitated by other firms that may enter the industry in the long run and compete for the excess profits enjoyed by existing firms. For example, a firm may acquire a sustainable advantage through the creation of a brand name that comes to be associated with quality or "value for money" and is difficult for other firms to replicate. The St. Michael's label has enabled the British retailer Marks and Spencer to establish a reputation of this kind in the clothing and food retailing industry.

Acquiring a Competitive Advantage Firms ac quire a competitive advantage by creating more value than their competitors in the value chain. The latter is the system of activities (both primary and support activities) that the firm undertakes in the process of value creation. As goods pass through the value chain, value is created at each stage, from upstream suppliers to downstream sales and marketing outlets. Equally important is the contribution made by nonproduc tion activities such as research and development (R&D) and management services. In this process, an

important decision is how to configure each of the activities within the value chain and how to coordinate these activities. Configuration refers to decisions about where to locate each particular activity and how many locations to have for each activity. Coordination relates to the decisions about how to link together the same activity performed in different locations and how to coordinate that activity with other activities in the value chain.

National Competitive Advantage In a later work titled *The Competitive Advantage of Nations*, Porter introduced the notion of national competitive advantage to refer to "the decisive characteristics of a nation that allow its firms to create and sustain competitive advantage in particular fields" (Porter 1990, 18). Such a concept must be distinguished from the concept of comparative advantage used in classical trade theory to refer to the relative cost advantage that a nation enjoys when entering into trade with another country. In classical trade theory, such an advantage was measured in terms of the relative amounts of labor time that producers in different countries required to produce different goods. Later, neoclassical trade theorists explained such differences in terms of factor endowments and the different factor proportions required to produce different goods. While recognizing the usefulness of the concept of comparative advantage for explaining patterns of trade, Porter called for a "new paradigm" based on competitive advantage.

Porter argued that what matters when determining why a particular nation succeeds in a particular industry is the competitive environment of the nation, as this shapes the success of the firms based in that country. This is determined by a number of factors, including the following:

1. *Factor conditions*. These consist of human resources (quantity, quality, and skills of the workers), physical resources (abundance, quality, accessibility, and cost of land and other natural resources, including climatic conditions and location), knowledge resources (scientific, technical, and market knowledge), capital resources (amount and cost of capital to finance industry), and infrastructure (including transportation system, communications

system, health care system, housing, cultural conditions, and quality of life). While neoclassical theory explained national comparative advantage in terms of factor conditions, it assumed that countries were endowed with fixed amounts of these factors. However, although some factors are given (e.g., land and natural resources), countries can add to their stock of other factors through factor creation or investment by individuals or firms.

2. *Demand conditions*. Three broad attributes of domestic demand matter   its composition, its size and rate of growth, and the ways in which it is internationalized. With regard to the composition of domestic demand, the segment structure matters (by giving firms an advantage in segments where domestic demand is strong), as does buyer sophistication (with firms gaining an advantage in sectors where domestic buyers are among the world's most sophisticated and demanding) and the presence of anticipatory buyer needs (domestic buyers are ahead of buyers in other countries). With regard to demand size and the pattern of growth, a large market can enhance competitiveness through economies of scale and learning effects. Also, where demand is rapidly growing, firms may invest more and adopt new technologies more quickly. Finally, it matters how domestic demand is internationalized, pulling a nation's products or services abroad. This can happen as sales of the product to multinational buyers increase and through domestic needs being transformed into foreign needs. The latter can happen through travel and is particularly applicable to cultural goods, such as films or television programs.

3. *Related and supporting industries*. This refers to the presence within a country of internationally competitive supplier industries or other related industries. Porter identified two mechanisms through which a competitive advantage in one industry could benefit other related industries. First, a supplier industry may provide a downstream industry with regular supplies of low-cost inputs and possibly privileged access to these inputs. Second, close working relationships between suppliers and an industry will result in more sharing of information and may result in more rapid innovation within the entire industry.

4. *Firm strategy, structure, and rivalry.* First, the way firms are managed in a particular country and choose to compete matters a great deal. The country's managerial system, the management practices and training, the way in which firms are organized and run, and the extent to which firms are globally oriented and willing to compete internationally are all part of this. Second, the goals of firms within a particular country, along with the motivation of employees and managers, may also contribute to a country's being successful in a particular industry. Third, the more vigorously firms compete with one another in a particular industry, the more likely that a country will develop and successfully sustain a competitive advantage in that industry. Policies designed to create "national champions" by encouraging two or more firms to merge rarely succeed. An important aspect of domestic rivalry is also the ease with which new businesses can be set up in a country and the extent to which they are.

The Porter Diamond Traditionally, these factors are represented by the "diamond" diagram shown in figure 1. In addition to these four factors shaping the competitive environment of a country, Porter emphasized the importance of two other factors that may separately contribute to a country's acquiring a competitive advantage or prevent its doing so. The first is the role played by *chance* events, such as an invention, shortages of key inputs, a sudden rise in the costs of inputs, significant shifts in exchange rates, wars, or the political decisions of government. The second is the role of *government* policy, which may influence firms in a particular industry either positively or negatively. The extent to which government intervention has contributed to the emergence of a national competitive advantage in particular countries is hotly debated. Advocates of government intervention point to the experiences of Japan and Korea as examples of how such intervention can work. By contrast, the same policy largely failed when applied by West European governments to Europe's electronics industry. Government intervention is viewed by Porter as working through the four main determinants of the diamond rather than constituting a fifth factor.
Figure 1
Porter's diamond

An important aspect of the phenomenon of national competitive advantage is that it is an evolving process, in which all the factors interact, with each determinant influencing the others. This process of interaction is as important as the presence or absence of each of the factors viewed separately. Thus factor conditions at any given time are determined by factor creation in the form of investment in education and infrastructure and, more important, investment in the creation and upgrading of advanced and specialized factors such as science and technology. Such investment is stimulated by a strong element of rivalry between domestic firms. Demand conditions are also affected by the existence of intense rivalry, which helps create a large domestic demand for the product through investment in marketing, aggressive pricing policies, and the introduction of more varieties of the same product. The development of related and supporting industries is affected by all of the other factors, as is the degree of domestic rivalry among firms.

Clustering and Sustainability An especially important role in this process is played by the geographical concentration of industries in a particular region, resulting in the phenomenon of clustering. Clustering is a readily observable feature of the economies of most countries. It exists because of the relationships among the four factors in the diamond and the need for firms to be close to exploit these advantages. Within a cluster, the competitive advantage enjoyed

by one industry helps create or sustain the competitive advantage enjoyed by another in a mutually reinforcing process. An example of this is where competitive supplier industries enable a country to sustain a competitive advantage in downstream industries. The same dynamic process may equally well happen in reverse, however.

A further aspect of Porter's diamond model concerns the importance of sustaining a competitive advantage. It is not sufficient for firms in a country to obtain a competitive advantage in a particular industry; that advantage must be sustained by a processing of widening and upgrading. Some of the factors that give rise to a competitive advantage are also important in sustainability. These include investment in institutions that undertake research and generate new ideas, the composition of demand and the intensity of domestic rivalry, and the extent to which the different factors in the diamond interact.

A Multiple Diamond Approach One of the major criticisms leveled at Porter's model is that it fails to adequately address the role of multinational enterprises in the determination of national competitive advantage. In 1993, John Dunning argued that Porter was mistaken in arguing that the firm-specific advantages of multinational companies could be explained purely and simply in terms of the competitive advantages of their home countries (Dunning 1993). Multinational companies derive their advantage from the national diamond existing in a number of countries, not just the home country. If Porter's model is to be applied to international business, Alan Rugman has argued that a "multiple diamond" approach is needed (see Rugman and Verbeke 2001). The weakness of the Porter model, argue Rugman and Verbeke, is that it concentrates entirely on what they call "non-location-bound" firm-specific advantages that are developed by firms in home countries before they engage in foreign direct investment (FDI) and which can then be transferred to other branches of the firm. This ignores, however, the advantages that multinational companies, which have already engaged in FDI, enjoy from having value-added activities in several locations and

from their common governance. Some of these advantages are "location bound," which means that they derive from a particular geographical area and cannot easily be transferred abroad.

The need for such a multiple diamond approach is especially relevant in the case of small countries, where firms are able to overcome the problems of a small domestic market by increasing their sales in the markets of other countries. Rugman and Collinson have illustrated how the Porter model could be applied to the analysis of the problem of international competitiveness with reference to firms in Canada (Rugman and Collinson 2006). Using a double diamond model, Rugman and Collinson show how Canadian firms have used exports to the United States and their rivalry with U.S. firms to develop a global competitive advantage in particular industries. In effect, the Canadian and U.S. markets served as two domestic markets through which Canadian firms could become globally competitive. Such an advantage may be acquired through developing new innovative products and services for consumers in both markets, drawing on support industries and infrastructures in both countries, and making freer and fuller use of the physical and human resources of both countries (Rugman and Collinson 2006).

Competitiveness One of the effects of the focus on competitive advantage since the 1980s has been an increased fascination with competitiveness rankings of countries. Two examples of this are the Global Competitiveness Report by the World Economic Forum (WEF), and the World Competitiveness Center's Yearbook. Such listings seek to rank countries in terms of competitiveness using a range of criteria such as economic performance, government efficiency, business efficiency, and infrastructure. The 2006 rankings of the WEF placed Switzerland, Sweden, and Finland respectively in the top three places in the world. It should be pointed out, however, that it is *comparative*, not *competitive*, advantage that determines what goods a country specializes in. This is because trade is a positive-sum game in which all countries gain, not a zero-sum game in which one country gains only at the expense of another.

This point is well made by Paul Krugman in a short essay first written in 1994, in which he comments on what he called the "dangerous obsession" with competitiveness (Krugman 1996). Using the example of Japan achieving a higher level of productivity than the United States, Krugman writes, "While competitive problems could arise in principle, as a practical, empirical matter, the major nations of the world are not to any significant degree in economic competition with each other. Of course, there is always a rivalry for status and power   countries that grow faster will see their political rank rise. So it is always interesting to *compare* countries. But asserting that Japanese growth diminishes US status is very different from stating that it reduces the US standard of living   and it is the latter that the rhetoric of competitiveness asserts" (Krugman 1996, 10).

Achieving a national competitive advantage is important in enabling some countries to grow faster than others. An obsession with competitiveness, however, is dangerous, as Krugman argues, because it can lead to protectionism and trade conflict, as well as misguided public spending designed to create and sustain a national competitive advantage over other trading partners and the promotion of national champions.

To summarize, acquiring and sustaining a competitive advantage can be seen as the primary strategic aim of firms in the modern world economy. The source of national competitive advantage is to be found in the competitive advantage obtained by the firms operating in the country, both domestically owned and foreign owned. This, in turn, is the product of a complex set of factors that interact with one another to shape the competitive environment of the country. Unlike comparative advantage, however, competitive advantage is a dynamic concept, in which national competitive advantage continuously evolves. In a world in which multinationals are dominant, the source of such advantage often results from firms operating in more than one country. Despite its usefulness in explaining why some countries develop a specialization in a particular industry or branch, an emphasis on attaining a competitive advantage can cause governments to pursue

misguided policies that lead to trade conflict. It remains the case that trade is a positive-sum game in which all can benefit.

■ conflicted virtue

In the world's monetary system, only a few major currencies mainly the U.S. dollar and the euro dominate as units of account for the internationally liquid assets or debts of developing countries or emerging markets. The consequences of this international asymmetry among currencies are profound. It leads to the problems of original sin (the inability of a debtor country to borrow in its own currency) and conflicted virtue (the inability of a creditor country to lend in its own currency).

Any creditor country that cannot lend in its own currency cumulates a currency mismatch called con-flicted virtue a concept introduced by McKinnon (2005). A country is "virtuous" if it has a high saving rate and tends to run surpluses in the current account of its balance of payments, that is, make loans to foreigners. Because the surplus country cannot lend in its own currency, however, it builds up claims on foreigners in foreign exchange, usually U.S. dollars. This situation has led foreign debtor governments particularly the U.S. government to complain that the surplus country's ongoing flow of trade surpluses and official reserve accumulation of dollars is an unfair result of having an undervalued currency. Debtor governments may then try to pressure the surplus country to appreciate its currency against the dollar in the often mistaken belief that an appreciation of the surplus country's currency will reduce its trade surplus.

The greater the foreign mercantile pressure for appreciation, the greater the concern of domestic private holders of dollar assets that they will suffer capital losses in their home currency. As holders of dollar assets switch into the domestic currency and out of dollars, the government is "conflicted." An appreciation would dampen exports and, if expected to be repeated, induce serious deflation with a zero percent interest liquidity trap (a situation in which the nominal interest rate is close to zero and the country's central bank is unable to stimulate the economy with monetary policy), as in Japan in the 1990s. But the American government may threaten trade sanctions if the creditor country under siege does not allow its currency to appreciate substantially. This is the essence of the syndrome of conflicted virtue.

Conflicted Virtue in East Asia Conflicted virtue would not arise in creditor countries whose money is the dominant vehicle currency in international finance. In the 19th century, Britain was the largest creditor country, with large current account surpluses financed by large net capital outflows. Most of the British claims on foreigners, however, were denominated in the pound sterling, the British currency. Thus British investors were happy to accumulate large sterling claims on foreigners without provoking a depreciation of their foreign claims

against their domestic ones. Similarly, for 25 years after World War II, the United States had trade surpluses and was the world's biggest creditor. By then, however, the dollar had displaced sterling as the world's dominant vehicle currency. Because U.S. claims on foreigners were denominated mainly in dollars, there was no internal currency mismatch in U.S. private portfolios.

The East Asian economies (and, increasingly, oil-rich Middle Eastern countries) are unusual, however, in that they are significant international creditors whose currencies are relatively little used outside their own countries. In Japan, large current account surpluses have persisted since the late 1970s. Taiwan's and Singapore's current account surpluses have been significant since the 1980s. Since 1998, previous debtor economies such as Korea have run current account surpluses (reflecting their "virtuously" high saving rates), resulting in high net capital exports. Sometimes these are offset by foreign direct investments (FDI) abroad. But the common mode of finance is to build up liquid claims either privately or as official exchange reserves in international monies such as the dollar. Japan's current account surpluses continued into the new millennium. By 2005, Japan's net holdings of liquid claims on foreigners (largely in dollars) reached a new high of U.S. $1.7 trillion, of which about $830 billion were official exchange reserves (McKinnon and Schnabl 2006).

Although China's buildup of liquid dollar claims has a much shorter history than Japan's, it has been accentuated by large inflows of FDI relatively illiquid long-term liabilities. By the end of 2005, China's liquid dollar-denominated assets were roughly $1 trillion, of which $819 billion were official exchange reserves a higher proportion than in Japan. The cumulative joint holding of dollar claims of all East Asian countries amounts to nearly $3 trillion. In China, household consumption, wages, and claims on financial intermediaries such as banks (deposits) and insurance companies (annuities) are mainly in yuan. Thus private Chinese households and firms will hold dollar assets only if there is a substantial business convenience in doing so, or if the interest rate on dollar assets is higher, and if the im-

mediate threat of yuan appreciation (dollar devaluation) is absent.

Effects of Conflicted Virtue China and other East Asian governments worry about the sudden loss of export competitiveness should their currencies be forced to appreciate. Beyond this, when the world price level measured in dollars is stable, any such appreciation would be followed by a domestic deflationary spiral as in Japan from the mid-1980s through the 1990s as a result of the erratically appreciating yen. McKinnon and Ohno (1997) describe the nature of an American mercantile pressure to appreciate the yen from the 1970s to the mid-1990s, then analyze the subsequent deflationary consequences for Japan.

Governments in creditor economies with conflicted virtue may cut domestic short-term interest rates to forestall or slow the conversion of privately held dollar assets into domestic currency. Insofar as people believe that low short-term rates will persist, domestic long-term interest rates also fall. At any given exchange rate, a new portfolio equilibrium can be found in which private agents would be willing to finance the nation's ongoing current account surplus by building up higher yield liquid dollar claims rather than the government accumulating official exchange reserves.

Japan has the longest experience with current account surpluses, and the associated buildup of dollar claims, from the early 1980s into the new millennium. Between 1978 and 2007, the interest rates on long-term (10-year) Japanese government bonds (JGBs) averaged about 3 to 4 percentage points less than those on long-term U.S. treasuries. Short rates are more volatile, but were bid down close to zero in the mid-1990s. In November 2006, when the American interest rate on overnight federal funds was 5.25 percent, the corresponding Gensaki rate in Tokyo was just 0.25 percent. As long as interest rates on yen assets are sufficiently below those on dollar assets, the Japanese private sector banks, insurance companies, trust funds, and so on can still be persuaded to fund Japan's ongoing current account surpluses by accumulating dollar assets with higher yields. This interest differential reflects both the ex-

pectation that the yen will appreciate on an upward trend, as was important from the late 1970s to the mid 1990s, and a negative risk premium that arises when the yen simply fluctuates against the dollar so as to make the ever-larger private holdings of dollar assets more risky in yen terms as was the case in the first few years of the new millennium.

But there are limits on how negative this risk premium on yen assets, and on how wide the associated interest differential, can become. When American interest rates fell to abnormally low levels, with short-term rates down to just 1 percent in early 2004, the spread was not (could not be) big enough because Japanese nominal interest rates were bounded from below by zero. Then the Japanese private sector refused to keep acquiring enough dollar assets to finance the current account surplus. Indeed, private agents in Japan started dishoarding previously accumulated dollar assets in order to acquire near-zero-yield yen assets! In 2003 4, the Bank of Japan intervened massively in the foreign exchange markets to acquire more than $330 billion mostly from private Japanese financial firms in order to prevent the yen from appreciating sharply.

Since 2004, China has run a larger current account surplus, mainly financed by a huge buildup of official exchange reserves. This buildup has led to calls from the American government for China to appreciate its currency the threat thereof leading to a fall in internal Chinese interest rates and the unwillingness of private Chinese wealth holders to acquire overseas assets. Therefore, the rapid accumulation of official exchange reserves becomes even larger. Conflicted virtue in creditor countries, with their overhangs of dollar assets, continues.

contagion

In economics, *contagion* refers to the spread of a crisis from one country to others. Such a spread can show up in a variety of ways, such as its effects on interest rates, asset prices, exchange rates, capital flows, or the probability of a crisis. Economic usage of the word *contagion* draws on the analogy to the spread of contagious diseases. Thus the currency crisis in Thailand that spread to much of the rest of East Asia in 1997 was often referred to as the "Asian flu" or the "Asian contagion." The use of the term *contagion* became particularly popular with the crisis in Mexico at the end of 1994, which was felt throughout most of Latin America and became known as the "tequila crisis." Academic attention to contagion had been stimulated by the earlier crises in the European Monetary System in 1992 and 1993.

Defining Contagion There is considerable debate among economists about how to define contagion. Some hold that it refers to any general transmission of shocks from one market to another. Others argue that contagion exists only if there is a significant increase in cross-market relationships beyond what can be explained by the fundamental state of a country's

economy ("fundamentals"). Still others contend that contagion spreads only through certain channels. In an influential analysis, the economist Paul Masson (1999) defined contagion as a consequence of sudden shifts in market expectations and investors' confidence. Such shifts are particularly relevant in the context of second-generation crisis models in which a country's fundamentals can be in an intermediate vulnerable zone between good and bad. In such situations, a crisis in one country can directly affect expectations of the situation in other countries, and hence move an economy from a good equilibrium to a bad one and end in a crisis. Masson distinguishes contagion from other types of shocks. He calls a common external shock that affects a group of countries "monsoonal effects," referring to the example of a monsoon season affecting several countries in a region. This type of effect, Masson argues, should not be considered contagion. Another example of a monsoonal effect is a shock to oil prices or supply that affects many countries at the same time. Still another is the effect on developing countries of major changes in the interest rates of large industrial countries. Both of the latter two examples helped contribute to the Latin American debt crises of the 1980s.

During noncrisis periods, contagion is usually related to the linkages of the economic fundamentals between one or more countries, and is typically called *interdependence*. Possible factors leading to contagion include trade linkages, common external shocks, and political or economic policies. Contagion is more frequent during crisis periods than noncrisis periods, however, and is an important explanation of emerging market crises of the late 20th and early 21st centuries. Crisis contagion beyond what can be explained by fundamental links is often called "pure contagion." "Unjustified" contagion refers to pure contagion resulting from panic and other forms of irrationalities and market imperfections. No commonly accepted name has yet been given to rational pure contagion that is transmitted through financial channels such as portfolio rebalancing. A country can be an "innocent victim" of fundamental-based contagion or of pure contagion. For example, the con-

tagion effect from Argentina to its small neighbor Uruguay in 2001 was due primarily to economic interdependence, while the spread of the Asian crisis has often been attributed to panic contagion. The degree of a country's innocence and the degree to which contagion is unjustified by fundamentals are often matters of considerable dispute.

Causes and Channels of Contagion Contagion can be transmitted through real or financial linkages, or through other channels such as global investors' behavior and market imperfection. Causes of contagion are often closely related to its transmission channels. Real linkages, such as trade, economic policies, shared fundamentals, and common shocks, all lead to increased interdependence among economic and financial markets. Contagion effects generally have a strong regional concentration (the Russian crisis in 1998 is a major exception). This has led many economists to stress the role of direct macroeconomic linkages, especially through international trade, as an important channel for contagion.

If contagion is taken to include the general interdependence among economic fundamentals, it can be measured using comovements of financial or economic variables. Pure contagion measurements typically test for cross-country relationships beyond fundamentals. Treatments of what are considered fundamentals also vary substantially. Typically, the broader the range of factors that analysts consider fundamentals, the less pure contagion they see.

Contagion also can spread through financial connections. Global portfolio diversification allows large capital flows to enter emerging markets but also makes inflows quickly become outflows during a crisis. Such abrupt reversals of capital flows are often called "sudden stops." In order to maintain the liquidity of their portfolios, institutional investors tend to sell their cross-border investments in one market when another market is in trouble. Portfolio diversification and rebalancing alone are often enough to explain contagion effects without invoking market imperfections. Similarly, common lender problems also lead banks to rebalance their assets portfolio and refuse to roll over debt to countries with risk characteristics similar to those countries in

default. If several countries share the same type of investors, correlations among these countries' financial assets increase, even among countries with few economic similarities. If investors trade only certain categories of assets, the probability of selling out that type of asset during a crisis also increases.

Financial market imperfections, such as asymmetric information, a situation in which one party has more information than another, and ill-designed incentive structures for fund managers, can also contribute to the spread of a crisis from one market to another. When a market is less transparent and information is not readily available, investors are more likely to herd. When investors are relatively uninformed they may assume that if someone else takes an action, it is because that person has better information. Such behavior would increase the size of market swings.

Fund managers' compensation contracts, even if optimal at the firm level, may lead to inefficiencies at the macroeconomic level. Fund managers, for example, are usually evaluated on short time frames, which restrict them from taking advantage of mispricing. Moreover fund managers are typically evaluated against a benchmark, encouraging them to form a portfolio very close to that benchmark or to follow the actions of other fund managers. Such "separation of brain and resources" contributes to fund managers' pursuing short-term profits and herding, which can cause cross-border contagion.

Owing to similarities among the countries, their geographic proximity, and limited information, investors may not always be able to differentiate among common shocks and country-specific shocks. As a result, they might make heuristic decisions. Herding and rational ignorance are such "rule of thumb" responses to market imperfections, and contagion is the consequence.

Investors' sentiments   panic, overoptimism, overreaction, and shifts in expectation   can also lead to contagion. During a crisis, investors might panic and pull out funds in the entire crisis region regardless of each country's fundamentals. They can be overly optimistic before a crisis. A crisis in one country might force them to reevaluate investments that they

initially should have investigated more thoroughly. Thus a crisis in one country can serve as a wake-up call prompting a reevaluation of investments in other countries with shared characteristics.

Of course, if markets were already fully efficient there would be no need for such reevaluations. However, many economists and finance experts are now giving much greater attention to ways in which financial markets may be less than ideally efficient. Such analysis is called behavioral finance. It varies from emphasis on external constraints such as the high cost of information to possible psychological biases. Behavioral analysis is still at an early stage of development, but it promises a number of fruitful insights into the behavior of actual financial markets that fall between the extremes of ideally efficient markets and wildly irrational ones (see Willett 2000).

Examples of Crisis Contagion Discussions of contagion often suggest that the spread of crises is especially associated with the effects of panic in financial markets. This panic contagion view has become particularly widespread in light of the 1997 98 Asian crisis as the countries hit had strong macroeconomic fundamentals. Subsequent analyses, however, showed that many of the countries in crisis had microeconomic and financial weaknesses that suggested some justification for the spread.

Since many crisis countries in Asia had impressive economic growth records, balanced government budgets, and conservative monetary policies, some economists started to analyze the role market psychology and investors' behavior played during the crisis. South Korea is a prime example. Despite its good macroeconomic fundamentals, Korea suffered devastating losses during the crisis largely because of financial and microeconomic weaknesses. Because of implicit guarantees against large depreciation of the exchange rate and the prospect of government bail out of failing institutions, the banking sector in South Korea had incentives to engage in excessively risky loans. As a result it became burdened with nonperforming loans while the corporate sector took on large dollar-denominated, short-term debt. Similarly, a large number of Indonesian and Thai corporations had been borrowing heavily in U.S.

dollars. They and their overseas investors had believed that their countries' exchange rates were safe from large depreciations. When this assumption proved false, there was a rush to cover their positions, which in turn generated large capital outflows.

Furthermore, while many initial analyses treated the whole set of crises as a single event, the crisis developed over a period of months and had several distinct phases. The first phase, between July and October 1997, started with the run on the Thai baht. Its subsequent depreciation spread mainly to Indonesia, Malaysia, and the Philippines, all of which were forced to allow large depreciations of their currencies. The financial markets of a much broader group of countries felt ripples, but did not experience strong speculative attacks or capital flight. In the second phase, which started in October 1998, the devaluation of the Taiwan dollar generated fears that the Hong Kong dollar would follow. The Hong Kong stock market lost 40 percent of its value, which led to the devastating devaluation of the South Korea won in less than two months. While Korea felt some immediate repercussions from the Thai crisis, they were relatively mild. The strong speculative attacks on the won did not occur until months later. Simple panic contagion would not explain such a protracted spread.

The Asian financial crisis drove down raw material prices. This had severe consequences for Russia, which was highly dependent on exports of raw materials. Even though interest rates soared to 150 percent to attract investors to buy government bonds, by mid-1998 Russia was in need of help from the International Monetary Fund (IMF) to maintain its exchange rate. However, the Russian government failed to implement a realistic budget and necessary legislation to meet IMF requirements. Fearing the IMF might pull the plug on its loans, global investors continued to flee Russia, and Russia soon after defaulted on its debt, sending shock waves through financial markets across the globe.

The financial market expected a substantial devaluation of the ruble, but most observers believed that Russia was too important geopolitically to be allowed to default. Thus markets were stunned.

Combined with the near collapse of the hedge fund Long-Term Capital Management in the United States, the Russian default set off a shift to extreme risk aversion among investors. Risk premiums rose substantially, and emerging market countries found it difficult or impossible to find investors for new international credit instruments for many months.

Policy Implications The best ways to prevent contagion and to deal with it when it occurs vary depending on its causes and channels. A number of policies that are good in their own right, such as the promotion of sound economic fundamentals and the development of better policies in both the public and private sector for assessing and managing risk, also help reduce problems from inflation. The role played by contagion during the crises of the 1990s prompted many proposals for greater national and international control over international financial flows.

Confusion has resulted from the tendency of the popular press to use the term *contagion* to describe any effects of a crisis in one country on currency or financial markets of other countries. The crisis in Iceland in 2006 was felt in currency markets as far away as Eastern Europe and Africa, but these fairly mild ripple effects from Iceland were of a quite different magnitude than the devastating crises that hit a number of Asian countries after Thailand's currency crisis. The global repercussions of the Russian default in 1998 fell between these extremes.

The available evidence clearly suggests that major shocks often do cause indiscriminant contagion in financial markets, but with the exception of the Russian default this tends to last for only a brief period, measured in hours, days, or weeks. Medium-term responses from the currency and financial markets tend to be much more differentiated, although the determinants of these more focused medium-term responses can be quite complex, including both trade and financial linkages and a broad range of fundamentals including financial and political as well as economic considerations. Since information is often quite imperfect, perception of the fundamentals can shift without any change in the actual fundamentals themselves. Thus a crisis in one

country can act as a wake-up call that generates re-evaluations of conditions in other countries. The Thai crisis provides a vivid example.

In general, the fallout on other countries and markets from the crises occurring since the Russian default have been much milder, and as a consequence support for major reforms in the international financial architecture has fallen off. Many economists, however, still believe that there is a strong case for strengthening the capabilities of the IMF to act as an international lender of last resort to deal with liquidity crises, especially those that would have the potential to generate considerable contagion.

■ Convention on Biological Diversity

The Convention on Biological Diversity (CBD) aims to promote the well-being of both nature and humans. Negotiated under the auspices of the UN Environment Program (UNEP), adopted on May 22, 1992, and entered into force on December 29, 1993, it is built on a threefold, interacting objective: "the conservation of biological diversity, the sustainable use of its components and the fair and equitable sharing of the benefits arising out of the utilization of genetic resources" (art. 1). The convention is comprehensive in scope, as it includes all species and ecosystems worldwide, as well as the genetic diversity within species. There are currently 188 parties to the convention, which is governed by a conference of the parties (COP) that is supported by a Subsidiary Body on Scientific, Technical, and Technological Advice. The CBD secretariat is located in Montreal and has about 60 professionals and support staff.

The background for negotiating and strengthening the CBD was an increasing awareness and agreement among scientists that the current rate of species extinction was (and remains) extremely high compared to the natural average rate (Wilson 1988; Heywood 1995, 232). A rapid loss of genetic diversity in domesticated plants, with risks of reduced food security, was another central concern. Of the

estimated 7 to 30 million species on earth, only 1.9 million have been scientifically described   most of what is lost is scientifically unknown. Moreover, developments in the biotechnologies have increased economic interests in the world's genetic resources. Genetic resources constitute important input factors in biotechnology, including the pharmaceutical sector and all development and breeding of plants and animals. Wild relatives of domestic crops provide genetic variability that can be crucial in circumstances such as overcoming disease outbreaks or adjusting to climatic changes. Species may contain compounds (genes, proteins) that can generate valuable pharmaceuticals or other products at some future date (Laird and Wynberg 2005).

Provisions on access to genetic resources, including the equitable sharing of the benefits of their use, form a central element of the CBD and are regarded as a prerequisite for the two first objectives of conservation and sustainable use. The CBD reconfirmed national sovereign rights to genetic resources (art. 15.1) and equitable sharing of benefits from use of those resources (art. 15.7). Access to the resources is based on mutually agreed terms and subject to prior informed consent (art. 15.4 and 15.5).

The value of products derived from genetic resources worldwide has been estimated at between U.S. $500 billion and $800 billion (Ten Kate and Laird 1999). In addition to the direct economic values of genetic resources, biodiversity as a whole provides a great range of ecosystem services, such as local water and climate regulation, and materials for building and firewood. There is also a great range of noneconomic values attached to biodiversity, such as cultural and intrinsic values. The average annual loss of wild habitats and populations is estimated to deprive people of ecosystem services with a net worth of about U.S. $250 billion every year (Millennium Ecosystem Assessment 2005). The CBD parties have pledged to halt and reverse the loss of biodiversity by 2010.

To this end, the CBD parties have agreed to develop national biodiversity strategies, integrate biodiversity conservation in all policy levels and sectors, identify and monitor biodiversity, establish systems of protected areas, and identify activities that are likely to have adverse effects on biodiversity. Moreover, the parties must adopt economically and socially sound measures to act as incentives for conservation and sustainable use, establish programs for scientific and technical education and training for identification and conservation, and provide support for such training in developing countries. The CBD is equipped with a monitoring mechanism in the form of national reporting and an incentive mechanism in the form of the Global Environment Facility (GEF). The GEF has invested nearly U.S. $4.2 billion for biodiversity conservation in developing countries since its establishment in 1991.

In several respects, the CBD constitutes a framework agreement open for further developments and specifications. For example, article 19.3 commits parties to the CBD to consider the elaboration of a protocol to protect biodiversity from potential risks from genetically modified organisms. On this basis, the parties negotiated the Cartagena Protocol on Biosafety, which was adopted in 2000 and entered into force in 2003. The protocol builds on a precautionary approach and establishes an advance informed agreement (AIA) procedure to help countries make decisions before agreeing to the import of such organisms into their territory.

The COP has initiated work on seven thematic work programs. These address marine and coastal biodiversity, agricultural biodiversity, forest biodiversity, island biodiversity, the biodiversity of inland waters, dry and subhumid lands, and mountain biodiversity. In addition, work has been initiated on biosafety; access to genetic resources; traditional knowledge, innovations, and practices (art. 8[j]); intellectual property rights; indicators; taxonomy; public education and awareness; incentives; and alien species.

The ecosystem approach is the primary framework for action under the convention. It is a strategy for integrated management of land, water, and living resources that aims to promote conservation and sustainable use in an equitable manner. The ecosystem approach recognizes that humans, with their cultural diversity, are an integral component of eco-

systems. As the greatest threat to biodiversity lies in the replacement of undeveloped land by alternative systems of land use, the approach recommends management in an economic context in order to reduce market distortions, which undervalue natural systems and provide perverse incentives and subsidies.

The COP has requested close collaboration with relevant international instruments and processes to enhance policy coherence. These include biodiversity-related conventions (Convention on International Trade in Endangered Species, Ramsar Convention on Wetlands, Convention on Migrating Species, and World Heritage Convention), the UN Framework Convention on Climate Change (UNFCCC), and the Convention to Combat Desertification (CCD), as well as intergovernmental organizations, such as the Food and Agriculture Organization, UNESCO, the Intergovernmental Oceanographic Commission, and the World Trade Organization (WTO). There is a joint Web site for biodiversity-related conventions (see Further Reading, at the end of this article).

The CBD and the Ramsar Convention on Wetlands are implementing a joint work plan, including the River Basin Initiative. The secretariats of the CBD and the CCD are developing a joint work program. The COP has also called for greater cooperation with the UNFCCC on issues such as drylands, forest biodiversity, coral reefs, and incentive measures. The Intergovernmental Panel on Climate Change examines linkages between climate change and biodiversity and prepares scientific advice on the integration of biodiversity considerations into implementation of the UNFCCC and its Kyoto Protocol. The Secretariat is collaborating with UNESCO on the development of a global initiative on biodiversity education, training, and public awareness. The COP also emphasizes the importance of developing a common understanding of the relationship between the CBD and the WTO agreements, including the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS). It has called for further work with respect to the relationship between intellectual property rights (IPRs), relevant provisions of TRIPS, and the CBD, in particular those on technology transfer and on traditional knowledge and biological diversity. The COP has invited the WTO to explore the interrelationship between the CBD and the TRIPS. The COP has also sought to initiate cooperation with the World Intellectual Property Organization (WIPO) on the issue of IPRs arising from the implementation of the convention, such as those in access and benefit sharing and article 8(j) and related provisions. A memorandum of cooperation was signed with WIPO in 2003.

■ Convention on International Trade in Endangered Species (CITES)

The Convention on International Trade in Endangered Species (CITES) is a mature international treaty that became effective in 1975. At the beginning of 2007, 169 sovereign states had ratified or acceded to the treaty.

Global trade in animals and plants is not measured by any one organization or individual; it occurs as $20 tourist items or as single blue fin tuna worth $40,000 for the Japanese sushi market, as well as reptile skin shipments worth more than $1 million. The total amount of trade in wild plants and animals is very difficult to determine, but one comprehensive estimate for the 1990s suggested an annual value of $15 billion, excluding timber and fisheries, which by themselves may have a value of $140 billion. Estimates of illegal trade in endangered species range between $5 billion and $10 billion per year. It is widely accepted that the value of illegal wildlife trade is second only to the illegal drug trade.

Approximately 5,000 species of animals and 28,000 species of plants are listed for some level of protection under CITES. Most well-known animals and plants are within the umbrella of the treaty: bears, elephants, whales, large cats, rhinos, sea horses, corals, orchids, and mahogany are but a sample of the species. The only group that is not well represented on the list is commercial fish from the open ocean. This absence has to do more with international politics than biological status.

The purpose of the treaty is to control the international movement of treaty-listed wild plants and animals, alive or dead, whole or parts thereof (specimens of species) in such a manner as to be assured that the pressures of international trade do not contribute to the endangerment of a species. This treaty does not deal with trade issues within a country or with the issues of habitat protection or preservation. CITES is implemented by way of permit requirements for the listed species. These permits are operative at the customs level as trade moves across national boundaries.

This is an active treaty regime; representatives of all the member states meet every two years to consider what adjustments need to be made to the list of protected species and what management and policy issues need to be addressed.

Listing of Species The treaty creates categories into which species of concern or at risk of extinction may be placed: appendix I and appendix II. Those on appendix I are species threatened with extinction and which are affected by international trade. Appendix II lists species that *may be* threatened with extinction and are part of international trade.

The placement of a species in appendix I or II is a group decision made at the conference of the parties (COP) and requires a two-thirds vote of the parties. Any state that disagrees with a listing decision may take a reservation on the species listing within 90 days of the vote. As of 2007, approximately 228 mammals and 146 bird species were listed on appendix I, and 369 mammal and 1,401 bird species on appendix II.

Since a consequence of listing a species on appendix I is that commercial trade in the species will be prohibited, proposals for placing new species on appendix I receive very close scrutiny by the delegates at the COP.

Permit Responsibilities Once a species is placed on either appendix I or II, then the protection of the treaty is triggered by the treaty requirement that each state must prohibit the transboundary movement of the species unless a permit has been issued by the relevant country. As there is no international police system to enforce the obligations of CITES, the treaty presumes that enforcement will be done at the national level. Indeed, a specific obligation of the treaty is for each state to adopt domestic legislation that will carry out the requirements of the treaty.

Appendix II species normally will be allowed in international trade so long as a CITES export permit has been issued by the state of export. Before issuing such a permit, the authorities of the state of export must make a key ecological finding: the scientific authority of the state of export must advise that such export will not be detrimental to the survival of that species. This is a particularly challenging requirement in developing countries where wildlife science for many species is nonexistent. If detrimental trade is allowed, knowingly or unknowingly, then the goal of the treaty is frustrated.

Appendix I species, those already identified as at risk of extinction, require two permits: an exporting permit and an importing permit. The criteria for the exporting permit are the same as with appendix II species. Note that the importing states must also make a finding that the purpose of the import will not be detrimental to the species. For the import permit the key requirement is that the management authority of the state of import must be satisfied that the specimen is not to be used for primarily commercial purposes. Although the determination of what is a primarily commercial purpose would seem to be straightforward in the main, on the margins it is a difficult question. Sport hunting trophies are generally not considered to have a commercial purpose even though they may have a market value. Importation of animals by zoos is likewise not prohibited by CITES custom even though the zoo will pay for the animal and generate money from its display.

The limitation on commercial use of appendix I species is controversial, in that some states argue that economic utilization of appendix I species would be useful for obtaining the resources and political motivation for the protection of the species for example, the sale of elephant ivory could raise funds to help protect elephants. Additionally some states are troubled by the fact that the importing county (primarily the developed countries) can block trade that the exporting country (primarily developing countries) believes is acceptable. These issues have been settled by the language of the treaty and it would take an amendment of the treaty to change the existing approach. Although an amendment process is provided for in the treaty, it is highly unlikely to occur.

Enforcement The enforcement problems faced by CITES are not just the limitations of the treaty language but also limitations within individual party states:

Lack of adequate domestic laws.

Lack of an adequate number of government employees and lack of pay and training for the employees that do exist.

Lack of scientific experts within a country, unwillingness to give power to them, and a lack of resources for the scientists that are present.

Lack of support from the police and courts for wildlife crime prosecutions and lack of serious punishment when a prosecution is successful.

Lack of a public education component.

Wild plants and animals are important to both local and international economic activity. The overconsumption of these resources is a critical issue in many countries. The CITES treaty provides a legal mechanism and obligation to control trade in endangered species and to protect these resources. In an environment of limited government resources, however, enforcement is often difficult.

■ convertibility

Convertibility refers to the ability of a currency to be freely transformed into foreign exchange. There are two types of convertibility: current account convertibility and capital account convertibility. The first term applies when the purpose of such transformation is to acquire foreign goods or services activities that are typically recorded in the current account. The second term is used when the purpose is the acquisition of foreign assets, such as foreign stocks and bonds activities that are typically recorded in the capital account.

Currency convertibility has direct consequences for international trade, capital mobility, and economic growth. When a country imposes restrictions on the conversion of domestic currency for foreign exchange, it necessarily impedes transactions between domestic residents or entities and foreign ones: most foreign counterparts will not accept a currency that is hard to convert into foreign exchange as a form of payment. Without current account convertibility, the cost of engaging in international transactions increases, leading to fewer transactions and to a lower level of trade. So important is current account convertibility that member nations of the International Monetary Fund (IMF) are required to fully adopt it under article VIII, sections 2, 3, and 4 of the Articles of Agreement.

Capital Account Convertibility and Growth A similar consensus, however, does not exist regarding capital account convertibility. The debate is more empirical than theoretical in nature. Theory tells us that in a perfect world, countries with full capital account convertibility can successfully exploit international capital markets to smooth out their consumption patterns over time; such countries can borrow from the rest of the world at a time when domestic consumption and investment are high relative to domestic income, and lend to the rest of the world when domestic consumption and investment are low relative to domestic income (Cole and Obstfeld 1991; Obstfeld and Rogoff 1995). Countries that have the ability to smooth out these income-expenditure patterns are theoretically better off than they would be otherwise. Without the ability to tap into international capital markets, a country would have to rely primarily on its own savings to fund domestic investment. Such a situation could limit future economic growth if domestic savings could not match the domestic level of investment demand.

According to the theory, countries that adopt and maintain full capital account convertibility should be

able to grow faster than countries that do not. Empirical studies, however, have not been able to settle this issue convincingly. Some researchers have found that convertibility has a positive effect on growth; others argue that it has either no effect or a negative effect.

During the late 1970s, many countries systematically removed restrictions on — that is, liberalized — their capital accounts. The experiences of these countries presented an opportunity for researchers to test the hypothesis that liberalization is associated with subsequent output growth. Although some researchers found empirical support for this hypothesis (e.g., Quinn 1997), others found positive effects only for high-income countries, not for emerging-market economies (Edwards 2001). More recent research has examined the microeconomic consequences of capital account restrictions to ascertain whether they affect different industrial sectors or even firms differently.

A case study of capital controls in Chile during the 1990s found that these restrictions changed the way firms chose to do their financing. Specifically, firms in Chile switched from relying primarily on short-term debt to relying on internal funds for financing investment spending (Gallego and Hernandez 2003). This change is what one would expect to observe if capital controls introduced a cost wedge between domestic sources of funds and international capital markets. Although the results suggest that capital controls were costly for at least some firms, they cannot be used to judge the desirability of imposing or removing controls. Such policy decisions must be based on their effects on society as a whole rather than on a particular sector of society.

Although some evidence suggests that convertibility influences growth at some stages of development, research also suggests that such influence is limited at best and negative at worst. For example, one study estimates standard growth regression equations and does not find that capital account convertibility is associated with long-run growth (Rodrik 1998). Another study finds that many European countries enjoyed impressive growth rates during the 1950–73 period not despite having capital account restrictions, but instead precisely because they had them (Wyplosz 1999).

Theory versus Reality Why does research find capital account restrictions to be beneficial for growth when basic economic theory tells us otherwise? The discrepancy appears to stem from the fact that the "real world" is more complicated than basic theoretical models make it out to be. In a world with asymmetric information (i.e., buyers and sellers do not have the same information) and other capital market distortions, the conditions for smoothly operating markets do not exist. Many researchers note that with free capital mobility — or full capital account convertibility — a country is exposed to the whims and fads of investors and traders who make trading decisions for all kinds of reasons, some of them rational but many of them seemingly irrational. When enough of them decide to pull their investments out of a country, the sudden demand for foreign exchange may trigger a currency crisis with devastating consequences for the banking sector and the rest of the economy. Work by Kaminsky and Reinhart (1999) offers empirical evidence substantiating this effect.

The lack of consensus in the empirical literature reflects the beneficial effects of full capital account convertibility for some countries but not others (Prasad et al. 2003). As a result, the literature has shifted its focus to ask whether countries must have a set of institutions or economic conditions before they adopt full capital account liberalization, and whether the sequence of capital account liberalization matters. For the first question, researchers have hypothesized that sound macroeconomic conditions — such as low and controlled fiscal deficits or low and controlled inflation — are crucial for countries considering full capital account liberalization (Sen 2007; Williamson, Griffith-Jones, and Gottschalk 2005). Other researchers believe that countries must implement a set of reliable institutions in the financial sector, such as imposing minimum information requirements, prudential supervision and regulation of the banking sector, and investor protection, when pondering the adoption of full current account convertibility (Chinn and Ito 2002; Arteta et al. 2001; Gelos and Wei 2002).

Research has also investigated whether the method and timing of liberalization (or the

sequencing of liberalization) matter as well. It is well known that short-term capital flows (such as portfolio investment) tend to be much more volatile than long-term flows (such as foreign direct investment). Given that this is the case, it is more prudent to liberalize long-term capital flows before liberalizing short-term ones. The idea is, of course, to reduce the country's exposure to what the literature has popularized as "hot money": short-term funds that enter and leave countries very suddenly and unexpectedly.

China and India are examples of countries that have considered adopting full capital account convertibility. Some commentators have argued that countries should always strive to adopt full capital account convertibility as soon as possible in order to reap all of its benefits (Forbes 2005). Others, however, argue that given the potentially disastrous consequences of implementing a liberalization program too rapidly, it is more prudent to go at it slowly and only when the country is "ready" (that is, when it has met all of the necessary preconditions). Given the theoretical complexities involved and the ambiguity of the empirical results, the advice that all researchers should probably offer to countries embarking on a full convertibility program is "proceed with caution."

■ **corporate governance**

Corporate governance determines, among other things, how control over the firm's resources is allocated, and how control and a monitoring hierarchy are created within a firm. Corporate governance acts as a facilitator, enabling managers and shareholders to move toward the optimal governance structure within the firm. Even though policymakers are often concerned with finding an optimal legal, institutional, and regulatory framework to protect the interests of investors and other stakeholders, it is difficult, in practice, to establish a single model that meets the needs of all parties. Given the broad and vague definition of *corporate governance*, there can be situations where the importance of other stakeholders such as employees and creditors may be central to a corporate governance system. Naturally, a corporate governance regime does more than regulate the ownership and control arrangements inside the firm. A "good" corporate governance system, for example, provides rules and institutions that enforce internal ownership and control arrangements, but it also contains measures that protect other stakeholders from the opportunistic behavior of

insiders. Such a framework, which is mainly concerned with a company's investors but extends to wider interests, arguably provides a solid analytical basis on which a framework for understanding the key components of a good corporate governance system can be created.

What Is Corporate Governance and Why Does It Matter? The importance of corporate governance has become increasingly recognized for companies' and countries' prospects (Claessens 2006). As a consequence, regulators and policymakers in many countries diagnose weaknesses in their legal regimes and propose new arrangements said to foster higher firm performance, greater entrepreneurship, and better developed capital markets. Recent audit-based scandals in Europe and the United States have prompted investors to pay more attention to the institutions of corporate governance (Armour and McCahery 2006). Moreover, as allocation and monitoring of capital among competing purposes and investments have become more complex, financial instruments, corporate structures, and accounting have all become more sophisticated and often more risky. This has made monitoring of management by shareholders and other stakeholders more difficult, involving higher costs. The other side of the coin, of course, is that firms with good governance will benefit through higher market premiums (Gompers, Ishii, and Metrick 2003).

Corporate Governance Systems There are two main systems of corporate governance, which have significant differences: (1) the market-oriented corporate model, and (2) the relationship-based (or network-oriented) corporate system (Bratton and McCahery 1999; Roe 2003).

Market-oriented systems are characterized by dispersed equity holding through capital markets, a portfolio orientation among equity holders, and a broad delegation to management of discretion to operate the business. Two governance problems are said to result. The first is the shareholder management agency problem. Collective action problems prevent close monitoring of management performance by widely dispersed shareholders of small stakes. Imperfect performance incentives result

for managers, who may rationally sacrifice shareholder value to pursue their own agendas. Market systems address this management incentive problem with three corrective mechanisms: the hostile takeover, shareholder legal rights against management self-dealing, and the inclusion of outside monitors on boards of directors. The second productive disadvantage of the market system is a time horizon cost that stems from shareholders' tendency to rely on short-term performance numbers. This problem has been attributed to information asymmetries. Management has superior information respecting investment policy and the firm's prospects, but this information tends to be soft or proprietary and therefore cannot credibly be communicated to actors in trading markets. At the same time, market systems fail to provide clear-cut protections to managers who make firm-specific investments of human capital, a failure due in part to these systems' reliance on takeovers, proxy fights, and boardroom coups to control agency costs.

Market systems have countervailing advantages. Their shareholders can cheaply reduce their risks through diversification. Compared to shareholders in relationship-based systems, they receive higher rates of return on their investment. Market systems' deeper trading markets facilitate greater liquidity. These capital markets also facilitate corporate finance, providing management with greater flexibility on the type and source of new capital than do the markets in relationship-based systems. More generally, they provide an environment relatively more conducive to management entrepreneurship, as reflected in increased investment in new technologies.

Relationship-based systems are characterized by a majority or near majority of stock held in the hands of one, two, or a small group of large investors who hold blocks of shares. Like market systems, relationship-based systems leave management in charge of the business plan and operations. But large block investments imply a closer level of shareholder monitoring (Becht, Bolton, and Röell 2003). In addition, the coalescence of voting power in a small number of hands means earlier, cheaper intervention in the case of management failure. The other

primary benefit of relationship-based systems stems from the blockholders' access to information about operations. This decreased information asymmetry permits blockholders to invest more patiently. The longer shareholder time-horizon, in turn, frees management to invest for the longer term and creates a more secure management environment for firm-specific investment of human capital.

There are corresponding costs and benefits. Where the blockholder is a firm, internal agency costs can constrain its effectiveness as a monitor. Indeed, whatever the identity of the blockholder, its heightened oversight incentive does not appear to result in sharp oversight of management investment policy. Freedom to make long-term investments thus often means pursuit of growth in market share at the cost of suboptimal return on equity investment. Trading markets in relationship-based countries tend to be thinner and less transparent than in market-oriented countries. Meanwhile, the blockholders themselves forgo the benefits of diversification and, given the thin trading markets, the possibility of easy exit through sale. Finally, there is a shortage of loyalty. Blockholders, having sacrificed diversification and liquidity, extract a return in the form of private benefits through self-dealing or insider trading (Dyck and Zingales 2004). Legal regimes in network-oriented systems facilitate this quid pro quo with lax protection of minority shareholder rights and lax securities market regulation. The judiciary in network-oriented systems, unlike some market-oriented systems (which play a much more proactive role in shaping the actual contents of the corporate governance framework than in continental European jurisdictions), is more confined to interpreting the statutes and codes enacted by legislators (LaPorta et al. 1997).

Typology of Legal Strategies for Protecting Investors There is a wide collection of strategies for protecting shareholders and creditors from expropriation by managers and controlling shareholders. A basic division is between two categories: (1) regulatory strategies, through which the law mandates the terms of relationships among principals, agents, and the firm; and (2) governance strategies, through which the law channels the ongoing articulation of

the terms of corporate agencies (Kraakman et al. 2004). The strategies within each category are designed to provide different solutions to principal-agent problems ex post or ex ante.

On examination, it turns out that there are two categories of corporate law that pursue regulatory strategies. The strategies in the first category impose performance mandates on agents. These agent constraints apply on an ex ante basis by rule and on an ex post basis through open-ended standards of conduct. The strategies in the second category govern the terms of the principal's financial engagement with the firm. These affiliation terms apply on an ex ante basis when capital is transferred to the firm and on an ex post basis when capital is withdrawn or shares are sold. There are three other categories of corporate law measures that pursue governance strategies. The first category, appointment rights, concerns the ex ante selection of agents and their removal. The second, decision rights, concerns control over the terms of the firm's governing contracts and its business plan. Ex ante decision rights control the initiation and amendment of investments, divestitures, contracts, restructuring, and corporate legislation; ex post rights go to the ratification or veto of investments, divestures, contracts, restructuring, and legislation. The third set of governance strategies, agent incentives, concerns the incentives of the firm's agents. Ex ante these relate to the agents' qualifications as responsible fiduciaries; ex post they are related to the agents' financial rewards. From this analysis ten categories emerge, which are given in table 1.

A typology can be used to create indexes that capture the effectiveness of these five strategies to protect shareholders. The evidence shows that the strategy of giving shareholders strong legal rights in the appointment or removal of board directors has more measurable benefits for shareholders in common law countries such as the United Kingdom, which has tough rules on the removal of directors, than civil law regimes in continental Europe, where management has more discretion to address shareholder and creditor interests, and there are limited circumstances where a director can be removed. The evidence also points to potentially high benefits of

shareholder involvement in corporate decision-making, such as in the case of directors' remuneration. In the case of affiliation rights, the exit right of shareholders is addressed by corporate law strategies, developed albeit differently across Anglo-American jurisdictions, that effectively constrain management in frustrating a hostile bid and facilitate an exit right by ensuring shareholder approval of the bid. Changes in continental European takeover law to promote affiliation rights are still required, notwithstanding efforts by the European Commission to provide better constraints on target management in the Takeover Directive (McCahery and Renneboog 2003).

By comparison, the agent incentives strategies are often left to the contractual discretion of the board of directors. Codes of conduct set forth requirements in the area of board structure, the committee structure of the board, the role, monitoring and performance of the board and nonexecutive directors, and directors' remuneration. Codes of conduct and stock exchange rules draw up highly specific requirements concerning conflicts of interests and transactions where shareholder approval is necessary. According to a recent study that measures the board's independence from large shareholders, the legal strategies that deal with constraining the board and giving shareholders more authority are more effective in Anglo-American jurisdictions than civil law countries. Meanwhile, the empirical studies that focus on the reward strategy are voluminous (see, e.g., Jensen and Murphy 2004). This line of research reveals a number of problems in the design of appropriate criteria that link shareholder welfare to performance

criteria for directors and managers (Bebchuk and Fried 2004).

The above typology suggests a broad approach to corporate governance: (1) market value is the principal measure of shareholder interest; (2) other constituents should be protected by contract and outside regulation; (3) ultimate control should rest with the shareholders; (4) managers should be obligated to manage in the interests of the shareholders; and (5) noncontrolling shareholders should be strongly protected. These organizing factors, and the five corresponding regulatory strategies that constrain major shareholders and managers, provide a sufficient basis for evaluating corporate governance systems in differing jurisdictions and regions.

Good Corporate Governance In recent years, the increased focus on good corporate governance among academics, policymakers, and business leaders has given rise to investigations about how shareholders' rights and judicial enforcement vary across countries. This work has led to discussions which show that specific legal rules and practices are necessary to run a business and maintain corporate governance. Furthermore it shows that the best practices vary across countries (LaPorta et al. 1997). The impact of legal rules and institutions may vary, for example, depending on the judiciary's ability to quickly resolve disputes (Berglöf and Claessens 2004).

Similarly there is a growing awareness of how the variety of corporate governance arrangements and extralegal mechanisms are specific to firm type, industry sector, and sources of finance (Carlin and Mayer 2000). These findings suggest that a good

corporate governance system requires, inter alia, legal rules that promote a system of disclosure and accounting and audit systems that function effectively to provide investors with timely and accurate information to make effective investment decisions. The key message for lawmakers is that the agenda for governance reform is broad and challenging, but delivering in the key areas will enhance performance (Black, Jang, and Kim 2006).

The positive impact of corporate governance can be felt not only on firm performance but also on the level of financial market development. Countries with better property rights and strong investor protection tend to have higher-valued securities and deeper capital markets. Enhanced creditor-protection rights are also associated with deeper and more developed banking and capital markets. Recent theoretical and empirical work highlights that countries with better investor protection are also less vulnerable to external economic shocks. In the end, corporate governance can induce countries to adopt higher standards which can have a major impact on realizing their objectives.

■ corruption

Corruption is commonly defined as the abuse of public office for private gain. It involves bribe taking and deviation from public duties by officials in var ious governmental spheres such as the grant of licenses and permits, implementation of public programs, and enforcement of government policies. This view of corruption is meant to be a working definition only and it does not capture the context-specific and multidimensional nature of corrupt acts.

The difficulties in arriving at a commonly ac cepted definition are many. Corruption has moral, legal, and sociological dimensions. It need not be confined to the public sector. Corruption need not involve bribes or monetary payments. Moreover, in certain societies the culture of gifts, networking, and reciprocal favors is quite common, and these acts are socially acceptable.

Corruption, in one form or other, is present in most countries in varying degrees. Many poor and devel oping economies, however, are perceived to be highly corrupt, and the recent attention in academic as well as policy circles tends to focus on the type of corrup tion prevalent in these countries. Many development economists view corruption as a major problem.

Corruption is a fairly new field of inquiry in economics, although the earlier literature on rent-seeking activities is related and has influenced re search in corruption. The phenomenon of corrup tion, however, is certainly very old. There are several accounts of governmental corruption in England, Italy, and China in the 18th and 19th centuries. References to bribery and the punishments for bribery can be found in many ancient sources, such as Babylon's Code of Hammurabi (22nd cen tury B.C.), Egypt's Edict of Harmhab (14th century B.C.), and Kautilya's Arthasastra (14th century B.C.).

Types of Corruption Many scholars make a dis tinction between two types of corruption: grand corruption and petty corruption (e.g., Rose-Acker man 1999). The latter category refers to bureaucratic corruption in which officials take bribes to grant fa vors in violation of their formal duties. Grand cor ruption refers to corruption by politicians and high-level decision-makers who accept payments from clients to influence policies or laws. This can be viewed as a form of state capture.

It is also useful to make a distinction between collusive and extortive corruption. Suppose an official is in charge of screening projects by granting approval only to socially desirable projects. Collusion occurs when the owner of an unqualified project manages to get approval by bribing the official. Extortion occurs when the official demands a bribe to approve qualified projects. The granting of permits and licenses by bureaucrats with near monopoly power resembles this type of corruption. Corruption can also take the form of embezzlement and appropriation of public funds. This is the more dominant form of corruption in many public education, health, and antipoverty programs.

Measuring Corruption Irrespective of their legal status, corrupt acts are always held in secrecy, and it is difficult to unearth systematic information on corruption. To a large degree research on corruption has suffered on this account. Early discussions of corruption tended to rely on journalistic accounts in newspapers and reports, on anecdotal evidence, or in a few cases, on prosecutorial evidence. Recently, there have been several attempts to construct more systematic measures of corruption.

Many authors have used perception measures of corruption. These measures are based on perceptions by various types of respondents such as local and multinational businessmen, country experts, and citizens. Two common measures are the corruption perception index (CPI) of Transparency International and the corruption control index (CCI) of the World Bank Institute. Transparency International has been publishing these indexes on an annual basis, and they now cover more than one hundred countries (Transparency International 2006). The CCI is more recent and it is available for selected years (Kaufmann et al. 2004). These indexes are based on many different polls conducted by several independent organizations. These polls use different methods and different sets of questionnaires about the business environment and corruption.

More recently, there have been attempts to use experience-based measures of corruption. The World Bank conducted a Business Environment and Enterprise Performance Survey (BEEPS) in 1999, in which selected firms in 26 East European and central Asian countries were asked various questions about the extent of bribe payments and the reasons for making such payments. In general, these surveys take care to elicit bribe-related information from the firms. Firms are seldom asked about their own payments; rather they are encouraged to talk about the average payment made by a similar firm in the industry.

Similar surveys have been conducted in some other countries to elicit information about corruption-related experiences of the general public. Despite their imprecise nature, these surveys convey useful information about corruption in different branches (police, judiciary, public services) of the government. There have been recent attempts to collect such information through field experiments.

In addition to the perception-based and experience-based measures, economists have also looked at several indirect measures. For example, by tracking government expenditure from its origin to the destination, one can get an estimate of the extent of leakage of public funds. This leakage may be viewed as a measure of corruption.

Causes Recent research into the causes of corruption focuses on the role of factors such as an oversized public sector, poor quality of regulatory institutions, the lack of democratic governance, low wages of public officials, and lack of economic competition. Researchers have used country-level perception measures to explore these causal links. Although there is disagreement about the nature and strength of these links, one can identify certain common features of the countries perceived to be highly corrupt.

In general, low levels of development (measured in terms of per capita income) and low human capital (measured in terms of years of schooling) are associated with high levels of perceived corruption. These two can be viewed as structural features, which could change only in the long run. But there are several other features that reflect the policy choices made by these countries.

For example, most of these countries also have a highly regulated business environment with a plethora of rules and bureaucratic procedures. A study by

Djankov et al. (2002) shows that in a cross section of countries the minimum official time required for a business startup varies from 2 business days in Canada and Australia to a high of 152 days in Madagascar. The association between the number of days required to start a legal business and the extent of perceived corruption is positive and robust. The presence of the rules allows bureaucrats to exercise monopoly power and extract bribes from private business.

A related feature is the absence of economic competition. The regulatory environment tends to discourage entry of new firms and helps to maintain the profitability of the few existing firms. These existing firms, in turn, transfer part of their profits as bribes to the politicians and bureaucrats. The concentration of economic power and wealth is more pronounced in smaller economies where economic activities rely on abundant natural resources or primary exports. The initially unequal distribution of assets (land, natural resources) leads to concentration of wealth in the hands of a few who use the corrupt system to increase their own wealth at the cost of others.

In many of these countries salaries of public officials are substantially lower than salaries in the private sector. This creates an inducement for the officials to seek illegal bribe income. Since in most cases the punishment for bribery involves loss of job and future income, low salaries also reduce the cost of engaging in corruption.

Other features such as lack of strong democratic traditions and lower level of press freedom are associated with higher levels of corruption. Among the democratic countries the forms of the government and the nature of electoral competition also seem to be associated with different levels of corruption. A presidential form of government is likely to be less corrupt than a prime ministerial form because of greater accountability, but this result crucially depends on the nature of checks and balances in place. Similarly, among electoral rules, a proportional representation system of voting tends to be associated with higher corruption. In a proportional representation system voters do not directly elect any particular political candidate, reducing the ability for voters to punish corrupt officials.

It is possible that noneconomic variables such as culture, values, religion, and geography also play roles in contributing to the levels of corruption. In a widely cited paper, Triesman (2000) finds support for the view that countries with histories of British rule and Protestant traditions tend to be less corrupt. Though such a result is by no means robust, it is a reminder that cultural determinants of corruption cannot be ignored altogether.

Consequences Some scholars argue that corruption can enhance efficiency. In the presence of a rigid bureaucracy and ill-planned regulations, corruption can facilitate speedy implementation of productive investment proposals. According to this view, corruption could grease the wheels of commerce and promote growth. There is very little support for this view in contemporary theoretical or empirical research, however. At best, corruption could result in a partial and temporary efficiency gain. Officials who benefit from such grease money would always have a tendency to increase red tape for their own benefit. Recent research has shown that corruption leads to inefficient allocation of resources with adverse effects on growth, investment, and foreign direct investment.

Mauro (1995) initiated one popular strand of empirical research on corruption by examining the link between corruption and growth in a cross section of countries. Using the CPI as an explanatory variable, he observed that growth and investment rates are adversely affected by corruption levels. Later studies tend to confirm this broad relationship, though the exact nature depends on several region-specific variables. One possible exception to this relationship is the experience of many high-growth Asian countries that are perceived to be highly corrupt. Though there is not enough evidence to suggest that corruption has promoted growth in these countries, it suggests that the corruption-growth link is quite complex.

Various studies have claimed that corrupt countries tend to have high inflation rates, greater military expenditures, and less public investment in education and health. The direction of causation is far from established, but the possibility that corruption

distorts governmental spending programs cannot be ignored.

Corruption adversely affects inequality and poverty also. Poverty is affected because corruption tends to lower growth, affects the (pro-poor or otherwise) orientation of public spending, and undermines the implementation of many of the antipoverty programs. This issue has generated concerns among national governments, nongovernmental organizations, and international organizations such as the United Nations, the World Bank, and the European Union. Empirical research in this area is somewhat limited, however.

At a more micro level, corruption undermines enforcement policies in a variety of fields such as tax collection, environmental regulation, and policing. Hence a higher level of corruption would lead to lower tax revenues, poor environmental standards, and a deteriorating law and order situation.

Anticorruption Strategies Views on anticorruption strategies differ considerably, ranging from mild tolerance to advocacy of draconian measures. Even though corruption is perceived to be a problem associated with low levels of development, it is unlikely that corruption will fade out on its own with rising income levels in these countries. First, corruption might constrain the growth process itself. Second, corruption has a tendency to spread and persist across time. Third, apart from generating various economic inefficiencies mentioned earlier, corruption undermines people's faith in democracy and other human development objectives. Hence curbing corruption is both a goal in itself and an instrument for achieving other goals.

Anticorruption strategies involve design of suitable incentives and organizational structures and, at a more general level, improvements in institutional quality. To a large extent, a person's decision to be corrupt is based on calculations of associated costs and benefits. Hence many have proposed incentives measures that seek to reward honest behavior and punish the corrupt. This, of course, requires better monitoring and information gathering and a quick and fair judicial process. Such measures have proved to be successful in some of the recent tax enforcement

reforms exercises, such as those carried out by the Philippines, Singapore, and Brazil. Studies based on field experiments also support the view that better monitoring is effective.

Additionally, one can reduce the scope of corruption by increasing transparency, reducing discretion, and encouraging competition where appropriate. This involves measures such as simplification of laws and easier access to information by the public. There must also be ways to generate and transmit credible and hard information about governmental decisions where there is potential for corruption. A recent study shows how a newspaper campaign about the amount of funds allocated to schools in certain areas helped stakeholders (parents) to hold the disbursement officials accountable and reduce the leakage of funds. The role of local bodies, activists, and an independent press is quite vital in this respect. Last, bureaucratic and other forms of corruption are unlikely to thrive without corrupt politicians. As pointed out earlier, electoral competition and forms of democratic governance influence the scope and extent of corruption by political representatives. Hence a successful anticorruption strategy may require reforms in the political and electoral process as well.

■ countervailing duties

Countervailing duties (CVDs) are tariffs imposed by a country to offset a foreign subsidy. The General Agreement on Tariffs and Trade (GATT) has permitted the imposition of CVDs since 1947 to offset "actionable" subsidies if the government determines that these subsidized imports are causing or threatening to cause injury to the domestic industry. Actionable subsidies are subsidies that are not explicitly prohibited under the GATT but are subject to challenge if they cause adverse effects on another country.

CVDs are similar to anti-dumping duties, the tariffs imposed to protect domestic industries from products imported at unfairly low prices, in that both seek to counteract the "unfair" trade practices of a foreign trade partner. Anti-dumping duties are much more prevalent than CVDs in the world today, however. Between 1995 and 2005, World Trade Organization (WTO) members imposed 1,804 anti-dumping duties compared to just 112 CVDs. As a result, CVDs have provoked significantly less research and debate than anti-dumping duties.

Some economists emphasize that importing countries should welcome subsidized imports rather than punish the exporting country through the use of CVDs because foreign subsidies lower import prices and increase domestic welfare at the expense of the foreign government. Other economists and lawyers stress that CVDs can improve welfare by eliminating economic distortions caused by subsidies and discouraging the future use of these subsidies. It is unclear whether current CVD regulations are solely used to offset foreign subsidies; some empirical evidence suggests that CVDs are often geared more toward imposing additional trade protection rather than eliminating economic distortions that arise from foreign subsidies. In order to understand the current debate over CVDs, it is important to understand the economic arguments for and against the use of CVDs, the evolution of CVD regulations and their worldwide use, and how future international trade negotiations could alter the use of CVDs.

Economic Consequences of CVD Laws Economists generally agree that CVDs can improve global economic welfare, at least in principal. Consider, for example, Canadian lumber exports to the United States. Trade theory suggests that Canadian subsidies would lower the price of Canadian lumber exports to

the United States. The United States would benefit from these lower prices as long as it is a net importer of lumber. In other words, U.S. consumers of lumber would gain more from the lower, subsidized prices than U.S. lumber producers would lose from lower prices and the loss of market share to Canadian producers. In this situation, the imposition of a CVD would increase the import price, restore the welfare of U.S. lumber consumers and producers to their pre-subsidy levels, and transfer money from the Canadian government to the U.S. government.

The imposition of the CVD causes total U.S. welfare to fall in this scenario because the gain to the U.S. government and U.S. lumber producers does not offset the loss that U.S. consumers experience from the higher prices. Even in this situation, however, the imposition of the CVD could result in an increase in global economic welfare. If the subsidy allows Canadian producers to export lumber to the United States even though U.S. producers harvest lumber more efficiently, then it creates an economic distortion. A CVD that offsets this subsidy should eliminate the unnatural advantage and the distortion, thus improving total economic welfare. By imposing the CVD, however, the U.S. government improves world welfare at the expense of a net decrease in U.S. economic welfare.

Since the late 1980s, most economists have agreed that under certain conditions CVDs can improve domestic welfare. Assume that there are two firms serving the world market for aircraft, one in the United States and a second in the European Union. Both firms, taking the output of their foreign competitor into consideration, choose output levels to maximize their profits. European production subsidies will artificially lower the cost of production, causing the European producer to increase its output. The U.S. producer will react by cutting its production level to try to maintain a higher price. The subsidy lowers the world price of aircraft, although not by the full amount of the subsidy as in the lumber example. It also increases European profits and lowers U.S. profits. The production subsidy can increase total European welfare as long as the gain to European consumers and producers offsets the cost

to the government. In contrast, the subsidy may decrease U.S. welfare if the loss of profits to the domestic aircraft producer is greater than the gain to U.S. consumers.

Using theoretical models, both Dixit (1988) and Collie (1991) show that the optimal response of the U.S. government in a situation like this is to retaliate with a CVD that partially offsets the subsidy. The CVD increases European production costs, thereby increasing the price of aircraft and transferring some of the profits of the European producer to the U.S. government and the U.S. producer. The CVD can increase U.S. welfare in this case because the gain to the U.S. producer and government will offset the loss to the U.S. consumer.

Collie also shows that a foreign country should be deterred from subsidizing exports when a domestic country uses CVDs. This theoretical prediction implies that the threat of the imposition of CVDs should be enough to eliminate subsidies. The continued use of subsidies and CVDs, however, reveals that this is not the case. Qiu (1995) develops a model to show that the coexistence of subsidies and CVD regulations can be explained by things such as lengthy delays in the imposition, and restrictions on the level, of CVDs.

Countervailing Duties from 1890 to the Present In 1890, the United States enacted the first CVD law, which applied only to certain grades of sugar. Belgium enacted the first CVD law targeting all subsidized imports in 1892, and the United States expanded its CVD coverage to all imports in 1897. By 1921, nine additional countries had passed CVD legislation.

The 1947 GATT formally sanctioned the use of CVDs to counteract foreign subsidies. The CVD portion of the 1947 GATT was largely based on the U.S. law at the time, with one important exception. The GATT allowed for the imposition of CVDs only if subsidized imports were causing or threatening to cause injury to a domestic industry. The United States was granted a grandfather provision and thus did not require proof of injury until 1974. International rules governing the imposition of CVDs remained largely unchanged until the 1979 Tokyo

Round GATT Agreement on Subsidies and Countervailing Measures and the 1994 revision of this agreement that resulted from the Uruguay Round of trade negotiations.

Under the version of the agreement finalized in 1994, governments may initiate a CVD investigation at the written request of the domestic industry. Prior to imposing a CVD, the government must determine that the imports from the country under investigation have (1) benefited from a prohibited or actionable subsidy, and (2) the subsidized imports have caused or threatened to cause "material" injury to the domestic industry. If the government makes a final determination that subsidized imports have injured the domestic industry, it may impose a CVD up to the calculated amount of the subsidy per unit of imported product.

In general, the agreement does not detail how countries should measure either the amount of the subsidy or the degree of injury to the domestic industry. The agreement does specify, however, that the amount of the subsidy should be consistent with some generally accepted guidelines, such as:

- The difference between the amount paid by the firm on a government loan or a government-guaranteed loan and the amount the firm would pay on a comparable commercial loan obtained in the private market; and
- The difference between the market price of a good and the price paid to the firm by the government in the purchase of goods, or the difference between the market price of a good and the price paid by the firm to the government in the provision of goods.

Injury determinations should be based on an examination of the volume of subsidized imports, the impact of these subsidized imports on domestic output and prices, and the subsequent impact of the imports on the domestic industry. In conducting this examination, the government should evaluate all economic factors associated with the industry, including the actual and potential decline in output, market share, profits, and capacity utilization, as well as other factors that may be causing injury to the

domestic industry. No CVDs may be imposed if the government determines that the amount of the subsidy is less than 1 percent of the import price or the volume of subsidized imports is negligible.

Investigations must be concluded within 18 months of their initiation. CVDs should remain in force only for as long as necessary to counteract the subsidies causing injury. The duties must be eliminated after five years unless the government determines during a sunset review that revocation of the duties would be likely to lead to a recurrence of injury caused by the subsidies.

Countries have a great deal of latitude in the way they conduct CVD investigations. Most countries have either a bifurcated approach, in which the injury and subsidy investigations are conducted by two different governmental entities, or a single-track approach, in which both investigations are conducted by the same entity. For example, in the United States, the International Trade Administration of the Department of Commerce determines the level of subsidies, while the International Trade Commission determines whether the subsidies have caused injury to the domestic industry. In contrast, the Trade Directorate of the European Commission makes both determinations in the European Union.

In 1956, 20 countries had CVD legislation, although only 8 actually used the legislation. The United States, which has historically made much greater use of CVDs than other countries, imposed only 62 CVDs between 1897 and 1959. Under the Tokyo Round Agreement, however, the use of CVDs by a small subset of countries rose dramatically. For example, the United States imposed CVDs in more than 90 cases between 1980 and 1988 alone. Between 1989 and 1993, 7 signatories to the GATT initiated 150 CVD investigations, of which the United States accounted for slightly more than 45 percent.

Since the completion of the Uruguay Round Agreement, more countries have imposed CVD measures, although its use is still highly concentrated among a few countries. Seventeen WTO members initiated 182 CVD investigations between 1995 and 2005. Of these, 61.5 percent, or 112 investigations,

eventually resulted in the imposition of CVDs. The United States and the European Union initiated 64 percent of all CVD investigations between 1995 and 2005. Half of all CVD investigations during this time period were filed against exports from India, Korea, Italy, Indonesia, and the European Union. Metals, particularly steel products, accounted for nearly 40 percent of all CVD petitions; other leading industries targeted for CVD actions include food products and footwear.

Some economists argue that many of these CVDs were used primarily to protect domestic industries from targeted imports, whether subsidized or not. For example, Marvel and Ray (1996) find that U.S. CVD petitions tend to be made against multiple nations simultaneously and are closely linked with anti-dumping petitions. Moreover, most CVD investigations define any financial contribution to the foreign firm as a subsidy, regardless of whether it lowers the foreign export price and creates an economic distortion. Based on these characteristics, Marvel and Ray conclude that CVDs are used primarily to provide the domestic industry with protection from imports rather than to counteract subsidies.

Other researchers have found empirical evidence that political pressure may explain the imposition of some CVDs. As summarized in Blonigen and Prusa (2003), there is a large literature that tests the economic and political determinants of the injury decisions in both CVD and anti-dumping investigations. Most research in this area has analyzed U.S. investigation outcomes and found that although economic factors significantly influence outcomes, political pressure also positively influences the likelihood that a CVD or anti-dumping investigation will result in the imposition of duties.

The Future of CVD Laws Stiglitz (1997) suggests that CVD laws can be beneficial as long as they are not used to protect domestic industries from import surges. He and others suggest that regulations be revised to include a higher standard of proof for establishing the existence of subsidies. In 2001, the members of the WTO agreed to "clarify and improve" CVD regulations during the Doha Round of

trade negotiations, although the clarifications will not necessarily resolve the problems economists have with CVD laws. Negotiators developed a long list of proposals to consider, including specific changes to regulations governing the calculation of the amount of the subsidy and the injury determinations.

In summary, a countervailing duty is a tool that countries can use to offset the unfair use of production subsidies by foreign governments. The use of CVDs is relatively rare today compared to other trade remedy tools such as anti-dumping duties. There is no clear consensus among economists on the impact of CVDs on the economy. Although traditional international trade theory predicts that the imposition of a CVD will increase global welfare at the expense of the imposing country, more recent theoretical models have shown that CVDs can improve domestic welfare under certain conditions. Empirical evidence suggests that CVDs may be geared more toward imposing additional trade protection rather than offsetting foreign subsidies; therefore some economists have urged the WTO to revise current regulations governing the use of CVDs.

■ **currency board arrangement (CBA)**

A currency board is a monetary arrangement based on two simple rules. First, the exchange rate between the domestic currency and an appropriately chosen foreign currency is fixed. Ideally, the fixed exchange rate is written into law in order to signal a long-term commitment. Second, there is full convertibility between the domestic monetary base and the foreign anchor currency. The currency board stands ready to exchange domestic into foreign currency, and vice versa, at the fixed rate, on demand, and without limit.

These two defining features have immediate and important implications. Under a currency board arrangement (CBA), every note or coin of the domestic currency in circulation is backed by foreign currency. Therefore, the currency board needs to hold a large amount of liquid foreign exchange reserves at least 100 percent of the monetary base, and perhaps more in order to provide a cushion against potential capital losses on the reserves. Domestic assets (also known as "domestic credit") on the balance sheet of the currency board should be zero or, more realistically, should be held constant. There should be no scope for creating money by expanding domestic credit. In practical terms, this prohibits the monetary authority from lending to the domestic government or commercial banks. In other words, the currency board is not allowed to monetize budget deficits or to act as a lender of last resort to troubled commercial banks. Therefore, in order to succeed, a CBA must go hand in hand with fiscal discipline and a healthy banking system.

On the continuum of exchange rate regimes, a CBA falls between a conventional fixed exchange rate and an outright monetary union. Under a conventional peg, there is only partial coverage of the monetary base by foreign reserves and there is no long-term commitment to the level of the exchange rate. Under a monetary union, a country gives up its currency altogether. A CBA is a more credible arrangement than a conventional peg but less credible than a monetary union.

Under a CBA, the adjustment mechanism for achieving external equilibrium is completely automatic. The monetary authority plays a passive role; it simply stands ready to exchange domestic notes and coins into foreign ones, or vice versa, as necessary. The money supply is endogenous and determined solely by market forces. If a country faces a balance of payments deficit (perhaps because private capital inflows are insufficient to cover the current account deficit), the monetary authority will face a loss of foreign exchange reserves. Under the operating rules of the currency board, the money supply will con-

tract. In asset markets, this will push domestic interest rates up, which will attract greater private capital inflows into the country. In goods markets, the falling money supply will exert deflationary pressure, and prices and wages will tend to fall over time. This will make domestic tradable goods relatively cheaper in world markets, and the current account deficit may shrink. High interest rates and the real depreciation caused by deflation will stifle domestic aggregate demand, particularly the demand for imports, thus contributing further to the current account improvement.

This should sound familiar. It is very similar to the adjustment mechanisms operating under the classical gold standard. In fact, some economists have argued that the gold standard was a special case of a CBA, with a commodity (gold) replacing the foreign anchor currency. Given the key role of price and wage adjustment in the mechanism just described, a successful currency board needs flexible goods and labor markets.

History The history of currency boards spans approximately 150 years. There have been around 80 CBAs throughout the world. During the colonial era, various dominions of the British Empire operated more than 70 different CBAs. Currency boards combined centralized control by the colonial center with the retention of domestic monies in the periphery. They were designed to facilitate trade and financial flows within the British Empire. Currency boards fell into intellectual disfavor and were gradually replaced by conventional central banks after the demise of colonialism in the 1950s and 1960s. Central banks better fitted the political drive for national independence. The transition also reflected the period's intellectual climate, which was infused with a sunny optimism about the effectiveness of discretionary government policies.

Currency boards came back into fashion beginning in the early 1990s, due to a collapse of faith in discretionary monetary policy, especially in developing countries. A cursory look at some countries that have operated currency boards in the 1990s and early 2000s (Hong Kong, Argentina, Estonia, Lithuania, Bulgaria, and Bosnia and Herzegovina) shows

that CBAs have been successful in ending hyperinflation, facilitating the transition to a market economy or to national independence, assisting postwar reconstruction, and restoring stability in an international financial center plagued by political uncertainty and banking crises. CBAs were also proposed in the aftermath of macroeconomic crises in Indonesia, Russia, Brazil, and Turkey, although none of these proposals ultimately came to fruition. Modern CBAs have been subject to occasional speculative attacks   Hong Kong in 1997, and Argentina in 1995 and 2001. In general, exits from CBAs have been uneventful, with the single spectacular exception of Argentina in early 2002.

Most real-world CBAs have reserved some degree of discretionary powers, and thus deviate from the definition of an orthodox currency board. The ratio of foreign exchange reserves relative to the monetary base may be allowed to dip below 100 percent. This coverage ratio may also be allowed to go above 110 115 percent in order to sterilize capital inflows, finance a lender-of-last-resort function, or smooth fluctuations in domestic interest rates. The monetary authorities in almost all contemporary currency boards have reserved the right to change the required reserve ratio for commercial banks, which might thwart the operation of the automatic adjustment mechanism described earlier. (The monetary authority regains some degree of control over the broader money supply.) Almost all modern CBAs have volatile domestic assets on their balance sheets.

Argentina's CBA was the one with the most loopholes, which probably contributed to its ultimate demise. First, Argentina's CBA was allowed to lend to the government. Second, throughout 2001 the long-term commitment to the fixed exchange rate was undermined by switching the peg from the U.S. dollar to a currency basket, and by instituting a complicated scheme of export subsidies and import surcharges, which amounted to a sneak devaluation.

Debating the Pros and Cons Professional economists have advanced various arguments about the advantages and disadvantages of CBAs. Perhaps the single biggest advantage of a currency board is its simplicity and transparency. It may enable a

government to commit credibly to monetary discipline at the expense of flexibility. In essence, through the currency board, the monetary authority can import the anti-inflationary credibility of the central bank issuing the anchor currency, typically the U.S. Federal Reserve or the European Central Bank. The domestic monetary authority becomes a mere warehouse for foreign cash.

A credible CBA reduces currency and default risk, which leads to lower domestic interest rates. It can boost the development of long-term financial markets, which are sorely lacking in many developing countries. By reducing transaction costs, the fixed exchange rate can promote trade and foreign direct investment. Finally, by establishing monetary discipline, a currency board can serve as a catalyst for a broad range of other reforms.

A serious drawback of currency boards is that they make the adopting country more vulnerable to external shocks, particularly terms-of-trade shocks, large capital inflows or outflows, or shocks emanating from the country issuing the anchor currency. Arguably, high interest rates in the United States and the strength of the dollar against the euro and the Japanese yen contributed to the demise of Argentina's CBA, in addition to lack of fiscal discipline within the country, especially at the provincial level.

As Argentina's experience with deflation in 1999 2001 also demonstrates, currency boards (or indeed fixed exchange rates in general) are probably not a good monetary arrangement for relatively closed economies. The less open the economy is, the larger the real depreciation necessary to eliminate a given balance of payments deficit. Under a fixed exchange rate, real depreciation can happen only through a fall in domestic prices. Such price adjustments can be slow and painful.

One reason to introduce a CBA is to arrest high inflation, but currency boards can generate overvalued real exchange rates and large current account deficits. Real appreciation results from the combination of a fixed nominal exchange rate and persistent domestic inflation. The introduction of a currency board can also be burdensome and time-consuming. In order to make the arrangement credible, policymakers must build political consensus, rewrite laws, and reorganize institutions.

Critics of CBAs have pointed out that counter-cyclical monetary policy is impossible under a CBA, and therefore output, employment, and prices would be more volatile under such an arrangement. Proponents of CBAs have countered that ending discretionary monetary policy is the intended purpose of such institutional arrangements: discretionary monetary policies in developing countries have been the prime source of macroeconomic instability, and currency boards have helped to restore macroeconomic stability by imposing a monetary straitjacket on the government. Monetary policy is an extension of fiscal policy   printing money is a government's revenue source of last resort. Therefore, a currency board can be beneficial in imposing a hard budget constraint on the country's treasury.

Opponents have noted that currency boards either abolish or sharply curtail the capacity of the monetary authority to serve as a lender of last resort to the banking system. Proponents counter that a lender-of-last-resort function is still possible under a CBA through assistance from the treasury, a deposit insurance scheme, or contingent credit lines from abroad. Bailing out domestic banks involves redistribution of income, and a currency board removes a nontransparent (and therefore politically cheap) tool of income redistribution. By making bank bailouts more politically costly and therefore less likely, a currency board limits the moral hazard problem of the banking system (the problem of a party insulated from risk engaging in riskier behavior). In essence, it imposes a hard budget constraint on domestic financial institutions.

Currency boards are unable, by definition, to create money by expanding domestic credit. Therefore, they cannot earn extra seigniorage through discretionary money creation. Currency boards still make profits on the difference between interest earned on their assets (highly liquid foreign securities) and their operating costs. Seigniorage revenues are somewhat lower under currency boards than under conventional central banks, however, both because CBAs cannot expand domestic credit and because foreign reserves may pay a somewhat lower

interest rate than domestic assets. Of course, many economists would count the reduction in seigniorage as a *benefit* of CBAs, given that it is an inefficient and nontransparent way of raising revenue.

The Empirical Record Although theoretical arguments have dominated the debates about currency boards, little empirical work has been undertaken on the subject. The most authoritative empirical analysis available (Ghosh, Gulde, and Wolf 2000) finds that currency boards are associated with lower inflation than either floating or conventional fixed exchange rate regimes. This result is highly robust. Currency boards also appear to be associated with higher rates of gross domestic product (GDP) growth, although the reasons for this are not clear. It may be that countries with better overall economic policies self-select in choosing to establish a currency board. It may be that most countries introduce a currency board following a severe macroeconomic crisis, and the better growth performance observed in the first few years of the new arrangement reflects a postcrisis "rebound effect." At the very least, currency boards have not been associated with *lower* GDP growth rates, although there is some evidence that output tends to be more volatile. Finally, CBAs appear to be associated empirically with lower money supply growth rates, smaller budget deficits, and better export performance.

In conclusion, a CBA offers significant benefits but also has serious drawbacks. Although it is neither a quick fix nor a panacea for all economic ills, in some cases it can deliver monetary discipline and low inflation.

■ currency competition

Traditionally, *currency competition* refers to competition between privately issued monies or between privately issued and government-issued monies for use as means of payments. This entry will focus on such competition. Competition between government-issued monies the pound sterling and the euro, for example is discussed in the entry on multiple currencies.

Types of Money To understand the ideas related to currency competition it is useful to define a few terms. First, *commodity money* is money that has some intrinsic value. The value is embedded in the commodity that makes the coin. Gold and silver coins are examples of commodity monies. In principle, it is possible to melt such coins and the resulting metal would sell for a value approximately equal to that of the coins. In contrast, *fiat money* is intrinsically worthless. The paper on which a $20 bill is printed is worth very little. The value of such a bill comes from the belief that other people will accept it in exchange for goods or services. *Inside money* is a claim on the

assets of the issuer of that money. It is a liability of the issuer. Traveler's checks are an example of inside money, as the issuer must, by law, repay such a check. Another example is bank deposits. In contrast, *outside money* is not a claim on its issuer. An issuer of outside money does not have a legal obligation to exchange its notes against some goods or services. Government-issued notes are examples of outside money. Central banks are not required to back the notes they issue with any kind of commodity.

Hayek and Currency Competition The economist Friedrich Hayek introduced the idea of currency competition in 1976. At that time, a number of countries were experiencing high inflation. The collapse of the Bretton Woods system of fixed exchange rates in 1971 had removed a constraint on the conduct of monetary policy for many monetary authorities. It also removed any remaining link between currencies and a metallic standard (gold in this case). Freed from these constraints, many central banks increased their money supply too quickly, spurring inflation.

Although there was broad agreement that inflation was undesirable, it was not clear how to give monetary authorities incentives to maintain the value of their currencies. Hayek reasoned that the lack of incentives came from the monopoly that monetary authorities held over the issuance of money. Competition from private issuers could force these authorities to maintain the value of their currencies. Indeed, if a money lost too much of its value, consumers and businesses would have the option to use another money. Hayek proposed to give banks the authority to issue notes that would compete with government-issued currency.

The interest generated by Hayek's proposal led a number of economists to study historical episodes during which banks were allowed to issue notes. Such episodes typically involved commodity money, however. Since the value of commodity money is intrinsic, there is not much scope for an issuer of commodity money to modify the value of its currency.

Economists have also been interested in competing inside monies. Such monies are typically denoted in some outside money, however. For example,

traveler's checks are often denominated in U.S. dollars. For this reason, it does not appear that inside money can affect the incentives of the issuer of outside money in the way Hayek intended.

What Hayek specifically had in mind was competition between *outside fiat* monies. He proposed to allow banks to issue intrinsically worthless notes that would not be liabilities of these institutions.

Private Issue of Outside Money For the kind of competition that Hayek proposed to occur, private institutions must be able to issue outside money. A number of economists have argued that a time inconsistency problem makes private issuance impossible. These economists point out that if a private institution could issue valued fiat outside money, profit maximization would induce the institution to issue money up to the point where the marginal benefit of an extra unit of money equaled its marginal cost. That is, since the cost of producing an additional unit of fiat money is negligible, the institution would issue money up to the point where it was worthless. Moreover, the issuing institution would have no obligation to redeem the note for something of value since it would be issuing outside money. Anticipating this outcome, nobody would want to hold the money in the first place.

Private issuance of fiat outside money may be possible provided agents hold certain expectations. The key is to find a way to prevent issuers from increasing their supply of notes to the point where the value of such notes is zero. Suppose everybody believes that the notes of a private issuer have value if the number of notes issued is less than some number. This threshold number is common knowledge. If the number of notes issued exceeds the threshold, then everyone believes that these notes are worthless. A serial number on a note indicates the quantity of notes issued previously.

Consider someone who is offered a note with a serial number that is greater than the threshold level above which notes are no longer valued. This person believes that nobody will be willing to accept the note in exchange for goods or services in the future. Hence, this person will not accept the note, and the belief that the note has no value is self-fulfilling. This

kind of belief limits the ability of the issuer to print too many notes, which makes private issuance possible.

A Concept for the Future Although private issue of outside fiat currencies is possible in theory, there are few examples of such currencies. Some currencies used in online multiplayer games may be the best examples of fiat outside money. These currencies are almost costless to produce and are not backed by any asset. Moreover, online auction sites, such as eBay, provide a platform on which such currencies trade for U.S. dollars in a way that is similar to a currency exchange market. Although we are still far from Hayek's vision of currency competition, technological progress and new information technologies could make it happen.

■ currency crisis
Currency crises are among the most dramatic events in global financial markets. They generally involve large outflows of funds from currencies that investors fear may devalue or sharply depreciate. When a government lowers the level at which a currency is pegged to other currencies this is referred to as a devaluation, while a fall in the value of a market determined exchange rate is called depreciation. To keep their currencies from depreciating in the face of exchange market pressure, governments must run down their foreign currency reserves, borrow from abroad, hike interest rates, and/or impose capital controls to slow down outflows. If they are successful, the speculation dies down, at least for a while, and the currency value is maintained. More often, exchange rates are eventually forced to adjust. Although the vast majority of currency crises involve downward pressure on currencies, sometime there are strong market pressures for surplus countries to let their currencies appreciate; a vivid example is China beginning in the early 2000s. Crises can vary in their effects as well as in their causes, but they have in common a high degree of exchange market pressure.

International speculators are widely blamed for generating crises, especially by government officials eager to shift the blame from themselves. In reality, however, much of the pressure usually comes from "normal" domestic and international firms that are trying to protect themselves against losses rather than to generate speculative gains. Even the speculators are more often the messengers that there are problems than the independent cause of currency crises. Speculative attacks occur when international businesses and investors anticipate a change in the value of the currency, thus adding speculative outflows to the underlying balance of payments deficit.

Crises, though always uncomfortable, can sometimes have good effects, stimulating policy reforms and promoting economic recovery. In other cases, however, especially in developing countries with weak financial systems and considerable debt denominated in foreign currency, the effects of crises can include large recessions and widespread suffering. This is particularly likely when a currency crisis either leads to or was generated by a domestic banking crisis a so-called "twin crisis."

In general, the underlying causes of a currency crisis are inconsistencies between a country's exchange rate policy and its domestic economic policies so that the currency is either over- or undervalued relative to the currencies of other countries. Economists have developed a variety of theoretical models

to explain currency crises, and most of these models can be classified into three types. First-generation models consider cases where the government is either unable or unwilling to correct inconsistencies between its exchange rate and other domestic policy goals. As these become more serious, a crisis eventually becomes inevitable. Second-generation crisis models analyze cases where these inconsistencies place the economy in a "zone of vulnerability," making a crisis possible but not inevitable. In these cases, the potential for a crisis outbreak depends critically on market perceptions of the government's willingness and ability to take corrective action. Finally, newer crisis models have focused on financial sector weaknesses and the role of politics in the emergence of currency crises.

First-Generation Crises: Fundamental Disequilibriums The classic theoretical explanations for currency crises — the so-called first-generation models — focus on fundamental economic disequilibriums such as large government budget deficits. In these models, governments are assumed to pursue fiscal and monetary policies that are inconsistent with maintaining their fixed or slowly adjusting pegged exchange rate regimes. The resulting balance-of-payments deficits are financed by running down foreign reserves. When the level of reserves falls to a certain threshold, there is a sudden balance-of-payments crisis. Capital flight by domestic residents escalates, even if the country has borrowed little from abroad. This leads to a loss of reserves and forces the government to devalue its currency or float the exchange rate. In these models, expansionary policies and the resulting bad economic fundamentals push the economy into crisis.

The particular causes of the fundamental disequilibriums in past crises have been varied. They often result from a lack of fiscal discipline, but first-generation-type currency crises have also been caused by budget deficits in the center country of a pegged exchange rate system (the center country is the nation to whose currency another country's currency is pegged) or external developments such as export slumps. These problems generally coincide with weak governments facing strong political pressures

that prevent them from addressing the emerging disequilibriums by cutting spending or raising taxes to keep monetary expansion under control. Very often, this inability to balance the budget results in high rates of inflation. When economic problems emerge, markets initially often give governments the benefit of the doubt, especially when they have large stores of international reserves. But as imbalances continue, market participants frequently realize well before governments do that the problems are not temporary. The capital outflows that result from this realization involve not only currency speculators but also businesspeople wanting to hedge against the risk of exchange rate adjustments. These flows in turn tend to increase payments imbalances further and eventually lead to a crisis and a forced adjustment.

Examples of first-generation-style crises include the currency crises of Latin American countries in the post–Bretton Woods period, such as Mexico in 1976 and Brazil on several occasions. In these cases, the government financed large deficits by creating more money, resulting in inflation. Combined with pegged or slowly adjusting exchange rates, such high levels of inflation led to progressive overvaluation of exchange rates and generated numerous currency crises. Inflation does not need to be in triple or quadruple digits in order to generate currency crises, nor are inflation-driven crises a threat only to developing countries, as demonstrated by Italy's crisis in 1992. As a member of the European Monetary System (EMS), Italy had pegged its exchange rate to the deutschmark. Although its inflation rate was far below triple digits, it was still well above the inflation rates of most of its partners in the EMS, and in particular higher than that of the center country, Germany. The resulting disparity eventually led to a currency crisis in 1992. Large budget deficits can at times cause currency problems even if they do not lead to monetary accommodation and rising inflation; one example of this is the 2001 crisis in Argentina. As part of a "shock therapy" program designed to break out of a cycle of high and rising inflation, Argentina had adopted a currency board in 1991 that took money creation out of the hands of

the government by fixing the domestic currency to a foreign anchor currency, and maintaining full convertibility between domestic currency and the foreign anchor currency. This proved to be highly successful in bringing inflation under control but fiscal profligacy continued. As external developments contributed to a worsening of the situation, the result was a combined debt and currency crisis that ended in abandonment of the currency board and default on the government's foreign debt.

The collapse of the Bretton Woods system in the 1970s provides an example of an exchange rate system failing due to budget deficits in the center country (in this case the United States). For domestic political reasons, the U.S. government delayed tax increases required to pay for the large increases in expenditures associated with the Vietnam War. Seeking to prevent interest rates from escalating, the Federal Reserve Board financed a sizable portion of the resulting budget deficits with monetary accommodation. The consequent overheating of the U.S. economy led to increasing balance-of-payments deficits and ultimately to the currency crisis that was the final straw leading to the widespread abandonment of the Bretton Woods regime of adjustably pegged exchange rates.

Another type of first-generation crisis that need not be directly caused by bad domestic policies involves export slumps. Generally, monetary and fiscal policies that are sustainable under good circumstances become unsustainable when circumstances take a turn for the worse. In a country whose government's budget depends on export revenues, a sharp decrease in those revenues can cause a similarly sharp change in investor expectations of that country's ability to meet its debt-servicing obligations. A clear example of this is the 1998 Russian ruble crisis. By the mid-1990s Russia had tamed the runaway inflation that followed the breakup of the Soviet Union and its economic prospects had substantially improved. The domestic coalition favoring economic reform and stability was fragile, however. In the aftermath of the 1997 Asian crisis, oil prices fell to half of their precrisis levels due to decreased demand for oil in Asia. As a result, the Yeltsin government,

dependent as it was on oil revenues to fund its fiscal programs, found its treasury rapidly being emptied. Initially investors' belief that Russia was "too big to fail" and their perception that the Russian government was attempting to alleviate the situation by negotiating a loan package from the International Monetary Fund (IMF) and seeking to implement dramatic fiscal reforms caused most investors to give Russia the benefit of the doubt. After the IMF negotiations failed and the Russian legislature, the Duma, removed the most critical components of Yeltsin's proposed fiscal reform plan, however, it became clear that Russia was not going to be able to adjust its policy enough to avoid a fiscal crisis. In August 1998, there was a severe speculative attack on the ruble, and the Russian government announced that it would no longer support the crawling peg and would default on its foreign-held debt. The remaining investors immediately and frantically sought to divest themselves of the Russian liabilities and the ruble plummeted.

Second-Generation Crises: The Role of Expectations A surprising feature of a number of the currency crises of the 1990s was that they hit countries whose macroeconomic fundamentals were not particularly bad. First-generation models were unable to explain, much less predict, many of these crises. In response, a "second generation" of crisis models was developed that focused on investors' expectations and governments' conflicting policy objectives and predicted that speculative attacks could occur when a country's fundamentals were merely in an intermediate or vulnerable zone. Although these models retained the assumption that speculators would not attack countries with good fundamentals, they showed that once a country finds itself in a vulnerable zone, a change in the private sector's expectations about the future course of government policy can trigger a second-generation crisis.

In contrast to the passive role of policymakers in first-generation models, governments in second-generation models are able to take corrective measures, though they may prefer not to. For many governments, exchange rate stability is only one

objective among many. Governments often make a trade-off between maintaining a pegged exchange rate and achieving other policy goals (such as low unemployment) that gain political salience when there is an economic downturn. In such situations speculators can lose confidence in the government's commitment to the exchange rate peg and can decide suddenly to attack the currency. The cyclical state of the economy can thus become an important factor in these models, since the tight monetary policies necessary to defend a currency are politically more costly when the economy is in recession than when it is booming.

Speculators are also collectively in a position to influence the future course of policy in second-generation models. The greater the proportion of speculators who expect the government to defend the peg at the expense of a worsening recession, the smaller the capital outflows and the more feasible a defense of the exchange rate peg. On the other hand, if most speculators bet against a defense, capital outflows will be larger and the costs of a defense will be higher. Since these outflows themselves can be detrimental to a government's ability to defend the pegged exchange rate, market expectations can thus prove to be self-fulfilling. Such speculation is not irrational, nor is it in itself destabilizing in the sense of going contrary to the fundamentals. It is, however, sometimes thought of as destabilizing in the sense that it can be the proximate cause of a crisis that may not necessarily have been inevitable.

In formal second-generation models, shifts in investor expectations from optimistic to pessimistic are treated as arbitrary. The resulting outcomes are therefore often referred to as "sunspot equilibria." This can give a misleading impression, however, since in the typical cases of major speculative attacks on currencies, certain events trigger the shift from a "good" to a "bad" equilibrium. In the past, such triggers have included the assassination of a presidential candidate (Mexico in 1994) and crises elsewhere that lead to a reevaluation of underemphasized fundamentals (the wake-up call concerning financial sector weakness that was a major aspect of the contagion in Asia in 1997).

An example of what many experts consider to be a second-generation crisis is the 1992 93 crisis in the EMS, particularly the speculative attacks on the French franc. The proximate cause of this crisis was the reunification of Germany, which led to a large increase in German government expenditures. As German policymakers were unwilling to offset this higher spending with higher taxes, a large budget deficit emerged. In response, the Bundesbank (Germany's central bank) raised interest rates. Since Germany was the EMS center country, the logic of the currency system required all other EMS members to tighten monetary policy as well, even though this ran counter to the requirements of their macroeconomic situation at the time. As we have already discussed, this generated crises that led to the breakdown of the EMS system. The crises in Italy and, arguably, the United Kingdom were quite consistent with first-generation models since both the lira and the pound appeared to be overvalued. The 1993 attack on the French franc was not as easy to explain, however, since some of France's fundamentals were even stronger than Germany's.

What proved to be more important was the lack of willingness of the individual EMS countries to adjust to the mutual payments imbalances that had emerged. Here Germany held the cards. Even so the EMS member states put considerable pressure on the Bundesbank to lower interest rates, but the independent German Bundesbank refused to back off its tight monetary policies. When it became known that Germany would also not continue providing short-term financing to maintain the pegged rates of the EMS, the only alternatives left for the other EMS members were depreciation or a substantial tightening of their own macroeconomic policies. Given the state of the economy in many of these countries, international financial market participants therefore increasingly questioned policymakers' willingness to implement policies that would further slow growth and increase unemployment. Eventually, financial markets launched speculative attacks, forcing governments to choose between unpalatable options: abandoning the peg, which they had worked hard to maintain, or facing a deepening recession. In the case

of France, for example, the authorities withstood several bouts of speculative pressure before finally devaluing the franc in 1993.

The fact that France's fundamentals had not been particularly bad led many commentators, especially French officials, to conclude that France had been the innocent victim of destabilizing speculation. France was indeed an innocent victim in this case, but of geopolitical developments in Germany and its own commitment to the European pegged-rate system, not of capricious speculators. This illustrates that crises do not always fit neatly within one type of crisis model or another. Some economists consider France's crisis to be a classic second-generation example, but others argue that it was more of a first-generation crisis because of a fundamental disequilibrium generated by Germany's huge budget deficit. The crisis certainly had elements emphasized in both types of models, as did the 1997 Asian crisis, to which we now turn.

Financial Sector Weakness Most of the financial world and many economists were shocked in 1997 by the occurrence and the severity of the Asian financial crises. A crisis in the Thai exchange market had been at least partially anticipated, as there had been concerns about the possible overvaluation of the baht for some time. But the spread of the crisis to other countries was almost entirely unanticipated. Most if not all of the affected countries had enjoyed low inflation and robust economic growth for quite some time and appeared by and large to have strong enough economic fundamentals to preclude the type of crises predicted by first- and second-generation crisis models. In order to explain these events, economists developed what is sometimes referred to as the "third generation" of crisis models, which place a greater emphasis on the micro-foundations of currency crises. Among these refinements are the considerations of financial sector weakness, moral hazard, contagion, and stock as well as flow disequilibriums.

Traditional macroeconomic models paid little attention to the financial sector, and the crises of the 1990s demonstrated that this was a major mistake. The discovery of serious weaknesses in financial

sectors can generate major changes in international capital flows, especially where countries have weak international liquidity positions (i.e., high short-term foreign debt relative to international reserves). Such a situation can quickly turn into a run on the currency without requiring any outright speculation; the scrabble to cover open positions could be sufficient. Indeed, many of the flows of funds during the Asian crisis were of this risk-covering nature.

One of the factors that can contribute to financial sector weakness is a high level of moral hazard, referring in the currency crisis context to the propensity to lend, borrow, or invest in enterprises under circumstances that would usually be considered excessively risky. In some cases, lending institutions or borrowers may have had either explicit or implicit guarantees that the government would cover any losses should the loan or investment fail to return a profit. In this way the contingent liability burden is shifted from the lender, investor, or borrower to the government, creating the situation described by economist Paul Krugman (1996) as a bet of "heads, I win; tails, the taxpayer loses." If this practice is sufficiently prevalent, even a minor shock to the economy could result in a dramatic increase in government financing to prop up banks whose nonperforming loans have suddenly rendered them insolvent.

Many of the other factors described earlier, most notably financial sector weakness, also played key roles in precipitating the Asian crises of 1997. Although public finances in all of the crisis countries were relatively strong by conventional measures, domestic financial sectors were in bad shape. Both the high levels of nonperforming loans and heavy unhedged foreign borrowing were generated at least in part by problems of moral hazard. The combination of moral hazard and weak risk management and regulatory systems had led to many ill-advised loans, so that in a number of countries the financial sectors were suffering from serious solvency and liquidity problems. While good statistics were not generally available to reveal these problems, international funds continued to pour into these emerging markets because of their apparently strong

macroeconomic statistics and as a result of capital account liberalization.

In July 1997, the already overvalued Thai baht came under speculative attack when the severity of Thailand's problems with nonperforming loans in the financial sector became apparent. Highlighting Thailand's financial sector problems, this crisis served as a wake-up call to international financial markets, alerting them that Thailand's unhedged foreign borrowing was much riskier than many had believed. This in turn prompted foreign investors to reassess the vulnerability of their investments to financial sector risks. Thailand was not the only country found to have serious problems in the financial sector, and investors' assessments of some countries previously perceived to have well-aligned exchange rates, such as Korea and Taiwan, changed (those exchange rates were now seen as overvalued), prompting a run for the exits. Although financial sector problems were not the only contributing factors (as mentioned, the Thai baht was overvalued and political instability in Indonesia contributed importantly to the length and depth of the crisis there), the Asian crisis did highlight that crises could occur even when data on traditional economic fundamentals indicated a strong economic situation.

The Political Economy of Currency Crises Recent research has also recognized that political considerations can have an important influence on crises through a number of channels. Since economic policies are generally determined through the political process (one exception being when monetary policy is administered by an effectively independent central bank), political developments can have a strong influence on expectations about future economic policies. Thus political instability and expectations about the election of new administrations can have an important effect on capital flows even before there is any actual change in policy. Political considerations are also one of the major causes of the development of inconsistencies among policies that lead to fundamental disequilibriums. Because the costs of corrective action often show up faster than the benefits, short-run political pressures can lead to delays in undertaking needed policy adjustments,

especially if elections are approaching (see Willett 2007).

One key example of how political considerations can play a role in the outbreak of crisis is the 1999 crisis in Brazil. Past fiscal excesses had left Brazil with a large public debt burden, which was substantial but manageable so long as interest rates remained moderately low. In 1999, polls increasingly indicated that leftist presidential candidate Lula da Silva and another leftist politician were likely to prevail in the impending elections. Lula's past as a trade unionist raised doubts among market participants over whether Brazil's sound economic policies would be continued after the election. Although a return to hyperinflation was not likely, the high debt levels meant that even a moderate loosening of fiscal policy might be sufficient to force default. As a consequence, a crisis of confidence and a speculative attack on the real ensued. It is important to note that this crisis was precipitated not by actually implemented policies, but rather on the evaluation of expected future policy.

The 1994 Mexican crisis provides another example of the importance of political events in understanding crises. The country had successfully brought down inflation from triple- to single-digit levels, but the combination of strong capital inflows and a slow rate of depreciation designed to limit domestic wage increases had resulted in a large current account deficit and a substantially appreciated real exchange rate. Thus although Mexico's domestic economic fundamentals were strong, the economy was vulnerable to a drop in capital inflows, and as with the Brazilian crisis to severe shocks to political stability. In this case, the shock was the assassination of the leading opposition (and proreform) presidential candidate, which prompted rapid reassessment on the part of investors as to whether necessary reforms in Mexico would be implemented, along with fears of a more volatile political climate. The combination of monetary tightening in the United States, temporary preelection loosening of fiscal policy in Mexico, and the emergence of domestic political instability brought the dreaded sharp fall in inflows and the crisis was on.

Political scientist Andrew MacIntyre (1999) has argued that Thailand and Indonesia illustrate ways in which different types of governments can exacerbate their vulnerability to crises. Thailand's political system with its large coalition governments tended to produce great policy stability (or paralysis) due to the difficulties in making policy changes. Intracoalitional politics caused budget and financial regulation reforms to be delayed, further weakening confidence in the Thai financial sector and generating uncertainty about the government's capacity to act once the crisis occurred. In contrast, Indonesia's political system was highly centralized and imposed little constraint on executive action. This led to its own set of problems by opening the way for erratic policy behavior. When crisis spread from Thailand to Indonesia in late July 1997, the Suharto government responded decisively and preemptively by widening the band within which the rupiah was allowed to fluctuate from 8 percent to 12 percent. As the rupiah continued to slide, Suharto appeared to be taking appropriate action by agreeing to a series of dramatic reforms as part of an IMF assistance program. Appearances can be deceiving, however, and in this case they certainly were, as Suharto quietly reneged on many of these reforms and as members of his government and family openly undermined others. It is not surprising that investor confidence in the Indonesian government plummeted, not because investors doubted whether Suharto *could* make the necessary reforms but instead because they doubted that he *would*. Where Thailand's case can be characterized as inaction in the face of a looming crisis, Indonesia's can be characterized as action but of the wrong kind.

Crisis Prevention and Management There is widespread agreement that it is usually far easier to prevent crises than to fix them once they occur. Unfortunately, prevention is not easy to accomplish. Although analysis has often been able to identify sound reasons for crises after the fact, these reasons are not always easy to identify beforehand. The perception of crises as arising from the unjustified behavior of fickle financial markets doubtlessly stems at least in part from this dilemma. Significant advances have been made in the development of economic "early warning systems" for crises, though these tend to detect occasions when a country is vulnerable to a crisis rather than predict precisely when a crisis will occur.

Even when the threat of a crisis is unmistakable, however, countries often fail to take preventive actions in time. Sadly, it often takes the actual outbreak of crises to prompt major policy adjustments, as governments often find it politically difficult to take the actions needed to reduce vulnerability. Consequently, governments are often observed to initially respond to potential crises by addressing capital flows rather than macroeconomic fundamentals by running down international currency reserves, increasing domestic interest rates to make the country a more attractive capital destination, or implementing restrictions on the flow of capital into or out of the country. When the country is facing a temporary liquidity crunch, such measures may be all that is required (see the 1997 case of Hong Kong, where some of these measures were successfully used to avoid the most serious potential repercussions of the crisis). If, however, the country faces a fundamental disequilibrium (such as is described in first-generation crisis models), such measures can only delay, not prevent, crises; borrowing and running down reserves cannot indefinitely offset the effects of a fundamental disequilibrium. In such cases, reserve cushions can only give countries the option of adjusting more gradually. Second- and third-generation models, however, provide insights into ways that strong reserve positions can help avoid crises. When countries are in vulnerable zones, shocks that would generate a run on the currency of a country with high levels of short-term foreign debt relative to its international reserves might not generate such a run if the country had a strong international liquidity position. In other words, although strong reserve positions can do little to deal with insolvency (fundamental disequilibrium) problems, they are a valuable instrument for countries with merely vulnerable fundamentals.

The effectiveness of high interest rate policies and capital controls has been the subject of considerable

controversy. Because so many factors are typically at work during a crisis it is hard to accurately measure the effects of particular policies. High interest rates may send an ambiguous signal to currency markets, as excessively high interest rates may indicate to the markets that the country is in desperate need of capital — not an encouraging sign if the market is already concerned about the safety of investing in that country (Russia in 1998 provides an example of this dynamic). During the Asian crisis, high interest rates in Indonesia did not keep the rupiah from plummeting, because it was not clear at the time whether the high interest rates reflected tight monetary policy or premiums for inflation and political risk.

The effectiveness of capital controls also depends a great deal on how they are interpreted by the market. Capital controls can be seen as prudential measures taken to protect an otherwise stable economy from overly volatile international capital markets, in which case they can be effective in reassuring foreign investors. Capital controls can also be seen, however, as stopgap measures intended to prevent capital from flowing out of an already risky economy. In this case, the implementation of capital controls can itself be a signal to the market that the economy is in worse shape than previously thought. As with international reserves, the introduction of capital controls seems more promising when the economy is in a vulnerable zone than when it exhibits strong fundamental disequilibriums. The introduction of capital controls by Malaysia in 1998 has been the subject of different evaluations along these lines. Probably the best we can say about the Malaysian case is that the controls proved to be neither the disaster predicted by some critics nor the panacea envisioned by some advocates.

Recent crises also remind us that international financial flows can be fickle and that being the darling of international investors today is not a safe indicator of future stability. Although there remains considerable disagreement among economists about the conditions (if any) under which direct controls on international capital flows can be desirable, there is little disagreement that such flows and financial sectors more generally need to be subject to effective prudential regulation. Such policies need to be

carefully crafted: in many countries, policies have contributed as much or more to the generation of crises (through moral hazard and other perverse incentives) as to good prudential oversight.

One of the most notable characteristics of recent currency crises has been the frequency with which they are associated with efforts to maintain various types of adjustably pegged exchange rate regimes. This phenomenon, which has been labeled "the unstable middle hypothesis," was a basic cause of the breakdown of the regime of adjustably pegged exchange rates of the Bretton Woods system. Few analysts dispute that without effective capital controls such adjustably pegged exchange rate regimes are highly prone to crises in the face of substantial international capital mobility. The debate is whether it is necessary to move all the way to one extreme or the other — hard fixes or relatively free floats — to substantially reduce vulnerability to crisis, or whether moving to crawling bands or managed floats is sufficient.

The role of the IMF in crisis prevention and management has been the subject of considerable controversy. Although far from perfect, its ability to identify emerging crisis situations has been much better than its ability to get countries to adopt the necessary preventative actions; the ability of its "seal of approval" to calm crisis situations has also suffered substantial erosion. The IMF has displayed considerable learning, but efforts at substantial reform of the international financial architecture have been largely unsuccessful, and the IMF's ability to act as a crisis manager and international lender of last resort has, so far, only marginally improved. This has resulted in greater self-help efforts undertaken by many countries, especially in Asia, to accumulate high levels of international reserves at both the country and the regional levels. Crisis liquidity is clearly most efficiently provided at the international level, but the failure of substantial reforms at that level makes these individual and regional efforts quite understandable.

■ currency substitution and dollarization

Currency substitution refers to a broad set of conditions under which two or more currencies can be used as media of exchange. If currency substitution is a continuum within which domestic and foreign currencies cocirculate, dollarization occurs at one end of that continuum, when the foreign currency   most times, the U.S. dollar   is preeminent in domestic transactions in goods and/or assets. Since 2002, the term *euroization* has also emerged. Dollarization may occur either as a formal decision of governments or as the choice of most economic agents in a country. These are known as de jure (official) and de facto (unofficial) dollarization, respectively.

Currency Substitution Currency substitution may refer to foreign currency, deposits denominated in foreign currency units held in domestic banks, or to deposits of domestic residents at foreign banks. The currency reports of the U.S. Treasury are used to determine where U.S. dollars go abroad, but dollars that travel between countries outside the U.S. are not traced (see Feige et al. 2003.) Moreover, shipments of currency in amounts less than $10,000 are not recorded. Several estimates in a 2003 U.S. Treasury report put $300 billion to $400 billion of U.S. currency outside the country, with 25 percent elsewhere in the Western Hemisphere and about 40 percent in Europe and the former Soviet Union.

Motives for currency substitution can come from seeking money as either a store of value or as a medium of exchange. Often economic agents will hold U.S. currency for store-of-value considerations or for use in larger transactions, while the local currency cocirculates for smaller purchases. This characterizes most of the Latin American experience with currency substitution. At risk of loss of their monies due to confiscatory currency reforms of the past, many households in Eastern Europe in the late 1980s held wealth in foreign currencies because they had no alternative assets available. On the other hand, sometimes foreign currencies are needed to provide media of exchange because local currency is in short supply. This can occur, for example, when the central bank is defending an overvalued exchange rate peg.

Institutional factors play a major role in the evolution of currency substitution. In Latin America, for example, most countries have suppressed or limited the holding of foreign currency deposits for a time, only later to remove restrictions as the demand for foreign currency has grown. This has an obvious impact on the quantity of foreign currency held. Other countries have permitted foreign currency holdings from the start (the most extreme case being Panama's decision to adopt the U.S. dollar as the sole currency). A country's policies with regard to currency substitution can and do change over time. Increasing financial development leads to more alternatives to foreign currency as a store of value and removes the necessity of restrictions on its holding.

Once currency substitution occurs, it can become irreversible through what is sometimes referred to as *dollarization hysteresis*. In short, each agent holds currencies based on what it expects other agents to hold. Once other currencies are introduced, a substantial shock must occur to induce agents to return to holding just local currency (Feige et al. 2003).

Dollarization De jure, or official, dollarization most often occurs after a period of high inflation, when a country either finds itself unable to create a new domestic currency that would hold value or is unwilling to endure the output loss needed to create credibility. Unofficial, or de facto, dollarization could include currency as well as asset substitution. Feige (2003) provides a breakdown of the separate currency and asset dollarization channels and their relative sizes. For example, there is almost no currency substitution in the Former Yugoslav Republic of Macedonia, but foreign-denominated monetary assets in Macedonian commercial banks are 2.5 times the size of domestic-denominated monetary assets (excluding cash). In general, however, currency and asset substitution indexes are highly positively correlated (i.e., currency substitution and de facto dollarization). We therefore focus on de jure, or official, dollarization.

De jure dollarization benefits countries if they are small and well integrated into world markets, and if their capital is highly mobile (Mundell 2003). Many but not all of the smaller countries of Europe that

are not part of the European Monetary Union Andorra, Kosovo, Montenegro, Monaco, San Marino, and Vatican City use the euro; only one (Kosovo) has a population of more than 1 million. Many of the island states of the Pacific use the U.S. dollar; a few use Australian or New Zealand dollars. Other states have granted legal tender status to the U.S. dollar and had their own currency circulate alongside. In Panama, which has the longest such history, the dollar is used for most transactions, but Panamanian coins circulate for minor trade. Panama is also highly integrated into the international capital markets. Guatemala and the Bahamas are other examples of de jure dollarized economies in the Western Hemisphere.

In many instances, de jure dollarization occurs through the creation of a currency board, such as in Argentina, but it need not be so. Ecuador makes an interesting example. The largest country by population to dollarize, it chose to abandon the local currency, the sucre, after that currency had depreciated precipitously at the end of 1999. The government declared the dollar legal tender, and the sucre was removed from circulation. The International Monetary Fund sent a technical assistance mission in support of dollarization.

Although official dollarization has helped many countries by imposing monetary discipline, its history in creating fiscal discipline is more mixed. Domestic currencies can gain revenue for a country through seigniorage; dollarization limits the ability of governments to collect an inflation tax (Willett and Banaian 1995), and so dollarization may remove any temptation for governments to resort to it. As a result, many economists have hypothesized that dollarization should produce fiscal discipline since additional spending would more likely be paid for with taxes. But as long as a government can borrow, fiscal discipline is muted. Moreover, if interest rates are reduced because of dollarization and greater monetary policy credibility, fiscal policy may become *more* lax. Fiscal deficits in dollarized Panama were higher than in nearby Latin American countries between 1970 and 1998 (Goldfajn and Olivares 2000). Additionally, dollarization through a currency board

did not help Argentina's fiscal authorities become more restrained. Therefore another expected benefit of dollarization lower interest rates has not always been realized.

The most ardent supporters of dollarization argue that when it comes from the decisions of individuals and is the result of a competition between note issuers, it provides benefits to an economy. Allowing the choice protects the property rights of households and ensures that their earnings cannot be confiscated by the inflation tax. Panama's adoption of the U.S. dollar as the sole legal tender in 1904 stands as the leading case of dollarization in most analyses.

Although many economists argue that the costs of dollarization are real and the benefits ephemeral, others argue that the benefits can be large only if the commitment to dollarization is made official, either through the abandonment of the domestic currency or through the creation of a currency board arrangement. But perhaps the biggest objection to dollarization is the country's lost pride. Few countries come into existence without some national fervor, and that fervor often seeks expression in historical pictures of the native landscape on paper, in the form of domestic currency. Many new currencies quickly become subject to inflationary pressures, but that seldom stops the next new country from thinking that it can do better and celebrating independence with new fiat money.

■ customs unions

Customs unions are arrangements among countries in which the parties do two things: (1) agree to allow free trade on products within the customs union, and (2) agree to a common external tariff (CET) with respect to imports from the rest of the world. Cus toms unions and preferential trade arrangements more generally have become increasingly important in recent years. The most famous example of a cus toms union is the European Union (EU). Trade among the member states of the EU flows tariff free, and regardless of which country in the EU imports a product, the same tariff is paid. The CET is what distinguishes a customs union from a free trade area. In a free trade area, trade among the member states flows tariff free, but the member states maintain their own distinct external tariff with respect to imports from the rest of the world. The North American Free Trade Agreement is the best known example of a free trade agreement. Canada, the United States, and Mexico do not share a common external tariff, de spite allowing free trade on products traded among the three countries.

With the exception of high protection on agri cultural products and some "sensitive" products, the EU generally has low tariffs, and the competitive markets of the EU in manufactures have been cred ited with improving the economic performance of

the EU countries. The impact of customs unions among developing countries (or "South-South" customs unions) on the development of the participating countries has been ambiguous at best, however. There are many examples of customs unions among developing countries, including Mercosur (Argentina, Brazil, Paraguay, Uruguay, and, as of 2006, Venezuela), the Central American Common Market (Guatemala, Nicaragua, Costa Rica, Honduras, and El Salvador), the Eurasian Economic Community (Russia, Belarus, Kazakhstan, Kyrgyzstan, Tajikistan, and Uzbekistan), the East African customs union (Kenya, Tanzania, and Uganda), and the Southern African Customs Union, which is the oldest customs union in the world, comprising South Africa, Botswana, Lesotho, Namibia, and Swaziland.

Both economic theory and empirical evaluations of customs unions and free trade agreements are ambiguous regarding the usefulness of these arrangements for the growth and welfare of the participants. The reason these agreements can be harmful is that "trade diversion" can occur. Since the agreements are discriminatory, tariffs are paid on imports from the rest of the world but not from partner countries. Private individuals may import a tariff-free product from producers in partner countries, even though the price on world markets (the tariff exclusive price) of the goods is cheaper from suppliers in the rest of the world. For example, suppose a partner country will supply a product at $1.25, while a nonpartner will supply it at $1. If the same tariff is charged on imports from all countries, the home country will import from the cheapest source and pay $1. Under a customs union, however, if the tariff exceeds 25 percent, private individuals will have an incentive to import from partner countries; then the home country will lose the tariff revenue charged on nonpartner imports and will pay more in foreign currency for imports. This is known as trade diversion. When partner countries are the low-cost suppliers in the world, then lowering tariffs preferentially will result in benefits to the importing country from increased imports from the most efficient world suppliers a phenomenon known as "trade creation." Excluding market access considerations, eco-

nomic theory tells us that nondiscriminatory tariff reduction would bring the country the gains of trade creation without the losses of trade diversion, and therefore nondiscriminatory tariff reduction dominates preferential trade arrangements on economic grounds. An additional important result of economic theory is that welfare-worsening customs unions (those where trade diversion dominates) can be made welfare improving if the external tariff of the customs union is lowered sufficiently. For example, in the case just discussed, if the tariff is lowered to less than 25 percent, the home country will import from the most efficient supplier on world markets and avoid the trade diversion.

The first incarnation of the Central American Common Market (CACM 1) is worthy of examination, in part because it resulted in an unusually large expansion of intracustoms union trade from 7.5 percent of total trade in 1960 to about 22 percent between 1976 and 1982 and because it is an example of extensive trade diversion. Using high effective protection on manufacturing goods, the CACM countries significantly expanded their manufacturing industries during this period by selling manufacturing products to one another and reducing their imports of these products from the rest of the world. These products were not competitive on world markets, however, and traditional agricultural exports, such as coffee, remained the primary export products to the rest of the world. That is, the increase in intraunion trade in CACM was accomplished primarily by costly trade diversion. After the debt crisis of the early 1980s, many of these industries and intraunion trade went into decline. CACM 1 used the customs union to focus production inward, that is, for import substitution industrialization, and did not use the customs union as a means of fostering competition.

When the CET of the customs unions results in a significant amount of trade diversion or fails to protect influential domestic industries, countries often exclude these products from the CET of the customs union (such as the agriculture product exclusions in the customs union agreement between the EU and Turkey and the many exclusions in the

Mercosur agreement). In the case of the Eurasian Economic Community, the CET is reportedly applied to less than 60 percent of the tariff lines for most of the countries in the customs union through selective application of the CET without prior agreement on exclusions.

Although Kemp and Wan (1976) showed that it is theoretically possible to design a common external tariff (with lump sum transfers among partner countries) that leaves excluded countries no worse off and at least one partner country better off, numerical and econometric assessments indicate that countries that are excluded from preferential arrangements will typically lose. The reason is that due to the tariff-free intrablock trade, buyers within the preferential trade area divert purchases away from excluded countries toward partner countries. This reduces demand and the price that sellers from excluded countries may obtain in the preferential trade area.

An advantage of customs unions over free trade areas is that customs unions eliminate the need to have "rules of origin" schemes among the member countries. That is, in free trade areas, traders may import a product into a member country with a low tariff and then resell it to another member country with a high tariff. In order to prevent this kind of tariff rate arbitrage, traders must document that the product crossing borders within the free trade area is produced within the free trade area. Rules of origin are then typically established that determine the conditions under which the product may be considered as one produced within the free trade area. These rules of origin can be rather cumbersome and difficult to administer, and they often impede trade.

For a country that desires to use trade policy as a means of expanding exports and competing on world markets, a crucial disadvantage of a customs union relative to a free trade area is that the country cedes the power to lower its tariff to the customs union's tariff-setting authority. Some economic theory and empirical work suggests that tariff-setting authorities in customs unions are less likely to lower tariffs than individual countries. Faced with high-cost imports from a partner country, the individual country in a free trade agreement has the liberty to lower its ex-

ternal tariff to reduce or eliminate this trade diversion. For that reason, Chile refused to join the Mercosur customs union but has vigorously pursued free trade areas with most of its trading partners so that more than 90 percent of its imports enter tariff free, while also lowering its uniform tariff from 11 to 6 percent.

Customs unions are said to provide the advantage of political cooperation, which contributes to peace and security. Peace between France and Germany in the EU is the best example of this. But if there are costs to some of the participants, the customs union could have the opposite impact. The U.S. Civil War was partly motivated by resentment of the southern states over having to pay high prices for northern states' manufacturing products due to high tariffs on European imports. In the East African customs union, the Kenyan manufacturing sector was more developed than that in Tanzania and Uganda. The latter two countries complained of bearing most of the trade diversion costs due to having to pay high prices for manufactured products from Kenya, but they could not independently lower the tariff on these products. Reportedly resentment over the uneven costs of the customs union contributed to border hostilities between Tanzania and Uganda in 1979.

Although theoretically unambiguous conclusions about customs unions are difficult, a key rule of thumb is to use the customs union to increase competition. Crucially, tariff reduction can reduce the costs of trade diversion and foster competition. "Deep integration" that fosters competition is important. Notably, the customs union agreement can be used to reduce nontariff barriers, such as regulatory and administrative barriers to trade, and commitments to increase the rights of foreign investors can provide for competition in key sectors important for economic development, such as business services. Both Schiff and Winters (2003) and Harrison, Rutherford, and Tarr (2003) suggest that another rule of thumb is that developing countries are more likely to gain from customs unions with industrialized country ("Northern") partners. By virtue of their size, Northern countries are more likely to introduce

competition in the markets of developing countries, and Southern countries are more likely to obtain technological advances from trade with Northern countries.

Customs unions form an important feature of the world economy as evidenced in the EU, Mercosur, and other examples of this kind of regional trade agreement. Consequently, the assessment of customs unions remains an important task for both theoretical and applied trade policy analysis.

■ debt deflation

Debt deflation can occur if falling prices raise the real costs of repaying loans, thereby boosting the costs of debt service and leading to higher bankruptcy rates and debt defaults. Rising debt defaults then produce increasingly weaker business conditions, further fueling the downward spiral and leading to a vicious circle that the economist Irving Fisher believed to be an important element prolonging and deepening the Great Depression of the 1930s in the United States. Fisher's perspective represented a sharp departure from the earlier conventional wisdom that occasional deflation was a natural result of productivity gains and, as such, was to be more welcomed than feared. Such was clearly not the case with the contracting economy of the early 1930s, for which Fisher's mechanism emphasized the link between declines in goods prices and declines in asset prices. Although economists often discount the role played by the October 1929 Wall Street crash, under Fisher's debt-deflation mechanism an event like this serves as a catalyst for defaults that could, if widespread enough, induce deflation in the economy as a whole.

The role of balance sheet effects is also important in fueling a debt-deflation process (Bernanke 1983). Debtors who default forfeit their assets to banks. Sudden, large drops in the prices of the forfeited assets then hurt bank balance sheets and potentially threaten the solvency of the banking sector. If banks curtail lending as a result, firms dependent on bank credit could face a credit crunch that leads to further production cutbacks and intensifies the deflationary spiral. Firms' borrowing difficulties may be further exacerbated if declines in asset prices reduce the value of their loan collateral.

Country Experiences with Deflation During Japan's slide into deflation after 1989, land and equity price declines hurt firms' loan collateral at the same time that the banks' own direct exposure to the stock market weakened their balance sheets. Together, these factors made firms less creditworthy at the same time that banks became more reluctant to lend at all. Japan in 1989, like the United States in 1929, clearly suffered from a sudden decline in asset prices as the stock market crashed. In the U.S. case, the unprecedented debt buildup during the 1920s, coupled with a sudden shift from a stable price environment to a deflationary environment at the beginning of the 1930s, meant that firms and households may have faced an unexpected rise in their debt service costs at the very time that their ability to fund their debt diminished. The unanticipated nature of the rising real debt burden at the beginning of the 1930s would have been a key factor in the operation of a debt-deflation process during the Great Depression in the United States (Fackler and Parker 2005). The agricultural sector was especially vulnerable in the U.S. case, and as falling prices made it harder and harder for farmers to repay loans, banks dependent on farm credit suffered as well. It is much harder to make a case for the importance of the debt-deflation process outside the United States, however, given that other major economies such as the United Kingdom did not appear to face any such dramatic debt buildup during the 1920s.

In addition to the more familiar U.S. and Japanese experiences, a debt-deflation mechanism may have been at work in late 20th-century emerging market crises such as those experienced in Mexico, Russia, and Southeast Asia. Output declines can be fueled by credit constraints that limit firms' access to working capital. These binding credit constraints in turn trigger debt deflation under this approach, leading to the dumping of assets and falling asset prices that further tighten the existing credit constraints. Once under way, deflation then lowers the marginal product of and real rates of return on factors of production. Vulnerability to this process increases with leverage, and economist Enrique Mendoza (2006) points to a surge in leverage ratios (as reflected in the ratios of debt to firm sales, book value of firm equity, and market value of firm equity) of listed corporations in Indonesia, Korea, Malaysia, and Thailand in the period leading up to the 1997 Asian financial crisis. As with the earlier debt-deflation literature, the unfolding of this process requires a high debt buildup. Otherwise the binding collateral constraint would not come into play.

While the actual prevalence of debt deflation remains a subject of debate among economists, almost all would consider the potential triggers, or facilitating factors, for such a process undesirable. That is, it is hard to see how sudden asset price declines, the sudden onset of deflation, or high debt levels and leverage ratios could be considered desirable policy goals. The Federal Reserve in the 1920s and the Bank of Japan in the 1980s, in arguably fostering an extended period of easy credit policies followed by sudden tightening, may well have played a major role in producing these very conditions. The pattern of sudden collapse following an extended period of excess liquidity seems to have been repeated in Southeast Asia in the 1990s. Unfortunately, such patterns often become more obvious after the fact than they were before the declines began.

Moreover, even though sudden tightening may trigger a debt-deflation process, expansionary monetary and fiscal policy will not necessarily reverse it in the absence of expectations of recovery on the part of consumers, businesses, and banks. Consumer and business unwillingness to spend, and bank unwillingness to lend, may well become ingrained among survivors of a debt-deflation process. In the Japanese case, for example, the bad debt problems of many Japanese corporations and the risks of future loan defaults help to explain why, even with ample zero-interest-rate money available, banks remained reluctant to lend. At the same time, Japanese banks were seeking to bolster their own balance sheets, which had been hurt not only by nonperforming loans but also by the sharp drop in the market value of their equity holdings. The banks' reduced willingness to lend and to circulate the new money being created by the Bank of Japan meant that these funds were often simply held within the banking system, thereby doing little to fuel new spending and combat ongoing deflation in the second half of the 1990s.

Prevention May Be Easier Than Cure Debt-deflation concerns only add to the argument that the most effective way to fight deflation is to keep it from starting, or at least to keep it from lasting long enough to become entrenched in expectations. Indeed, once consumers come to anticipate continued falls in prices, they have an incentive to postpone nonessential purchases, to save now and consume later. Anticipation of deflation also encourages people to accumulate cash balances in the hope that their purchasing power will grow over time. All this further reduces the current demand for goods and services, adding to the problems that businesses face. And, once deflation has set in, even a zero *nominal* interest rate policy, as the Bank of Japan maintained for some years, cannot prevent real borrowing costs from rising in the face of further price declines. This reflects the fact that the purchasing power of the funds borrowed increases over the course of the loan, producing a gain for the lender and a loss for the borrower even if no nominal interest payment is collected. Indeed, the worse the deflation gets, the more the automatic rise in the *real* interest rate is likely to further curtail business spending and exacerbate the downward pressures on economic activity.

There certainly are a number of reasons for authorities in low-inflation environments to balance the risks of deflation against those of accelerating

inflation. The onset of declining prices can be particularly dangerous for a highly indebted economy vulnerable to debt deflation. Sudden interruption of a long period of easy credit and rising asset prices certainly had dire consequences for the United States at the end of the 1920s and Japan at the end of the 1980s. The somewhat analogous boom-bust cycle in the emerging market economies of Southeast Asia in the 1990s, although it did not produce sustained deflation of goods prices, nevertheless led to an extended period of decline in both output and asset prices following the outbreak of the Asian financial crisis in 1997.

■ democracy and development

Although there is a strong positive association across countries between democratic governance and economic development, the exact nature of the relationship between these two concepts is less than perfectly clear and has been the subject of extensive study and intense debate. This entry will describe mechanisms by which democracy may or may not promote development, mechanisms by which development may or may not promote democracy, and causal effects from other variables on both development and democracy.

Democracy has many definitions, but recent scholarly literature has concentrated on variants of the following: democracy is the form of government in which political leaders are selected by periodic elections conducted reasonably honestly under conditions in which all political interests can compete. In addition to the right to vote, citizens have the rights to form political organizations, to try to influence public opinion, to put pressure on officeholders, and to compete for offices. This competition must take place under conditions of free expression through the media and the right of peaceful assembly. Note that this definition does not imply that all groups in the population, in particular the poor, are effectively represented in governmental decision making. Whether democracy results in implementation of the preferences and interests of the majority of citizens is an empirical question, not part of this definition of democracy.

Two widely used empirical measures of democracy are those of Freedom House and Polity IV. Since 1972, Freedom House has provided annual ratings of political rights and civil liberties for most of the countries of the world. Polity IV has combined measures of the competitiveness and openness of executive recruitment, the competitiveness of political

participation, and constraints on the executive into annual scores of democracy and autocracy for some 140 countries; Polity IV's data go back to 1800 for some countries. Przeworski et al. (2000) constructed a dichotomous annual measure of democracy for the period 1950 90; their definition adds the requirement that an incumbent party has lost an election and turned over power to the opposition. Despite the differences in definition, there are generally high correlations among these and other similarly inspired empirical measures of democracy.

Democracy Promotes Development A considerable literature in institutional economics contends that the economic rise of the West is inextricably linked to the economic institutions of secure property rights and third-party contract enforcement through impartial courts, and that these economic institutions were founded on political institutions of separation of powers and representative government (North 1995). The contention is that autocratic governments, unconstrained by constitutional limitations backed by independent legislatures and courts, failed to provide secure property rights over the long term. The political institutions under which modern economic growth emerged in Europe and its offshoots (especially North America and Australasia) allowed the market system to flourish and the business class to invest and innovate, fairly secure from government predation and social unrest. The regimes also began to supply free public education, which further contributed to economic progress (Lindert 2004). The fact that these political regimes were able to provide a good investment climate despite substantial restrictions on the franchise owes something to the legacy of political and social deference by the lower classes, a deference that gradually disappeared. Prior to World War I the partial democracies of Europe and its offshoots were able to accommodate the rising demands of the middle and lower classes without a great deal of social unrest or harsh repression. By 1950 the political attitudes that tolerated restrictions on the franchise had virtually disappeared; in the postwar period, democracy essentially implies full adult suffrage.

This institutional economics literature claims that democracy promotes economic development by providing secure property rights, impartial third-party contract enforcement, social peace, and public education. There are exceptions to these generalizations, however, as some autocratic regimes have expanded educational opportunities far faster than the typical democracy, and a great deal of economic expansion has taken place under nondemocratic rule, presumably with secure enough property rights to encourage investment and innovation. A few autocracies in East Asia, namely South Korea, Taiwan, and Singapore, created institutions and followed policies that have fostered economic miracles, raising their populations from poverty to middle-income status in four decades, and it is arguable that their autonomy from democratic pressures was instrumental in their rapid growth in the early stages of industrialization. All of these regimes expanded educational opportunities and physical infrastructure more rapidly than similarly situated democracies. Strong bureaucracies provided contingent rents to entrepreneurial activities and withdrew privileges if performance did not match targets. Most other autocracies in the decades since World War II have not provided an environment conducive to growth, or they did so only for brief periods.

Well-functioning democracies have links between civil society and political parties that translate popular desires into government programs (Lipset and Lakin 2004) and civil services that can implement these programs. Countries meeting the definitional requirements of democracy may lack these institutional features of good government and fail to provide physical infrastructure, secure property rights, high-quality public education, and macroeconomic stability.

Economists have examined how inequality and type of regime affect economic growth. A high level of income and wealth inequality may promote growth by putting income into the hands of people who will save and take entrepreneurial risks, but inequality probably also inhibits growth through its effects on sociopolitical instability and inequality's adverse effects on the level of human capital (because

of the inability of credit-constrained families to finance highly productive investments in human capital and because of the unwillingness of the rich to finance public education). Many models (e.g., Benabou 2000) incorporate the idea that democracy reduces inequality through redistributive fiscal policy; this redistributive policy has ambiguous effects on growth in the models. It inhibits growth through distortion of labor supply, saving, and risk-taking, but it promotes growth through its effects on human capital accumulation, especially if human capital generates positive externalities. The empirical literature finds little support for the proposition that democratic redistribution impairs growth through distortion of effort and saving incentives (Lindert 2004), but human capital accumulation probably does promote growth. A remaining question is whether the models are correct in assuming that democracy does in fact bring about redistribution of the growth-promoting variety. We take up this question later.

The econometric literature on economic growth in the postwar period has yielded mixed results on the effects of democracy on economic growth. No study prior to 1987 found in favor of democracy, and no study after 1988 found in favor of dictatorship (Przeworski et al. 2000, 178), but it is clear that growth can occur under either type of regime. Przeworski et al. (2000) find that democracy causes somewhat more rapid growth in output per worker, but regime type makes no difference to growth in very poor countries. There is some evidence that democracy reduces income inequality (Tavares and Wacziarg 2001), which is probably conducive both to economic growth and to the survival of democracy, but the same study finds that democracy inhibits investment, with a pronounced negative effect on growth.

The ambiguous effects of democracy on growth seem to be the result of multiple causal chains that offset one another. One of the ways democracy affects growth is through its effects on political instability. A regime change, such as from democracy to autocracy or vice versa, or the replacement of one dictator by another through unconstitutional means,

seems to have an adverse effect on growth, at least in the short run. At low levels of income regime change is no less likely under democracy than under autocracy, but as income level increases (either over time or in the cross-section) the failure of democracy becomes progressively less likely. Another aspect of political instability is social unrest, as manifested in strikes, antigovernment demonstrations, and riots. These events are actually more common under democracy than under dictatorship, but their occurrence has much more adverse effects on growth under dictatorship than under democracy (Przeworski et al. 2000). In other words, democracy accommodates this kind of social unrest without serious adverse effects on growth, but dictatorships in general do not.

Another channel through which democracy may affect economic growth is education. Many authors have asserted that extension of the franchise to all the people results in governmental support of mass education. This seems a very plausible statement when one looks at the spread of primary education and the franchise in Europe and the New World in the years before World War II (Lindert 2004). A landed elite, especially one that is ethnically different from the bulk of the population (as was the case in much of Latin America and the Caribbean), would not want to tax itself to provide mass education and might well fear that such education would threaten its hold on power. In fact, the extension of the franchise and the growth of primary education are fairly highly correlated across these countries in this period. The argument is less clear as applied to the postwar world, for while there is some econometric evidence showing a positive effect of democracy on primary and secondary enrollment rates while controlling for income level (e.g., Tavares and Wacziarg 2001), the evidence of a large effect is not strong. Moreover, one careful study failed to find a significant effect of democracy on the share of public expenditure on education in national output (Mulligan et al. 2004). This finding is not surprising, given the way democracy is defined in these studies.

Some countries that meet the empirical definition of democracy are so lacking in governmental capacity and in political parties and electoral institutions that

reflect the popular will that the public investments in human capital and infrastructure are not forthcoming. But if one adopts a more substantive concept of democracy (as in, for example, Tilly 2007), it seems safe to say that fully democratic regimes will provide more of these investments than the average autocracy (leaving aside that small number of autocratic "developmental states" in East Asia, some of which have now become democracies).

In a surprising finding, Przeworski et al. (2000) note that fertility is lower under democracies than under dictatorships, after adjusting for many factors that affect fertility. One of these factors is the parents' desire for security in their old age, which might be provided by having a large number of children, or by having a smaller number of children who are more likely to survive and earn enough to assist their parents, or by accumulating financial assets or pension rights. Przeworski et al.'s interpretation is that democracy provides greater confidence in the continuity of economic policies, as well as lower infant and child mortality, and thus tips the balance in favor of having fewer, better-educated children rather than many offspring.

Development Promotes Democracy A large literature in political science and political sociology attributes the emergence and spread of democracy to various aspects of economic development. In traditional society a landholding or bureaucratically based elite is able to hold the reins of political power and preserve its privileges, but as development occurs, structural changes weaken the power of the traditional elite. Wealth accumulates in the hands of industrial and commercial interests, rural people move to the cities, an industrial labor force grows in factories and mines, and education expands at both primary and higher levels. Some scholars (e.g., Lipset 1959) contend that, in addition to these structural changes in the economy, modernization associated with economic development increases the level of rationality in individual decision making, encourages toleration of opposing points of view, and attenuates the struggle over economic resources. A pervasive theme in much of the literature is that, whether through structural changes or changes in political

culture, economic development makes authoritarian rule less viable and promotes the emergence and survival of democratic regimes. Strong versions of this perspective would contend that democracy is unlikely to survive in very poor countries and becomes inevitable as countries become highly developed. This modernization theory was heavily criticized as many relatively well-off democracies (especially in Latin America) succumbed to military coups and authoritarian rule and many other countries grew rich without showing any signs of democratization. The theory enjoyed a resurgence in the 1990s as the "third wave" of democratization around the world became manifest, and the empirical studies of that decade confirmed the association of income and democracy (Lipset and Lakin 2004).

An alternative view is that, rather than development leading more or less automatically to democratization, countries are on different paths of institutional and economic development. As a result of historical factors, some countries developed political institutions of constitutional government that encouraged economic development and led ultimately to full democracy, while other countries got onto paths of continuous or intermittent autocracy that have not evolved into stable democracy, despite considerable levels of economic development. A prominent idea is that experience with electoral contestation under a limited franchise established an institutional basis of political parties and civil society organizations that supported well-functioning democracy. As mentioned earlier, the representative governments of Europe and its overseas offshoots followed such a path, although less successfully in Latin America than in the United States, Canada, Australia, and New Zealand. Among the former colonies that achieved independence after World War II, there is a remarkable association between British colonial status and uninterrupted democracy, which is probably attributable to these colonies' experience with electoral contestation and independent judiciaries under British tutelage. Around 2000, there were eleven low-income countries   that is, with incomes less than Costa Rica's   that had been

continuously democratic since independence; all were former British colonies.

A complementary approach that refines elements of modernization theory links democracy to structural changes in the economy that affect the power relationships among class-based interests. Democracy becomes more probable as the land-owning aristocracy loses political power to industrial interests and the middle class. An important study by Rueschemeyer, Stephens, and Stephens (1992) contends that in Europe, Latin America, and the Caribbean the working class was decisive in the push for full democracy. Some scholars doubt that interpretations based solely on the conflict of social classes are adequate explanations of democratic transitions; they stress elite choices and elite consensus on democratic rules, relatively independent of class interests. Collier (1999) analyzes the role of working-class organizations in Europe and Latin America and presents a rather mixed picture, with elites playing the dominant role in some of the cases.

In contrast to the nonformal approach of most of the sociological and political science literature, some economists and analytically minded political scientists have developed formal models of the determinants of democracy. A central question in these models is, under what circumstances will an authoritarian ruling social class decide to extend political rights to other social classes? In one type of model (Bourguignon and Verdier 2000), political participation depends on the individual's level of education; thus a decision to finance education for the lower classes may threaten the elite's political control. The elite benefits economically from the external effects of educating the lower classes, however, and hence may decide to finance public education, despite the fact that the new, larger electorate may impose redistributive fiscal policy to the detriment of the elite. In this model, the greater the initial inequality of income, the less likely is the elite to pursue a policy of public education that leads to a more democratic regime. In another type of model (Acemoglu and Robinson 2006), the ruling elite faces occasional threats of disruption or revolution by the middle or lower classes, who are demanding some redistribu-

tion of society's resources. These classes would not be satisfied with a promise by the elite to redistribute, because they know that the threat of disruption or revolution is temporary, and the elite could renege on their promise once the emergency has passed. The installation of democratic institutions, however, permits the elite to commit to redistribution and thereby avoid both the costs of repression and the danger of revolution. This framework gives rise to a very rich set of models describing precise mechanisms by which economic structures and social stratification may or may not lead to democratization and the survival of democracy.

The Econometric Literature By the 1990s abundant data had become available on national accounts and other economic and social indexes and on measures of democracy covering various periods from the 1950s to the present. Barro (1999) used democracy measured at five-year intervals as the dependent variable; independent variables included economic and social characteristics such as income and education and also the lagged value of democracy. His regression results suggest that a country's level of democracy will converge gradually to a level determined by the economic and social variables. The positive coefficients on income and life expectancy (viewed as a measure of standard of living) are consistent with the idea that these variables cause democracy to be more likely. In this particular study education does not have a statistically significant coefficient (but of course it is highly correlated with the other variables). A dummy variable for countries heavily dependent on oil exports has a negative sign, indicating that high income produced by petroleum exports does not have the same positive effect on democracy as income earned from other sources. It makes sense that the struggle to control large amounts of unearned government income would imperil democratic government.

Przeworski et al. (2000) studied the frequency of transitions from democracy to authoritarian rule and vice versa, and they related these frequencies to various country characteristics. A notable finding is that the probability of transition from authoritarian rule to democracy is only modestly positively related to

income, but the transition from democracy to authoritarianism declines sharply as income rises. In fact, above an income level of Argentina in 1975, there were no transitions away from democracy during that period (or since). The authors conclude that the positive observed correlation between income and democracy at a point in time is primarily due to the fact that once democracies attain a moderately high level of income, they seldom fail, rather than to a tendency for countries to transition to democracy at higher rates as they become richer. They note that countries can remain under authoritarian rule for many years after attaining middle- or high-income status. (Their statement would have been even stronger if they had included six high-income oil-producing authoritarian countries in the Middle East.) These authors also find an independent effect of education: at each income level, democracies with higher levels of education are less likely to fail. They also find that a high level of income inequality or a small labor share in value added in manufacturing increases the failure rate of democracies.

Acemoglu et al. (2005) have presented an empirical challenge to the received wisdom that income causes democracy. The challenge is based on an econometric technique in which the estimated effect of income on democracy is determined solely by variations over time within countries. They find that changes in a country's income do not predict changes in that country's level of democracy. Their interpretation of the data is that prior to the Industrial Revolution some countries developed political institutions that constrained their monarchs and limited the powers of the elite, and these countries evolved along a path of prosperity and increasing democracy, while other countries with different historical characteristics evolved under autocratic and elite-dominant institutions. They report that for various periods from 1840 to the present, there is no tendency for countries that grew more rapidly to experience greater improvements in their democracy scores, compared to countries that grew more slowly. Similarly there is no tendency for countries with greater increases in education to experience greater improvements in their democracy scores. In those parts of the world where the disease environment encouraged European settlement and the displacement or extinction of the local population, the settlers demanded and obtained representative institutions that evolved into democracy, but in the tropics, where death rates of Europeans were high, the Europeans set up institutions designed to extract resources from the colonies for the benefit of the mother country. These extractive institutions were conducive neither to economic growth nor to an evolution toward democracy. They support their interpretation by noting that after adjusting for the rates of settler mortality in the 19th century and population density in 1500, they find that the apparently strong positive effect of income on democracy is severely attenuated.

The interactions between democracy and development have been the subject of much theoretical and empirical investigation. The recent availability of comprehensive data sets has permitted careful statistical studies, which have challenged interpretations derived from casual empiricism. The processes are complex, data limitations persist, and much remains unresolved, however. Scholarly opinion on causal effects is likely to continue to evolve, not least because the world will continue to throw up unexpected developments.

■ dependency theory

Dependency theory argues that the process of underdevelopment in the global economic periphery is intrinsically connected to the process of development in the center. Dependency theory appeared in the 1950s as a critical reaction to the conventional approaches to economic development that emerged in the aftermath of World War II. There are two dependency theory traditions (Dos Santos 2002). The first is the Marxist tradition, influenced by Paul Baran and Paul Sweezy and developed by André Gunder Frank with important ramifications in the works of Samir Amin, Theotônio dos Santos, Arghiri Emmanuel, and Aníbal Quijano. The second dependency tradition is associated with the structuralist

school that builds on the work of Raúl Prebisch, Celso Furtado, and Aníbal Pinto at the Economic Commission for Latin America and the Caribbean. This structuralist approach is best represented by Fernando Henrique Cardoso and Enzo Faletto and by the subsequent contributions from Peter Evans, Osvaldo Sunkel, and Maria da Conceição Tavares. Other schools of thought were heavily influenced by dependency theory and espouse, in some respects, very similar views   in particular, the so-called world-systems tradition of Immanuel Wallerstein and his followers (Topik 1998).

Both groups would agree that at the core of the dependency relationship between center and periphery is the inability of the periphery to develop an autonomous and dynamic process of technological innovation. The lack of technological dynamism and the difficulties associated with the transfer of technological knowledge lead to underdevelopment of the periphery with respect to the center. The main contention between the two groups was ultimately related to the possibilities of economic development in the periphery. Marxists would argue that development in the periphery   meaning fundamentally catching up with the center   was impossible, while structuralists would argue that dependent development was feasible.

Vigorous growth in some parts of the developing world in the 1950s and 1960s seemed to justify the views of the latter group. The enduring process of stagnation after the 1980s debt crisis, however, has led to a reconsideration of the relevance of dependency situations. In particular, some authors argue that a new form of dependency has emerged, one in which technological backwardness and the international division of labor are of secondary importance, and the real obstacle to development is financial dependency, reflected in the inability of peripheral countries to borrow in international markets in their own currencies (Vernengo 2006). The following section discusses the main differences and similarities between the two dependency traditions, and the last one analyzes the financial dependency literature.

External versus Internal Limits to Development For Baran and other Marxists the origins of the center-periphery relation were strictly technological and determined by the international division of labor. The center produced manufactured goods for itself and the periphery, while the latter produced commodities mainly for the center, as well as maintaining a relatively large subsistence sector. Marxist *dependencistas* explained the lack of dynamism in the underdeveloped world as the result of its particular insertion in the world economy. In this view, the process of development depended on capital accumulation, which, in turn, hinged on surplus extraction. A larger surplus led to more accumulation of capital and a higher growth rate. Furthermore, for Marxists it was in the uses of the surplus that the differences between developed and underdeveloped regions were most evident. In the most backward countries, where the process of industrialization did not take hold and agriculture was still dominant, underdevelopment resulted from the patterns of land tenure that led to excessive concentration of ownership.

The predominance of large estates in plantation societies implied that a great part of the surplus remained in the hands of landowners, who emulated the consumption patterns of developed countries. Excessive and superfluous consumption of luxuries then reduced the potential for investment and capital accumulation. Conspicuous consumption implied that the surplus was not reinvested in the periphery, but ended financing investment in the center. Hence, conspicuous consumption was the cause of stagnation in the periphery. The international division of labor, which promoted the export-oriented plantation system in a large part of the developing world and reinforced the need for luxury imports, was at the core of the dependency relation.

If industrial development took place, then a new pattern of dependency would emerge. Industrialization would take place with participation of foreign capital, which would tend to control domestic markets. The periphery then would jump into the monopolistic phase of capitalistic development. The surplus extracted by monopolistic capital would not be reinvested in productive activities in the host country, however. Part of it would simply be sent abroad as profit remittances, while the other

part would be spent on conspicuous consumption. Frank (1967) concluded that the only way to break with the circle of dependency would be a political revolution.

The significant economic development in a good part of the periphery during the 1950s and 1960s led to a critique of the Marxist tradition by structuralist authors. Cardoso and Faletto (1967) argued that not only was capitalist development in the periphery possible, but foreign capital also had a tendency to be reinvested in the host country so that foreign investment might in fact stimulate domestic investment. Hence the nature of dependency was such that partial or dependent development was viable. As a result, dependency was not a relationship between commodity exporters and industrialized countries, but one between countries with different degrees of industrialization.

Cardoso and Faletto also distinguished between political and economic variables in explaining dependent development. Development and underdevelopment were economic categories related to the degree of development of the productive structure, and to its level of technological advancement. On the other hand, dependency and autonomy referred to the degree of development of the political structure, and the ability of local political elites to take economic decision making into their own hands. As a result, dependent development in association with foreign capital was possible and occurred in countries such as Argentina, Brazil, and Mexico, and in parts of East Asia, one might add. These were the countries that corresponded to what world-systems authors refer to as the semiperiphery. These were countries in which the simple dualistic vision of a center and periphery, where development was impossible in the latter group, did not seem to fit the real experience.

Cardoso and Faletto emphasized the importance of domestic internal developments, in contrast to the external forces of the world economy, as the main determinant of the situation of dependency. It was the internal political process that led to outcomes that favored foreign actors in the process of development. Furthermore, national capitalist development was not incompatible with the absorption of technological knowledge from multinational firms. Arguably, if the goal was to achieve development, dependent development was a reasonable road to it, even if autonomous development was politically more interesting.

In refuting the Marxist emphasis on the relevance of external factors, however, the structuralist version of dependency went to the other extreme and claimed that internal forces were the almost exclusive determinant of development. The inability to generate technical progress domestically, the domestic patterns of consumption, and the limitations of the domestic elites that opted for political dependency were to blame. If the successful industrialization of some parts of the periphery showed the weakness of the Marxist tradition, then the debt crisis of the 1980s and the failure to renew the process of development in the 1990s proved that the optimism of the structuralist approach was not necessarily warranted.

Financial Dependency and the Original Sin
The debt crises of the early 1980s indicated that the development possibilities in the periphery were not limited just by the inability to catch up technologically. Tavares (2000) argues that the technological division of labor in which the periphery concentrates in the production of commodities for the center, while the latter produces manufacturing goods for the former is of very limited historical relevance. Industrialization and technical progress in the periphery were not sufficient to break the dependency ties with the center. Financial dependency is reflected in the inability of peripheral countries to borrow in international markets in their own currencies and constitutes the real obstacle to development. The new interpretation of dependency situations puts "international money and not technical progress as the expression of financial capital domination over the periphery in the last 150 years" (Tavares 2000, 131 32).

The inability of domestic capitalists and governments to borrow in international markets in their own currencies reflects the inability of the domestic currencies of peripheral countries to acquire all the functions of money, as reserve of value, unit of account, and medium of exchange. The ability to

function as international money is a question of degree. Cohen (1998) suggests that there is a pyramid that reflects the geography of money, with internationalized currencies at the top and fragile currencies, on the verge of currency substitution, at the bottom. The main problem associated with the inability to provide all the monetary functions is that financial markets remain underdeveloped in peripheral countries, and the process of capitalist accumulation is hindered.

Mainstream economists have also dealt with financial dependency. Eichengreen, Hausmann, and Panizza (2003), following previous contributions by Hausmann, argue that underdevelopment results in part from the so-called original sin, that is, the fact that the currencies of developing countries are inconvertible in international markets. In this view, the external instability of domestic currencies in the periphery hinders the process of capital accumulation. Although mainstream and dependency authors agree on the importance of currency inconvertibility, they disagree on the solutions. Mainstream authors emphasize the importance of sound fiscal policies and monetary rules that promote credibility, while dependency authors emphasize the need for capital controls and reduced integration with international financial markets.

■ deposit insurance

Deposit insurance is part of the "safety net" for the banking system, but also can contribute to the system's instability, depending on its coverage and design. Deposit insurance has cross-border implications through its impact on banking crises that potentially spread to other nations.

In most countries, the regulatory structure for banks is much farther reaching than regulation of nonfinancial firms as well as of nonbank financial

institutions. The case for regulation is based on special characteristics of banks and perceived market failures in banking. First, the double role of banks as liquidity providers and participants in credit and capital markets makes them potentially vulnerable to bank runs, since a large share of the assets cannot be liquidated quickly in case depositors want to convert their funds to cash. Second, banks are relatively opaque entities, making it difficult for depositors and other creditors to evaluate the default risk of each bank. The limited information among depositors about the risk and value of bank assets can lead to the spread (contagion) of bank runs from one bank to another (Diamond and Dybvig 1983). Third, there are generally substantial amounts of very short short-term interbank liabilities, which contribute further to the risk of contagion. The potential for contagion implies that the banking system is subject to "systemic risk" to a greater extent than other providers of credit. Fourth, banks play a key role in payment and settlement systems, with the implications that large failures can disrupt economic activity.

The risk of runs on a bank and contagion implies that speed of action is of the essence when a bank is perceived to be near failure. Conventional liquidation and restructuring procedures for corporations are too time-consuming to be applied to banks without modification.

Some economists argue that banks are not qualitatively different from other firms and that markets provide sufficient discipline on banks' risk taking. These economists, who generally are proponents of "free banking," are few, however. From a policy point of view it is most important which view dominates among policymakers. It can safely be said that in times of crisis they will not be willing to experiment in order to find out which group of economists is right.

The need for rapid intervention, lack of effective rules for dealing with a bank in distress, and fear of contagion work in tandem to compel governments to intervene in a crisis by issuing blanket guarantees to all creditors or bailing most or all of them out. Anticipating this government behavior, depositors,

other creditors, and sometimes shareholders as well perceive themselves as implicitly insured even if there is no explicit deposit insurance.

The Safety Net for the Banking System The features of banking described earlier have led to the implementation of a number of measures in most countries that together constitute the safety net for the banking system. The typical components of the safety net are:

1. A lender of last resort (LOLR)
2. Deposit insurance
3. Supervision and regulation of banks' risk taking
4. Capital requirements

These aspects of the safety net should jointly protect the "safety and soundness" of the banking system while providing banks with the appropriate rules and incentives to allocate credit efficiently. Deposit insurance can limit the risk of bank runs by guaranteeing that depositors receive some, or all, of their deposited funds with reasonable speed in case their banks become insolvent or illiquid. The central bank can also act as a LOLR by lending to a solvent bank facing a liquidity squeeze as a result of a run by depositors. To limit the LOLR to cases of illiquidity, the central bank can require collateral to provide liquidity support.

Regulation of banks' behavior and asset allocation, and supervision of banks' credit allocation and risk management systems, have the purpose of limiting banks' risk taking, which can be excessive. In addition, capital requirements reduce risk-taking incentives by ensuring that there is always shareholder capital at risk. Capital also serves as a buffer against unanticipated losses.

International agreements with respect to capital requirements as well as principles for supervision are negotiated within the so-called Basel Committee. The first Basel Agreement was completed in 1988 (Basel I). After years of debate, a substantially revised Capital Adequacy Accord (Basel II) was completed in 2004. This accord was to be implemented in the European Union (EU) in 2007 and 2008, but it remains controversial, particularly in the United States.

Deposit Insurance, Risk Taking, and Banking Crises The flip side of the positive role of deposit insurance as a safeguard against bank runs and as a consumer protection device is its role in inducing banks to shift risk to a deposit insurance fund or tax payers. These risk-shifting incentives are caused by limited liability of shareholders and explicit or implicit protection of depositors and other creditors. The so called moral hazard problem caused by these factors implies that banks have incentives to take on excessive risk on the asset side or to keep the equity capital low. Thus deposit insurance systems can contribute to the very problem (systemic risk) they are designed to reduce.

One solution to the moral hazard problem would be to design a deposit insurance premium structure reflecting banks' risk taking. Risk-based pricing encounters the problem of defining banks' risk taking contractually. For this reason a private deposit insurance market is not likely to function well. The existence of explicit and implicit insurance also undermines the scope for private insurance. In the United States, the Federal Deposit Insurance Corporation (FDIC) sets insurance premiums based on levels of capital.

The substantial resources devoted to the design of a capital adequacy framework by central bankers and regulators in the Basel Committee indicate that there is a strong concern about incentives for excessive risk taking. Bank managers, by contrast, tend to deny that there are incentives for excessive risk taking because they do not deliberately set out to take "excessive" risk. Incentives need not reveal themselves as incentives for deliberate risk taking, however. Instead, it is the competition among banks with the opportunity to finance their lending activities at a near risk-free interest rate that induces them to prefer debt financing to equity financing. Furthermore, competition for funding will not be based on banks' risk evaluation and risk management skills. Increased resources devoted to regulation and supervision and increased sophistication of supervisors have done little to reduce the incidence of banking crises. For this reason several academic economists have called for increased reliance on market discipline in the regulatory framework for banks.

The existence of implicit insurance implies that it is not necessarily the extent of explicit insurance that determines creditors' and, indirectly, banks' behavior. Absence of explicit insurance does not constitute credible noninsurance if political realities require supervisors and governments to rapidly intervene in banking crises to protect creditors. On these grounds a deposit insurance scheme with limited coverage can maximize the market discipline by making it credible that noninsured deposits and creditors will not be bailed out (Angkinand and Wihlborg 2006). The appropriate coverage depends on a number of country-specific institutional factors affecting credibility of noninsurance. In particular, effective procedures for dealing with a bank in distress can reduce the likelihood of bailouts.

The empirical evidence on the relationship between the coverage of deposit insurance schemes and risk taking is ambiguous. Much work has been devoted to analysis of the relationship between deposit insurance coverage and the occurrence of banking crises around the world.

Differences in results across studies suggest that institutional differences matter greatly for the effect of deposit insurance on the likelihood of banking crisis. The economists Demirgüç-Kunt and Detragiache (2002) consider the effectiveness of prudential regulation and supervision, as well as the strength of the legal system, finding that deposit insurance contributes less to the probability of banking crisis in countries with a high level of institutional quality.

Banking crises and excess risk taking have also been analyzed at the bank level. On this level it is necessary to take into account that capital and risk taking are determined simultaneously. The economists Nier and Baumann (2006) found that bank capital is decreasing in deposit insurance coverage, increasing in uninsured deposits, and decreasing in government support. These results provide evidence that market discipline depends on explicit coverage as well as the credibility of noninsurance.

Dimensions of Deposit Insurance Systems

Several dimensions of explicit deposit insurance schemes can discourage bank runs and incentives for risk taking. In discouraging bank runs, speed and credibility of insurance compensation in case of a bank failure are particularly important.

Risk-taking incentives are influenced by the existence of groups of creditors with incentives to monitor banks and to withdraw funds if they find that a bank takes unacceptable risks. Demirgüç-Kunt and Detragiache (2002) constructed a "moral hazard index" for a large number of countries from data on coinsurance features, coverage of foreign currency and interbank deposits, type of funding, source of funding, management, membership, and the level of explicit coverage. Coinsurance implies that those insured are responsible for parts of the losses. Foreign currency and interbank deposits are not covered in most countries. Private participation in the deposit insurance system can also be required.

Funding can be through insurance premiums that are used to build up a fund, or governments can cover payments out of tax revenues when compensation is due. The existence of a fund enhances the credibility of the system and it implies that banks pay insurance premiums, which can be based on proxies for risk. Most countries either do not charge a premium or they charge a certain percentage of deposits. The method to replenish losses to a fund, and assign responsibility in case the fund is insufficient, also affects incentives. If banks are held responsible for the replenishment of a fund, the subsidy component to the insurance system is reduced and banks have stronger incentives to watch the soundness of the system. Finally, membership in the system can be voluntary or required.

The economists Hovakimian, Kane, and Laeven (2003) have estimated implicit insurance premiums for banks in a number of countries based on the insight that deposit insurance can be interpreted and valued as a put option on banks' assets (i.e. the right but not obligation to sell). The authors find that some risk-adjustment of the insurance premium for each bank, the existence of coinsurance, and the funding of the deposit insurance along with deposit insurance coverage affect the variation in implicit insurance premiums across countries.

Deposit Insurance in Cross-Border Banking

Banks are involved in cross-border activities through direct lending to foreign banks, companies, and governments; through subsidiaries; and through branches operating in foreign countries. In the first case the domestic deposit insurance system affects the incentives for lending to foreign entities and protects domestic depositors. Implicit insurance can also be provided by international financial institutions, in particular the International Monetary Fund (IMF). The IMF's role in helping Mexico during the crisis in 1995 has been widely blamed for contributing to the Asian crisis in 1997. The IMF does not protect banks directly but by helping countries such as Mexico in balance of payments crises, it indirectly provides protection for banks that have lent to banks and the government in a crisis country. As a result banks may consider loans to foreign governments and banks protected by the same governments to be relatively safe.

Foreign subsidiaries are separate legal entities. Depositors in subsidiaries are therefore protected by host country deposit insurance systems. Host countries are also responsible for supervision of the subsidiaries while home countries are responsible for supervision of the consolidated bank. Since subsidiary operations often are closely integrated with the parents in complex financial organizations, there are opportunities for shifting of risk between the entities. If a subsidiary or the consolidated bank fails there is scope for conflicts of interest between host and home countries with respect to the sharing of the burden for losses that are not clearly attributable to one of the entities. The absence of predetermined procedures for crisis resolution in banks makes conflicts more likely. It is common for home and host countries to have memoranda of understanding on crisis resolution for banks, but these memoranda are typically so general that they offer little guidance if a bank fails.

A bank can also run its host country operations through branches. Since branches are not separate legal entities, the challenges for authorities in home and host countries are different. The EU's Banking Directive provides banks with the opportunity to operate across borders within the EU through branches under home country supervision. Deposit insurance in the EU is also a home country responsibility. Thus banks of different nationalities can operate in the same country offering different levels of deposit insurance. If a host country has a higher coverage, local branches of foreign banks can be offered the opportunity to "top up" their deposit insurance. The EU rules with respect to deposit insurance and supervision are consistent in the sense that the responsibilities for insurance and supervision coincide. Nevertheless, there is substantial worry in host countries that their interests will not be well represented if a foreign bank fails. These concerns partly explain why the Banking Directive has not been put into large-scale practice; instead, most cross-border banking is organized in subsidiaries.

The situation in the United States is different. Branches of foreign banks must participate in the U.S. deposit insurance system, although they are foreign legal entities and formally relying on the same capital as buffer against losses. To protect the American interests in case a foreign bank fails, branches of foreign banks are "ring-fenced," meaning that the branches must hold separate capital for their activities in the United States. Therefore, the difference between a subsidiary and a branch in the United States is almost in name only.

■ development

Development refers to a process that includes and goes beyond economic growth. Whereas growth is defined narrowly as an increase in real income per person, the Nobel laureate Amartya Sen (1999) defines development as the expansion of human freedom, including freedom from hunger, ignorance, political oppression, and disease. Although income clearly matters for development a richer society can build and staff more schools, courtrooms, and hospitals it is also clearly not all that matters.

In defining development the challenge is to find measures of social evolution that come closer to Sen's notion of expanding human freedom but are still concrete enough to permit meaningful measurement and study. Making choices about which social goals are emphasized and how their attainment is mea-

sured is of necessity a value-laden exercise, and because values vary sharply across cultures and individuals, no measure of development can safely claim to be either universal or entirely objective. Despite this inherent limitation, the inadequacy of economic growth as a measure of development has led to an ongoing effort to find alternative measures of development. Here we consider several dimensions of development economic, human, and social noting how each has been defined and measured and considering the relationship of development to economic growth.

Economic Development Economic development includes three dimensions that go beyond rising per capita incomes. The first involves the development of a country's economic system. Economic development is generally facilitated by a number of structural changes, including urbanization, the rise in the size of firms, the relative decline of the agricultural sector in terms of employment and output with expansion of manufacturing and services, the geographic expansion of markets, and increases in the diversity of goods produced and traded. These changes in the organization of economic activity are the hallmark of permanent shifts in economic activity. Income gains that are not accompanied by these changes, such as natural resource booms, are easily reversed. Furthermore, the expansion of markets and increases in the diversity of goods produced raises welfare by expanding the range of goods available to consumers and providing a form of insurance by diminishing the impact of dramatic changes to the local economy or particular industries.

The second dimension of economic development concerns the distribution of the gains from economic growth. A rise in the average income level means nothing more or less than a rise in national income divided by population size. As such, there is no guarantee that economic growth makes a majority of people better off or results in income gains for the poorest members of society. This point is particularly important for less-developed countries, in which calls for economic growth are motivated largely by the desire to reduce widespread poverty.

The perception that the gains from growth in the 1960s and 1970s were unequally distributed led to calls to redefine development in a manner that placed greater emphasis on poverty and inequality (see, e.g., Streeten 1981). Skepticism about the gains from growth also reflected the influence of economists such as the Nobel laureates W. Arthur Lewis and Simon Kuznets, who argued that industrialization was characterized by an initial period of rising inequality with limited benefits for the poor. In addition, many economists noted that the way in which growth rates are calculated gives greater weight to increases in the incomes of rich individuals: a 10 percent increase in an individual's income adds more to average income the richer that person is. One suggestion was to replace growth with a poverty-weighted index that measured the growth of the incomes of the poorest 20 to 40 percent of the population.

Although development economists remain concerned with the distribution of the gains from growth, the idea that growth is inherently biased against the poor is not supported by recent empirical work. For example, a study by Dollar and Kraay (2002) finds that on average the incomes of the poorest 20 percent of the population grow at the same rate as average income. Similarly, in a cross-country analysis of income inequality, Li, Squire, and Zou (1998) find that inequality is highly stable within countries over the postwar period. Prominent exceptions include rising inequality in the United States and falling inequality in several fast-growing East Asian economies. Although these results do not guarantee that the poor always benefit from growth, they undermine the presumption that growth is systematically biased against the poor.

The final dimension of economic development is sustainability (see, e.g., Goldin and Winters 1995). The UN's Brundtland Commission (1987) defined sustainable development as development that "meets the needs of the present generation without compromising the ability of future generations to meet their own needs." Viewed in terms of sustainability, income growth rates can be misleading measures of development, since consuming natural resources simultaneously increases income and reduces a country's stock of natural wealth. Correctly measuring sustainable development requires adjusting income levels to account for the depletion of natural resources and degradation of environmental quality. This has led to the development of "green" national accounting, in which the national saving rate is adjusted for resource depletion. Adjusting income levels for the negative impact of pollution is more difficult, since the value of environmental quality varies widely across individuals, societies, and time.

The relationship between economic growth and environmental quality is not clear cut. Economic growth clearly increases the pressure on natural resources and systems. The challenges to sustainability include the consumption of nonrenewable resources such as oil and coal reserves, loss of biodiversity, depletion of ocean fisheries, deforestation and desertification, and reductions in air and water quality, all of which reduce either the productivity or consumption of future generations. But rising income levels also increase a society's willingness to pay for environmental quality, its ability to mobilize political pressure, and the technologies and resources it has available to reduce or reverse environmental damage. Together these forces result in complex relationships between environmental quality and average income levels. For example, as income levels rise, access to clean water increases, carbon dioxide emissions worsen, and the output of industrial pollutants such as sulfur dioxide rises and then falls.

Human Development If income matters for development, it is because it measures the ability of individuals to satisfy their needs and create personally fulfilling lives. In brief, a higher income is at best a means to the end of greater development. Recognizing this led to several efforts to measure the "ends" directly, resulting in attempts to quantify numerous dimensions of consumption, including consumption of food, medical care, housing, and energy. Many of these measures were subsequently criticized as being based on Western norms and consumption patterns   larger houses counted but larger weddings did not   reducing their usefulness as general measures of development. A more gener-

ally accepted approach is the Human Development Index, which has been published annually since 1990 as part of the UN's Human Development Report.

The Human Development Index, or HDI, gives equal weight to three components measuring income, health, and educational attainment. For each component, a country's outcomes are graded on a scale from 0 to 1, where the ends of the spectrum are defined by the lowest and highest observation for other countries. Health is measured by life expectancy at birth. Life expectancy is highly sensitive to infant and child mortality rates. Since these depend on widespread access to nutrition and health care, life expectancy is highly sensitive to economic and social inequality. Education is a fundamental determinant of economic and social mobility, and as such plays an important role in determining the range of choices available to an individual. The educational index is calculated as two-thirds adult literacy and one-third current enrollment rates, making it sensitive to both educational inequality and future educational attainment. The HDI includes a measure of income to proxy for all aspects of human development not captured by health and education. The index of income levels uses the natural log of per capita income. This choice places greater weight on income increases among poor nations, since it implies that proportional increases in income are measured equally: the increase from $1,000 to $2,000 is equal to that from $10,000 to $20,000.

Although it is still clearly limited, the HDI is the most widely known and commonly used alternative to per capita income as a measure of development. To see how the HDI differs from per capita income as a measure of development, it is useful to compare country rankings using the HDI and per capita income levels. Using data from the 2007 Human Development Report, we find that major oil exporters and countries with significant AIDS crises do worse when ranked according to human development, results that probably reflect the HDI's sensitivity to inequality and life expectancy. Similarly, the United States ranks lower using HDI than it does using per capita income, an outcome that reflects inequalities in access to education and health care

relative to other wealthy countries. Alternatively, current and formerly socialist countries, such as Cuba, Venezuela, and the former Soviet countries, tend to rank higher using the HDI, reflecting both their commitment to the provision of education and health care and their relative inability to generate high incomes for their citizens. These differences aside, differences in per capita income explain more than 88 percent of the variation in the HDI, suggesting that income is the most important determinant of both health and educational outcomes. With higher incomes societies can build schools and hospitals and hire the teachers and doctors to staff them.

Social Development Social development refers to development of society as a whole. A number of dimensions of social development have been measured and subjected to analysis, often as part of the UN's Human Development Report, including political development, human rights, human security, and gender equality. Here we consider two aspects of social development: political development and gender equality. It should be noted that in attempting to define social development, it is impossible to escape from subjective value judgments that vary widely across individuals and cultures. In particular, the measures presented here have their roots in Western Enlightenment thinking that is both secular and individualistic. To the degree that other cultures emphasize competing values based on family or community or religious devotion, these measures may be inappropriate.

We measure political development along two dimensions, the extension of democratic political rights and freedom from corruption. Democratic political rights may be viewed both as an end in themselves and as the means to achieve other development goals. For example, democratic political rights and the civil rights that sustain them, such as the freedoms of speech, association, and the press, are central to self-expression and to full participation in the social life of a country. They may also play an instrumental role in reducing income inequality and raising incomes by securing access to health care and education. As Sen (1981) famously pointed out, despite instances of widespread crop failure, there has

never been a famine in a democratic country: letting too many people starve is bad for reelection. Though it is difficult to measure democracy objectively, there appears to be a strong relationship between average income and democratic political rights. It is hard to disentangle cause from effect, and there appear to be important links in both directions. For example, democracies tend to have higher levels of education but also higher taxes, with conflicting implications for economic growth, and the demand for political rights may increase as rising incomes satisfy more basic physical needs (see, e.g., Barro 1996).

While democracy focuses on how political leaders are chosen, governance refers to their behavior once in office. Democracy may be seen as a means to the end of good governance. An important aspect of governance is corruption, defined as using public office for private gain. Measures of corruption are constructed using survey data and tend to be highly correlated with one another and with other measures of governance such as the quality of bureaucracy. Freedom from corruption tends to rise with per capita income, though less strongly than the Human Development Index. For example, using data from 2007, the correlation between the natural log of per capita income and Transparency International's Corruption Perceptions Index is 0.63. As with democracy, causality appears to run both ways. Clean government results in the better use of tax revenues and provision of public goods, and higher incomes increase the demand for good government and the ability to supply it.

Gender equality involves equal access for women and girls to economic opportunities and resources and full participation in the social and political spheres of life. Gender equality was first included in the Human Development Report in 1995. The Human Development Report now reports a Gender-related Development Index (GDI), which measures the inequality of health, education, and income outcomes by gender using the same indexes as the Human Development Index. Gender equality is both a fundamental measure of women's rights and opportunities and an important contributor in securing other development objectives. As with political development, there are complex relationships between gender equality and political and economic development. Expanding women's political participation may reduce corruption and increase the provision of education and health care, while women's economic participation both raises incomes directly and has important impacts on the well-being of future generations.

■ digital divide

The term *digital divide* refers to the disparity between those who have the resources and capabilities to use telecommunications technologies and those who don't. This gap exists within nations (varying by geography, social class, age, and other social dimensions) and between nations (essentially reflecting more fundamental differences in social and economic development). Blending telecommunications with computer technology, the advent of the Internet constitutes one of the latest revolutions in how the world conducts its business, thereby making the digital divide ever more salient. Evolving from modest beginnings as a U.S. Defense Department project in the 1960s to a mass communications technology linking the world's cities, the Internet/World Wide Web has quickly outgrown its original role as a special tool of governmental and educational elites. As such, this new technology is simultaneously hailed as the fifth neo-Schumpeterian "long wave" of global economic expansion (Castellacci 2006) and cursed as a new, powerful tool of exploitation created by international capitalism (Parayil 2005). This debate, between those Norris (2001) labels as Internet "optimists" and "pessimists," animates much of the scholarly literature, but the truth about digital diffusion is probably more complicated (and less economically crucial) than many analysts suggest.

There is no doubt that the debate is driven by a real phenomenon. Although the number of Internet users has expanded exponentially from approximately 40 million in 1995 to more than a billion people in 2007, the Western world's share of the total number of users worldwide is still around 50 percent, even though the West makes up only about 17 percent of the world's population. On the other hand, the combined share of users from Africa, the Middle East, and Latin America (about a quarter of the globe's population) constitutes only about 13 percent of all users, suggesting a considerable disparity. Even more telling, as of 2007 about 70 percent of the populations of the United States and Canada used the Internet, while only 11 percent and 3 percent of Asia's and Africa's populations, respectively, did the same (Internet World Stats 2007).

For all intents and purposes, then, the Internet/World Wide Web is still very much a creature of well-developed markets. Although optimists hope that developing countries can use the Internet to "leapfrog" over the industrial phase of development and move directly into postindustrialism (Steinmueller 2001), the commodification of information is sufficiently different from material goods and other services to cast doubt on this proposition. Many goods and services are produced for final consumption, whereas information is typically produced as an intermediate commodity, something used to improve the efficiency of production or the distribution of goods and services, much like transportation (Mowshowitz 1992; Crenshaw and Robison 2006a). This explains why the need for information grows as social and economic complexity increases, and thus why demand for information as a commodity is contingent on large and complex markets.

Since it is clear that the Internet is firmly rooted in developed economies and is likely to remain so, it is the *diffusion* of Internet technology to the developing world that dominates the current scientific literature on the digital divide. Rogers (1983) defines cultural diffusion as "an innovation that is communicated through certain channels over time to a receiving society." Not surprisingly, the current literature focuses almost exclusively on these "receiving societies," attempting to gauge their *structural conduciveness* as adopters of complex information and communications technologies (ICT). The most consistent structural attributes that have been found conducive to Internet diffusion fall into a modest number of categories: (1) economic complexity, infrastructure, and income; (2) mass education and literacy; (3) public policies relating to the provision of telecommunication services; and (4) the relationship between government and civil society, with special emphasis on political rights and property rights. In general, higher incomes, a dominant services sector, more extensive telephone and electrical infrastructure, mass education and literacy, public policies related to telecommunications competition, reasonably priced telecommunications services, participatory democracy, and protection of property rights

correlate positively with more rapid adoption of the Internet.

Diffusion theory stresses *contact* in addition to conduciveness, however. Indeed, the major reason Internet optimists think that "leapfrogging" is possible is that the Internet makes the world's most complicated economies accessible to a wide range of less-developed communities, even those that are relatively isolated. The thinking suggests that the Internet provides conduits that allow the populations of relatively undeveloped countries to access a complex global economy. In short, the optimistic view of Internet diffusion is predicated on a fairly benign view of globalization.

Globalization typically refers to a plethora of international networks composed of intergovernmental organizations, governments, multinational corporations, and many other actors. Although limited globalization has long been a part of human history, contemporary globalization is accomplished through unprecedented technological capacities, flows of material and information, and growth in international governance. Given this dynamism, it seems plausible to assume that globalization might "jump-start" Internet development in otherwise unlikely locations. The question is, therefore, whether globalization can ease the constraints placed on Internet diffusion by structural requisites (i.e., conduciveness).

Given that the Internet was created in the postindustrial West, contact with the West (and/or other advanced economies) may form postindustrial "bridges" or "beachheads" in developing countries (the choice of term depends on one's view of global capitalism). One interesting analogy is Crosby's (1986) notion that European colonialism was far more successful where local conditions allowed the formation of "neo-Europes" territories where climates and disease regimes were conducive to the importation of European flora and fauna, which in turn displaced many native species and invited European settlement. The bridges (or beachheads) provided by the conduits of globalization may be creating something similar for ICT growth islands of postindustrialism amid seas of the preindustrial.

Essentially, globalization creates postindustrial microcosms that generate *demand* for ICT where it would not otherwise exist.

The possible conduits of globalization should be familiar to students of international development. For instance, megacities (i.e., cities populated by millions of people) have proven to be important gateways for ICT diffusion (Crenshaw and Robison 2006a, 2006b). Urban areas generate extremely diverse labor and consumer markets and, as major service nodes, tend to host Internet service providers (ISPs) even in very poor nations. For instance, Nigeria is one of the world's poorer nations, and yet its capital of Lagos (a city of approximately 11 million people) had more than 90 ISPs in 2003. Thus such megacities can provide "islands" of postindustrial demand independent of a nation's other structural characteristics.

International investment and trade also provide conduits that create favorable environments for ICT development. One of the major reasons that a digital divide exists among developing nations is that trade and foreign investment are likewise unequally distributed. For instance, in the early 21st century, sub-Saharan Africa accounts for only 2 percent of the world's merchandising exports, and receives only about 8 percent of the foreign investment going to developing economies. If ICT diffusion tends to follow pathways blazed by trade and investment (Crenshaw and Robison 2006a), inequalities in Internet capacity and growth are probably inevitable.

While large commercial cities and international investment and trade probably play dominant roles in the spread of Internet traffic in the developing world, noncommercial/nonstate actors and flows of immigrants, some permanent and some temporary (i.e., tourists), also contribute to the diffusion of ICT. For instance, nongovernmental organizations (NGOs) and international nongovernmental organizations (INGOs) are carving ever-expanding niches in the world's cross-cultural networks. Indeed, the Union of International Associations estimates that around 70,000 NGOs and INGOs existed as of the mid-1990s (UIA 2008), and regardless of the myriad purposes of such organizations, the one thing

they have in common is dependence on international telecommunications to spread their messages and coordinate their activities. As past research demonstrates, in all likelihood this growing web of nonstate organizations makes a substantial contribution to Internet connectivity in otherwise unlikely places (Drori and Jang 2003; Crenshaw and Robison 2006a).

Tourism also promotes Internet use in the developing world. Tourist destinations that cater to affluent visitors create nodes of strong demand for instant and up-to-date information and real-time communications, not only for the tourists themselves but also for the global travel industry. As with other global connections, however, global tourism is also unevenly distributed. For instance, American tourists disproportionately travel to the Caribbean and Europe, whereas Africa and many other destinations languish in relative obscurity. Western tourism has been found to promote Internet usage (Crenshaw and Robison 2006a, 2006b), and there is very little reason to expect this dynamic to equalize Internet capacity in the future.

On balance, then, what can be said is that structural conduciveness in the form of affluence, democracy, and political and property rights does invite the spread of digital technology. Moreover, other forces, particularly economic, political, and social globalization, contribute to the digital revolution, even in places where social structural conditions may be unsuitable (e.g., poor nondemocratic countries). None of these forces, however, easily lend themselves to policies that might "jump-start" the Internet revolution, nor does the current literature suggest that Internet development is crucial for economic growth in the developing world. Rather, the global digital network is an epiphenomenon of more fundamental economic, political, and social forces, and policies *focused* on Internet development are likely putting the cart before the horse. New technologies in laptop computers and wireless connectivity will ease the supply problem constraining Internet development, but solutions to the bedrock problem underlying the digital divide — the lack of demand that results from national poverty and isolation from the world

economy — also depend on political reform, domestic production, economic trade, and tourism.

■ **discipline**

There is a long history of arguments for the use of a fixed exchange rate regime as a source of discipline over domestic monetary and fiscal policies. Advocates of the view generally believed that governments had a tendency to debase their currencies (by generating inflation) as a way of financing their often excessive expenditures. Supporters of "sound money" were often opposed to the issuance of paper money for fear that it would lead to undisciplined money creation and hence inflation.

In the first decades of the post World War II period, such arguments were made primarily by advocates of a return to a gold standard. Mainstream Keynesian economists claimed that these arguments reflected a conservative concern with inflation to the exclusion of other macroeconomic objectives. Indeed the mainstream view was that international monetary regimes, to the extent that they were consistent with other objectives, should be devised to minimize the constraint imposed on domestic macroeconomic policymaking.

By the 1960s, however, this mainstream consensus began to fray. The combination of unemployment and inflation ("stagflation") that developed in most industrial countries during the 1960s and 1970s prompted many to question the Keynesian premise that government policies would be operated predominantly in the public interest to help correct macroeconomic instabilities generated by the private sector. Often government policies seemed to be the cause of macroeconomic instability. Although politicians were quick to adopt the Keynesian perspective that favored cutting taxes and increasing government expenditures during a recession, they were much less interested in the other side of the strategy: that taxes be raised and expenditures be cut when the economy was overheating.

Such lack of government discipline provided fertile ground for a new generation of political scientists and economists who explored why governments might deviate from the pursuit of macroeconomic stability. One influential line of thinking argued that reelection objectives could generate incentives for political business cycles (see Drazen 2000; Keil and Willett 2004). Prices tend to adjust more slowly to changes in macroeconomic policies than does output. Thus a well-timed expansion before an election might boost employment and output in the short term but lead to higher inflation in the long term. On the other hand, restrictive policies to reduce inflation might generate a recession before most of the benefits of price stability were felt.

Theoretical developments and empirical evidence helped clarify views on the trade-offs between inflation and unemployment and the time inconsistency problems to which they can give rise. These arise from differences between short term and longer run effects that lead optimization of short run net benefits

to generate greater longer run costs. In the short run, higher inflation and lower unemployment often do rise and fall together as emphasized in traditional Keynesian economics. Over the longer run, however, these effects disappear as higher or lower inflation becomes expected. Indeed, because higher inflation tends to generate greater uncertainty, over the longer term higher inflation is likely to depress employment and economic growth. Thus concerns with limiting inflation came to be seen more as a trade-off between short-term and long-term effects than between inflation and unemployment.

The new emphasis on the importance of credible commitment suggests that in addition to providing constraints over domestic macroeconomic policies the adoption of such commitments could substantially reduce the unemployment cost of disinflation by increasing the credibility of such policies. This gave rise to the popularity of exchange-rate-based stabilization strategies.

Exchange-Rate-Based Stabilization The traditional arguments for the adoption of pegged exchange-rate regimes as a means of keeping inflation low were based on the "discipline hypothesis," which proposes that pegged rates take away a government's ability to run inflating policies, or at least increase the costs of pursuing such policies.

The credibility argument, based on the theory of rational expectations, combined with the successful disinflations in the 1970s of a number of countries belonging to the pegged-rate-based European Monetary System (EMS), contributed to the popularity of exchange-rate-based stabilization (ERBS) in the 1980s. According to the credibility hypothesis, high-inflation countries can peg their exchange rates to the currency of a low-inflation country, thus sending a signal to the public that they intend to adopt and maintain a low-inflation policy. The track record of countries carrying through anti-inflationary policies to a successful conclusion had frequently been poor, so the initiation of such a program often failed to generate initial expectations that it would be successful. Therefore, there would be little initial adjustment in inflationary expectations, and the short-run effects of restrictive macroeconomic poli-

cies would show up primarily in higher unemployment and slower economic growth, which in turn made it more difficult for the government to maintain these policies. If the government could effectively signal a stronger commitment to maintaining these policies, then inflationary expectations would fall more quickly and the effects of the restrictive macroeconomic policies would show up more in lower inflation and less in higher unemployment. This in turn would enhance the odds of success.

A major focus of the credibility hypothesis is that adopting pegged exchange rates would discipline not only policymakers, but also private agents. Rational expectations theory suggests that credible institutional commitments would also discipline actions by influencing the expectations of private agents. Although some of the earlier discipline arguments for fixed exchange rates also posited that wage discipline would be enhanced since high wage increases would be less likely to be accompanied by expansionary monetary policies and hence would be likely to generate more unemployment, the emphasis on effects on private sector behavior is the focus of the rational expectations analysis (Tavlas 2000).

In the 1980s and 1990s many countries, especially in Latin America, adopted various forms of pegged exchange rates to counteract high inflation. Many academics and International Monetary Fund (IMF) officials advocated the ERBS policy, in part because of its touted ability to rapidly decelerate inflation while generating an initial boom. The advocates of ERBS, however, rarely acknowledged that the fall in inflation was often not rapid enough to prevent overvaluation of the currency. Once the currency becomes overvalued, a country's exports become less competitive, resulting in a recession and currency crisis. For ERBS to succeed, the government adopting it must also enact noninflationary fiscal and monetary policies, and convince speculators of the program's credibility.

Some advocates of ERBS have argued that such strategies should be abandoned before the need for large nominal devaluation after an excessive real overvaluation, in order to avoid a currency crisis. The propensity of ERBS to contribute to crises can easily

be seen in Latin America. Faced with rapid rates of inflation in the 1990s, many Latin America countries, including Mexico, Chile, Brazil, and Argentina, turned to ERBS, hoping for salvation. In most cases, inflation did indeed fall substantially after the ERBS had been put in place. It typically did not fall sufficiently, however, to avoid exchange rate overvaluation and eventual currency crises.

Some economists therefore began to advocate premature exits from initial pegs without fully recognizing that the temporary nature of these pegs would likely undercut their credibility. Further analysis suggested that the same types of time inconsistency problems that created the need for discipline in the first place would also make it difficult for governments to exit from a peg in a timely manner (Willett 1998). Thus pegged exchange rates are less of a constraint on inflationary policies than genuinely fixed exchange rates and generate greater incentives to pursue those same policies.

Not only did many of the ERBS efforts of the 1980s and 1990s end in crises, but research also questioned whether the EMS countries had really been able to disinflate more effectively and at lower costs in the 1970s than other industrial countries that had adopted flexible exchange rates. We should not conclude from these experiences that ERBS never makes sense, but there is now widespread recognition that many early advocates oversold its benefits and underestimated its costs. The success of the credibility hypothesis rested on a government's ability to persuade the private sector that it would pursue sound macroeconomic policies to avoid the high exit costs associated with abandoning the peg.

Discipline from International Financial Markets In contrast, the foundation of the discipline hypothesis is coercion. In the 1970s many commentators argued that international financial markets could provide external discipline. The participants in these markets would carefully monitor national economic policies and provide early warning signals if policies started to go astray. If the warnings were ignored, the resulting capital outflows and increases in interest rates could force governments and the general public to take corrective actions. Because international financial markets may not always operate in such an efficient manner, however, some analysts argue that the discipline generated by international capital flows can be capricious rather than beneficial, and high international capital mobility may reduce rather than increase discipline, thus becoming a source of instability.

■ **distortions to agricultural incentives**
The majority of the world's poorest households depend on farming for their livelihood. Two sets of policy interventions have depressed earnings from farming in many developing countries since the 1950s: own-country policies, which typically have had a prourban, antiagricultural bias, and high-income country policies, which typically assist and protect farmers with import barriers and subsidies. Governments in numerous developing countries have made considerable progress over the past two decades in reducing their own sectoral and trade policy distortions to market signals, and many of them now believe high-income countries should reduce their remaining protectionism that restricts market access for developing country exports of farm products. Indeed, developing country governments have called for such commitments on farm policies in the World Trade Organization's (WTO's) current round of multilateral trade negotiations (the

Doha Development Agenda, or Doha Round) before they consider any further reform commitments of their own.

Research reported in Anderson, Martin, and van der Mensbrugghe (2006) suggests that the agricultural protectionist policies of high-income countries harm many developing countries. That research, using the global economy wide applied general equilibrium (AGE) model known as Linkage, along with similar research using the global GTAP Model (Anderson and Valenzuela 2007), also suggests full global liberalization of merchandise trade would raise value added in agriculture (that is, net farm incomes) in most developing country regions, and by more than it would raise value added in the rest of those economies (while doing the opposite in the protective high-income countries of the northern hemisphere).

Origins of Agricultural Protection While much of the government intervention in agricultural trade over the centuries has been aimed at stabilizing domestic food prices and supplies, such policy interventions tend to change in the course of a country's development from effectively taxing agriculture relative to other tradable sectors to effectively subsidizing farmers. From the late 1100s to the 1660s, prior to the first industrial revolution, Britain used export taxes and licenses to prevent domestic food prices from rising excessively. During 1660 90 a series of acts gradually raised food import duties (making imports prohibitive under most circumstances) and reduced the export restrictions on grain, provisions that were made even more protective by the corn law of 1815. The famous repeal of the corn laws in the mid-1840s heralded a period of relatively unrestricted food trade for Britain, but agricultural protection returned there in the 1930s and has been increasing since then. In many other Western European countries, similar tendencies have been observed, although on the Continent the period of free trade in the 19th and early 20th centuries was considerably shorter, and agricultural protection levels since the early twentieth century have been somewhat higher than in Britain (Kindleberger 1975). Gulbrandsen and Lindbeck (1973) estimate that the

average nominal rate of agricultural protection in Western Europe (the proportion by which domestic prices are raised by import restrictions) increased from less than 30 percent in the 1930s through the early 1950s to around 40 percent in the late 1950s and 60 percent by the late 1960s. Meanwhile, tariffs on Western European imports of manufactured goods have progressively declined since the General Agreement on Tariffs and Trade (GATT) came into force in the late 1940s. This divergence in protection trends for farmers and industrialists in developed countries was foreshadowed, as early as 1958, as a potential problem for the GATT contracting parties by a high-level panel of experts chaired by Haberler (1958).

Japan provides an even more striking example of the increasing tendency to assist agriculture more than other industries. Its industrialization began later than in Western Europe, after the opening up of the economy following the Meiji Restoration in 1868. By the early 1900s Japan had switched from being a small net exporter of food to becoming increasingly dependent on rice imports. This was followed by calls from farmers and their supporters for rice import controls. Their calls were matched by equally vigorous calls from manufacturing and commercial groups for unrestricted food trade, since the price of rice at that time was a major determinant of real wages in the nonfarm sector. The heated debates were not unlike those that had led to the repeal of the corn laws in Britain six decades earlier. In Japan, however, the forces of protection triumphed, and a tariff was imposed on rice imports beginning in 1904. That tariff gradually rose over time, providing a nominal rate of protection for rice of more than 30 percent during World War I. Even when there were food riots because of shortages and high prices just after that war, the Japanese government's response was not to reduce protection but instead to extend it to its colonies and to shift from a national to an imperial rice self-sufficiency policy. That involved accelerated investments in agricultural development in the colonies of Korea and Taiwan behind an ever-higher external tariff wall that by the latter 1930s provided a nominal rate of

rice protection for the empire of more than 60 percent. After postwar reconstruction, Japan continued to increase its agricultural protection, just as countries in Western Europe did, but to even higher levels.

Meanwhile, in the 1950s a liberated South Korea and Taiwan adopted an import-substituting industrialization strategy that harmed agriculture. That strategy was replaced in the early 1960s with a more neutral trade policy that resulted in very rapid export-oriented industrialization in those densely populated economies. That export-led development strategy in turn imposed competitive pressure on the farm sector, which, just as in Japan in earlier decades, prompted farmers to lobby (successfully, as it happened) for ever-higher levels of protection from import protection in those newly industrialized economies as well (Anderson and Hayami 1986).

Policy Developments since the 1950s The historical tendency for countries to change gradually from taxing to subsidizing agriculture relative to other sectors in the course of their economic development has not been universal. The exceptions are rich countries with an extreme comparative advantage in agriculture (such as Australia and New Zealand) and poor countries with an extreme comparative disadvantage in agriculture (such as South Korea, as with Japan earlier, and some oil-rich states in the Middle East). Poor-country farmers also were disadvantaged by an antirural bias in public investments in infrastructure and human capital (education, health, agricultural research and development), and sometimes also by having to effectively finance urban consumer food subsidy programs (Pinstrup-Andersen 1988). Within the agricultural sector of each country, import-competing industries tended to enjoy more government support than those that were more competitive internationally (Krueger, Schiff, and Valdes 1988; Herrmann et al. 1992). The study by Krueger, Schiff, and Valdes also reveals that, at least up to the mid-1980s, direct disincentives for farmers such as agricultural export taxes were less important than indirect disincentives in the form of import protection for the manufacturing sector or

overvalued exchange rates, both of which attracted resources away from agricultural industries producing tradable products.

This pattern of distortions to incentives is wasteful from a global viewpoint, and detrimental to the vast majority of the world's poorest people, who are small farmers in developing countries. Currently fewer than 15 million relatively wealthy farmers in developed countries, with an average of 78 hectares per worker, benefit at the expense of not only consumers and taxpayers in those rich countries but also the majority of the 1.3 billion relatively impoverished farmers and their families in developing countries, who have to earn a living from just 2.5 hectares per worker, on average. The evolution from taxing to subsidizing farmers as countries develop suggests that, if left unchecked, agricultural protectionism would continue to spread to newly industrializing countries in the decades ahead as governments sought to protect domestic producers from import competition as the farm sector came under pressure to shrink in relative terms and, eventually, in terms of absolute numbers of people engaged.

Such a prospect contributed to the resolve of several groups in the 1980s to try to counter those political forces. For example, agricultural-exporting countries formed the Cairns Group and succeeded in ensuring that GATT members included an agreement on agricultural trade and subsidy reform in the Uruguay Round outcome. Over the same period, international financial institutions made a more concerted effort to encourage developing countries to reduce unilaterally their distortions against agriculture. Accession to preferential trading agreements and to the WTO, and the demise of communism, have helped in some cases too.

Several groups have attempted to measure the extent of distortions to agricultural incentives since the 1950s. Anderson and Hayami (1986) report annual nominal rates of protection estimates for East Asian and high-income countries from 1955 to the early 1980s. Krueger, Schiff, and Valdes (1988, 1991) calculate both direct and indirect distortions to agricultural incentives for 17 developing countries from the early 1960s to the mid-1980s.

Tyers and Anderson (1992) estimate that the global welfare cost of agricultural protection doubled during the 1980s. And the Organisation for Economic Co-operation and Development (OECD 2006) has provided annual estimates in a consistent way since 1986, for developed countries plus Korea, Mexico, and some of Europe's transition economies, of what are now called producer support estimates (PSEs) and consumer subsidy equivalents (CSEs) for agricultural and food products. These efforts use somewhat different methodologies, so there was a clear need to provide a comparable set of estimates for both developed and developing countries using a standard methodology. A World Bank research project took on that task, covering the period since the late 1950s for as many as 73 large economies. Together those countries account for about 90 percent of both global income and farm output. Below the methodology is briefly described and the findings summarized, details of which can be found in Anderson (2008).

Methodology for Estimating Distortions to Incentives The simplest indicator of distortions to agricultural incentives is provided by the nominal rate of assistance (NRA), defined as the percentage by which a country's government policies have raised (or lowered if it is negative) gross returns to producers above (below) what they would be without the government's intervention. The NRAs are based on estimates of assistance to individual farm industries. Most distortions to industries producing internationally tradable products come from trade measures, such as a tariff imposed on the import price or a tax or subsidy imposed on exports at the country's border. An ad valorem tariff or export subsidy is the equivalent of a production subsidy and a consumption tax expressed as a percentage of the border price, and that is what is captured in the NRA (and can also be captured in a consumer tax equivalent, or CTE) at the point in the value chain at which the product is traded. To get the NRA for the farmer, it is necessary to determine the extent of pass-through back along the value chain to the farm gate (and likewise forward to the consumer at the retail level to get the CTE). The NRA thus differs from the OECD's PSE, since

the PSE is expressed as a percentage of the distorted price and hence is lower than the NRA, which is expressed as a percentage of the undistorted price. But like the PSE, this NRA also captures any significant product-specific input price distortions by estimating their equivalence in terms of a higher output price and including that in the NRA for individual agricultural industries, and also adds non-product-specific distortions into the estimate for the overall sectoral NRA.

The degree of coverage of products for which NRA estimates are generated was 70 percent of the gross value of agricultural production (the same as for the OECD's PSE coverage). The OECD assumes the NRA for the residual noncovered products is the same as the average for covered products. However, in developing countries at least, policies affecting the noncovered products are often very different from those for covered products. The nontradables among them, for example, are often low-quality food staples that are subject to no distortionary policies. The World Bank project therefore provides three sets of estimates of the NRAs for noncovered farm products, one each for the import-competing, exportable, and nontradable subsectors. A weighted average for all agricultural products is then generated, using the values of production at unassisted prices as weights.

Since the late 1980s there has been a tendency in some high-income countries to move away from trade measures to more direct forms of assistance to farmers. This is largely in response to domestic pressures to reduce trade distortions to improve policy efficiency, as well as to pressures from abroad during and following the GATT's multilateral trade negotiations that resulted in the Uruguay Round Agreement on Agriculture. Some of those new measures are less decoupled from production incentives than others, so their production and trade effects have not entirely disappeared. And they still bestow a transfer on farmers. Hence it is helpful to show the NRA both with and without "decoupled" measures for those high-income countries adopting them.

It is not sufficient to look just at agricultural NRAs in isolation, because *relative* prices and hence relative rates of government assistance are what affect producers' incentives. In a model of a two-sector economy, an import tax has the same effect on the export sector as an export tax, and this carries over to a model that also includes a third sector producing only nontradables, to a model with imperfect competition, and regardless of the economy's size (Vousden 1990). The reason the result carries over with nontradables is that if an import tax of rate t is replaced by an export tax at rate t, all traded goods prices are reduced by $1/(1 + t)$ and therefore the price of all nontradables has to also change by that same amount if the market for nontradables (in which the quantity supplied domestically has to equal the quantity demanded) is to remain in equilibrium. Thus if one can assume there are no distortions in the markets for nontradables, the overall distortion to agricultural incentives can be captured by the extent to which the tradable parts of agricultural production are assisted or taxed relative to producers of other tradables. By generating estimates of the average NRA for nonagricultural tradables, it is then possible to calculate a relative rate of assistance, RRA, defined as:

$$RRA = 100[(1 + NRAag^t/100)/ (1 + NRAnonag^t/100) - 1]$$

where $NRAag^t$ and $NRAnonag^t$ are the average percentage NRAs for the tradable parts of the agricultural and nonagricultural sectors, respectively. Since an NRA cannot be less than -100 percent if producers are to earn anything, neither can the RRA. This measure is thus useful for providing an internationally comparable indication over time of the extent to which a country's policy regime has an anti- or proagricultural bias.

Caution is needed in interpreting the RRA. If it is negative for developing countries, and especially if it is positive for high-income countries, that probably indicates that farmers in developing countries effectively faced prices that were less than they would have been if there were no government distortions to goods markets. But there is the possibility that if all such distortions were removed globally   and even more so if they were removed only by developing countries   the international terms of trade could

deteriorate for developing countries. Whether that would be so severe as to make developing-country farmers worse off than without such reform is a moot point. One would need a series of global economy wide AGE models calibrated to each year in the time series to estimate the full general equilibrium effects on net farm incomes over time.

New Global Estimates of Distortions, 1955–2004 The World Bank research project's sample of 73 large economies comprises 22 high-income developed countries (HICs); 13 East European and Central Asian (ECA) economies in transition from socialism; and 17 African, 13 Asian, and 8 Latin American developing countries. Since these economies together account for around 90 percent of global income and of farm output, and since there are a similar number of developing countries as higher-income (including transition) countries, their NRAs and RRAs are very representative of each of those two groups and for the world as a whole.

Figure 1 illustrates the RRA estimates for the highest level of aggregation. It shows the strong upward trend in assistance to farmers in high-income countries from the mid-1950s to the late 1980s, rising from around 20 percent to 50 percent. Their rates have since come down somewhat, although less so when so-called decoupled assistance is included (the dashed uppermost line).

For developing countries there has also been a strong upward trend in the RRA estimate, but starting from a very low level. According to these estimates, the RRA averaged −50 percent in the latter 1950s, but this has risen steadily each half-decade since then. By the end of the 1990s the discrimination against agriculture by developing-country governments had virtually disappeared on average, and the RRA had even become slightly positive for the first time by the first half-decade of this century.

The weighted average for the two groups combined provides a global average RRA, shown as the middle line in figure 1, again with the so-called decoupled assistance included in the dashed upper part of that line. That line suggests global agricultural production was discouraged up to the mid-1980s, but
Figure 1

Relative rates of assistance to agricultural industries, showing weighted averages for high income countries, developing countries, and the world, 1955 to 2004 (percent). Source: Anderson (2008).

has since been encouraged on average: even though in the past two decades agricultural protection has come down a little in high-income countries, agricultural taxation in developing countries has been replaced by positive assistance that has been more than offsetting. There thus appears to be a convergence toward a positive RRA in both sets of countries.

These weighted averages of RRAs of course hide a great deal of diversity among countries. Within the high-income group the estimated RRAs in 2000 2004 range from virtually zero in Australia and New Zealand to more than 10 percent in North America, more than 30 percent in the European Union, and more than 100 percent in both the rest of Western Europe and Japan (and in Korea and Taiwan). For developing countries, the RRAs in 2000 2004 averaged 5 percent in Africa, 0 percent in Latin America, 1 percent in China, 6 percent in South Asia, and 20 percent in Southeast Asia. With even more diversity within each of those developing country regions, these estimates suggest there are many countries that could boost their overall economies by reducing those RRAs.

Within most countries including those with RRAs close to zero there is also still much diversity in rates of assistance to different farm industries. Almost all countries assist their import-competing farmers more than their more competi-

tive agricultural export industries. Given that exporters tend to be more productive and more innovative than other producers, this antitrade bias is slowing agricultural and overall economic growth.

As for the distribution across commodities, there is very strong support for the "rice pudding" products: rice, sugar, and milk. In high-income countries, rice has the dubious honor of being the most assisted, thanks especially to Japan. In 2000 2004 its NRA averaged 375 percent, compared with 125 percent for sugar and 65 percent for milk (with cotton and beef trailing close behind with NRAs of 55 and 45 percent, respectively). In developing countries the NRA for rice averaged "only" 17 percent in those years, but sugar and milk were higher at 41 and 32 percent, respectively. By contrast, developing countries continue to tax major export crops: their weighted average NRAs for cocoa, groundnuts, and cotton are still below zero.

Evidently there has been a great deal of reform in recent decades. The massive and widespread discrimination against farmers in developing countries that was identified empirically two decades ago in the seminal study by Krueger, Schiff, and Valdes (1988, 1991) has been much reduced and has even disappeared for some developing countries. Also, the growth in agricultural protection from the 1950s to the 1980s in high-income countries, identified empirically in Anderson and Hayami (1986), has slowed and, for the European Union, even reversed. There remains, however, plenty of scope for further welfare-enhancing reforms to policies distorting agricultural incentives. Reducing the remaining variance among rates of assistance to the various industries within each country's agricultural sector, and especially reducing the antitrade bias in current policies, would help. That in turn would reduce the wide range of NRAs across commodities globally, bringing down the present extreme positive rates for items such as rice, sugar, and milk and reducing the effective taxation of tropical cash crops such as cocoa.

The biggest uncertainty now is whether the RRAs for developing and high-income countries will continue their recent convergence and, if so, whether that will involve more reform by high-income countries

or a continuing upward long-run trend in RRAs for developing countries. Some commentators cite the tariffication and tariff bindings in the Uruguay Round Agreement on Agriculture as a reason to expect countries not to raise their agricultural assistance in the future. However, there is a great deal of "binding overhang" in those WTO commitments for many members and especially for developing countries (WTO, ITC, and UNCTAD 2007), meaning they could raise their applied import tariffs substantially on farm products before reaching the legally bound rates. It thus remains to be seen whether the forces of economic rationalism will be more or less powerful than the perennial agricultural protectionist forces in the decades ahead.

■ Doha Round

The Doha Round, launched in 2001 and formally named the Doha Development Agenda (DDA), was the first round of global trade negotiations held under the auspices of the World Trade Organization (WTO). To understand the dynamics of the Doha Round, it is important to understand its genesis.

The creation of the WTO was one of the major results of the Uruguay Round of multilateral negotiations. The WTO began operations on January 1, 1995. Its early years were dominated by negotiations to finalize agreement on several services sectors (finance, telecommunications, maritime transportation) and to liberalize trade in information technology (IT) products. With the exception of the

maritime services talks, these were successful: telecom and financial services agreements were concluded in 1996; the Information Technology Agreement (ITA) a so-called zero-for-zero deal under which signatories abolished tariffs on a common set of IT products entered into force in 1997.

Flush with these achievements, the first ministerial conference of the WTO, held in Singapore in December 1996, agreed to a work program for the following years. Members of the Organisation for Economic Co-operation and Development (OECD) proposed to put government procurement, trade facilitation, competition law, and policies on foreign investment on the WTO agenda. A minority (led by France and the United States) also sought to launch discussions on labor standards. Opposition by many developing countries kept labor standards off the WTO agenda, but members did agree to create working groups to discuss and study the relationship between trade and competition and investment policy disciplines, transparency in government procurement, and trade facilitation. These subsequently came to be known as the "Singapore issues."

In the years that followed, OECD members failed to agree on a Multilateral Agreement on Investment; furthermore the East Asian financial crisis and follow-on crises in other parts of the world added to skepticism on the part of many developing country governments and numerous vocal nongovernmental organizations that the WTO was a balanced and "fair" organization.

Research supporting aspects of this skepticism began to emerge in the late 1990s, concluding that the net benefits for many developing countries in narrow market-access terms were limited and may even have been negative as the result of the new requirements under the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) to enforce patent rights and other forms of protection for intangible assets. TRIPS was the first example of a multilateral trade agreement that involved a significant element of policy harmonization. Although most economists accept that there is an economic logic to protection of intellectual property, both theory and economic history suggest that

harmonization is unlikely to be an optimal outcome for all countries, in particular poor economies. Whatever one's view of the economics, TRIPS greatly increased the awareness of many developing countries of the need to carefully scrutinize the likely impacts of agreements that entail regulatory harmonization.

A major feature of the WTO was that developing countries became subject to numerous rules of the game that they had not been affected by as members of the WTO's predecessor, the General Agreement on Tariffs and Trade. The costs of implementation of some of these WTO disciplines, if defined not just narrowly in terms of required legal and regulatory changes, but in terms of what is necessary to benefit from them, could be significant. Assistance to meet the costs of implementation was a matter for governments to request from national and international development agencies. Many developing countries argued that the provision of such assistance had been inadequate.

These considerations help explain why only a few years after the establishment of the WTO, efforts were made to initiate a new round of trade negotiations. The requirement in the Uruguay Round agreements on agriculture and services to initiate new negotiations in these two areas in 2000 provided an additional rationale for launching a broader round, as this would allow for cross-issue linkages and trade-offs.

Countries had very different objectives, with some (mostly developed countries) seeking to build on the Singapore ministerial and launch talks on the new areas as well as the core market-access agenda, and others (mostly developing nations) seeking to address implementation and related problems associated with existing agreements.

The attempt to launch a "Millennium Round" at the 1999 WTO ministerial meeting in Seattle failed to achieve the necessary consensus, largely reflecting opposition by many developing countries to engage in new negotiations when they had yet to digest the Uruguay Round and a perception that implementation concerns were not being taken sufficiently seriously, as well as resistance on the part of the

European Union (EU) and several other OECD countries to engaging in talks to significantly reduce support for their farmers. Many developing countries also opposed proposals to negotiate WTO disciplines for the Singapore issues, environmental policies, and (minimum) labor standards. Notwithstanding the deep differences in views, additional preparatory discussions in 2000 2001 allowed the first round of multilateral negotiations under WTO auspices to be launched at the 2001 Ministerial Conference in Doha, Qatar.

Major Players and Issues The name given to the round the Doha Development Agenda arose for two reasons. First, many WTO members held the view that a multilateral effort to reduce trade-distorting policies was part of an appropriate response to the terrorist attack on New York and Washington, DC, on September 11, 2001. The view that trade cooperation could help address some of the causes of terrorism by promoting economic growth was strongly espoused by the then U.S. trade representative Robert Zoellick and helped to change the political atmospherics that up to that point had not generated sufficient support for the launch of new trade talks. Second, the name reflected recognition of the view of many developing countries that the Uruguay Round had been "unbalanced." Making "development" a prominent goal of the round had a major impact on the subsequent negotiating dynamics.

Reflecting the differences in objectives of the participants, the negotiating agenda of the round was multidimensional. It spanned market access for goods and services, the WTO's existing rules, potential new disciplines on the Singapore issues, implementation problems, and a renewed emphasis on "special and differential treatment" (SDT) for developing countries.

The major protagonists were the EU and the United States on the side of OECD countries, and Brazil and India on the side of the developing countries. In addition to these four giants, a variety of coalitions played an important role, both in the run-up to the Doha Round and during the negotiations. Influential groups included the so-called Like Minded Group of developing countries, which argued for more SDT, for addressing implementation concerns, and for nonreciprocity in negotiations; the Africa Group, which espoused a similar position; the least-developed countries (LDC group) and a variety of "G-x" groups, where "x" is a number indicating how many countries were participants in the launch of the group. The most prominent of these was the G20, a group of countries led by Brazil and India that also included China and South Africa. The G20 had a fluctuating membership, with some countries leaving sometimes as the result of pressure (inducements) offered by the United States (the departure of several Central American countries following the formation of the Central American Free Trade Agreement being an example) and others joining. Other groups included the G90 comprising almost the totality of developing countries in the WTO and the G11, a group of developing countries that were active in the nonagricultural market-access talks.

As many developing countries were not convinced that launching negotiations on the Singapore issues was in their interest, a last-minute compromise reached at the Doha Ministerial Conference was that negotiations on these four subject areas would commence at the 2003 meeting of WTO ministers. Based on an intervention by India, it was specified that a precondition for such negotiations was an "explicit consensus" among WTO members on their modalities.

The EU, Japan, and the Republic of Korea were the primary *demandeurs* for negotiations on all four Singapore issues. Three groups of developing countries the African Union; the LDCs; and the African, Caribbean, and Pacific group of countries had all agreed at the ministerial level in 2003 that they did not support launching negotiations on any of these topics. They were joined by a number of middle-income countries, such as Malaysia. Some countries argued that these were marginal issues, with only limited benefits for developing countries; that they could give rise to potentially significant implementation costs; and that they would divert scarce negotiating resources and political attention away from the more important

market-access agenda. Although many middle-income economies, including most Latin American countries, did not have serious concerns about launching negotiations on the four subjects, it became clear in 2003 that an "explicit consensus" did not exist. As a result, the 2003 Cancún Ministerial Conference failed   the second one to do so in the WTO's short history.

The failure was not due solely to differences on the Singapore issues. Disagreements were particularly prominent on agriculture. Developed countries' farm subsidies   with the EU's Common Agricultural Policy (CAP) and the U.S. system of farm subsidies being the most prominent   were major bones of contention. Opposition by the EU to liberalization of its agricultural policies and stronger disciplines on farm subsidies was a fundamental factor impeding agreement. In addition, U.S. unwillingness to address demands by West African cotton producers to reduce production subsidies as a priority also played an important role in souring the atmosphere in Cancún.

A "Framework Agreement" negotiated in July 2004 removed three of the Singapore issues from the negotiating table (retaining only trade facilitation), specified that LDCs were not expected to make any market-access concessions (taking up then EU trade commissioner Pascal Lamy's call that these countries should benefit from the round "for free"), and established negotiating frameworks for the key areas of agriculture and nonagricultural market access. It was agreed that formulas were to be used to reduce trade barriers in both areas, and that export subsidies in agriculture were to be prohibited by a specific date to be negotiated.

One result of the decision to take three of the Singapore issues off the table was that to a much greater extent than in the Uruguay Round negotiations centered on tariffs. Although in principle services were another important market-access negotiation, WTO members were not willing to make significant liberalization commitments   in part because of a desire first to determine what the contours of a possible deal would be for merchandise trade, agriculture in particular. A major challenge

confronting negotiators was to agree to substantially lower remaining tariff peaks. As average tariff rates in most industrial countries are now relatively low, the main payoff from both a development and an economic efficiency perspective would come from reducing the dispersion in tariff protection by lowering the highest tariffs more than the average. A straightforward way of doing this is to apply a nonlinear tariff reduction formula to each country's prevailing tariffs.

WTO members agreed to make tariff-cutting formulas a core negotiating modality in the Doha Round, with eventual emergence of variants of the so-called Swiss formula   first used in the Tokyo Round (1973 79)   as the basis of discussion for merchandise trade liberalization. The Swiss formula is defined as $T_1 = MT_0/(M + T_0)$, where T_1 is the new tariff commitment, T_0 is the prevailing one, and M is a coefficient   the maximum level of the permitted tariff. The formula generates nonlinear cuts, with higher proportional reductions for higher tariffs. It was decided that (at least) two coefficients would be used, one for developed countries and another for developing nations, such that developed countries would reduce their tariffs proportionally more in accordance with the notion of SDT for developing countries. Limited exemptions would be permitted to allow governments to maintain higher levels of protection for a subset of "special" and "sensitive" products. Given that the major developing country coalitions such as the G20 spanned a differentiated set of countries, insistence on undifferentiated SDT for all members made it more difficult to agree on a coefficient and resulted in much attention also being given to the criteria that would apply for possible exemptions from the formula for "sensitive" products.

Disagreements on the specification of the formulas and the magnitude of allowable exceptions for specific products could not be overcome during 2004 7. Negotiations between the so-called five interested parties in agriculture Australia and Brazil, representing export interests, the EU and India, representing the "defensive" interests, and the United States (both an exporter and a provider of

substantial support to its farmers) did not manage to identify a package of mutually acceptable reforms. Much of the discussion centered on technical issues such as how to go about converting specific tariffs (taxes that are based on volume rather than the value of imported products) into ad valorem equivalents. Although these were important, the fact that such technical matters needed to be addressed by ministers illustrated the depth of the political sensitivities that prevented lower-level officials from agreeing on negotiating modalities in Geneva.

The 2005 ministerial meeting in Hong Kong did not lead to any major breakthroughs, with the exception of (conditional) agreement to ban export subsidies for agricultural products in 2013, promises of an increase in development assistance ("aid for trade"), and a promise by rich countries to extend duty-free, quota-free access to their markets for at least 97 percent of exports originating in LDCs. As noted by many commentators, the last promise did little to go beyond the status quo, and the exclusion of 3 percent of tariff lines was enough to permit countries to maintain tariffs on the most competitive LDC exports if they desired to. Ministers renewed their commitment to conclude the DDA by the end of 2006. A roadmap for key decisions was agreed on, including a target date of April 30 to agree on modalities (formulas and liberalization parameters) for agriculture and nonagricultural merchandise trade. Comprehensive draft schedules based on these modalities were expected to be submitted by July 31, 2006. This was also the deadline for a second round of revised market opening offers in services.

As of mid-2006, the contours of a possible agreement on merchandise trade liberalization had emerged. It was described as a 20-20-20 package by the director general of the WTO. Under this proposal the EU would cut its bound agricultural tariffs by an estimated 54 percent (following the proposal made by the G20), the United States would cap its total trade-distorting agricultural subsidies at a maximum of $20 billion, and developing countries would agree to a maximum tariff on manufactures of 20 percent. A deal along the lines of the 20-20-20 package would have implied a significant reduction not only in tariff bindings but also in applied policies. Negotiators could not agree on a specific compromise, however. The G20 sought deeper cuts in EU tariffs and both the G20 and the EU wanted the United States to accept a lower ceiling on its domestic farm subsidies.

By this time the original endpoint envisaged for the Doha Round (January 1, 2005) had been missed by a wide margin, as were nearly all deadlines that had been set during the talks. This pattern extended into 2006 7. The inability of the major protagonists to make concessions led the director general of the WTO to suspend the negotiations in mid-2006. Despite efforts in early 2007 to resuscitate the process, which led to a high-profile meeting between four of the major protagonists (the EU, the United States, Brazil, and India) in Potsdam in June, no agreement could be reached on how much to cut farm subsidies and tariffs on agricultural and industrial goods. Developing countries remained disappointed by the United States' offer on agricultural subsidies and the EU's unwillingness to open its agricultural markets. Conversely, the EU and the United States were unsatisfied by what they regarded as inadequate offers by Brazil and India on industrial tariffs. At the time of writing (April 2008), prospects for an imminent conclusion of the Doha Round appeared dim. The expiry of Trade Promotion Authority a provision previously called "Fast Track," which precludes the U.S. Congress from introducing amendments to a multilaterally negotiated deal in June 2007 removed an important focal point for a timely conclusion of the talks. The political calendars of several major players suggested that the Doha Round was unlikely to conclude before 2009 10.

Progress and Prospects Despite the torturous negotiating process, some progress was made during the Doha Round to deal with several development-related concerns that had become prominent in the period immediately following the creation of the WTO. Thus in a Declaration on the TRIPS Agreement and Public Health, developing countries without the capacity to produce pharmaceuticals

were permitted to import generics from countries that do have capacity under compulsory licensing arrangements.

A consensus also emerged around the notion that trade negotiations should be complemented by assistance for developing countries, both to help address implementation costs associated with specific WTO disciplines and, more generally, to bolster the competitiveness of domestic firms through actions to reduce the costs of trade and doing business. The recognition that trade negotiations must be complemented by actions to help address the prevailing constraints in many poor countries that inhibit exploitation of trade opportunities was an important development. Insofar as the Doha Round has led development organizations to focus greater attention on the trade agenda and constraints in developing countries, this should be counted as a positive outcome.

Why so little success in obtaining agreement? A number of reasons can be identified. Many of these revolve around the argument that there was not enough on the table to mobilize support within the OECD countries to accept greater agricultural liberalization. Concerns on the part of a number of smaller developing countries that they would suffer losses from the erosion of trade preferences following agreement among the larger WTO members to reduce tariffs on a most-favored-nation basis also played a role.

It is important to consider that the Doha Round took place during a period in which there was a boom in world trade, in part driven by trade liberalization that was implemented unilaterally by governments. World Bank research suggests that the uniform tariff equivalent of applied tariffs for merchandise products in 2007 was 7 percent in high-income countries and 15 percent in developing countries. The numbers are heavily influenced by the substantially higher protection of agricultural products, around 40 and 25 percent, respectively. They are much lower for manufactures (4 and 14 percent).

The implication of the relatively low levels of applied tariffs in many countries is that there is less

to play for. This translates into fewer export interests having an incentive to invest significant (political) resources in engaging in trade talks and providing the political support that is needed for liberalization. As most protection is now concentrated in agriculture, matters are complicated further by the fact that this sector is of significant export interest to only a subset of WTO members. Less than 10 percent of world trade is in agricultural products. Although trade volumes no doubt would be higher if rates of protection were lowered, it is trade in other merchandise that dominates, and much of this trade is relatively free.

Because WTO negotiations are barter exchanges, concessions in agriculture by high-income countries need to be balanced by concessions on the part of the agricultural exporting nations that will benefit in mercantilist, export volume terms. Although average levels of protection have fallen in these countries, there are still significant barriers to trade. The low prevailing averages mask relatively high tariff peaks in both agriculture and manufactures in many countries. In services, despite significant liberalization of trade and investment in recent years, numerous barriers persist. Finally, it is important to consider that the negotiating coin of the WTO is policy bindings the levels of protection that a country commits itself not to exceed. These bindings are valuable even if a specific commitment does not imply much, if any, reduction in applied levels of protection, as they create greater certainty that past liberalization will not be easily reversed.

In principle it would appear therefore that even with the relatively narrow market-access (tariff) agenda that dominated the Doha Round after 2004, a bargain should have been feasible, with "payment" for OECD agricultural liberalization taking the form of traditional market-access liberalization by major developing countries. In practice, however, developing countries appeared unwilling to offer enough in terms of liberalization and bindings to induce the OECD countries to move enough to allow a deal to be struck. This in turn suggests that the major players perceived their best alternatives to a negotiated agreement to dominate an outcome

under which they would have had to make additional concessions in order to get more liberalization from their major trading partners.

What the outcome of the Doha Round will be remains to be seen. The same is true regarding the consequences of the Doha Round for the WTO as an institution. The difficulty in attaining a consensus to negotiate on the Singapore issues, and the limited progress that was made on extending the coverage of services commitments, suggest there may be limits regarding the set of policies that can (should) be subject to binding multilateral disciplines.

■ dollar standard

In the absence of a purely international form of money, a strong national currency is central to international commerce. Outside Europe, the dollar dominates as a vehicle currency in interbank foreign exchange, as an invoice currency in international trade and capital flows, and in official exchange reserves. How did the dollar establish its preeminent international role?

After World War II, the United States had the world's largest economy and the only stable financial system with open foreign exchange markets. Inflation and exchange controls proliferated throughout Europe as well as in Japan and most developing countries. Thus the dollar naturally became the world's vehicle currency for (private) interbank transacting between any pair of national currencies and became the intervention currency that governments used for stabilizing their exchange rates. Foreign governments as well as private corporations could build up their dollar reserves knowing that they had a liquid market in which to sell them.

The Bretton Woods agreement of 1945 formally ratified the dollar as the dominant currency. Under Article IV, countries outside the communist bloc declared dollar parities, while, as center country, the United States had a passive foreign exchange rate policy except for its residual tie to gold.

The Dollar as Facilitator of International Exchange But why does the dollar standard continue even when most other industrial countries, such as Japan and those in Europe, no longer have exchange controls and Article IV was amended in 1976 so that member countries no longer need to declare dollar parities? Suppose there are 150 national currencies in the world economy. To facilitate international exchange, the markets themselves would always pick just one as the central money for

intermediating nearly all international payments. Transaction efficiency increases because the number of active bilateral foreign exchange markets necessary for clearing international payments, both spot and forward, is thereby reduced.

A little algebra helps explain continued dollar predominance in a world of N national currencies. The total number of country pairs in the system is the combination of N things taken two at a time ($^{N}C_2$). If foreign exchange dealers tried to trade across each pair — say, Swedish kronor against Australian dollars, or Korean won against Japanese yen — there would be a huge number of active foreign exchange markets. With 150 national currencies in the world (N = 150), if dealers tried to trade each pair bilaterally that would lead to 11,175 different markets!

It is expensive for any bank to set up a foreign exchange trading desk. Thus, rather than trading all pairs of currencies bilaterally, in practice just one currency, the Nth, is chosen as the central vehicle currency. Then all trading and exchange takes place first against the vehicle currency before going to the others. By having all currency trading against that one currency, the number of markets in the system can be reduced to N-1. Thus, with 150 countries, we need just 149 foreign exchange markets against the U.S. dollar (instead of 11,175 bilateral exchange rates against each other). Unlike the Bretton Woods system, where all countries other than the United States set official dollar parities, this result does not depend on any formal agreement among governments. In private markets today, choosing one currency such as the dollar to be the intermediary currency is the most natural way of economizing on foreign exchange transacting.

But history is important. If one country starts to provide the central money, as the United States did in the late 1940s, it becomes a natural monopoly because of the economies of scale. The more countries that deal in dollars, the cheaper it is for any one of them all to deal in dollars as unit transaction costs fall — particularly in forward exchange markets that are much thinner and potentially much less liquid than spot markets. If you are a Japanese importer of Swedish Volvos, to pay for the Volvos you would first have your bank convert your yen into dollars on the open market, then use the dollars to buy Swedish kronor. Volvo Corporation receives the Swedish kronor, and the importer gets the Volvos. But the dollar is the intermediary currency: two interbank transactions involving dollars are cheaper than trying to trade yen directly for Swedish kronor at different terms to maturity.

Using the standard textbook classification of the roles of money, table 1 summarizes our paradigm of the dollar's central role in facilitating international exchange. For both the private and government sectors, the dollar performs as medium of exchange, store of value, unit of account, and standard of deferred payment for international transactions on current and capital accounts — as it has done since 1945.

First, the dollar is a *medium of exchange.* Because the foreign exchange markets are mainly interbank, the dollar is the vehicle currency in interbank transactions serving customers in the private sector. The dollar is on one side or the other of about 90 percent of interbank transactions worldwide. Thus, when any government intervenes to influence its exchange rate, it also finds it cheaper and more convenient to use the dollar as the official intervention currency. (The major exception to this convention is a fringe of European countries to the east of the euro area, which mainly use the euro as their central money.) Although the dollar is the predominant money in foreign currency trading, London has the largest foreign exchange market — bigger than New York's. And large dollar-based markets also exist in Singapore and Hong Kong.

Table 1
The U.S. dollar's facilitating role as international money since 1945

	Private	Official
Medium of exchange	Vehicle	Intervention
Store of value	Banking	Reserves
Unit of account	Invoice	Peg
Standard of deferred payment	Private bonds	Sovereign bonds

Second, the dollar is an international *store of value.* Corporations and some individuals hold dollar bank accounts in London, Singapore, and other offshore banking centers—as well as in the United States itself. It is estimated that more than half the stock of coin and currency issued by the U.S. government circulates abroad in Latin America, Russia, Africa, and other financially distressed areas. In developing countries, as a whole, about two-thirds of their official exchange reserves are in dollars.

Third, the dollar serves as a *unit of account* for much of international trade. Trade in primary commodities shows a strong pattern of using the dollar as the main currency of *invoice*. Exports of homogeneous primary products such as oil, wheat, and copper all tend to be invoiced in dollars, with worldwide price formation in a centralized exchange. Spot trading, but particularly forward contracting, is concentrated at these centralized exchanges—which are usually in American cities such as Chicago and New York, although dollar-denominated commodity exchanges also exist in London and elsewhere.

Invoicing patterns for exports of manufactured goods are more complex. Major industrial countries with strong currencies tend to invoice their exports in their home currencies. Before the establishment of the European Monetary Union, more than 75 percent of German exports had been invoiced in deutsche marks, more than 50 percent of French exports invoiced in francs, and so on. (McKinnon 1979 provided a rationale for this difference in invoicing practices between primary commodities and manufactures.)

Within Asia, however, foreign trade is invoiced mainly in dollars. In Korea, for example, the proportion of imports invoiced in U.S. dollars is about 80 percent, and even higher for exports. Other less mature economies in East Asia, such as China, use dollars even more intensively in invoicing their foreign trade. In Japan, the most industrialized and richest economy in East Asia, almost half of its exports and three-quarters of its imports are invoiced in dollars.

Fourth, as *a standard of deferred payment*—which is also a traditional role of money—private

and sovereign bonds in international markets are heavily denominated in U.S. dollars, though the euro seems to be as important. The growth of a broadly based euro-denominated bond market within Europe has made it much more attractive for foreigners to borrow by issuing euro bonds. The euro area is unusual in that it is a net creditor in the world economy that can lend in its own currency. Other net creditors are more or less confined to lending in dollars.

Despite the increasing importance of the euro in international bond markets, U.S. Treasuries are still taken as the benchmark, or "risk-free" asset. That is, dollar-denominated sovereign bonds issued by emerging markets the world over have their credit ratings measured relative to U.S. Treasuries. Thus, risk premiums in interest rates on these bonds are typically quoted as so many percentage points over U.S. Treasuries.

The Dollar as Nominal Anchor Beyond the traditional roles of money outlined in table 1, the dollar has a second and complementary international function. Foreign monetary authorities may better anchor their own domestic price levels by choosing to peg, officially or unofficially, to the dollar. By opting to keep their dollar exchange rates stable, foreign governments are essentially opting to harmonize—without always succeeding—their monetary policies with that of the United States. This monetary harmonization has two avenues: (1) international commodity arbitrage—the *arbitrage avenue*, and (2) the *signaling avenue*, where other central banks take their cue from actions of the U.S. Federal Reserve Bank.

For the dollar to function successfully as nominal anchor, however, two important conditions must be satisfied: (1) The U.S. price level, as measured by a broad index of tradable goods prices, is stable and expected to remain so. (2) Most countries, and certainly neighboring ones, are on the same international standard, that is, they also fix their exchange rates to the dollar.

In the history of the post–World War II dollar standard, these two conditions were satisfied in some periods but not in others. Indeed, in contrast to the

dollar's continued robustness as the facilitator of international exchange under either fixed or floating exchange rates, its function as nominal anchor has continually metamorphosed. It was strong in the Bretton Woods period of the 1950s and 1960s of fixed dollar parities, weakened greatly in the inflationary period of the 1970s into the 1980s, and then strengthened in the 1990s into the new millennium when the American price level again became fairly stable. The current proclivity of most Asian economies (with the major exception of Japan) and many emerging markets elsewhere to peg to the dollar, if only softly and informally, is sometimes called Bretton Woods II.

Consequences of International Currency Asymmetry Developing countries and a few industrial ones cannot borrow internationally in their own currencies   a phenomenon that has been dubbed *original sin*. Those developing countries that are dollar debtors live on sufferance: their domestic monies are only "provisional." Any economic or political disturbance at home provokes the suspicion that these foreign currency debts may not be repayable and that the domestic currency will depreciate against the dollar   as in the East Asian crisis of 1997 98.

But what about the biggest international debtor of all? After running trade deficits for more than 25 years, the United States is a net debtor: its liabilities in 2006 exceeded its claims on the rest of the world by about $4 trillion. At about 30 percent of U.S. gross national product (GNP) in 2006, America's net international indebtedness was higher than that of any other industrialized country   and higher than, say, Brazil's, which was only 20 percent of Brazilian GNP. Yet, unlike Latin American currencies today, and unlike East Asian currencies in 1997 98, the dollar is not threatened by a loss of confidence. As long as its purchasing power is seen to be stable, that is, as long as the Federal Reserve keeps price inflation very low, the dollar cannot be attacked in the usual sense. Default risk associated with foreigners holding dollar assets is virtually nonexistent. If need be, the Fed could always print more money to redeem U.S. Treasury bonds outstanding. Thus the United States has an indefinitely long line of credit with the rest of the world.

But this virtual invulnerability of the center country as debtor to foreign exchange risk means that this risk shifts to creditor countries that, Europe aside, cannot *lend* to the United States in their own currencies   a circumstance known as *conflicted virtue*. Creditor countries such as China and Japan with trade surpluses, reflecting their high domestic savings, simply accumulate large volumes of liquid dollar claims on the United States, leaving them vulnerable to unwanted currency appreciations. Conflicted virtue in creditor countries is the mirror image of original sin in debtor economies. Both creditor and debtor economies are exposed to serious currency risks should their currencies fluctuate against the dollar. The only country exempted from exchange risk is the United States itself.

■ domestic content requirements

Domestic content requirements compel firms to purchase a certain percentage of their inputs from domestic firms as a precondition for local market access or preferential policy treatment. In general, domestic content requirements act as a protectionist measure, since they usually improve the competitive position of domestic firms in relation to foreign firms. Nonetheless, the ultimate effect of domestic

content requirements depends on the form of the requirements, the characteristics of demand, market structure, and the nature of the production process.

Motives and Form In their simplest form domestic content requirements oblige firms to purchase a certain percentage of their inputs from domestic firms. If a firm fails to meet the requirement, it may be denied market access or its exports may be hit with additional tariffs. Alternatively, the firm may fail to qualify for policy benefits such as production subsidies. Although domestic content requirements usually apply to all firms, they typically have no impact on domestic firm production decisions, since domestic firms generally use a higher percentage of domestic inputs in their production than foreign firms do, and the political economy determinants of these measures generally result in domestic content requirements that surpass the natural domestic content selected by unconstrained foreign firms but are met or exceeded by the natural domestic content selected by domestic firms.

The implementation of domestic content or local content requirements is usually motivated by a country's desire to assist domestic firms or to increase the level of domestic economic activity. For example, many developing countries used domestic content regulations as an element of their import substituting industrialization policies. Domestic content regulations have also been imposed to influence the activities of foreign investors, with the goal of increasing foreign firm investment in the domestic economy or of increasing the domestic share of input purchases by foreign firms that already operate in the domestic market. Such policies have been especially common in large manufacturing industries, such as automobile assembly, where domestic countries preferred that investors provide many jobs in the local economy, rather than simply doing a small amount of local assembly using foreign materials. Since the imposition of local content requirements on foreign investors violates the national treatment principle of the General Agreement on Tariffs and Trade, however, the Uruguay Round included a trade-related investment measures agreement, which requires countries to remove domestic content re-

quirements on foreign investment. Nonetheless, such requirements may still remain in place, though in less transparent forms.

Content regulations have proliferated in a regional context as countries have entered into an ever-increasing number of free trade agreements. Since free trade agreements eliminate tariffs on all trade among member countries while leaving tariffs on nonmembers unchanged, free trade agreements create an incentive for tariff-shopping by nonmember exporters that wish to sell their products in the member market. To prevent tariff-shopping, free trade areas typically include rules of origin that stipulate the percentage of area content or area value added that the traded product must contain if it is to qualify for the preferential tariff treatment extended to member-country products.

Content preferences are generally implemented to protect domestic or regional markets. However, the Generalized System of Preferences (GSP), which provides tariff reductions for products exported from developing countries to developed countries, usually requires products to contain a minimum level of domestic content from the developing country. Finally, it is important to note that domestic content requirements are also imposed in service sectors, where regulations may require, for example, that a certain percentage of broadcast programming originates from domestic providers.

Impact of Content Requirements When domestic inputs are of similar quality and lower price than foreign inputs, firms will willingly meet or exceed the domestic content requirement and the requirement will have no effect on firm decisions. Since domestic content requirements are set in a political environment, however, they generally force foreign firms to purchase a larger fraction of their inputs from domestic sources than they would if they were unconstrained, while domestic content requirements usually have no effect on the sourcing choices of domestic firms. The best response for a cost-minimizing foreign firm is to exactly meet, though not exceed, the purchase criteria of the domestic content requirement. Alternatively, the foreign firm may decide to pay the tariff penalty that is associated with

noncompliance if the tariff cost is less than the extra cost of purchasing more domestic inputs. Either way, since domestic content requirements raise the relative production costs of foreign firms, they benefit domestic producers of final goods by increasing domestic firm sales or profits. In addition, they may reduce competition in the final goods market if they reduce the volume of goods sold by the foreign firm in the domestic market.

Whether they are imposed by the domestic country or by an importing developed country that is administering its GSP tariff preferences, domestic content requirements protect domestic intermediates producers. Since these policies increase production costs, domestic content regulations harm domestic customers, who face higher prices for the goods they buy. In addition, programs such as the GSP have an ambiguous effect on developing country welfare, as the increased demand for imports of the final good from the developing country will be offset, and possibly even reversed, by the cost increases that are associated with the content requirement.

Domestic content requirements take many different forms. For this reason, the form of the requirement has great influence on its economic effects. For example, domestic expenditure on capital is often excluded, while domestic labor is generally counted toward the domestic content requirement. When this is the case, firms respond to the relative cost incentive by investing in more labor than they would if the treatment of labor and capital were uniform. Other common variations in implementation relate to the domestic content benchmark, and whether it is defined as a percentage of physical inputs, sales, costs, or value added.

The effects of domestic content regulations are also determined by firm responses. To begin, it is commonly understood that imports may impose market discipline. If the market that implements domestic content regulations is served by a monopoly input supplier, limits on the use of foreign inputs will reduce competition and allow the domestic input supplier to exploit its market power. In this case, domestic content requirements may even reduce domestic output of the final good, as the domestic input supplier reduces its production and consequent sales to take advantage of its market power. Second, if it is possible for firms to change the scale of their production at low cost, domestic content regulations may fail to shift consumption toward domestic varieties. Finally, if the domestic content requirement is at a level that is too high, foreign firms may reevaluate their decision to supply the domestic market.

The effects of domestic content requirements are also shaped by the nature of the production process. For example, when a content standard is based on value added, whether final good output increases or decreases depends in part on the relationship between labor and the intermediate inputs in production, and whether they are complements or substitutes. Similarly, depending on the relationship between the usage of labor and intermediate inputs, the imposition of a domestic content requirement based on value added may cause the volume of imported intermediate inputs to rise or fall. In addition, the composition of intermediate input imports may change. In particular, if there are many imported intermediate inputs, and the relative price of foreign inputs differs across inputs, a value-added requirement will shift purchases toward foreign inputs whose relative foreign price is the lowest.

In the case of foreign investment, the desire to foster greater domestic activity may be subverted by domestic content regulations. First, since foreign firms are placed at a disadvantage, they may place fewer of their activities in the local market. In addition, when the scale of their operations is reduced, the overall productivity of the foreign operation may suffer from a failure to achieve full economies of scale in production.

Due to the rise of vertically integrated production networks that cross national borders, the proliferation of free trade areas has created new difficulties in defining and meeting content requirements. In particular, when a hub country forms free trade areas with different associates, which are not linked to one another through any common partnership, the definition of content and rules of origin becomes increasingly complicated. The difficulties posed by

multiple partnerships of differing membership groups is acknowledged, for example, by the European Union's creation of the Pan-European Cumulation System in 1997, which integrates bilateral rules into a multilateral framework that enables firms to determine "European" content.

■ dominant currency

A currency dominates other currencies when it is used more frequently as a unit of account, medium of exchange, and store of value. Local currencies tend to dominate foreign currencies as means of exchange partly because the bulk of transactions is local and partly because governments discriminate in favor of the currency they issue. Legal tender laws and the fact that governments generally disburse funds and receive tax collections in the government-issued currency raise the cost of using other currencies as alternative means of payment in the domestic market. Currency substitution the replacement of domestic money with a (better) foreign money is a slow process even when it is permissible. Inflation must reach high rates before individuals switch out of a currency. For example, an inflation rate of 10 percent a month in the German hyperinflation of the 1920s led to a currency substitution of only 5 percent of the money stock.

At the international level, where legal restrictions matter much less and national currencies can freely compete, specific types of transactions tend to be denominated in international currencies to enhance market transparency, and international investments in different currencies are regularly held as a store of value. In the search for the preferred currency, transaction costs are one of the most relevant considerations. These costs decline as the transaction domain of a currency expands; call this the network value of money. Currencies that are not widely used have a low network value and are at a competitive disadvantage against widely used currencies. Once a currency reaches a dominant network value, it may

gain from inertia: newer currencies with similarly low transaction costs may not be able to quickly upstage the dominant currency (Rey 2001).

Historical evidence indicates that one currency tends to dominate others as an international medium of exchange and a store of value. The Roman silver *denarius* was the first world currency; the Byzantine *solidus* was the unchallenged coin from the 5th to the 7th centuries. But the international role of the *solidus* was challenged by the Islamic *dinar*, which eventually made the crossover; both lasted until the 12th century. In the 13th century, Italian coins came to prominence: the Genoese *genoino*, the Florentine *fiorino*, and the Venetian *ducato*. All three coins circulated side by side for quite some time (Cipolla 1956). In the 19th century, Britain was the leading industrial economy in the world, and the British pound became the leading international currency. Britain's economic preeminence came to an end after World War I, but the key status of the pound lasted for more than four more decades (Eichengreen 2005). As late as 1965, 20 percent of official reserves were denominated in pounds, demonstrating how slowly a dominant currency can decline. The U.S. dollar emerged as the dominant international currency after World War II, but lost some ground toward the end of the 20th century, first with respect to the deutsche mark and the Japanese yen and later to the euro.

The U.S. Dollar and the Euro as Dominant Currencies Several different functions are subsumed under the label of "international role of a currency": to invoice internationally traded goods and services, to employ as a vehicle currency (that is, as neither the exporter's nor the importer's currency) in foreign exchange markets, to denominate assets held by monetary authorities and the private sector, and to serve as a reference currency in defining fixed exchange rates (Cohen 1971; Kenen 1983).

The dollar remains the dominant invoice currency, even though the extent of its dominance has declined since the advent of the euro (Goldberg and Tille 2006). Specifically, according to available data,

the U.S. dollar remains the dominant invoice currency outside of Europe, where the euro has surpassed the dollar. The dollar is the largest currency traded in the foreign exchange markets, with a market share of 45 percent of daily transactions; the euro follows with a share of 20 percent (BIS 2005). These shares remained stable between 2001 and 2004. The greatest advances made by the euro as an international currency are in international bond issues. According to data published by the Bank for International Settlements (2006, table 13 B), international bonds and notes denominated in euros exceeded those denominated in dollars. The ascendancy of the euro coincides with the increased degree of efficiency, liquidity, and integration of the euro financial markets (Portes and Rey 1998).

Following the depreciation of the dollar relative to the euro after 2002, the financial press focused on the prospect that central banks with large and increasing stock of international reserves   especially those in Asia   may want to substantially diversify their holdings out of dollars and into euros and, in the process, bring an end to the dominance of the dollar in official portfolios. Yet, according to data published by the International Monetary Fund (2005, table I.2), the dollar still retained the same reserve share in 2005 that prevailed at the end of the Bretton Woods system. The novel aspect in the data is that the euro has gained at the expense of currencies other than the dollar (the euro share in official reserves has gone from 6.7 percent of the combined shares of the legacy currencies mark, franc, and guilder in 1973 to 25 percent in 2004). It is safe to say that the euro is becoming an established alternative to the dollar (Chinn and Frankel 2005).

With the United States and the euro area converging to similar economic and financial size, the race is now between two currencies that are backed by large and diversified regions and are integrated with the rest of the world both in trade and finance. Differences in policies will determine the outcome of the match for dominance. Hence the concern that the decline of the dollar may pick up speed if fiscal policy in Washington does not change.

Benefits of Currency Dominance The United States benefits from the dollar as the preeminent international currency in a number of ways. First, it earns a "foreign" seigniorage on the dollar currency held abroad; data indicate that as of 2005, $352 billion, approximately 50 percent of outstanding U.S. dollar currency, is in the hands of nonresidents (Survey of Current Business 2006). Second, the special role of the dollar has permitted the United States to issue liquid and short-term foreign liabilities and invest in illiquid and long-term foreign assets; that is, the United States is the "banker of the world" (Despres et al. 1966). By borrowing cheaply relative to rates of return achieved on foreign assets, the United States has relaxed the external constraint typically faced by other countries. This is one reason that, as of 2007, the United States had accumulated a staggering net foreign debt without yet incurring a financial crisis.

Finally, U.S. importers are largely insulated from exchange rate movements because virtually all U.S. imports are invoiced in dollars, and only a small fraction of a change in the exchange rate is passed through import prices. This reduction in exchange rate risk means that a depreciation of the dollar does not have the traditional effect of significantly reducing the demand for imports and does not lead to a deterioration of the terms of trade. The policy consequence of this benefit to U.S. consumers is that a dollar depreciation is a weak tool to produce a switch from imports to domestic goods and services and that a reduction of the trade deficit occurs mostly through the export side.

In sum, the dollar remains the dominant international currency; the euro is a distant second most important international currency. Whether the euro will eventually overtake the dollar depends on the inertia accorded to the dominant currency and on the policies that will be pursued on both sides of the Atlantic.

■ dual exchange rate

The term *dual exchange rate* refers to a situation in which more than one exchange rate applies between one currency and another. The term arises most often when a country's authorities establish one exchange rate for certain transactions involving foreign exchange/currency and a second rate governing other transactions. Many countries in Europe and the developing world use a fixed exchange rate for commercial (current account) transactions and another rate, either fixed or floating, for other (e.g., financial account) transactions. Another type of dual exchange rate occurs when a country's authorities require certain foreign exchange transactions to take place at a prescribed exchange rate, leaving other transactions to take place at the rate prevailing in the commercial market or driving other transactions into an illegal ("black") market, again at a more expensive (i.e., more depreciated) exchange rate.

For example, some countries with currencies that are not freely convertible have required exporters to sell ("surrender") their foreign exchange earnings to the country's central bank at one exchange rate and then buy the foreign exchange they need in the commercial market at the prevailing, and probably more depreciated, market clearing rate. In some other countries, tourists must exchange a certain amount of foreign currency at a set exchange rate on entering the country, the rate being different from, and usually more appreciated than, that in the commercial market. When the second market is illegal, the difference between the official rate and that in the illegal market is called the black market premium.

Dual exchange rates have been created for various reasons. Many European and Latin American countries, for example, have used dual rate regimes to ease the transition from a fixed to a floating rate regime or to limit downward pressure from capital flight on the rate for current transactions (Marion 1994). In some centrally planned or developing economies with nonconvertible exchange rates, they have been created to support activities or sectors said to yield special benefits to the economy. Authorities have sometimes argued that certain imports   goods used in the manufacture of exports or imports for official purposes such as development projects   are more valuable than imports of consumer goods and thus deserve priority, including access to cheaper foreign exchange. Accordingly, they have allowed importers of such goods easier access to foreign exchange at the official exchange rate, or allowed them to purchase foreign currency at a less expensive exchange rate. Dual exchange rates of this type have often been linked to systems of import licenses, in which importers request permission from the authorities to obtain foreign exchange, specifying the purpose(s) for which the foreign exchange will be used.

Despite their political appeal, dual exchange rate systems introduce serious inefficiencies to the foreign exchange market. Dual exchange rate systems artificially segment the market for foreign exchange. When some activities obtain foreign exchange at less expensive rates while others must pay more, the result is a nontransparent system of subsidies to favored

sectors and taxes on those disfavored. This system distorts the allocation of resources and lowers output and real economic growth, as foreign exchange no longer flows to the most productive activities.

Dual exchange rate systems also create incentives to engage in wasteful activities (i.e., rent-seeking activities) as a way of obtaining foreign exchange at preferential rates. Importers, for example, may shift the composition of their imports or engage in illicit transactions to obtain a more favorable foreign exchange rate (Gros 1987). Exporters may engage in underinvoicing as a way to keep foreign exchange out of the country or to avoid having to "surrender" their foreign exchange earnings. Finally, dual exchange rate systems enable those in favored sectors to operate more cheaply, gain advantages relative to other sectors, or sell foreign exchange to those in less favored sectors, thus obtaining profits at the expense of others.

Because of the distortions created by dual exchange rate systems, economists typically discourage their adoption, and dual exchange rates have become far less common since the end of the 1980s. If national authorities wish to encourage certain activities, a more transparent system of subsidies and taxes has a less disruptive effect on the pricing signals created by exchange markets.

■ early warning systems

Early warning systems (EWSs) are used by policymakers, ratings agencies, and many financial market participants to assess the vulnerability of countries to currency crises. Emerging markets have been in the eye of the storm several times in the late 20th and early 21st centuries: Mexico in 1994, Southeast Asia in 1997, Russia in 1998, and Argentina in 2001, among others. The effects of some of these episodes were not confined to the countries themselves but spread to other economies as well. In addition, the speculative attacks against currencies participating in the European Monetary System in the 1980s and the early 1990s showed that developed economies are not immune from such events either.

The scope, spread, and severity of crises originating in the foreign exchange market highlight the importance of understanding their causes and predicting where and when they may happen. This need cannot be overstated in an increasingly integrated world economy where free-flowing capital exposes the world's markets to greater risks. The so-called first-, second-, and third-generation models of currency crises constitute the theoretical framework for explaining the mechanisms underlying episodes of increased speculative pressure in the foreign exchange market. EWSs empirically test the implications of these models with the aim to predict currency crises and inform the relevant policy actions.

Basic Components of an EWS The first challenge in the construction of an EWS is how to define a crisis from an empirical perspective. A variety of methods have been used to identify such episodes, ranging from straightforward measures of currency depreciation (e.g., Frankel and Rose 1996) to composite indexes incorporating changes in exchange rates, interest rates, and international reserves (e.g., Eichengreen et al. 1995). Measures focusing exclusively on developments in exchange rates can capture only the effect of successful speculative attacks, whereas wider market pressure indexes may, in addition, encapsulate failed attempts to destabilize an exchange rate regime or put downward pressure on a currency. This follows from the fact that policymakers may choose to use the interest rate or part of the stock of the country's international reserves in order to prevent a devaluation of the currency. If such intervention is successful, then the movement in the exchange rate may be limited (or even zero), in which case a simple measure based solely on exchange rate movements will not register the foreign exchange market activity. In contrast, a wider pressure index will capture such activity through the changes in the international reserves and/or the interest rate components of the index.

A second issue relating to the construction of an EWS concerns the choice of sample, data frequency, and variables to be included in the model. Samples can be limited to economies that share certain characteristics (e.g., the stage of their development or their geographical proximity, among other things) or can be extended to include all economies for which data are available. There is a trade-off between the need to avoid overaggregation and the need to maximize the number of observations available for analysis.

An interrelated issue is that of the frequency of the data. Higher-frequency data (e.g., monthly) will provide more degrees of freedom but several economic variables are observed at lower frequencies (e.g., annual). Hence, adopting a monthly frequency increases the number of observations for the available variables but precludes the use of variables that are observed at lower frequencies. Adopting an annual frequency allows the use of a greater number of variables but reduces the number of observations per variable. Furthermore, selecting an annual frequency may have implications for identifying crisis episodes, as the effects of a successful or unsuccessful speculative attack may have played out within the twelve-month period. In such cases, annual data will miss the crises altogether.

Also, a choice must be made of the variables or indicators to be included in the EWS. The selection is usually informed by the relevant theory. First-generation models stress the importance of fiscal and monetary indicators (e.g., the fiscal deficit, the change in the amount of money in the economy); second-generation models emphasize the role of variables related to market expectations (e.g., the interest rate differential with respect to the United States); and third-generation models focus on, among others, the need to monitor indicators of the health of the banking system (e.g., the ratio of non-performing loans to performing ones).

The decisions on how to measure a crisis, and what sample, frequency, and variables/indicators to use constitute one reason for the different types of EWSs that have surfaced in the literature. The other reason concerns the distinct methodologies employed, which range from signal extraction to estimating discrete binary choice and structural models.

The "Signals" Approach One of the most influential approaches in EWSs is the "signals" approach, pioneered by the economists Graciela Kaminsky, Saul Lizondo, and Carmen M. Reinhart (see Kaminsky et al. 1998). This involves monitoring a set of key economic variables over time. Whenever a value of a variable exceeds (or, depending on the nature of the variable, falls below) a predefined critical threshold the model issues a warning signal that a

crisis may be forthcoming within a specified time period. In order to assess the predictive ability of the model the incidence of signals needs to be compared with the incidence of actual crisis episodes.

Kaminsky et al. (1998) construct an exchange market pressure index using a weighted scheme involving changes in the exchange rate and the stock of international reserves. This is in turn converted into a binary crisis variable by assigning a value of one whenever a value exceeds the mean of the index by more than three standard deviations and assigning a value of zero otherwise. In that way, the ones correspond to crisis incidents and the zeros correspond to normal periods.

The critical thresholds for a signal to be issued are chosen on the basis of minimizing the ratio of "bad" to "good" signals, where a bad signal is one that is not followed by an actual crisis and a good signal is one that is followed by an actual crisis. Kaminsky et al. set a signaling horizon of 24 months, that is, if a signal has been issued that is followed by a crisis episode within this time window it will be considered a good signal. This is one of four possible outcomes. A second possible outcome is that a signal has been issued with no crisis occurring within the 24-month period. A third one is that a signal has not been issued but a crisis does take place within the specified time window. The final possible outcome is that a signal has not been issued and no crisis takes place.

We can summarize this information in a matrix. A is the number of months that a good signal was issued, B is the number of months that a bad signal was issued, C is the number of months that a signal should have been issued, and D is the number of months that a signal was, rightly, not issued. In terms

	Crisis (within 24 months)	No crisis (within 24 months)

No signal was issued	C	D

of this matrix, optimal thresholds are chosen so that [B/(B+D)]/[A/(A+C)], the "noise-to-signal" ratio, is minimized. These thresholds are expressed relative to the percentiles of an indicator's distribution. Several threshold levels are examined in the vicinity between 10 percent and 20 percent and the one minimizing the noise-to-signal ratio is chosen as the optimal threshold. This is then used as a reference level for all countries in the sample (of course, a given percentile will correspond to different actual threshold values in different countries).

Kaminsky et al. use 15 indicators classified in the following categories: capital account, current account, debt profile, international variables, financial liberalization, other financial variables, real sector, fiscal variables, institutional/structural factors, and political variables. They find that a range of indicators contain useful information, including the deviation of real exchange rate from trend, banking crises, exports, equity prices, the ratio of M2 to international reserves, output, excess M1 balances, international reserves, the M2 multiplier, the ratio of domestic credit to gross domestic product, the real interest rate, and the terms of trade. These results have been partly replicated using a different sample of countries and time period by others (e.g., Berg and Patillo 1999).

The Discrete-Choice Approach Another type of EWS uses probit (or logit) econometric estimations to calculate the probability of a crisis conditional on a set of variables. The dependent variable is a binary indicator with unity indicating a crisis observation and zero indicating a noncrisis observation. The main advantage of this approach is that a variety of potential "triggers" can be used as explanatory variables of crisis episodes. For example, the predictive ability of economic and structural variables corresponding to the first-, second-, and third-generation theoretical models of currency crises can be assessed in this framework.

An example of the discrete-choice approach is Frankel and Rose (1996). They use annual observations for 105 countries between 1971 and 1992. Controlling for a range of macroeconomic indicators, they focus on the composition of debt and capital flows. They define a crisis as a reduction in the value of the domestic currency of at least 25 percent that also exceeds the previous year's depreciation by at least 10 percent. This measure would not capture a failed speculative attack as the crisis definition does not include measures of international reserves and/or the interest rate. Using a probit model, the authors find that crisis probabilities are significantly influenced by developments in foreign direct investment, international reserve levels, domestic credit, U.S. interest rates, and the real exchange rate.

Large sample studies can be useful in identifying potential crisis-triggering factors. Pooling observations from regions with different economic, historical, and structural characteristics, however, calls into question the general applicability of the model's implications: it may be necessary to focus on individual crisis incidents so that valuable information, which may be specific to an incident, does not go amiss. The following type of model is dedicated to a more structural approach.

The Structural Approach This type of model is used to examine a country's vulnerability to a currency crisis by assessing certain economic characteristics. An example of the structural approach is Sachs et al. (1996). These authors construct a market pressure index involving the exchange rate and international reserves but, unlike the signals and the discrete-choice approaches, they do not convert it into a binary variable. Instead, they use the index as the dependent variable in a regression. The right-hand side of the equation includes a measure of real exchange rate misalignment, a measure of liquidity in the economy, and a set of dummies capturing weaknesses in fundamentals and low international reserves. The sample consists of a cross-section of 20 emerging economies, and the time span for the calculation of the variables concentrates on the time around the Mexican crisis of 1994. Even though the results reveal that the indicators in question have explanatory ability with respect to the effects of pressure in the foreign exchange market on financial crises, subsequent efforts by Berg and Patillo (1999) to forecast the 1997 Asian crisis using this approach were not successful.

The Way Forward The definition of a crisis, the methodology employed, sample selection, and other factors can affect the predictive ability of the three main types of EWSs. But despite their limitations, EWSs of financial crises are a useful tool for policymakers. Although there is no consensus in the literature about a definitive list of predictors of crisis episodes, certain indicators, such as the misalignment of the real exchange rate and excess liquidity, are important factors in several models.

This is a literature that is constantly growing. Recent advances in econometrics have resulted in the construction of increasingly sophisticated models. The challenge for researchers and policymakers is that different crisis episodes appear to have different causes. It remains to be seen whether our current knowledge will be sufficient to enable us to predict the next crisis.

■ Economic Community of West African States (ECOWAS)

The Economic Community of West African States (ECOWAS), also known simply as the community, is a regional trade organization comprising countries in the West African region. As of late 2007, Benin, Burkina Faso, Cape Verde, Côte d'Ivoire, Gambia, Ghana, Guinea, Guinea-Bissau, Liberia, Mali, Niger, Nigeria, Senegal, Sierra Leone, and Togo (after Mauritania withdrew in 1999) are members. The aims and objectives of the community are to promote trade, cooperation, and self-reliance in West Africa and to assist in the creation of the African Economic Community (AEC).

Origin and Background Like other regional economic groups in Africa, the community was formed based on the pan-African vision of economic integration, which gained prominence during the late 1950s and early 1960s. It was believed that the small and fragmented postcolonial national markets would constitute an obstacle to the economic development of Africa. The pan-African solution was to create a single common market for the continent. The pan-African approach to integration was a "bottom-up" process that would begin at the regional levels (central, east, north, south, and the west) and evolve into a continentwide common market by welding the regional organizations together. It was against this background that the community was created to overcome the isolation of the small West African countries following the colonial and postindependence nationalism periods.

The community was created by treaty in 1975 as a preferential trade area for the transformation of the West African region. The original plan for the community was to establish a free trade area by 1980 followed by a customs union by 2000, and an economic and monetary union by 2005. Owing to a number of factors, however, including internal sociopolitical and economic instability in member countries, poor coordination of macroeconomic policies at the regional level, weaknesses in the operational procedures of the community's institutions, and lack of commitment on the part of member countries to implement the community's priority programs, implementation of the integration programs has proceeded very slowly.

The ECOWAS Treaty was revised in 1993 to expedite the process of economic integration and to increase political cooperation in the region. The revised treaty articulates comprehensive cooperation and integration programs, including trade promotion and liberalization; the provision of better roads and telecommunications infrastructure; and the development of agriculture, industry, and the energy sector. The implementation of the trade liberalization programs was planned to occur in three stages. The first involves the full liberalization of trade in unprocessed goods and traditional handicrafts. The second entails a phased liberalization of trade in industrial products whereby the most advanced member countries (Nigeria, Ghana, and Côte d'Ivoire) were to remove all trade barriers in a period of six years, middle-group countries (Benin, Guinea, Liberia, Sierra Leone, and Togo) within eight years, and third-group countries within ten years. The third stage concerns the establishment of a common external tariff.

In order to accelerate the regional integration process, the revised treaty allows for a double-track (fast-track) approach to economic integration whereby a group of countries can take measures to accelerate integration among themselves. The revised treaty also assigned to the community the additional responsibility of preventing and settling regional conflicts.

Various institutions have been formed to facilitate the achievement of the broad aims and objectives of the community. These institutions include the decision-making organs responsible for the smooth functioning of the community, the Mediation and Security Council (for maintaining peace and security in the region), and the Fund for Cooperation, Compensation, and Development (which provides development capital). The decision-making organs include the Authority of Heads of State and Government (i.e., the supreme policy organ), responsible for the general direction and control of the community; the Council of Ministers, responsible for making decisions on programs and the functioning and development of the community; the Parliament (without legislative powers), which acts in a consultative and advisory capacity; the Economic and Social Council, which plays an advisory role; the Court of Justice, which interprets the provisions of the ECOWAS Treaty and settles disputes among member states that are referred to it; and the Executive Secretariat, responsible for the smooth functioning of the community and for the implementation of the decisions of the supreme policy organ. The community also has specialized technical commissions that prepare projects and programs for consideration by the Council of Ministers on all key sectors of the economy.

The member states of the community have diverse backgrounds. Their heritages vary from Anglophone to Francophone states and to independent Liberia. The region consists of mainly two geographical zones the Sahelian, semiarid, largely landlocked zone, and a more humid, forested coastal zone. Nigeria is a dominant economy in the region, accounting for more than half of the population and gross domestic product (GDP) of the region. Most of the other states are small in size (less than 5 percent) in terms of population and GDP. The region's resource endowments consist mainly of crude oil (in Nigeria) and agricultural products such as cocoa beans, coffee, and yams. The per capita GDP varies widely across the region. For example, in 2004, it was U.S. $141 for Liberia and U.S. $1,979 for Cape

Verde. In the same year, the UN Development Program ranked only Cape Verde and Ghana as medium human development countries and the rest as low human development countries.

Key Elements and Procedures Since the early 1990s, there has been some progress toward the establishment of a free trade area and a common market. For instance, visa and entry-permit requirements for ECOWAS nationals have been abolished and an ECOWAS passport has been adopted. In addition, ten countries (Benin, Gambia, Ghana, Guinea, Mali, Niger, Nigeria, Senegal, Sierra Leone, and Togo) have removed barriers on trade in unprocessed goods and three (Benin, Gambia, and Sierra Leone) have eliminated barriers on trade in industrial products. All member countries have abolished monetary nontariff barriers. Nonmonetary nontariff barriers still exist, however. A common external tariff was scheduled to be in place by the end of 2007.

In 1994, eight of the countries (Benin, Burkina Faso, Côte d'Ivoire, Guinea Bissau, Mali, Niger, Senegal, and Togo) took advantage of the double-track innovation and came together to create a customs union and a monetary zone called the West African Economic and Monetary Union (WAEMU). The WAEMU member states implemented a common external tariff in 1998 and have started to harmonize their policies in various fields. WAEMU has generally been perceived as successful. Intra-WAEMU trade as a share of the region's total world trade increased from about 10 percent in 1994 to about 16 percent in 2000. Also, the average annual GDP growth rate for the WAEMU subregion has been higher than that of sub-Saharan Africa as a whole. Six other countries of the community, Gambia, Ghana, Guinea, Liberia, Nigeria, and Sierra Leone, have followed suit and embarked on an initiative to form a second monetary zone with the aim to merge with the WAEMU and eventually create a single monetary zone for the ECOWAS region.

Until now, the community has operated as a preferential trade area. The member states apply tariff preferences under the common preferential tariff on goods originating from the community and charge national tariff rates on goods originating from nonmember countries. Member countries use the community's rules of origin to determine the tariff rate to levy on imported products. Products are deemed to originate from the community if (1) they are wholly obtained within a member state, (2) they have undergone sufficient processing in a member state (usually 40 percent value added), (3) 60 percent of the raw material used to manufacture the product comes from member states, or (4) they are local products or traditional handicrafts. Normally, a certificate of origin is not required for local products and traditional handicrafts of ECOWAS origin. For any other product, however, an importer who seeks to benefit from the preferential treatment must provide a certificate of origin.

Impact on Member States Regional economic integration agreements can be beneficial to member countries in both the static (short-run) and the dynamic (long-run) sense. In his analysis of static effects, Jacob Viner (1950) observed that while regional economic integration represents a movement toward free trade on the part of member countries (leading to trade creation), it can also lead to diversion of trade from low-cost nonmember sources that face tariffs to a high-cost member source that no longer faces tariffs. In the short run, member states can benefit as long as the trade creation effects exceed the trade diversion effects. Using the gravity framework, Jacob W. Musila (2005) estimated the two static effects for ECOWAS and found that trade creation exceeds the trade diversion effects. Therefore, member countries of the ECOWAS organization can be expected to obtain net gains in welfare. Céline Carrére (2004) also found that the formation of ECOWAS is associated with the increase in intra-ECOWAS trade and that the currency union, WAEMU, has helped to reduce trade diversion effects. The performance of intra-ECOWAS trade shows that its share in the region's total world trade increased from 2.4 percent in 1975 to more than 10 percent in the 1990s. During the period 1994 98, owing to the improvement of performance in the WAEMU zone, the share of intra-ECOWAS trade increased slightly but steadily from 10.7 to 11.9 percent.

The dynamic benefits of a regional integration occur through well-known channels, namely, increased efficiency through specialization, economies of scale, or increased trade and investment. Like static effects, however, the net impact of dynamic effects is not obvious. In the case of ECOWAS, exports comprise a limited range of agricultural commodities (only Nigeria is a net oil exporter), and manufactured goods are imported mainly from nonmember countries. Such pattern of trade can be a hindrance to long-term economic growth of the region since agricultural products are more prone to deterioration in terms of trade. Indeed, the sluggish growth that characterized the ECOWAS region in the late 1990s was partly attributed to the sharp fall in cocoa prices. Augustin Fosu (1990) finds evidence that supports the view that exporting primary commodities does not significantly improve a country's long-term economic growth rate. Antonio Spilimbergo (2000) shows that the importation of manufactured goods from rich countries (the North) by poor countries (the South) may not guarantee economic growth in the South. The learning-by-importing models, however, suggest that imports of high-technology goods can result in the transfer of technology which, in turn, stimulates domestic innovation and economic growth in the importing country.

Relation with External Actors The relation between ECOWAS and external actors in the world economy varies from region to region. ECOWAS and other African regional blocs seek to augment and deepen economic integration in their respective regions with a view to forming an AEC that will enable Africa to be in a stronger position when negotiating trade matters with other regional organizations such as the European Union (EU), the South American regional economic organization Mercosur, and the North American Free Trade Area. ECOWAS does not have overlapping memberships, which have been seen as an obstacle to market enlargement in some African regional integrations.

On the other hand, the relation between ECOWAS and non-African trade blocs is viewed by some analysts to be an impediment to regional integration. Jeffrey D. Lewis, Sherman Robinson, and Karen Thierfelder (2003) have argued that North-South trade is more attractive to most African countries than South-South trade because of the structure of their economies or colonial heritage. Indeed, ECOWAS member states trade with the EU and the United States more than with one another. This trade is set to increase even more following the opening up of the EU and U.S. markets under the Everything-but-Arms and the African Growth and Opportunity Act initiatives, respectively. This may work to further reduce the relative importance of intra-ECOWAS trade. In addition, the World Trade Organization provision that substantially reduces quotas and duties on goods originating from the world's poorest countries will also increase the region's trade with non-ECOWAS countries and further reduce the advantages that the community offers to its member states. The very processes of global trade liberalization and cooperation with non-African trade blocs have contributed to the evolution of ECOWAS, however. To reduce transaction costs, the EU, for example, prefers developing countries to negotiate as one group (instead of as numerous individual countries). Furthermore, the success of the EU also inspires the evolution of ECOWAS. Indeed, the ECOWAS institutional design is fashioned after the EU.

■ economic development

Economic development consists of socioeconomic changes that have the goal of raising economic wel fare and the standard of living of a population. Chief among these objectives are higher income per capita and lower poverty, but others involve increasing protection of the natural environment, health and life expectancy, literacy and the educational attain ment of current and future generations, and political freedom and civil liberties.

There are four major, proximate forces that in fluence economic development: population growth and demographic change; investment and physical capital accumulation; human capital and techno logical change; and land, agriculture, and geography. Underlying how these forces affect development, however, are policy choices. Three main areas of pol icy debates are discussed below: trade liberalization, international financial liberalization, and foreign aid. But these policies have underlying determinants as well. Public sector institutions and governance are influenced by political economy, social conflict, and the presence of large rents, among others. All of these forces have international linkages. The next sections highlight these connections of development to the world economy.

Population, Demographic Change, and International Migration The population in the devel oping world rose from 2.325 billion in 1960 to 5.489 billion in 2006. From Thomas Malthus to Robert Solow, a popular body of work has grown postulating how higher rates of population growth are linked to lower standards of living. Malthus focused on the impact of population growth on scarce food supplies. Solow postulated that increased population growth causes the amount of capital per worker to decline, reducing productivity and income per capita. Initial testing of Solow's hypothesis, such as that produced by Mankiw, Romer, and Weil (1992), showed that, holding other things constant, higher rates of pop ulation growth were indeed connected to lower in come per capita.

But a more nuanced view of the relationship has emerged from recent research, one that is mediated by the economy's dependency rate, defined as the sum of people less than 15 years old and those older than 64, divided by those aged 15 to 64. As popu lation growth expands, often as a result of the so called demographic transition, dependency rates first rise in response to the larger proportion of children in the population. But as this wave of chil dren becomes adults and enters the labor force it can lead to a surge in the saving rate, capital accu mulation, and productivity growth. The result is a period of increased economic growth. Bloom and Williamson (1998) find this demographic dividend to be important in explaining the rapid growth of the

East Asian economies in the period 1960 to 1990, accounting for 1.9 percentage points out of the 6.9 percent average rate of growth of these economies. As the population ages, however, dependency rates increase and growth is negatively affected.

Population flows across countries have exploded in recent years and international migration has become a significant development force. In 1960, there was a stock of slightly over 75 million people residing in countries other than their country of birth. By 2005, this number had expanded to 190 million. Most of these migrants 65 percent of them were born in developing countries.

The impact of emigration on developing countries has been a matter of debate. A partial-equilibrium approach would suggest that emigration reduces labor supply and raises wages in source countries. But in the Heckscher-Ohlin-Samuelson (HOS) general equilibrium framework used in trade theory, emigration has no lasting impact. As migrants leave and wages rise, production shifts away from labor-intensive products and into capital-intensive sectors. The overall demand for labor in the economy shrinks, matching the reduced labor supply induced by emigration (Rivera-Batiz 1983). But the assumptions of the HOS model under which this result is derived are stringent. Once these assumptions are relaxed, the theoretical analysis may yield complex and ambiguous effects of emigration on source countries (Rivera-Batiz 2008). The empirical evidence on the issue has grown in recent years, but remains exploratory (see, for example, Mishra 2006). In some countries, such as China, periods of emigration have been followed by a rise of reverse migration, which returns workers with accumulated skills to the source countries.

The impact of emigration in developing countries is often dominated by the flow of remittances. Measured in international purchasing power parity dollars, developing countries received more than $600 billion in 2005, and for some countries, such as Bangladesh, India, Mexico, Pakistan, and the Philippines, remittances are a major item in the balance of payments. Remittances raise households' standard of living, reduce poverty, and contribute to devel-

opment. But whether they simply raise current consumption instead of stimulating investment and future growth varies by country (Adams 2007).

Physical Capital Accumulation and Foreign Direct Investment Most development models emphasize the role played by investment and physical capital accumulation in economic growth. For example, by raising capital per worker and productivity, the Solow model links increased savings and investment rates to higher income per capita.

Evidence on the role played by physical capital accumulation in economic growth varies by country, but it can be substantial. Young (1995) finds physical capital accumulation explains most of the miraculous economic growth of Singapore between 1966 and 1990. Recent work on China shows physical capital has also been key to its rapid growth since 1980 (see Riedel, Jin, and Gao 2007).

Most capital accumulation is financed through increased national savings. But in some countries, foreign capital contributes as well. Foreign direct investment (FDI) represents investments made by foreign residents (usually foreign firms) involving the acquisition of a lasting and significant control or ownership of the enterprise in which the funds are invested. Most FDI increases physical capital in the recipient countries and can stimulate economic growth. But until the early 1990s, FDI occurred mostly among high-income countries. In 1990, for example, developing countries accounted for only 12.1 percent of net FDI flows. This situation led the Nobel Prize winner Robert Lucas to write a paper in 1990 titled "Why Doesn't Capital Flow from Rich to Poor Countries?" The answer pointed mostly to restrictions and taxes imposed by developing countries on FDI inflows. This changed in the 1990s, with a massive wave of economic reforms that liberalized the flow of capital to developing countries. As a result, flows of FDI going to developing countries rose from $36.7 billion in 1990 to $314.6 billion in 2006 (measured in 2005 constant U.S. dollars).

Inflows of FDI have a direct, positive impact on employment. They can also accelerate the adoption of new technologies. If the FDI sector has significant

forward and backward linkages with other industries in the economy, positive productivity spillovers will develop, further stimulating growth (Rivera-Batiz and Rivera-Batiz 1990). Forward linkages may emerge from other industries that use the products sold by the foreign firms (such as domestic pharmaceuticals using chemicals produced by foreign petrochemical companies) while backward linkages may be in the form of domestic suppliers of business services or other inputs used by the foreign firms in their productive activities (such as a multinational's use of local transportation services). The case of Ireland, the so-called Celtic Tiger, has been widely discussed as an example of the positive effects of FDI on development. As much as 50 percent of employment in Irish manufacturing is in foreign-owned firms and some simulations suggest that Irish growth would have been two percentage points slower each year since 1990 without the FDI inflows (Navaretti and Venables 2004). But the empirical evidence on the positive effects of FDI is mixed. There are potentially negative indirect effects, including the displacement of local firms, environmental damage, and the deterioration of working conditions, as present in sweatshops or in the employment of child labor, although the latter often occur due to lax domestic regulation and may apply as well to domestic firms (see Nunnenkamp 2004; and Moran, Graham, and Blomstrom 2005).

Technological Change, Human Capital, and Brain Drain William Easterly and Ross Levine have argued that, among developing countries, capital accumulation does not explain most economic growth (Easterly and Levine 2001). Indeed, the presence of diminishing returns in the accumulation of capital suggests that long-run economic development prospects must be aided by forces other than physical capital investment. Technological change is one such force.

But what factors foster technological change? Building on the work of Paul Romer, Robert Lucas, Philippe Aghion, and Peter Howitt, among others, on endogenous growth theory, research on this issue has multiplied since the early 1990s (see Aghion and Howitt 1997). Most of this research suggests that modern technological change is spurred by new product creation and imitation. Countries with high rates of research and development expenditures are able to create new products that allow   albeit temporarily   rents that are reflected in higher growth rates. Imitators destroy those rents but at the same time provide incentives for new products and niches that generate further growth. This process, called "creative destruction" by Joseph Schumpeter, is postulated by this literature as a major determinant of development (Helpman 2004).

In the development literature, some researchers initially developed so-called product life-cycle models that visualized developing countries as imitators, reproducing products originally created in high-income countries. More recently, however, research based on the cases of South Korea, China, and other countries indicates that, by expanding sectors of the economy that are technologically dynamic, developing countries can bypass product cycles and spur innovation, providing internationally competitive new products that can then act as an engine of exports and growth. In this context, the process of development is stimulated not by how much you export but what you export (see Rodrik and Hausmann 2006).

The work of Paul Romer focused on how the domestic supply of human capital dedicated to research and development is the key factor influencing technical change (Romer 1990). Empirical evidence confirms that increased human capital can have a major stimulating impact on growth. This was the case in the so-called East Asian miracle economies Hong Kong, South Korea, Taiwan, and Singapore where increased quantity and quality of schooling accompanied their development process (Hanushek and Kimko 2000). But the evidence also shows that increased schooling does not universally have a positive impact on development (Pritchett 2001). In countries where the quality of the public sector governance is low, many highly educated workers tend to end up employed in low-productivity sectors (Murphy, Shleifer, and Vishny 1991). In some countries, increased school enrollments have led to a deterioration of quality. In these cases, investments

in human capital have a smaller impact on economic growth.

Domestic supplies of human capital can be severely depleted by emigration. The majority of migrants from developing countries are relatively unskilled but for some countries the emigration of professional and technical workers the so-called brain drain is most significant. The highest skilled emigration rates in the world are in the Caribbean, where as much as 43 percent of the region's labor force that has completed some tertiary (college) education currently resides outside its borders. There are also relatively high rates of skilled emigration in Africa, where the highest skilled-worker emigration rates include Cape Verde (68 percent) and Gambia (63 percent).

The emigration of skilled workers may not have a significantly negative impact on domestic consumers if it only causes a reduction in the output of sectors that produce tradable goods because these products can be imported from abroad when the laborers leave the country. But when the workers are employed in service sectors that produce internationally non-traded goods, the impact of emigration can be potentially disastrous because domestic consumers can only obtain those goods and services locally. If doctors and nurses emigrate, the supply of health services can collapse, resulting in higher prices and acute shortages. A brain drain can therefore reduce sharply the economic welfare of those left behind. Remittances may or may not offset these negative effects (Rivera-Batiz 2008).

If human capital flees an economy, then the ability of those left behind to sustain innovation may be compromised, thus reducing an economy's economic growth. On the other hand, the emigrants may generate international networks that enhance the scientific and technological capacities at home. Evidence on the relative significance of these two effects is not available.

Land, Agriculture, and Geography Geography can be a major barrier to development in several ways. First is the burden generated by diseases, which impose their cost more heavily in the tropics. Malaria, for example, is a disease that kills about 3 million people each year in tropical areas. It also weakens those who survive the disease. Countries that suffer from severe malaria epidemics grow more slowly than others and suffer from increased poverty (Gallup and Sachs 1999).

A second mechanism through which geography affects development is through transportation costs. Transportation costs act as a barrier to trade and, therefore, to development. Coastal economies or those close to navigable rivers generally have higher income per capita than landlocked economies without access to navigable waters. Indeed, outside of Europe, there is not a single high-income landlocked country. Much of the population in developing countries particularly in Africa lives in landlocked locations.

A third way geography influences development is through its impact on the agricultural sector. Tropical areas tend to suffer from climate influences that reduce agricultural productivity between 30 and 50 percent compared to temperate zones, holding other inputs constant (Gallup and Sachs 1999).

Public policies can be used to compensate for the impact of geography, whether through investments in health, transportation infrastructure, or irrigation schemes that can raise agricultural productivity. Land reform and rural market development policies are also essential for the development of agriculture. Despite the relatively scant attention paid to them by the World Bank and other international organizations, such policies have strong poverty reduction effects since rural areas are where the poor are concentrated. In the case of China, one of the most dramatic drops in poverty occurred in the early 1980s, before international trade became a major force in that country's development efforts. Rural poverty fell from 76 percent in 1980 to 23 percent in 1985, largely in response to comprehensive land reform initiatives and the growth of local agricultural markets. In the international arena, the Doha round of WTO negotiations begun in 2001 seeks to reduce agricultural subsidies and the non-tariff barriers to trade imposed by high-income countries, which hurt the exports of poor developing nations.

Governance and Institutions Although physical and human capital accumulation, technical change, demographics, land productivity, and so on are all proximate influences on development, they are all subject to the social, cultural, and economic environment within which individuals and firms live and function. This environment is closely connected to the country's government, which sets its legal and economic frameworks. Indeed, the quality of governance in a country is a major underlying determinant of development. High-quality governance includes, among other things, bureaucratic effectiveness and agility, institutions that assure the swift and strong accountability of government administrations, and a strong rule of law and control of corruption.

Since the mid-1990s, the World Bank has been collecting data on the public sector governance of most countries in the world. Based on these data, the evidence shows that good public sector governance is essential for development (Kaufmann, Kraay, and Mastruzzi 2007). A case in point is the acceleration of economic growth in India, which can be seen as the outcome of governance reforms in the 1980s (Rodrik and Subramanian 2005). Nations able to generate high quality of public sector governance   such as some of the East Asian miracle economies, including Singapore and Hong Kong   have been able to cultivate institutions that complement the process of economic development, introducing policies that foster higher investment in physical and human capital and provide incentives for entrepreneurship and innovation.

But what forces generate poor or good country governance? A major force is political power. Different interest groups or classes within a country have conflicting interests over the distribution of resources, and their policy prescriptions are informed by such interests. Political institutions then determine how various groups get   or do not get   access to government and its legislative powers. Overall, the quality of governance is substantially higher in more democratic countries, even after holding other variables constant. Transparent democratic institutions mean that, over the long run, inept and corrupt officials will be voted out of office,

which is often more difficult under authoritarian regimes. More democratic institutions also facilitate the activities of the press and allow the dissemination of information to the public so that governments can be held accountable (Rivera-Batiz 2002). At the same time, there are cases of authoritarian regimes   such as Singapore and China   that have been able to provide high-quality public sector governance, spurring economic growth.

In many developing nations, a history of colonialism provides a backdrop for the creation of institutions that can hinder development efforts after independence (Acemoglu et al. 2006). Social conflict can also break down the government stability necessary for stable growth. Such conflict is endemic in the poorest developing countries and is fostered by relatively high proportions of poor young men with little education, ethnic or religious strife, and the presence of natural resources (such as diamonds or oil), which finance the armed conflicts (Collier 2007). Once social conflict starts, it generates a vicious circle, where conflict leads to poverty and poverty to more conflict. The more fragmented a country is   by ethnicity or social class   the lower its rate of economic growth. Many countries in Africa appear to follow this pattern (Easterly and Levine 1997).

Natural Resources and the Dutch Disease The presence of large rents can also give rise to poor governance and, as a result, constrain economic growth. Consider the case of countries that have rich endowments of natural resources. Surprisingly, the evidence shows that, despite their potential wealth, these countries have not grown faster nor have they been able to reduce poverty rates, holding other things constant (Sachs and Warner 1995b).

Consider the case of Nigeria, where massive oil reserves were discovered in 1965. The sum of oil revenues received by this country since that time has been more than $400 billion but its gross domestic product (GDP) per capita was about the same in 2000 as it was in 1970, when adjusted for inflation. In the meantime, poverty rates (using a $1 a day measure) rose from 36 percent in 1970 to 70 percent in 2000.

The lack of impact of natural resource exports on growth and poverty may be connected to the fact that, as countries pull resources into the exploitation of natural resources, they withdraw resources from other sectors. As a consequence, there is a crowding-out effect, with natural resource output crowding out manufacturing output, leaving no net impact on GDP. This has been called *Dutch disease*, referring to the case of natural gas exploitation in the Netherlands in the 1970s, which failed to generate sustained economic growth.

A second explanation links the increased exploitation of natural resources to a lower rate of technical change. The rewards for working in the natural resource industry are high and therefore a significant portion of a country's talent may end up employed in this industry. But the natural resources sector is not itself one that leads to great innovations or stimulates entrepreneurship. As a result, countries specializing in the production of natural resources may in fact have low rates of innovation and face lower long-run growth.

But in the case of Nigeria and many other countries, the culprit behind the lack of impact of natural resource exports on economic growth is poor public sector governance (Sala-i-Martin and Subramanian 2003). The consequence of massive economic rents is the emergence of a governance regime that permits those with greater political power to capture, by any means necessary, some of those rents. The result is corruption and slow growth.

The impact of natural resources on a country can be transformed from a curse to a blessing. For instance, some nations have been able to ameliorate the rent-seeking and corruption that is often associated with the export of natural resources. Part of the strategy has been to preempt possible corruption by earmarking or assigning a share of natural resource revenues directly to finance social programs, such as education and health. In the case of Indonesia, for example, revenues from oil exports were directed to a massive program of investment in education. More recently, Chile imposed a tax on copper production in order to finance a Competitiveness Innovation Fund that finances new technology projects. Through the use of innovative government policies, the exploitation of natural resources can have positive effects on development (Stiglitz 2005).

International Trade and Commercial Policy
The impact of international trade on economic development has been at the center of the debate on the consequences of globalization and is one of the most controversial issues in development economics. The key questions are whether trade liberalization reduces or increases poverty and inequality and whether it has a positive impact on economic growth.

The HOS model postulates that increased trade should reduce both poverty and inequality in developing countries. Trade induces a developing country to increase the production of goods in which it has a comparative advantage, that is, in sectors that use unskilled labor intensively. As production and export of these products rises, the demand for unskilled workers increases and this raises their relative wages. At the same time, the demand for and the rewards received by human and physical capital decline. Since unskilled workers are usually poor while the owners of both physical and human capital tend to be richer, the impact of international trade in the HOS framework is to reduce poverty and improve income distribution in developing countries.

The evidence on the impact of trade on poverty tends to support the HOS predictions. The data on extreme poverty, measured as people with consumption below the $1 a day level, show that world poverty has dropped sharply during the period 1981 to 2004, when globalization bloomed. Poverty declined from 40.1 percent in 1981 to 18.1 percent in 2004. This represents a halving of poverty rates and has meant a reduction in the number of poor in the world from 1,470,000 in 1981 to 969,480 in 2004 (Chen and Ravallion 2007). Furthermore, the two economies that have seen some of the sharpest increases in trade, China and India, are also the two economies where poverty has dropped the most. To cap off all of this, the region that has been the slowest to drop trade barriers, sub-Saharan Africa, is also the region where poverty failed to drop during the period.

On the other hand, the data show much less impressive drops in poverty when the poverty line rises to $2 a day. And metastudies that include a wide variety of developing countries show cases where poverty particularly regional poverty has risen as a result of trade (Harrison 2006). Furthermore, most of the estimates available suggest that the recent expansion of international trade in the world has been associated with a period of increased inequality. This inequality is displayed in both greater within-country inequality and higher cross-country inequality (Milanovic 2005).

The increasing inequality and declining poverty associated with globalization can be reconciled by the widespread evidence indicating that trade is linked to greater economic growth (Dollar and Kraay 2004; Wacziarg and Welch 2004). Economic growth tends to raise all boats and is associated with a reduction of poverty. But it has also been connected to rising inequality. One reason is that long-run growth in recent years has been closely linked to technological change. And this technological change has tended to be skill-biased, raising the demand for skilled labor at the expense of unskilled labor. Such a shift in demand raises the wages of skilled labor relative to unskilled workers, increasing inequality (Rivera-Batiz 2007).

For increased international trade to stimulate economic growth, domestic investment rates must be sufficiently high that new export industries can be developed. The evidence available suggests that, from South Korea to China, the implementation of active government policies designed to stimulate investment have been essential in allowing trade liberalization to generate growth and reduce poverty (Rodrik 1995). Without these and other complementary forces the impact of trade on growth is limited.

Financial Development and International Financial Markets One of the major forces that serves as a backdrop for economic growth is financial development. Although there is debate about the role of specific financial institutions, a growing body of empirical work shows that a well-functioning financial system has a strong, positive impact on economic growth and helps alleviate poverty by allowing the efficient transformation of savings into productive investments (Beck, Demirgüç-Kunt, and Levine 2007). The financial sector facilitates the trading, diversification, and management of risk, and it helps mobilize and pool savings by allowing savers to hold liquid assets and transforming those into higher-return long-term investments (Levine 2005).

While providing a solid, long-run basis for overall economic growth, the financial sector has nonetheless been prone to crises, with disastrous short-term consequences. In addition, traditional financial institutions have failed to fund the poor, who lack the collateral to access credit. In recent years, however, myriad microfinance institutions have emerged to provide credit to the poor. Microfinance institutions minimize the impact of a lack of collateral by pooling responsibility for loan repayment among communities of borrowers (Armendariz and Murdoch 2005). In addition, by having mobile operators who move among villages, they minimize transaction costs and mitigate adverse selection (which occurs when lenders cannot monitor the riskiness attached to borrowers' projects).

The conventional wisdom is that, as countries develop, the limits imposed by domestic savings may constrain development. From this perspective, international financial liberalization is a good thing for development, allowing developing countries with scarce capital to borrow in order to finance greater investment without the necessity of raising domestic savings. In addition, financial capital flows permit residents of different countries to pool risks, achieving more effective insurance than purely local arrangements would allow (Obstfeld and Taylor 2005; Prasad et al. 2003). International financial liberalization can also increase the efficiency of the domestic financial system, whether by enhancing the liquidity of local stock markets or by promoting contested markets and raising the efficiency of domestic banking.

But international capital market liberalization has its critics. Some argue that there is no systematic evidence that financial capital inflows cause greater

growth. Others observe that unregulated capital inflows can be disastrous for developing countries, pointing to the rash of financial crises in Mexico, East Asia, Russia, Argentina, and a variety of other emerging markets during the 1990s and early 2000s (Stiglitz 2003). These crises occurred after capital flows to developing nations began to rise sharply in the late 1980s and early 1990s in response to the elimination of many restrictions on international capital movements.

There were very specific factors connected to the East Asian and other emerging market crises of the 1990s and early 2000s. Fragile domestic financial institutions were unable to handle efficiently the expansion of credit, partly because they lacked the appropriate expertise and partly because governments had failed to implement adequate regulatory and supervision systems. The result was overinvestment, in the form of excessive lending to risky projects with low short-term returns. In addition, the reliance on highly volatile, short-term debt led to liquidity crises that resulted in financial panics and bank runs. These problems were compounded by the fact that the capital inflows caused real currency appreciation by generating inflation in fixed exchange-rate regimes. As the value of the currency rose in real terms, the current account balance deteriorated and external borrowing climbed. These changes then led to expected currency depreciations that fueled capital flight. When central banks stubbornly defended prevailing currency values, their foreign exchange reserves were eventually depleted, precipitating a foreign exchange crisis that spilled over into a financial crisis as well (Rivera-Batiz 2001).

Most countries in financial crisis have benefited from massive loan packages provided by the International Monetary Fund (IMF). But the conditions imposed by the fund to disburse its loans were sometimes so stringent that they sharply increased poverty in the short run and may have undermined future growth. The next section examines the role in development played by international organizations.

Foreign Aid and Development Many of the poorest developing countries lack access to world private capital markets. For these countries, official development assistance (ODA) grants and concessional loans made by governments and international organizations constitutes a major source of capital. In 2005, a total of $120.4 billion of ODA flowed to developing nations. This foreign aid can originate in other, mostly high-income countries (bilateral aid) or in groups of countries (multilateral aid), including international organizations such as the United Nations, the World Bank, and the IMF.

The impact of foreign aid on development has been a source of controversy, with proponents of aid (such as Sachs 2005) arguing for much greater flows while critics (such as Easterly 2006) argue that such aid is largely a waste of resources. Evidence of the positive impact of specific foreign aid projects on development is widely available. International efforts that funded campaigns to rid developing countries from various diseases, including smallpox, polio, and guinea worm disease, among others, have been found to be successful (Levine 2007). The role played by country donors and international organizations in the development of new seed strains as well as technological innovations now referred to as the Green Revolution is well known. And recent studies have used random experimental designs to show the success of educational and other development projects (such as the Progresa/Oportunidades program in Mexico), projects which have received substantial foreign aid support.

But many foreign aid projects have failed miserably. For instance, World Bank educational projects in the 1980s and early 1990s often requested that countries introduce public school fees in order to raise additional funding. But the outcome of those policies was to sharply reduce school enrollment. Another example is the possibility that the various market-oriented policies adopted by the World Bank and IMF toward agricultural markets may have undermined rural development efforts in low-income countries, especially in sub-Saharan Africa. Even the World Bank's own operations evaluation department finds that in the period 1995 to 2004, at least one-third of all projects in sub-Saharan Africa failed

to achieve their goals, more than half were unlikely to be sustained over time, and the great majority of projects did not have a substantial institutional impact on developing country governments. Some of this failure can be attributed to poor country governance. Nonetheless, systematically positive effects of foreign aid on overall economic growth have not been found (Rajan and Subramanian 2005).

A similar lack of support exists for the lending policies of the IMF. Despite the presence of apparently successful cases, such as Chile in the 1980s, South Korea in the 1990s, and Brazil in the 2000s, in other countries IMF-sponsored short-term reforms have not fared as well, including Bolivia in the 1980s, Indonesia in the 1990s, and Argentina in the 2000s. The evidence on the long-run growth effects of lending provided by the IMF under its conditionality agreements is mixed, with some studies finding negative impacts, especially among low-income countries (Vreeland 2003).

Macroeconomic Policies Notwithstanding the issue of the effectiveness of IMF stabilization policies, the IMF does not provide access to its lending facility unless asked by member countries in economic or financial distress. The available research suggests that macroeconomic mismanagement can be a major barrier to development (Montiel 2002).

Although the evidence on the relationship between low or moderate inflation and growth is mixed, the overwhelming evidence is that high inflation reduces growth and raises poverty (Barro 1995). By undermining the financial system and generating uncertainty, high and variable inflation rates inhibit investment and hurt growth. By acting as a tax on money balances, affecting especially those with fixed incomes, high inflation also hurts the poor.

Central banks, which manage the money supply, usually have as one of their goals the control of inflation. But a phenomenon economists refer to as time inconsistency means that, insofar as central banks are under the influence of the rest of the government, they may have an inflationary bias. This is associated with the fact that central banks have an incentive to break their own commitments to maintain low inflation rates because of the political

benefits of engaging in expansionary policies that provide greater output and employment in the short run (at the expense of higher inflation). As a result, countries that have more independent central banks also tend to have lower inflation (Cukierman 1992).

Government budget deficits can also act to constrain economic growth (Adam and Bevan 2005). Once the deficits rise over a certain level, the growing government financing needs can give rise to a wide array of negative consequences. Private investment may be crowded out by higher interest rates. And if the deficit is financed by borrowing, a ballooning external debt can raise country risk, leading to an expected currency depreciation and capital flight. If monetized, rising budget deficits can also lead to high inflation.

Currency regimes can provide a major boost to development or serve as a constraint. Both fixed and flexible exchange rate regimes have pros and cons (Agenor and Montiel 1999, chapter 7). Fixed exchange rates facilitate a stable trading environment that can foster exports and imports of goods and services. Therefore, among countries that are closely integrated, a fixed exchange rate regime or maybe even a common currency may be the optimal regime. But among countries that are not closely integrated, with substantial net flows of international capital, fixed exchange rate regimes become potentially subject to speculative attacks and to currency crises. Flexible exchange rates may allow the more stable management of capital flows and can serve as a policy instrument for the adjustment of relative prices. Furthermore, monetary policy loses its effectiveness in a regime of perfect capital mobility and fixed exchange rates. A mixture of fixed and flexible exchange rates may be the optimal outcome for some countries.

The variety of experiences with development policies reflects the complexity of development itself. As shown earlier, the links of development to the world economy are also complex and bring challenges as well as opportunities.

Washington, D.C.: International Monetary Fund. This report ex amines the impact of the liberalization of international financial flows on the economic growth and consump tion volatility faced by developing countries. Both the oretically and empirically, the authors find that financial liberalization has mixed effects. The overall impact on growth may be tenuous and the impact on volatility could be negative for some countries. They suggest that more positive effects of international financial liber alization may be obtained by countries that have the adequate institutions and domestic absorptive capacity necessary to handle the liberalization.

Rivera Batiz, Francisco L. 1983. "Trade Theory, Distribu tion of Income, and Immigration." *American Economic Review* 73 (2): 183 87. This paper examines the theo retical arguments of how migration affects the distribu tion of income. It concludes that although in the short run immigration can reduce wages in the host country and emigration can raise wages in the source country, there are long run forces that reverse these effects. As a result, the long run impact of migration on wages in host and source countries may be minimal.

Examining the causes and consequences of the East Asian financial crisis, the au thors argue that the crisis was precipitated by the impact of massive, unrestricted capital inflows in the late 1980s and the 1990s. These inflows generated inflation, a de terioration of domestic competitiveness in interna tional markets, current account balance deficits, and increased indebtedness, all of which eventually led to expectations of devaluation and to the massive exodus of the foreign capital, precipitating exchange rate and financial crises.

. 2002. "Democracy, Governance and Economic Growth: Theory and Evidence." *Review of Development Economics* 6 (2): 225 47. This article shows the theory and evidence on how democracy is related to growth. The conclusion is that the most important determinant of economic growth is the quality of the public sector governance in a country, independent of its political rights situation. However, evidence is also presented that, in the long run, having a larger number of demo cratic institutions is connected to greater quality of governance.

"The Effects of Direct Foreign Investment in the Presence of Increasing Returns Due to Specialization." *Journal of Development Economics* 34 (1): 287 307. This paper shows the theoretical connections between direct foreign investment and host country economic welfare. It demonstrates how foreign direct investment can provide positive gains to the host country through its employment effects as well as the potentially positive spillovers associated with the increased demand for local producer services by the foreign companies.

Rodrik, Dani. 1995. "Getting Interventions Right: How South Korea and Taiwan Grew Rich." *Economic Policy* 20: 55 107. This article examines why South Korea and Taiwan have been able to generate rapid growth. The author concludes that although the popular explanation has relied on export promotion and trade liberalization, the main factor that led to the economic miracles in these countries was increased investment rates (in physical and human capital), spurred by a wide array of government policies and incentives.

Rodrik, Dani, and Ricardo Hausmann. 2006. "What's So Special about China's Exports?" Working Paper RWP06 001. John F. Kennedy School of Government. Cambridge, MA: Harvard University. Examines the extent to which China's exports consist of products that have the technological sophistication of goods usually produced by higher income countries. The authors find evidence that, despite the popular view of Chinese exports as cheap, low technology products, a significant portion does consist of goods with substantial technological sophistication.

This article examines the links between increased international trade and economic growth. By developing a comprehensive index of openness to international trade, the authors are able to examine empirically the connection between such openness and economic growth in a cross section of countries. They find a strong, positive connection between openness and growth.

. 1995b. "Natural Resource Abundance and Economic Growth." NBER Working Paper No. 5398. Cambridge, MA: National Bureau of Economic Research. This paper studies the empirical connection between exports of natural resources and economic growth. Surprisingly, it finds that countries that have a greater share of natural resources in their exports tend to grow more slowly, holding other things constant.

Sala i Martin, Xavier, and Arvind Subramanian. 2003. "Addressing the Natural Resource Curse: An Illustration from Nigeria." Working Paper WP/03/139. Washington, DC: International Monetary Fund. This article examines why the oil exporting country of Nigeria has been unable to develop economically since oil reserves first began to be exploited decades ago. Although several hypotheses are explored, the authors conclude that the most significant factors were the low quality

public sector governance prevailing in the country and the increased corruption associated with the rent seeking connected to the oil exports.

■ economies of scale

International trade theory recognizes three fundamental reasons for countries to trade: *comparative advantage* (to exploit differences in countries' tastes, technologies, or factor endowments), *economies of scale* (to concentrate on fewer tasks in order to produce more efficiently), and *imperfect competition* (to expose firms to more competition). Comparative advantage has always been dominant in trade theory, although economies of scale also long played a secondary role. This changed in the late 1970s, when economists realized that the lion's share of world trade consisted of the exchange of similar (manufactured) goods between similar (rich) countries.

A common reaction to this realization was that such trade could not be due to comparative advantage. But if similar countries trade similar goods, price elasticities (the sensitivities of demands and supplies of goods to price variations) are likely to be high since the traded products will likely be good

substitutes. Similar countries would have similar relative prices in autarky (the absence of international trade), so comparative-advantage trade, establishing a world price between the two autarky prices, would imply a modest price change in each country. But, with high elasticities, this could still involve heavy trade. Likewise, dissimilar countries trading very distinct goods   manufactures for primary products, for example   could be expected to experience large price changes, but the resulting trade volumes could be small as price elasticities are likely to be low.

So, comparative advantage was not necessarily inconsistent with actual trade. Nevertheless, it was important to consider alternative possibilities because, although trade to exploit differences does *not* imply that the greater the differences, the greater the trade, it does imply, other things being equal, that the greater the differences, the greater the *gains* from trade. Thus one might conclude that the smaller part of world trade   that between dissimilar countries in quite different products   is more important for policy. But if trade patterns are significantly due to something other than comparative advantage, this conclusion need not follow.

Increasing returns to scale (IRS) and imperfect competition supply alternatives. This article considers the former, often also referred to as economies of scale.

Types of Scale Economies In practice, scale economies occur in great variety, so a classification of the more important attributes is useful.

Internal versus external (to the firm). Scale economies are internal if the individual firm can reduce average costs by operating at a higher scale (e.g., assembly-line operations and equipment made possible by large-scale production). They are external if the individual firm operates subject to constant returns to scale (CRS), but costs are lower the larger the industry in which the firm is located (e.g., well-developed infrastructure and a large supply of skilled workers consequent on a large industrial sector). Internal economies are inconsistent with a perfectly competitive equilibrium, and external economies are, well, externalities. Since the theory of compara-

tive advantage assumes perfect competition and no externalities, trade due to economies of scale alone *cannot* be comparative-advantage trade.

National versus international. Economies of scale may depend on the scale of operations within a nation (e.g., large plant size) or on the scale of operations globally (e.g., division of labor and free trade in intermediate goods). Either might be internal or external to the firm. An example of internal, international economies of scale is research and development (R&D) by a multinational firm that utilizes the results of the R&D in several countries.

Aggregative versus disaggregative. Increasing returns may be a property of manufacturing generally (e.g., the size of the industrial sector) or of individual manufactured goods (e.g., the number of red sedans).

These three considerations generate eight types of scale economies, each relevant in reality. Comparative-advantage trade can also be due to many causes, but they all matter *solely* in terms of how they influence differences in relative autarky prices. This imparts an attractive formal unity to that theory's predictions. Trade due to economies of scale is dramatically different: Basic implications are indeed very sensitive to the *type* of scale economy. Consider first national, aggregative, increasing returns external to the firm.

National, Aggregative Economies of Scale External to the Firm IRS can furnish a basis for trade independent of comparative advantage. Consider a simple model with two identical economies with two-good Ricardian technologies. Good A is produced with CRS, with one unit of labor required in each country to produce one unit of A. The B sector has IRS external to the firm: $B = k(L_B)L_B$, where $k(L_B) = k_0(L_B)^{\alpha - 1}$ for $\alpha > 1$. The individual firm takes k as a parameter.

Two such identical countries will have equal relative autarky prices. But there is still a basis for trade: with IRS in the B industry it is not globally efficient for both countries to produce both goods.

The no-trade case, with each country doing what it had done in autarky, is a free-trade equilibrium. But it will not be a very stable one. For suppose the home economy produces more B, and the foreign

economy less. Then k is greater than k^*, the foreign analog, so home B firms can undersell their foreign rivals, while the two countries can still produce A on equal terms. Home B producers can increase their market share at the expense of their foreign competitors, so foreign resources move into the A sector. Thus k rises further and k^* falls, increasing the home B advantage still more. This continues until a new equilibrium is reached with the home economy producing only B and/or the foreign economy producing only A. Indeed there is more than just a second equilibrium: since the two countries are identical we can find a third equilibrium by simply reversing the home and foreign roles.

The basic idea behind comparative advantage is that countries should do what they can do relatively well; this implies some particular role in the world economy. Scale economies on the other hand require countries to concentrate on a small number of tasks; who does what is secondary. Thus scale economies introduce a bias toward a multiplicity of equilibria.

The other equilibria might involve one country specialized in B and/or one specialized in A. Consider an equilibrium in which the home country specializes in B, with the (identical) foreign economy producing both goods. Since $k > k^*$, foreign wages must be lower than home wages and also lower than wages in autarky, so foreign real income must have declined. Likewise, the home wage must have risen relative to autarky. Thus trade has benefited the home economy, but has made the foreign worse off. There is also a "mirror-image" equilibrium in which the roles of the two countries reverse. Thus potential international conflict is inherent. We might call this the Graham case since it corresponds to Graham's (1923) argument for protection.

Suppose now that, instead, the dynamic adjustment ends with the foreign economy specialized in A and the home economy producing both goods. Since both countries produce A, wages must be the same internationally, in sharp contrast to the Graham case. Thus residents of both countries fare the same, and that common fate must be an improvement over autarky, since the home B sector has grown. There will again be another "mirror image" equilibrium,

but unlike the previous case this is of no consequence, because everyone fares the same regardless of country of residence. With identical economies, a wage-equalization equilibrium is associated with a large world equilibrium demand for A, so that one country alone cannot satisfy it. But with dissimilar countries, it is easy to construct examples in which either the larger or the smaller country specializes in A, and in which both countries lose relative to autarky.

The final possibility is that both countries specialize. Then the international equilibrium is efficient, unlike the other cases, where too little B is produced. The various types of equilibria are not mutually exclusive. That is, if tastes, technology, and size imply multiple equilibria, the equilibria could be of different types. It is the possibility of wage equalization and (especially) Graham equilibria that produces the real value added that can come from consideration of IRS. These equilibria can produce positive and normative implications in sharp contrast to those of comparative advantage and can therefore be used in support of quite different policy recommendations. They are of direct relevance to the old debates in developing countries over the wisdom of participating in the international trading system.

But this analysis of national external economies of scale is less than fully satisfying and has accordingly had to play a role very much subservient to that of comparative advantage. The indeterminacy of results due to the likelihood of multiple equilibria renders the theory cumbersome to use. Also, this investigation of scale economies was motivated in large part by a desire to address more directly a world in which the lion's share of trade consists of the exchange of similar commodities between similar economies. But the influence of scale economies, enhancing the possibility of specialization, and perhaps causing initially similar economies to become very dissimilar, is to move the discussion in just the opposite direction. Additional methods of modeling scale economies are needed.

Disaggregative Economies of Scale Consider now the same model as above, *except* that the B sector now consists of n distinct varieties, B_i, each with the technology described above. Note the following concerning international trade in such a model.

1. Wage equalization equilibria will again feature both countries producing some A, but no variety of B in common, so that both are equally well off with free trade. If one country specializes in A all trade will consist of the *inter*industry exchange of A for B, but if both countries produce some varieties of B there will also be an *intra*industry exchange of B varieties. We would expect the latter to be relatively more important the more similar the two countries are: if the two are exactly alike, there will be an equilibrium with only intraindustry trade.

2. Graham equilibria can still emerge whenever the two countries produce some variety of B in common but in different amounts. The country with the larger production must have the higher wage and therefore cannot be producing any A. However this now seems like a much less likely outcome than before, since a smaller B sector than in autarky need not condemn a country to a lower wage: it can just produce a smaller number of varieties while fully supplying the world demand for each.

International Economies of Scale External economies have often been identified with an increased division of labor made possible by a larger market: Adam Smith's pin factory and the Swiss watch industry are the prominent hoary examples. Less common are examples having to do with a larger volume of public information generated by a larger industry. In principle none of these requires an industry to be physically located in one place. A dispersed industry can realize a great division of labor if intermediate components can be shipped from place to place; public information can be dispersed within the industry if communication is efficient. What matters, under these conditions, is the global size of the industry, not its geographical concentration.

This suggests that returns to scale may depend on the size of the *world* industry, not the national industry. This is what is meant by *international* returns to scale. Suppose that resources are used to produce A and m. A production is characterized, as in the above

one-factor models, by CRS; m is an index of the scale of operations of the national B industry, subject to IRS. With *national* returns to scale, national B production B is related to m by

$B = km$ where $k = k(m), k' > 0.$

With *international* returns to scale, on the other hand, we have instead

$B + B^* = k(m + m^*)$ where
$k = k(m + m^*), \ k' > 0.$

Here an asterisk refers to the foreign country.

At first glance it might seem that we have complicated matters enormously. National production-possibility frontiers between final goods are not even defined, because productivity in each country's B industry depends on the size of the other country's B industry. But the situation becomes almost transparent as soon as we focus on patterns of resource allocation rather than on goods.

To see this, consider the world production-possibility frontier between A and B. A point on it can be found by maximizing world B production for a given feasible volume of world A production, that is, by choosing m, m^* to

maximize: $B + B^* = k(m + m^*)[m + m^*]$
subject to:
$T(m) + T^*(m^*) = some \ specified \ value.$

T and T^* denote the home and foreign production-possibility frontiers between A and m. Clearly, $B + B^*$ will be maximized by maximizing $m + m^*$: This problem has exactly the same solution as that of choosing m, m^* to

maximize: $m + m^*$
subject to:
$T(m) + T^*(m^*) = some \ specified \ value$

and the solutions to problems of the latter sort are just the comparative advantage predictions. Efficient patterns of world activity in A and B correspond to efficient patterns in A and m, ignoring the scale economies.

Productive efficiency is as with CRS, and firms behave competitively because the economies are external to them. The result is that the complex tendencies associated with Graham equilibria when scale economies are national disappear when they become international.

The second major implication of international IRS is that they imply a theory of the intraindustry exchange of intermediate goods between relatively similar economies. The essential idea behind international IRS is that a dispersed industry can realize the benefits of a large division of labor if intermediate goods can be shipped within the industry. Thus the more nearly equal in size m and m^* are, the greater the volume of intraindustry trade in B components.

All trade will be interindustry if the disparity between countries is great enough for the A exporter to specialize completely in A. Small international differences reduce the incentive for interindustry trade but cause the integrated B industry to be divided relatively evenly between countries, thereby inducing intraindustry trade. In the limiting case where the countries are identical, they will both be self sufficient in A. But they can gain from trade by establishing a single, rationalized B industry; all trade will be intraindustry.

Applications of Scale Economies Economies of scale can be a basis for trade, just like comparative advantage. But they can give a very different picture of the consequences of such trade. This has clearly emerged from recent work in the area.

The notion of international economies of scale, developed by trade theory, has been used to rejuvenate the theory of economic growth, as in the work of Romer (1986). If the division of labor is limited by the extent of the market, it is reasonable to suppose that indivisibilities in the production of intermediate goods is the reason why. So there is a role for imperfect competition with regard to the latter.

Imperfect competition and scale economies have been investigated in the context of both consumer goods, by Krugman (1979), Lancaster (1980), and Helpman (1981), and producer goods, by Ethier (1982a). As this literature does involve imperfect competition, it is beyond the scope of the present entry. More recently, scale economies have been central to the literature on trade with heterogeneous firms, as in the work of Melitz (2003).

Though scale economies were in trade theory from the beginning, their role was basically tangential until the late 1970s. Now it is central.

■ effective exchange rate

The effective exchange rate is a summary measure of the rate at which a country's currency exchanges for a basket of other currencies, in either nominal or real terms. Effective exchange rates become relevant when a country conducts trade and investment transactions with a number of other countries. These rates can vary along several dimensions, including country coverage, weighting, and whether or not the effect of inflation is taken into account (i.e., the distinction between nominal and real). The final selection of the appropriate definition and calculation of the effective exchange rate depends on a rather complicated interplay of the theoretical model of interest and data availability and reliability.

The first issue to confront in calculating an effective exchange rate is how to attribute relative weights to each of the partner currencies. In many circumstances, the exchange rate plays the role of a relative price of traded goods; hence, the relevant weights involve trade weights. Asset trade has become more prominent in recent decades, suggesting that the appropriate weights may be related to the assets owed by, or liabilities owed to, other countries.

Trade-Weighted Effective Exchange Rates By far the most common means of calculating an effective exchange rate is to weight the currencies by trade weights. To fix concepts, consider a geometrically weighted average of bilateral exchange rates.

$$s_t^{effective} \equiv \sum_{j=1}^{n} w_j s_t^j \tag{1}$$

$$q_t^{effective} \equiv \sum_{j=1}^{n} w_j q_t^j \tag{2}$$

where $s^j (q^j)$ denotes the log nominal (real) exchange rate relative to country j. The weights w_j are usually based on bilateral trade volumes (the sum of exports and imports, expressed as a proportion of total exports and imports).

Trade weighting can take on a more complicated form to allow for competition in third markets, however. This goal is usually accomplished by adopting the Armington (1969) assumption that goods are differentiated by location of production. The third market weight is equal to the weighted average over all third-country markets of country j's import share divided by a weighted average of the combined import share of all of country i's competitors, with the weights being the shares of country i's exports to the various markets. This simple expression is based on the assumption that all the differentiated goods share the same constant elasticity of substitution, which may not necessarily be appropriate in all instances (Spilimbergo and Vamvakidis 2003). For instance, goods originating from less-developed countries may not be equally substitutable with goods originating from industrial countries. Moreover, these weights can change over time continuously or discretely and infrequently, with the choice depending in large part on the trade-off between convenience and accuracy.

Nominal versus Real Often the economist will encounter a model wherein the real, or inflation-adjusted, exchange rate plays a central role. There are a number of real exchange rates, or "relative prices," that appear in the literature, however, so there is

ample scope for confusion. A decomposition of the most standard definition is useful. In this definition, the real exchange rate is given by:

$$q_t \equiv s_t - p_t + p_t^* \qquad (3)$$

where s is the log exchange rate defined in units of home currency per unit of foreign currency.

Most models of the real exchange rate can be categorized according to which specific relative price serves as the object of focus. If the relative price of nontradables is key, then using a broad price index encompassing tradables and nontradables is implied. One example of the use of a broad index is in productivity-based explanations of the real exchange rate such as the Balassa-Samuelson model. If, on the other hand, external balance (i.e., current account balance) is of paramount concern, some narrower index of traded goods may be the appropriate deflator. This variable is also what macroeconomic policymakers often allude to as price competitiveness a weaker domestic currency (in real terms) means that it is easier to sell domestic goods abroad. A related concept is cost competitiveness. Assuming a cost-markup model of pricing (i.e., prices equal some markup over cost), one can calculate a measure of the real effective exchange rate where unit labor costs are used instead of prices (Golub 1994). This real exchange rate is best thought of as a measure of the relative *production cost* rather than price of goods.

In practice, one has a choice of only a few price deflators. At the monthly frequency, they include the consumer price index (CPI), the producer price index (PPI) or wholesale price index (WPI), or the export price index. At lower frequencies, such as quarterly data, the set of deflators increases somewhat, to include the gross domestic product (GDP) deflator and price indexes for the components of GDP, such as the personal consumption expenditure deflator. Typically, the CPI weights nontraded goods such as consumer services fairly heavily. Similarly, the GDP deflator and the CPI will weight expenditures on nontradables in proportion to their importance in the aggregate economy. In contrast, the PPI and WPI exclude many retail sales services that are likely to be nontraded.

The unit labor cost deflated index is in a sense the most relevant for many issues related to trade, as unit labor costs are a measure of cost competitiveness. Unfortunately, there are many difficulties with using such indexes. First, unit labor costs (ULCs) are not always available on a timely or consistent basis, and are subject to substantial revisions. Second, their greater covariation with the business cycle impedes discerning trends in the ULC deflated series. Third, measured ULCs usually pertain only to manufacturing sectors, and given the increasing tradability of services, measured ULCs may provide misleading inferences. Fourth and perhaps most important, ULCs are typically available on a consistent basis for developed economies, so that ULC deflated effective exchange rates can be calculated only against a reference group of countries that may not, in the end, be the relevant group.

Asset and Liability Weights In the preceding discussion, it has been taken as a given that the appropriate weights are those associated with trade flows. Yet there is no reason why trade weighting should be appropriate for all questions. The economists Cedric Tille, Hélène Rey, and Pierre-Olivier Gourinchas have pointed out that exchange rate changes have had substantial effects on the net international investment position of the United States. Tille (2003) noted that because U.S. assets are predominantly denominated in foreign currencies, while U.S. liabilities are mostly denominated in dollars, dollar depreciation induces a large upward effect on the dollar valuation of U.S. foreign assets. Hence, over the short to medium term, the net international investment position is heavily influenced by dollar movements.

■ effective protection

Effective protection measures the change in value added per unit of output induced by tariffs and other policy measures on competing imports and inter mediate inputs. The concept has been widely used by trade economists and policy analysts interested in investigating trade policies' protective effects on do mestic production activities. They recognize that trade policies affect both the price of a good produced domestically and the price paid for any inputs in volved in producing that (final) good. The gross price of the final good is raised by a tariff on competing imports, giving rise to apparently positive protection in nominal terms and an incentive to increase pro duction. The net price or value added in the activity may still be reduced even where there is positive nominal protection, however, if the price-raising effects of tariffs on intermediate inputs more than offset the effects of the final output tariff.

Economists had long recognized the danger of focusing on output tariffs to analyze the protective effects of a tariff structure, but it was Max M. Corden (1971) who systematically organized his and others' seminal contributions during the 1960s into an in tegrated theory of effective protection.

Modeling of the Concept Within a partial equilibrium modeling framework with fixed tech nologies (no scope to alter the mix of factor and material inputs) and tradable inputs only, effective protection can be measured using information on output (t_j) and input (t_i) tariff rates and technological or input share coefficients under free trade conditions (a_{ij}). The resulting measure of effective protection (e_j) summarizes the impact of the tariff structure on value added in each activity and indicates the corre sponding production and resource allocation effects. For the single input and single output case:

$$e_j = \frac{t_j - a_{ij} t_i}{1 - a_{ij}} \qquad (1)$$

From equation (1) some key insights of the con cept can be derived. Effective protection is positively related to the output tariff and negatively related to the input tariff output tariffs implicitly subsidizing activity j and input tariffs taxing it. Effective pro tection can be positive or negative depending on the

structure of protection (whether output tariffs are greater or smaller than input tariffs) and on the shares of intermediate inputs. Further, the effective rate of protection will exceed the nominal tariff rate if there is an escalating tariff structure, with output tariffs higher than input tariffs, the effects of tariff escalation being magnified the higher the share of intermediate inputs (or correspondingly the lower the degree of domestic value added). Indeed, with sufficiently steep tariff escalation and highly (imported) inter-mediate-dependent activities, value added at world prices (i.e., in the absence of tariffs) can be negative.

Measurement and Application The effective protection concept seeks to provide a framework for thinking systematically about the structure of tariffs and other trade policy measures, and the resulting structure of protection and incentives. It offers a coherent explanation of why tariff escalation is a widely observed feature of trade regimes. It offers an explanation also of why the degree of actual and perceived protection may vary substantially across different types of activities and sectors. Since a given product (e.g., steel) can be a final product of one set of producers (steel producers) and an input good for another set (e.g., car manufacturers), it is not possible to ensure an escalating tariff structure for all pro-ducers. Therefore, the effective rate of protection is an analytical tool that offers an explanation for both idiosyncratic features of trade policy regimes and systematic biases: the possibility of high rates of ef-fective protection for many import-substituting ac-tivities but, at the same time, low negative rates for specific activities. Similarly, evidence has been found of systematic biases in favor of final goods production and against intermediate goods, as well as in favor of import-substitution activities and against export ac-tivities, both of which can be understood and quantified using the effective protection framework.

Following Corden's developmental work, a gen-eration of applied trade economists sought to mea-sure effective protection (mainly within the partial equilibrium modeling framework described earlier) and to use these measures for trade policy appraisal purposes, in particular but not exclusively in a de-veloping country context. Its tractability was attrac-tive for applied work. It can be applied at the firm or industry level, and it is relatively straightforward to allow for the complexities of multi-input and output activities, factor in nontraded inputs, distinguish sales of final goods to protected domestic markets from those to unprotected export markets, and ac-count for a range of taxing and subsidizing effects induced by policy instruments other than tariffs. Compared with applied and economywide general equilibrium models, partial equilibrium estimates have relatively limited data requirements. In addition to tariff data (and possibly other policy information), the main data requirement is information on the technology or input share coefficients available from input-output tables or firm-level surveys.

Following the major multicountry studies by Anne O. Krueger (1978) and Bela Balassa (1982), there was an explosion of developing country studies that measured and analyzed effective protection within a partial equilibrium framework (reviewed by Greenaway and Milner 1993). Although there has been a significant liberalization of trade policies in developing countries since the late 1980s, effective rates of protection are still measured and analyzed, including in the World Trade Organization's Trade Policy Reviews. There has also been a renewal of interest in the role of transportation and other non-trade policy sources of international transaction costs. These costs also have implicit taxing and sub-sidizing effects that can be represented and analyzed within an effective protection framework.

Theoretical Criticisms From the outset trade theorists, such as Ronald Jones (1971), who were interested in whether the interpretation of partial-equilibrium measures survived in general equilib-rium, closely scrutinized the concept of effective protection. A key assumption of the partial equilib-rium approach is fixed technological coefficients, and therefore no substitutability among material inputs and between material and factor inputs. Defining and interpreting changes in value added becomes more problematic if substitution is possible. This, and the wider limitations of using differences be-tween products or sectors in the scale of measured effective protection alone to comment on general

equilibrium resource pulls, led some economists to conclude that the concept was "fatally flawed." Others have been more willing to distinguish between the theoretically possible and the probable problems in practice. Some applied general equilibrium (AGE) modeling has compared the resource allocation effects of tariffs under alternative substitution assumptions, and the rank correlations between effective protection measures and tariff-induced production changes are not necessarily low. Effective protection measures do not necessarily, therefore, provide poor guidance on the allocative effects of tariffs. Further, in a review of the arguments, Greenaway and Milner (2003) point out that many applied economists have been careful to avoid interpreting differences between sectors or changes over time in measured effective protection as providing detailed and precise guidance on resource allocation effects. Rather, they have used the overall pattern of estimates to comment on the likely systematic biases and distortions of a trade policy regime and to offer guidance on the general direction of policy reform.

The development and refinement of economy-wide AGE models, and the associated developments in software that have eased their construction, calibration, and solution, have extended their use in trade policy evaluation. Where they are available, AGE models clearly give direct information on the resource allocation effects of trade policy changes. But the data demands of such models are high, even at the relatively high levels of product aggregation typically involved. The effective protection concept, and estimates of effective protection interpreted judiciously, will continue to be useful for analyzing trade policy regimes and their potential effects on incentives, resource allocation, and incomes. This will help to shed light on patterns of protection in the world economy.

■ electronic commerce

Electronic commerce, or *e-commerce*, has no settled definition. At its broadest, electronic commerce involves conducting business using most modern communication instruments: telephone, fax, television, electronic payment and money transfer systems, electronic data interchange, and the Internet. On September 25, 1998, the World Trade Organization (WTO) General Council adopted a broad view of electronic commerce in its work program on the subject: "The production, distribution, marketing, sale or delivery of goods and services by electronic means." In more recent times, the term *e-commerce* has become strongly associated with commercial activities on the Internet. For instance, the Organisation for Economic Co-operation and Development's discussions of e-commerce concentrate almost exclusively on Internet-based transactions.

341

In this article, electronic commerce is conceived of as conducting or facilitating business via electronic communications networks and computer systems. This includes buying and selling online, electronic funds transfer, business communications (including by telephone, facsimile, and internal data networks), and using computers to access business information resources. The WTO has recognized that commercial transactions can be broken into three stages: (1) advertising and searching, (2) ordering and payment, and (3) delivery. Common conceptions of electronic commerce involve business-to-consumer or business-to-business interaction at one or more of these three stages. Generally speaking, however, electronic commerce also encompasses activities that do not fit neatly into any one of these categories, such as electronic logistics tracking and business process outsourcing.

The Internet is of such critical importance to the world economy today that it necessarily dominates any discussion of electronic commerce. It offers greater possibilities for commercial interaction than do telephones or faxes, and has dramatically changed the way that information is exchanged and business conducted. The definition of electronic commerce adopted here deliberately extends beyond the Internet, however, not only to capture its predecessors, but also in anticipation of future technologies. If we have learned anything from the rapid development of computer and telecommunications technology over the last few decades, it is that what seems like an established technology today can quickly be replaced by another technology. The safest prediction about the future direction of technology is that it will be unexpected. Thus, as ubiquitous and permanent a feature of modern life as the Internet seems now, it may be replaced, and it is therefore appropriate to use a definition that is technologically neutral and forward looking.

The Economic Significance of Electronic Commerce Three factors contribute to the significance of electronic commerce to the world economy today: the rapid growth of the Internet, its ability to facilitate cross-border trade, and its ability to reduce transaction costs.

Although it became publicly accessible only with the inception of the World Wide Web in 1990, the Internet now has more than 1 billion users. In the early years of the World Wide Web, usage almost doubled from year to year, and it continues to grow. The benefit of conducting business online increases exponentially with the number of connections.

The Internet facilitates production and distribution across borders so that, for example, consumers in one country can respond to an advertisement published in another country for a product that was developed using a design team collaborating (using the Internet) in five other countries. Electronic commerce increases the range of services that can be traded internationally (e.g., medical, legal, educational, and gambling services) and can assist in opening markets that were previously closed. The dramatic increases in both online retail sales and advertising revenues are the most visible evidence of a much broader growth in electronic commerce in the global economy.

Electronic commerce has the potential to generate benefits beyond those of trade liberalization on its own. Benefits for suppliers and vendors include reduced transaction costs, reduced barriers to market entry, more rapid product innovations, and economies of scale. One source of reduced transaction costs is the possibility to dispense with traditional intermediaries (for example, in relation to the travel industry). In many cases, electronic commerce dispenses with the need for physical presence at the point of sale or for the provision of services, which can drastically reduce expenses relating to premises or personnel. Benefits for consumers include increased market transparency and reduced search costs, even if they make the final purchase in person. These benefits are particularly noticeable for consumers in smaller markets, who may not have enjoyed the same level of price and quality competition as consumers in larger markets. Challenges to increased consumer use of electronic commerce include concerns about information privacy and fraud, which have not been completely resolved. Governments also benefit from electronic commerce because it reduces the cost of

providing services to their citizens, while offering greater transparency and accountability.

These three factors have certainly altered the conditions in many preexisting markets for goods and services, but two markets are particularly useful in demonstrating these factors. First, consumer-to-consumer commercial transactions, facilitated by accessible online financial services, community, and auction sites, now have the potential to operate on a global, cross-border level. It is difficult to draw a bright line between consumer-to-consumer and business-to-consumer transactions, as the removal of many barriers to entry have allowed some consumers to play a role that was once available only to established global players. This reveals one reason for the exponential benefit of growth in the Internet's user base: unlike previous communications technologies, which facilitated one-to-one or one-to-many marketing and sales, Internet-based e-commerce allows a many-to-many business paradigm to become practicable.

Second, the market for digital products and services (those that can be supplied to the purchaser electronically) is arguably the most substantially affected by the growth of electronic commerce. Once they are provided in a digital format, goods such as music, movies, and software have negligible production costs for additional units and equally negligible delivery costs. Over the Internet, their delivery time is limited primarily by bandwidth and connection speed rather than distance or the speed of physical transport. Services that can now be provided digitally across borders are increasingly being outsourced to take advantage of cheaper labor markets. This phenomenon, called business process outsourcing, began in its modern incarnation with the outsourcing of software development to India. India remains the market leader in business process outsourcing exports today and has moved into many other areas such as sales and customer service call centers as well as intrabusiness services for example, information technology support and human resources. Other developing countries, such as Brazil and China, have also experienced strong growth in this area. As the uptake and speed of Internet con-

nections increase, the sale of digital products and services is likely to have a substantial impact on the world economy, not only in its own right, but also due to its disruptive effects on related "offline" industries.

Conversely, many factors militate against electronic commerce completely replacing traditional nonelectronic business models. Thus, despite its growth, the uptake of electronic commerce was slower than many expected. As mentioned earlier, the security of online payment and information transfer remains a primary concern. The market for digital products is especially affected by the lack of cost-effective micropayment methods (i.e., for low-value transactions). Additionally, due in part to the threat of fraud, or possibly more for sociological than economic reasons, many consumers and businesses prefer physical presence over electronic transactions, especially to conduct a physical inspection of goods before purchase. This has led to the perception that online retailers "freeload" off retailers with physical stock and showrooms, as customers can investigate the product in person in a retail store and then purchase it from an online store at a reduced price. Some manufacturers and suppliers refuse to sell to online retailers in order to protect their existing showroom-based retail outlets. Furthermore, although the growth of the Internet has been substantial, many use the Internet for recreational and communication purposes rather than commercial ones, and a majority of the world's population is still without regular Internet access.

Nevertheless, as electronic commerce matures and develops, it will undoubtedly play an increasingly important role in the world economy. Many of the impediments that it is presently facing are technological in nature, and given the speed at which new developments occur in information technology, it is only a matter of time before many of them are overcome.

The Role of the WTO Although electronic commerce involves new technology, at its heart it is simply another means of conducting international commercial transactions. Most countries have previously decided that such transactions should be dealt

with in the WTO. The advantage of locating electronic commerce within the WTO framework is that it provides a system of transparent, predictable, and enforceable rules. These rules are based on principles of nondiscrimination (most-favored-nation treatment [MFN] and national treatment) and transparency, which are as relevant to electronic commerce as they are to other forms of international trade. The WTO also has an established record of trade liberalization and takes an economic and commercial focus. This means that it is not particularly concerned with technology matters; rather it is intent on creating a system of trade agreements that apply to transactions regardless of the form of technology used to produce or deliver the product. Many WTO members share this belief in the principle of technological neutrality. It is important to scrutinize deviations from neutrality: for example, those resulting from the goods and services distinction created by the General Agreement on Tariffs and Trade (GATT) and the General Agreement on Trade in Services (GATS). Technological neutrality should not be used as an excuse for protectionism, however. The primary purpose of the WTO remains trade liberalization. Thus, for example, practices that liberalize trade in a good only where it has been created using a certain technology (i.e., technologically discriminatory liberalism) should be preferred to practices that create or maintain barriers to trade in that good however created (i.e., technologically neutral protectionism).

On May 20, 1998, during its second Ministerial Conference in Geneva, the WTO adopted a Declaration on Global Electronic Commerce, recognizing the growth of electronic commerce and its potential to increase international trade. The declaration directed the General Council to establish a comprehensive work program to examine all trade-related issues of global electronic commerce and to produce a report on the progress of the work program and any recommendations for action at the third Ministerial Conference of the WTO. The Council for Trade in Goods, the Council for the Agreement on Trade Related Aspects of Intellectual Property Rights (TRIPS), the Committee on Trade and De-

velopment, and the Council for Trade in Services each produced a report for the General Council in July 1999. The general view of members emerging from these and subsequent reports is that the electronic delivery of services falls within the scope of GATS, and that all the provisions of GATS apply to trade in services through electronic means. Members have not reached a consensus on issues such as the treatment of certain digitizable products, however, and work continues on resolving these issues. The General Council has held a number of dedicated discussions on "cross-cutting" e-commerce issues, in recognition of the fact that many e-commerce problems cut across a number of WTO agreements such as the GATS, GATT, and TRIPS. These discussions have covered topics such as the classification of digital products and the fiscal implications of e-commerce. The Councils for Trade in Goods, Trade in Services, and TRIPS as well as the Committee on Trade and Development have also held discussions on e-commerce issues relating to their respective mandates.

The general view of WTO members that GATS applies to electronic delivery of services and trade in services through electronic means is consistent with the prevailing academic view that electronic commerce, for the most part, falls under the purview of GATS. Many WTO members have expressed the view that all digital products should be classified as services so as to fall under GATS. GATS extends the scope of international trade obligations to cover services, which represent a significant and growing proportion of global trade. It imposes general principles of MFN treatment and transparency to services (subject to some exceptions), and it also provides for individual commitments by members to liberalization of trade in services, including commitments to provide market access and national treatment in specified service sectors.

Once WTO members agree on how to handle electronic commerce, WTO agreements and dispute settlement have the potential to profoundly aid or curtail the growth and impact of e-commerce, especially as regards cross-border trade. Other international bodies will also have an effect on the future

development of e-commerce, for instance the UN Working Group on Internet Governance. The proven effectiveness of the WTO in securing a degree of multilateral compliance with its international trade standards, however, makes it a key player in the regulation of electronic commerce.

Trends in Electronic Commerce A number of trends are evident in relation to electronic commerce that will affect the world economy. First, the value and number of digital products (e.g., music, books, and videos delivered electronically rather than physically) is likely to continue to increase. Second, communications technologies are gradually converging. If this trend continues, previously separate technologies such as the telephone, television, and the Internet may eventually be considered part of a single communications network. This would result in traditional media companies (such as television broadcasters) being compelled to shift to a more interactive, Internet-based model, and online vendors would benefit from greater reach to mobile and entertainment devices. Third, the Internet is continuing to affect consumer behavior. For example, consumers are spending more time and money online, and the value of their online purchases is increasing as they gain experience with online shopping and move to higher speed Internet. Fourth, transactions using notes and coins will continue to decline in favor of transactions using digital money. (Notes and coins make up only a small fraction of the total value of economic transactions, but they still comprise a significant proportion of the number of transactions.) Fifth, the growth in the business process outsourcing market has the potential to alter materially the structures and costs associated with many conventional businesses. Outsourcing specialized tasks to low-cost providers is becoming increasingly feasible, if not necessary, to compete on a global scale. This service, provided mainly by developing countries with cheaper labor, also has the potential to aid in integrating such countries into the global trading system.

The Role of Electronic Commerce in the Modern World Economy Electronic commerce will continue to play a significant role in the modern world economy in the coming years. Its potential will be limited, however, in the absence of a comprehensive understanding within the WTO or some other multilateral framework regarding how to treat international trade conducted using electronic commerce. So, too, may technological and regulatory limitations regarding issues such as privacy, financial security, and fraud hinder the development of electronic commerce beyond the level it has reached today. Experience with previous technologies and negotiations suggests that these hurdles will be overcome, however, particularly to the benefit of developing countries.

■ **equilibrium exchange rate**

Ever since the advent of floating exchange rates for the principle currencies in 1973, exchange rate misalignment has been an important issue for academics, practitioners, and policymakers. In flexible exchange rate regimes, exchange rates can spend long periods away from their equilibrium, or fair value, levels (that is, they can take long swings). Consequently, in order to understand whether exchange rates are misaligned or not, analysts need an underlying measure of equilibrium. How then may the equilibrium exchange rate be defined?

Purchasing Power Parity (PPP) Reconsidered
The equilibrium measure that many economists and policymakers first turn to is the concept of purchasing power parity (PPP). The PPP exchange rate is the ratio of some overall measure of domestic prices

relative to a comparable measure of foreign prices. Although there is controversy in the PPP literature regarding the correct measure of overall prices to use (e.g., consumer, wholesale, or some other measure) there is no longer a question about the "time dimension" of PPP. By this we mean how quickly exchange rates are expected to gravitate, or revert, to the PPP defined rate (MacDonald 2007).

Proponents of traditional PPP would argue that disturbances to PPP should be rapidly offset. But how rapidly should this be to be consistent with PPP? The classic disturbance that affects the relationship between the nominal exchange rate and relative prices is a liquidity disturbance, such as a monetary expansion. The latter, in the context of an economy in which there are sticky commodity prices, will not have an immediate effect on relative prices but would have their effect 18 months to 2 years thereafter. In this setting, therefore, a monetary shock is expected to move the real exchange rate in the short run, but the real exchange rate should revert to its mean value after around two years: a proponent of traditional PPP would argue that the so-called half-life of mean reversion would be one year.

There is now a huge empirical literature that indicates that the so-called half-life has a range of between three and five years, which is inconsistent with a traditional form of PPP; Rogoff (1996) labeled this the PPP puzzle. It is a puzzle because the stylized fact of the high volatility of real and nominal exchange rates is consistent with the interaction of liquidity shocks with sticky prices, but as we have seen, the slow mean reversion of real exchange rates is not.

Various attempts have been made to explain the PPP puzzle. One explanation, which is consistent with traditional PPP, is that the existence of transaction costs imparts a nonlinear process to exchange rate behavior, and when such nonlinear behavior is accounted for, real exchange rates behave in a manner that is consistent with traditional PPP they have a half-life of around one year. Such nonlinear explanations, however, are really nothing more than black box interpretations and are equally consistent with other interpretations of the PPP puzzle (MacDonald 2007). A second key explanation of the PPP puzzle,

which is not consistent with traditional PPP, is that real factors, such as productivity differences (usually motivated in terms of the Balassa-Samuelson effect) and a country's net foreign asset position, ultimately push real exchange rates away from their equilibrium values. A third key explanation of the PPP puzzle is the pricing-to-market behavior of multinational firms. Such firms, by altering their markup (in order to protect market share) as nominal exchange rates change, impart prolonged and persistent deviations from PPP. Although this latter view appears to capture an important determinant of the systematic behavior of real exchange rates, the second explanation may be more critical to understanding equilibrium exchange rates and, by implication, whether exchange rates are misaligned or not. We now consider these alternatives, all of which are based on an explicitly "real" interpretation of real exchange rate behavior.

Fundamental Equilibrium Exchange Rate The fundamental equilibrium exchange rate (FEER), developed by the economist Williamson (1983, 1994), is the rate at which both the internal and external balance are satisfied, where the internal balance is high employment and low inflation and the external balance is characterized as the sustainable desired net flow of resources between countries when they are in internal balance. The latter is usually derived by making some assumption about a country's net savings position, which, in turn, is determined by factors such as consumption smoothing and demographic changes. The use of the latter assumption, especially, has meant that the FEER is often interpreted as a normative approach and the calculated FEER is likely to be sensitive to the choice of the sustainable capital account. (The International Monetary Fund variant of the FEER approach attempts to remove the judgmental element in defining the desired capital account; see, e.g., Isard and Faruqee 1998; and Faruqee, Isard, and Masson 1998.) The FEER is an explicitly medium-run concept, in the sense that it does not need to be consistent with stock-flow equilibrium (the medium run is usually taken to be a period of about five years in the future).

There are essentially two widely used approaches to estimating a FEER. The first involves taking an estimated multicountry, macroeconometric model, imposing internal and external balance, and solving for the real exchange rate, which is then classified as the FEER. Such an approach is not very tractable and, consequently, by far the most popular method of generating a FEER involves focusing on a current account equation, setting it equal to a sustainable capital account, and then solving for the FEER (see Wren-Lewis 1992).

In addition to the difficulty in measuring a sustainable capital account, the calculation of trade elasticities has often meant that an extra layer of judgment has to be imposed before the FEER can be calculated. This is because the estimated trade elasticities often turn out to be effectively zero (see Goldstein and Khan 1985). Driver and Wren-Lewis (1999) assess the sensitivity of FEER calculations of the U.S. dollar, Japanese yen, and German mark to different formulations and assumptions. They find that two key factors impart a considerable amount of uncertainty into FEER-type calculations. For example, changes in the assumed value of the sustainable capital account (as a proportion of gross domestic product, GDP) of 1 percent can produce changes in the value of the FEER of around 5 percent. Since such changes in the capital account could easily be due to measurement error, this suggests caution in interpreting point estimates of the FEER. Although the FEER approach has been widely used by practitioners, the issues mentioned above often mean that it is used in conjunction with other measures of equilibrium.

Behavioral Equilibrium Exchange Rate The behavioral equilibrium exchange rate (BEER) approach of Clark and MacDonald (1998) is not based on any specific exchange rate model and, in that sense, may be regarded as a very general approach to modeling equilibrium exchange rates. As in the FEER-based approach, it takes as its starting point the proposition that real factors are a key explanation for the slow mean reversion to PPP observed in the data. In contrast to the FEER-based approach, the specific modus operandi of the BEER is to produce measures

of exchange rate misalignment that are free of any normative elements and in which the exchange rate relationship is subject to rigorous statistical testing.

To illustrate their approach, Clark and MacDonald (1998) take the risk-adjusted real interest parity relationship, which has been used by a number of researchers to model equilibrium exchange rates (see, e.g., Faruqee 1995; MacDonald 1997), where it is assumed that the systematic component of the real exchange rate is a function of net foreign assets, a measure of relative productivity, and the terms of trade. The approach is estimated using a vector error correction mechanism (VECM), which incorporates both dynamic interactions and long-run effects, and plausible measures of equilibrium have been reported for a number of real effective exchange rates (plausible in the sense that coefficients in the long-run relationship are correctly signed and statistically significant and also fast adjustment to equilibrium is reported).

Comparing the actual real effective exchange rate with the computed equilibrium gives a clear and sharp measure of misalignment. For example, the approach shows that the U.S. dollar was massively overvalued in the period 1980 86. It is worth noting that this finding is common to other BEER estimates (see, e.g., Faruqee 1995; MacDonald 1997; Stein 1999). It is also possible to calibrate the BEER with some normative structure placed on the fundamentals, much as in the FEER approach. The big advantage of the BEER, however, is that the influence of the normative elements is explicit as is the nature of the estimated exchange rate model and the adjustment to equilibrium. The BEER approach has been widely and successfully used for industrial countries, developing countries, and emerging markets.

Natural Real Exchange Rate The natural real exchange rate (NATREX) approach of Stein (1994, 1999) may be considered to be grounded in elements of the FEER and the BEER. It has similarities with the FEER because it appeals to an internal-external balance approach to motivate the model, and shares with the BEER what is essentially a reduced form approach in the empirical estimation. In the NA-

TREX, the sustainable capital account term is assumed equal to social saving less planned investment, where the key determinant of social savings is the rate of time preference and the key determinant of investment is Tobin's q. Additionally, savings are assumed to be a function of net foreign assets and investment a function of the capital stock, k. The inclusion of stocks in the flow relationships enables an equilibrium to be derived that is stock-flow consistent.

Stein (1999) proposes two forms of NATREX equilibrium. In "long-run" equilibrium the following criteria have to be satisfied. First, net foreign assets are constant and, in a nongrowing economy, the current account is equal to zero. Second, the capital stock is constant and the rate of capacity utilization is at its stationary mean. Real interest rate parity prevails, in the sense that real interest rates are equalized (since the real exchange rate is also in equilibrium, the expected change in the real exchange rate is zero). Finally, there are no changes in reserves or speculative capital movements. The difference between the medium- and long-run NATREX relates to the evolution of net foreign assets and the capital stock. As in the BEER approach, Stein (1999) uses a VECM to empirically implement the NATREX in a single equation context. The misalignment is then calculated as the gap between the estimated value of the VECM and the actual value.

New Open Economy Macroeconomic Class of Models Obstfeld and Rogoff (2001) have demonstrated how the New Open Economy Macroeconomics (NOEM) class of model can be used to calculate the currency movement needed to satisfy internal and external balance (where the latter is taken as a zero current account position). Specifically, it asks the question: How much would the exchange rate have to move to reduce a current account imbalance to zero? There are two key elements in this calculation: knowledge of the consumption elasticity of substitution, which governs how much relative prices have to move in response to changes in the relative consumption of home to foreign goods, and the required movement of the consumption of traded to nontraded goods. If a country has a current

account deficit as a proportion of GDP of 5 percent, for example, balance of payments statistics can be used to calculate how much the relative consumption of home to foreign goods has to move in order to return the ratio to zero. Given the elasticity of substitution, this adjustment can then be used to calculate by how much the exchange rate would have to move in order to facilitate the required consumption switch. The extent of exchange rate adjustment can be calibrated under different scenarios, such as sticky or flexible prices, pricing to market, or the inflation-targeting objectives of the central bank, and using different assumptions regarding the elasticity of substitution.

Since the NOEM approach requires little in the way of data, it would seem to offer a tractable way of calculating how much required exchange rate adjustment is necessary to achieve current account objectives. It may, therefore, be an appealing method of calculating equilibrium exchange rates for developing countries or transition economies where data constraints may make it difficult to implement some of the other approaches referred to earlier.

Other Approaches A somewhat different way of measuring equilibrium exchange rates is to use a time series estimator to decompose a real exchange rate into its permanent and transitory components and to interpret the permanent component as a measure of equilibrium and the distance between the permanent and actual exchange rate as the degree of misalignment. The permanent equilibrium exchange rate has been calculated using a variety of different econometric estimators. This approach often gives time series profiles of the equilibrium exchange rate, which are similar to those created using the BEER and NATREX methods, and is often used as a robustness check on estimates derived from these approaches.

To sum up, there is now a wide range of alternative real approaches to measuring equilibrium exchange rates. Indeed, central banks and practitioners often need to use a combination of these approaches when assessing whether a currency is over- or undervalued.

■ euro

The euro is the currency of the European Monetary Union (EMU). The euro (€) came into existence as an accounting currency on January 1, 1999, for 11 of the then 15 member countries of the EMU (Austria, Belgium, Germany, Finland, France, Ireland, Italy, Luxembourg, Spain, Portugal, and the Netherlands). Greece officially adopted the euro at the beginning of 2001. Britain, Sweden, and Denmark chose not to adopt the euro as their currency, but left the door open to do so in the future. The introduction of the euro marks the first time that a group of sovereign nations voluntarily gave up their individual curren cies in favor of a common currency, and it ranks as one of the most important economic events of the postwar period. Europe created the euro so that it could become a fully integrated economic market like the United States.

The official euro conversion rates for the curren cies of the original 11 members of the EMU were decided on December 31, 1998, by the Council of the European Union based on the recommendation of the European Commission (see table 1). Greece adopted the euro on January 1, 2001, at the con version rate of 340.750 drachmas to the euro. On January 1, 2002, the euro was introduced physically

as a circulating currency, and by February 28, 2002, it became the sole currency of the 12 members of the EMU, also known as the eurozone, euro area, or euroland. From January 1, 1999, until their final withdrawal, the national currencies of the participating countries had been locked against one another at the fixed exchange rates given in table 1.

The euro was introduced in 1999 at the value of $1.18 but, defying almost all predictions that it would appreciate to between $1.25 and $1.30 by the end of the year, it declined almost continuously to a low of $0.82 at the end of October 2000. Starting in February 2002, however, the euro appreciated almost continuously, reaching parity with the dollar in mid-2002 and a high of $1.44 at the end of October 2007. The euro exchange rate with respect to the Japanese yen followed a similar pattern of high volatility.

Euro as Legal Tender The euro is printed and minted, managed, and administered by the European Central Bank (ECB) and the European System of Central Banks (ESCB composed of the central banks of the member states) based in Frankfurt, Germany. The ECB has sole authority for determining the common monetary policy of the EMU.

Euro banknotes come in €500, €200, €100, €50, €20, €10, and €5 denominations, with the first two seldom used in everyday transactions. Coins come in €2, €1, 50 cents, 20c, 10c, 5c, 2c, and 1c, with the last two denominations seldom used.

Outside the 12 countries of the eurozone, the euro is the legal tender also of the ministates of Monaco, San Marino, and Vatican City (all of which can mint their own coins by agreement with the ECB). Andorra, Montenegro, and Kosovo, as well as eurozone overseas territories of French Guiana, Guadeloupe, Martinique, Mayotte, Réunion, and Saint Pierre et Miquelon also adopted the euro as their currencies, but they do not participate in the ECB or the ESCB.

In May 2004, 10 additional countries joined the European Union (EU), thus increasing its membership to 25 countries. The new members were Poland, Hungary, the Czech Republic, the Slovak Republic, Slovenia, Estonia, Lithuania, Latvia, Malta, and Cyprus. Bulgaria and Romania joined on January 1, 2007, and Albania, Bosnia-Herzegovina, Croatia, Macedonia, Serbia, Montenegro, and Turkey were negotiating accession. The Accession Treaty for the 10 new member states requires them to adopt the euro when they meet some strict criteria, such as a budget deficit not exceeding 3 percent of GDP, a government debt not exceeding 60 percent of GDP, a low inflation rate, an interest rate close to the EU average, and a fairly stable exchange rate. Slovenia adopted the euro on January 1, 2007, but the other new members were not expected to adopt the euro for several more years.

Euro as an International Currency From its birth, the euro was destined to become an important international currency because the EU (1) is as large an economic and trading unit as the United States, (2) has a large, well-developed, and growing financial market, which is increasingly free of controls, and (3) is expected to have a good inflation performance that will keep the value of the euro stable. If the international use of the euro were to match the EU's share of world GDP, exports, and financial market, the euro would become as important as the dollar as an international currency. This would mean that the

relative international use of the dollar would fall to 40 45 percent of the total (from 55 60 percent in 2007), with an equal share going to the euro and the remainder going mostly to the yen and a few other smaller currencies, such as the Swiss franc, the Canadian dollar, and the Australian dollar but mostly the yen.

There are equally good reasons why the euro probably will not displace the U.S. dollar as the leading international currency in the short term. These are: (1) most primary commodities (especially petroleum) are priced in dollars, (2) most non-European countries are likely to continue to use the dollar for most of their international transactions for the foreseeable future, with the exception the former French colonies in West and Central Africa; and (3) sheer inertia, which favors the incumbent (the U.S. dollar).

■ Eurocurrencies

Eurocurrencies are domestic currencies of one country on deposit in a second country. More precisely, the term *Eurocurrency* means the currency denomination of a bank deposit or loan that is on the books of a bank situated outside the currency's country of origin. For example, large amounts of U.S. dollar deposits and loans are booked in banks located in London, Frankfurt, Tokyo, Singapore, and many other international financial centers. Eurocurrencies are on the books of major banks with international operations, but not necessarily banks headquartered in the Eurocurrency's country of origin. For example, Eurodollar deposits and loans are offered by banks of many home jurisdictions, not just by offshore branches and subsidiaries of American banks.

More than 70 percent of the world's Euro-currencies are in U.S. dollars, with the rest in euros, yen, British pounds, Canadian dollars, Swiss francs, and Australian dollars. Individually they are often called Eurodollars, Euroeuros, Euroyen, and so on. The prefix *Euro* is an anachronism, since large amounts are booked in banks outside Europe. For a time, dollar deposits in Japan were called "Juro-dollars," Singapore "Singdollars," and so on, but the generic term *offshore* for these deposits and loans has become more common.

Eurodollar deposits were first offered in the 1950s by London- and Paris-based banks (particularly the Moscow Narodny Bank in London and the Banque Commerciale pour l'Europe du Nord in Paris) in order to accommodate the desire of the Soviet Union and other communist countries to avoid holding their large dollar surpluses in the United States. But the Eurodollar market first expanded to international

significance with the incursion of U.S. corporations into Europe in the 1960s. An added impetus was the imposition in the mid-1960s of a ban on U.S. corporations' borrowing in the United States for operations abroad, reflecting concern about a growing balance of payments deficit. U.S. firms quickly discovered that they could circumvent these regulations by borrowing in dollars from London-based banks. What began mostly in London with Eurodollars soon spread to the world's major financial markets and to other major currencies.

Causes of Growth The long-term growth of the Eurocurrency market was driven neither by politics nor by regulatory worries, but instead by economics. From the beginning, the British authorities set a precedent by not attempting to regulate Eurocurrency banking. To this day, in all of the world's major financial centers, neither home- nor host-country regulators impose any of the costly burdens that they place on domestic banks: requirements such as holding noninterest-bearing reserves, interest rate controls, deposit insurance, or high taxes. Typically also, restrictions on the entry of new banks are minimal. Moreover, "Eurobanks" that is, the international departments of big banks that offer offshore deposits accept only wholesale deposits, mostly $1 million or more. As a result of all these regulatory and economic advantages, Eurobanks are able to offer interest rates on deposits that are higher than in the currency's home country, and also interest rates on loans that are lower. In short, the "spreads" between loan and deposit rates are lower on Eurobanks' offshore deposits than at home.

A major impetus for growth of Eurobanking came with the virtual doubling of oil prices in the fall of 1973. In the context of heightened tension with the United States over its support for Israel, Middle Eastern oil exporters deposited much of their expanding oil revenues in Eurodollars in London. At the same time, oil-importing countries were hungry for hard currency loans. The Eurocurrency market expanded rapidly to meet this demand. Doomsayers had predicted disaster if the oil revenues were not "recycled." The International Monetary Fund (IMF) had until then been the conventional lender to deficit countries but lacked capacity to recycle such unprecedented amounts. The Eurocurrency markets grew seamlessly and saved the day.

By the late 1970s, the value of Eurodollar deposits exceeded the value of dollar deposits within the U.S. banking system. In December 1981, U.S. banking legislation was revised to allow U.S. banks to offer "international banking facilities" (IBFs) that is, dollar deposits and loans to nonresidents of the United States and to other IBFs that are immune from U.S. regulatory requirements. Hence U.S. banks could offer deposit and loan rates competitive with the larger Eurodollar markets in London and elsewhere. More than 75 percent of U.S. IBF banking is in New York, with almost all the rest in California and Illinois.

Interest Rates The Eurocurrency markets virtually pioneered the offering of long-term loans with floating interest rates. They "unbundled" the usual package, which fixed loan rates for the term of the loan. Eurocurrency deposits typically mature every 30 to 90 days; so to induce rollover of existing deposits, or to attract new deposits, current deposit rates must be paid.

Eurocurrency loan rates are usually revised every three to six months, based on current deposit rates. This protects banks from the interest rate risks of long-term maturity mismatching. More precisely, loan rates (in London) are based on the London Inter Bank Offered Rate (LIBOR), which is reset daily at the median rate that top-tier London-based Eurobanks offer to pay other banks for short-term deposits. Other offshore financial centers quote rates close to LIBOR. LIBOR is usually slightly above the rate paid on deposits from nonbank customers since interbank deposits can be acquired on demand, within minutes. In effect, Eurocurrency loans are based on banks' marginal cost of raising new funds. The actual rates charged are LIBOR + , where the premium varies from borrower to borrower depending on credit risk. Very creditworthy customers can borrow at LIBOR or even, occasionally, slightly below. In this sense, LIBOR is like the "prime" rate in the United States and other domestic markets, with the major difference that it is marked to market daily. Much of the Eurodeposit market is securitized: they

are certificates of deposit that are traded continuously; hence their yield varies continuously.

The practice of making long-term loans with variable rates was a key trigger for the so-called international banking crisis of 1982–89. In early 1980, the newly installed chairman of the U.S. Federal Reserve System, Paul Volcker, declared war on inflation, which had risen to double-digit levels in the United States and elsewhere. He more than doubled short-term interest rates, from about 10 percent to more than 20 percent. Because of the tight linkages to Europe and the rest of the world via competition between New York and London for Eurodollar deposits, short-term rates, based on LIBOR, doubled worldwide. By 1982, middle-income countries in East Asia, Eastern Europe, and especially Latin America had borrowed heavily via syndicated loan packages put together in the Eurocurrency markets. They were paying LIBOR + on their loans. By late 1981, their debt service burdens had doubled. This triggered a series of severe slowdowns and partial defaults, beginning with Mexico in August 1982.

Size of Market The size of the offshore markets including interbank loans as of 2007 was roughly $2 trillion in London, $1.5 trillion in New York, $1 trillion in Germany, and more than $0.5 trillion each in the Cayman Islands, Switzerland, and Japan. Net of interbank loans, the numbers are only about one-quarter of these. In other words, London Eurobanks had roughly $0.5 trillion worth of loans to nonbanks on their books in 2007. Nevertheless, interbank loans are important because they constitute the core of the world's trading in foreign currencies. Foreign exchange trading is part and parcel of the enormous offshore interbank market because Eurobanks typically find themselves with more deposits than loans in any particular currency, or vice versa. Also, unlike domestic retail banks, they often negotiate loan agreements before obtaining funding for them. For both reasons, Eurobanks trade trillions of dollars of deposits daily.

For example, a Japanese bank in London may find itself with $2 billion worth of yen deposits but only $1 billion worth of yen-denominated loans, with another $1 billion denominated in dollars. To avoid currency risk, the bank might "buy"—that is, borrow—$1 billion in dollar deposits (offering the going LIBOR interest rate for dollars) and "sell"—that is, lend—$1 billion in yen deposits. The transaction often takes the form of a "swap" of yen for dollars that is scheduled to be reversed in a few weeks or months when the $1 billion loan matures. In either case—whether it is structured as an outright sale of yen and purchase of dollars, or a swap—$1 billion of foreign exchange has been traded.

As another example, a London-based German bank that has already more or less matched the currency denominations of its loans and deposits may negotiate a $2 billion euro loan. In order to fund the loan it must buy deposits, offering the going LIBOR rate for euros on the interbank market. Because the largest volume of offshore interbank trading takes place in London, LIBOR is the international benchmark for short-term lending, with modifications for currency denomination, term to maturity, and risk.

In short, the Eurocurrency, or "offshore" interbank market for deposits, is the main means by which almost $2 billion of foreign exchange is traded daily. More fundamentally, the Eurocurrency market—which is in fact not just European but worldwide—is the main means by which the demands for and supplies of loanable bank funds are matched up internationally.

■ European Central Bank

The European Central Bank (ECB) is the central bank for the euro area. It opened its doors in June 1998 in Frankfurt, Germany. Together, the ECB and the national central banks that are members of European Monetary Union (EMU) form the European System of Central Banks (ESCB), also known as the eurosystem.

Before the ECB began to take responsibility for the conduct of monetary policy in the euro area, the member countries created the European Monetary Institute (EMI) in 1994 to facilitate the work toward transition to the era of the single currency. Its primary task was to address the technical needs for the switch to the euro. The EMI was responsible for reporting to the European Union (EU) on the progress toward convergence by individual member states, as pre-scribed by the Maastricht Treaty. The conduct of monetary policy remained under the responsibility of the individual member states. By the end of 1995, member governments approved a plan for change that focused on the need for rigorous acceptance of the convergence requirements. A legal basis for the single currency was necessary so that all who used the euro could be confident that it would be an accepted means of payment.

Objectives and Tasks of the ECB The primary objective of the ECB and, by implication, the ESCB, is to maintain price stability, a goal set but not de-fined by the Maastricht Treaty. The ECB defines price stability as an inflation rate close to 2 percent in

a Europewide index of consumer prices called the Harmonized Index of Consumer Prices over the "medium term." What is the medium term? The ECB does not provide a precise definition. It notes that monetary policy acts with long and variable lags, an idea made famous by Milton Friedman. Experi-ence, however, suggests that inflation can be con-trolled within the objectives set out by the ECB within a two-year horizon. To achieve this objective, the ECB decided to give prominence to money growth as well as to a wide range of indicators such as the exchange rate, the yield curve, and various fiscal indicators. More precisely, the ECB's strategy involves a so-called two-pillars approach. This means that, in setting interest rates for the euro area, the ECB considers developments both on the real side of the economy, which are of a shorter-term nature, as well as on the monetary side, which cap-tures the longer-run influences on monetary policy. Since current interest rate decisions have an impact on future decisions by individuals and firms, the ECB also receives guidance from forecasts of infla-tion and real economic activity for the euro area as a whole.

The ECB is headed by a president who serves a nonrenewable eight-year term. The first president of the ECB, Wim Duisenberg from the Netherlands, did not serve his full term, which would have ended in 2006; instead, Jean Trichet of France was ap-pointed as the president of the ECB in 2003. Since the president and other senior officials of the ECB are appointed by "common accord" by the heads of state or governments of EU members, national political imperatives play an important role in such appoint-ments. Therefore, it is unlikely that a country could have more than one representative on the executive board.

The principal decision-making body of the ECB is the governing council made up of the governors of the thirteen euro-area national central banks and the executive board. The executive board, which consists of six members chosen from the governing council, is responsible for the implementation of monetary policy and carrying out the day-to-day affairs of the ECB. The governing council of the ECB consists of

members of the executive board and all the heads of the national central banks that belong to the euro area. The governing council is mainly responsible for formulating monetary policy. The general council, largely an advisory body, includes members from both euro-area and non-euro-area countries that are members of the EU.

Both the executive board and the governing council meet twice a month, generally in Frankfurt. During the first monthly meeting the governing council announces the monetary policy decision made by the executive board. The second monthly meeting is reserved for making decisions related to the other tasks of the euro system. The schedule of meetings is published in advance so financial markets can prepare for the announcement of the interest rate decision. Additionally, in an emergency or crisis the governing council can meet in an extraordinary session, as happened, for example, following the terrorist attack on the United States in September 2001. The president of the ECB announces the interest rate decision immediately after the meeting and holds a press conference, but the ECB does not release minutes of the meeting.

In addition to its responsibility for defining and implementing monetary policy in the euro area, the ECB conducts foreign exchange operations, holds and manages member states' foreign exchange reserves, and helps promote the Europewide payments system. This payment system is called TARGET (Trans-European Automated Real-Time Gross Settlement Transfer System). Finally, the ECB, together with the individual national central banks, collects and disseminates a large variety of financial and economic statistics.

The primary monetary policy instruments consist of open market operations followed by a marginal lending facility that permits select financial market participants to borrow overnight from national central banks against eligible assets. Finally, banks in the EMU are required to hold reserves against short-term deposits.

Enlargement In 2004, a historic enlargement took place. Ten new member states joined the EU on May 1: the Czech Republic, Estonia, Cyprus, Latvia, Lithuania, Hungary, Malta, Poland, Slovakia, and Slovenia. In 2007, Romania and Bulgaria joined the EU. All of these countries must fulfill the Maastricht Treaty convergence requirements. The enlargement of the EU in 2004 introduced a potential organizational problem for the ECB's governing council. With 15 national central banks and six executive board members, the main decision-making body of the ECB originally consisted of 21 members. Following enlargement, membership would rise to a total of 31 members and, potentially, a still larger number once other countries are admitted into the EU. Therefore, in 2002, the ECB recommended a voting system that would limit the number of voting national central bank members to a maximum of 15. This means that there would be a rotation system among members of the eurosystem. The rotation system is designed to ensure that the national central bank governors with the right to vote are from member states that, taken together, are representative of the euro-area economy as a whole.

In spite of the growing pains experienced by the ECB, it remains a grand experiment that shows every sign of success, durability, and future expansion. The euro, which is the most visible expression of the ECB's existence, is a currency that may someday rival the U.S. dollar as a reserve currency. Finally, the economic size of the euro area is now larger than that of the U.S. economy, and it is likely that economic performance in Europe will have repercussions worldwide.

■ European Monetary Union

The establishment of the European Monetary Union (EMU) was an event without historical precedent. Although monetary unions have existed in the past, the EMU was the first union of sovereign states to agree on a single currency and a single monetary policy, but not on a common fiscal policy. The development of the EMU was an evolutionary process. The drive for greater European integration began shortly after World War II, but the actual path to the EMU originated with the European Monetary System (EMS), an initiative led by France and Germany in 1978 to stabilize exchange rates within Europe following the end of the postwar Bretton Woods exchange rate system.

Even before the Bretton Woods system of exchange rates collapsed during the 1970s, six European countries Belgium, France, West Germany (as it was then called), Italy, Luxembourg, and the Netherlands signed the Treaty of Rome in 1957, which led to the creation of the European Community (EC). This was an ambitious attempt, first to integrate the economies in Europe, and then to use such integration to fix currencies among members of the EC. Although the EMS fixed exchange rates between the member states, the arrangement permitted

bilateral exchange rates to fluctuate within a particular range or target zone. In practice, however, the rates were fixed to the German currency, the deutsche mark. When market-determined exchange rates came close to the permissible bands, central banks in the system intervened by buying or selling foreign exchange, usually German deutsche marks, to push the exchange rate back into the band.

Although most countries in the world participated in the Bretton Woods pegged exchange rate arrangement, almost immediately after the creation of the EMS, the original six members agreed that permissible exchange rate fluctuations would be limited to a band, or target range, narrower than that permitted by the International Monetary Fund at the time. The International Monetary Fund is one of two institutions, the other being what was eventually to be called the World Bank, that would govern the postwar international exchange rate system. The new European arrangement would be called the "snake within the IMF tunnel." In other words, the EMS was a miniature version of the Bretton Woods arrangement. The "snake," however, never functioned smoothly. (West) Germany and the Netherlands, for example, allowed their currencies to float temporarily. Eventually this system was abandoned in 1973, when a devaluation of the U.S. dollar led the EC to float all of its currencies for a time. Nevertheless, EC members reaffirmed their commitment to a fixed exchange rate system as a precursor to achieving eventual monetary and economic union.

Exchange Rate Mechanism In 1974, the second stage of the plan that would eventually lead to a currency union began when EC members pooled their foreign exchange reserves, increased short-term credit facilities to member states, and intensified coordination of members' economic and monetary policies. Despite a variety of setbacks and delays, the new and improved version of the EMS started operation in March 1979. Initially there were only six members in this club, namely the signatories of the original Treaty of Rome. Later, membership increased: Italy and Ireland joined in 1978, Greece in 1981, Spain and Portugal in 1986. The last holdout was the United Kingdom, which joined the

Exchange Rate Mechanism (ERM) in 1990, although it withdrew, along with Italy, in September 1992. Meanwhile, even nonmember countries, such as Sweden and later Denmark, effectively belonged to the EMS system by adhering to its rules, albeit not on a formal basis.

The system's monetary unit would be called the ECU or European Currency Unit. The ECU represented a basket of currencies weighted roughly by the relative importance of member countries' economies. The ECU would serve as a kind of *numéraire*, or unit of account, for the ERM, as there were no circulating ECU notes or coins. The EMS stipulated allowable movements of ±2.25 percent (±6 percent for Spain) in either direction of one another's currencies values, and an additional mechanism was added to provide economic support to the relatively less prosperous members of the EC. Allowable fluctuations were relative to a central parity, essentially the midpoint of the band around which the exchange rate was permitted to fluctuate. The EMS did permit an exchange rate realignment (revaluation) of the currencies that could not be sustained within the zone, but this was supposed to be only a last resort. For example, if one country experienced severe balance of payments difficulties, then by common agreement there would be a call for a realignment among the EMS members.

In spite of an agreement to fix exchange rates rigorously, there were 27 realignments of the currency relationships between 1979 and 1983, and 12 more during the 1984 87 period. After that, however, no further realignments were made, until September 16, 1992, known as "Black Wednesday," when the United Kingdom and Italy left the EMS. Also, Ireland, Spain, and Portugal all devalued their currencies against the German currency, the deutsche mark. The European exchange rate crisis of 1992 threatened to derail the whole EMU project. Instead, in August 1993, the bands were widened to ±15 percent, except for the Netherlands, which retained the narrower fluctuation band. This may have had the effect of reducing the incentive to test the resolve of the potential members of the single currency area to carry on with their project, although

economic recovery in Europe, assisted by an expansionary fiscal policy in Germany following reunification, also facilitated the return to a course toward the creation of the euro.

In principle, the chief advantage of the target zone system (ERM) is its ability to prevent large swings in a country's current account when there are sharp swings in the nominal exchange rate. Of course, the main drawback with EMS-type systems is that they may also be subject to speculative attacks. After all, the limits set by policymakers on exchange rate fluctuations will hold only if the policies of the countries that belong to the target zone system are credible and compatible with one another. Indeed, illustrations that advocates of floating rates point to, in favoring a more flexible exchange rate systems, are the impact of the large devaluation of the Mexican peso in early 1995 and the devaluations in several Asian countries in 1997. Advocates of pegged exchange rates reply by drawing attention to the sharp appreciation of the Japanese yen in 1992, the rapid appreciations of the Australian, New Zealand, and Canadian dollars in 2005 6, as well as the large swings in the euro U.S. dollar exchange rate since its introduction in 2002.

The EMS continues to exist as ERM II, which took effect on January 1, 1999, and resembles the original ERM, except that the fluctuation band of 15 percent became the accepted norm. The countries that joined the European Union (EU) must adhere to its rules prior to being admitted into the EMU and must belong to ERM II for at least two years.

Although the EMS and ERM were intended to foster greater economic integration within Europe, the actual blueprint for the single currency area can first be traced to the Werner Report of 1970. This report followed on the heels of a summit of European heads of state and government in 1969 held at the Hague. This meeting led to a decision that, henceforth, the EMU ought to be an explicit goal for the EC. Werner was the prime minister of Luxembourg, who was entrusted to provide a way to create a common currency area. The Werner Report proposed a reduction in the size of the fluctuation bands

for the currencies in the EMS in a first stage, a removal of all barriers to financial flows and enhancement of the integration of financial and banking sectors in a second stage, and an irrevocable fix in exchange rates in a third stage. Interestingly, the report was agnostic about the need for a single currency, as opposed to several currencies with a fixed exchange rate. Nevertheless, it called for greater fiscal harmony among the member states if the goal of a monetary union of some kind were to succeed. As mentioned earlier, the collapse of the Bretton Woods system interrupted the drive to the EMU, and problems with the EMS did not help matters either.

Delors Report and Beyond The next attempt to lay out a road map to monetary union was the Delors Report of 1989, named after the former French politician who is also a former president of the European Commission. Critical to achieving monetary union were the so-called convergence criteria. The goal, in principle, was simple: to ensure that the members of the area that would form a monetary union would have similar macroeconomic environments, as this would facilitate the introduction of a fixed exchange rate among the member currencies that would not be altered, which would pave the way for the introduction of a common currency.

One of the innovations of the Delors Report was its outline of the institutional environment under which monetary union would operate. A European System of Central Banks (ESCB) was to be formed and this body would formulate and implement monetary and exchange rate policy in Europe. The Maastricht Treaty would later enshrine the convergence criteria that were believed to be necessary for a successful monetary union, and it contained a recommendation to create a European Central Bank (ECB) that would bring together the ESCB under a separate institutional umbrella.

The need for economies that participate in a monetary union to look alike, in broad economic terms, is associated with the work of Robert Mundell, who was awarded a Nobel Prize for his work demonstrating the conditions that countries would have to fulfill to form an optimum currency area. In spite of the intellectual debt to Mundell's work, the EMU

project was fundamentally a political one, namely to encourage and enshrine integration among European countries, albeit underscored by the economic benefits of a single currency. These benefits are thought to include a reduction in transactions costs. Although tourists no doubt have seen the advantages of not having to exchange one currency for another as frequently, the evidence that the reduction of transactions costs is of macroeconomic significance is more dubious. As for the single currency fostering greater integration, the jury is still out, although there is evidence that participation in a currency area, or in a monetary union, can contribute to greater similarities in business cycle performance among the participants.

The establishment of the ECB was preceded by the European Monetary Institute (EMI). The creation of this institution marks the beginning of stage II toward the EMU. The EMI's task was to prepare the groundwork, at both the policy and the institutional level, until the ECB took over, that is, until the irrevocable exchange rates became a reality.

A second innovation of the Delors Report was the proposal for a single currency that would follow a transitional period leading up to the setting of irrevocable exchange rates. Unlike the Werner Report, however, there was considerably less emphasis on fiscal harmony within the proposed monetary union. The thinking was that the convergence requirements would represent sufficient discipline to bring the countries into line with one another. Events were to prove otherwise, as the Maastricht Treaty was later accompanied by the Stability and Growth Pact (SGP). The SGP was intended to generate a form of fiscal discipline that resembled the monetary discipline required of the Maastricht Treaty.

The original Delors Report called for European Monetary Union (EMU) by 1999. At the end of 1995, leaders of the EU announced in Madrid plans for a single currency that would be called the euro, and they reaffirmed the launch date of January 1, 1999. Events would delay the introduction of the euro but, in spite of considerable skepticism, the single currency project eventually saw the light of day. The goals of monetary policy for the euro area,

and the conversion of accounting standards, were agreed to and implemented by 1999. Eleven EU member states initially became members of EMU in May 1998, marking the start of the third and final stage toward the EMU, which effectively came into being on January 2, 2002. Hence, between January 1, 1999, and December 31, 2001, the euro replaced the ECU at an exchange rate of one to one, while EMU member states' exchange rates were irrevocably fixed at rates announced on December 31, 1998.

■ European Union

The European Union is both a vague aspiration and a concrete organization. The aspiration, never held by more than a small minority of Europeans, is for a federation of European states to replace the hodgepodge of sovereign states that has characterized the continent in modern times. The organization European Union (EU) is a complex entity with federal features that is less than a full-fledged state yet far more than a traditional international grouping of states. After it acquired two new members in January 2007, the EU comprised 27 countries with a combined population of nearly 500 million and a combined gross national product of approximately €10 trillion. Perhaps it is best understood as an association of countries (member states) that have agreed to share sovereignty in a number of policy areas and to coordinate closely in others, in order to pursue jointly key objectives such as economic growth, social protection, regional stability, and global security.

The EU has grown in size and stature over the years but is increasingly beset by serious political problems. Buffeted by weak public support, poor leadership, the myriad challenges of enlargement, and widespread concerns about the impact of globalization on Europe's generous welfare states, the EU faces an uncertain future. Although hardly destined to wither away or collapse in ignominy, neither is the EU likely to evolve into a superstate, let alone a superpower, as some ardent advocates of European integration would like to see happen.

Origins Today's EU originated in the European Coal and Steel Community, an organization that, in our age of bits and bytes, sounds quaint or even archaic. In the early 1950s, however, coal and steel were essential ingredients for economic recovery and resurgence, and cherished symbols of industrial strength and vitality. The name of the organization denoted the political and economic importance of coal and steel in postwar Europe as well as the special nature of the relationship among its member states. Despite an apparently narrow emphasis on industrial restructuring and revival, the new entity was a "community" and not simply a functional international organization. As such, its members acknowledged the necessity of reconciling national interests with common, overarching security concerns in order to avoid a repetition of Europe's disastrous past and help ensure a more peaceful and prosperous future. By launching the Coal and Steel Community, the original member states also launched the process of political and economic integration that has continued in Europe, through various ups and downs, to the present day.

There was nothing inevitable about the form or content of the EU's precursor. Initial discussions about European unity in the postwar period focused on grandiose federal schemes. In a famous speech in Zurich in 1946, Winston Churchill, Europe's best-known statesman, endorsed the idea of a United States of Europe. Altiero Spinelli, a veteran Italian antifascist and ardent European federalist, advocated a "big-bang" approach to sharing national sovereignty. War weariness and popular disillusionment with the status quo seemed propitious for bold international initiatives. Yet when Europe's leaders met in The Hague in 1948 to discuss political integration, rhetoric clashed with reality. Few of them were willing to surrender sacred national sovereignty to an all-encompassing European federation. What emerged instead was the Council of Europe, an arena for exchanging ideas and information on European integration that lacked political clout.

Meanwhile, Europeans were grappling with the challenges of reconstruction. The Marshall Plan had provided the means, in the form of scarce American dollars, to fuel Western Europe's rapid economic recovery. Motivated in part by escalating East-West tensions, it also accelerated the onset of the Cold War. In view of rapid economic recovery and deepening Cold War hostility, the fate of Germany became more pressing than ever. In 1948 the Western Allies agreed to establish the Federal Republic of Germany. Nevertheless, France did not want the new West German state to become economically powerful, at least not yet. In particular, France coveted Germany's abundant coking coal and sought to modernize its own steel industry before German mills and market share could fully recover from the destruction of the war. Such a policy was unacceptable to the United States, which sought to reconstitute Germany politically and economically as the cornerstone of Western Europe's resurgence and a bulwark against the spread of communism. Under intense American pressure, France had little choice but to come up with a new approach toward its historical enemy.

In response, Jean Monnet, a senior French civil servant and confidant of leading American politicians, proposed the Coal and Steel Community. Rather than pursue a beggar-thy-neighbor policy toward each other, France and Germany would cede responsibility for managing the coal and steel sectors to a supranational High Authority. Robert Schuman, foreign minister of France, announced the proposal in May 1950 and pushed it through a skeptical French government. German chancellor Konrad Adenauer strongly supported what became known as the Schuman Plan, which provided a means of binding the new Federal Republic into Western Europe, promoting reconciliation with France, and lifting Allied controls on Germany's heavy industry.

In his public declaration, Schuman said that the plan was open to the other countries of Europe. With the onset of the Cold War, in effect that meant Western Europe. Britain, with its newly nationalized industries, different war experience, and unwillingness to share sovereignty, decided not to participate. A number of other countries followed suit, whereas Spain, an international pariah after the war, was excluded by default. That left only Italy, which saw

European integration largely in anticommunist terms, and the three Benelux countries (Belgium, Netherlands, and Luxembourg), which were tied economically to Germany, to take up Schuman's offer. As a result, the Coal and Steel Community came into existence in 1952 with six member states.

Monnet had wanted the institutional structure of the new community to comprise only the High Authority and a Court of Justice. In the event, governments successfully pressed for the inclusion as well of a Council of Ministers, to provide a direct national input into decision making, and an Assembly, to lend democratic credence to the organization. Thus the institutional design of today's EU took shape, with the High Authority changing its name to the European Commission in the late 1950s, following the establishment of the European Economic Community (EEC).

The Coal and Steel Community played an unglamorous yet essential role in the postwar European settlement. Its significance was more political than economic, notably by providing a diplomatic solution to the contentious question of German reconstruction and rehabilitation. Conversely, the emergence of the EEC later in the decade had less to do with Franco-German rapprochement than with the immediate economic interests of the contracting states. In particular, the explosive growth of international trade in the 1950s led the Dutch, traditional advocates of economic liberalism, to push for a Western European common market. Adenauer, enamored of any idea that would strengthen European integration, took up the call, despite the objections of Ludwig Erhard, his economics minister, who feared that the proposal would damage prospects for global trade liberalization. France was torn between accepting greater competition, albeit in a regional framework, and maintaining a policy of trade protectionism. Champions of the common market in the French government won the day by including in the proposed community provisions for EEC-level agricultural subsidies and a preferential regime for current and former colonies of the member states. With a huge, heavily subsidized agricultural sector

and a large, fragmenting empire, France stood to gain handsomely from such side payments. Hence the origin of the Common Agricultural Policy (CAP) and the Cotonou Agreement, two of the most controversial, trade-distorting policies of the EU.

The same six members of the Coal and Steel Community went on to establish the broader Economic Community in 1958, Britain again having refused to participate. The launch of the EEC, later known simply as the European Community (EC), was far from an earth-shattering event. Few Europeans had followed the negotiations, which were highly technical and conducted mostly in secret. News at the time was dominated by Soviet threats against Berlin, the deteriorating situation in Algeria, and the imminent collapse of the French Fourth Republic. The EC, which would later insinuate itself into everyday life in Europe and, in the form of the EU, occasionally dominate domestic politics, began with a whimper, not a bang.

Development of the EC Almost from the beginning, the EC developed along two lines: widening and deepening. Widening refers to enlargement, as more and more countries requested membership. Deepening refers to the acquisition by the EC of responsibility for or involvement in additional policy areas, as member states agreed to transfer more sovereignty to the organization. Conceptually, widening and deepening are contradictory: the larger the membership, the more cumbersome and less cohesive the organization. The EU may have reached that point by 2007, although even with 27 members the institutions operated surprisingly well. Historically, in any case, widening and deepening went hand in hand. Indeed, member states deliberately undertook institutional reform and increased the EC's policy scope in part to ensure that wider would not mean weaker.

The first opportunity to do so came almost immediately after the establishment of the EC. Having first dismissed European integration as unworthy of a victorious Great Power, and then having tried to subvert the EC by establishing the rival European Free Trade Association, Britain accepted the reality of growing economic interdependence with the

Continent and applied for membership in 1961. It would be another 12 years before Britain   together with Denmark and Ireland   joined, thanks largely to the policy concerns and personal spite of French president Charles de Gaulle. De Gaulle wanted to ensure that the EC was ready for Britain, meaning that the CAP, and with it the EC's budget, were fully fleshed out. Because of different agricultural preferences, Britain would have objected to the establishment of the CAP in the form in which it eventually emerged in the late 1960s. By the time Britain joined, the CAP was already in place. By contrast, Britain subscribed fully to the customs union, which finally came into being in 1968 following the eradication of tariffs and abolition of quotas among member states. As a corollary to the customs union, the EC developed a common commercial policy, the basis for collective member state action in successive rounds of multilateral trade liberalization under the auspices of the General Agreement on Tariffs and Trade and the World Trade Organization.

International strategic and financial developments in the late 1960s prompted the member states to move European integration in two new directions: monetary policy and foreign policy cooperation. In response to international currency fluctuations and Germany's overtures toward the Soviet bloc, national governments launched two separate initiatives. One aimed to achieve economic and monetary union by 1980; the other to coordinate member states' foreign policies as closely as possible. These were dramatic examples of deepening in the run-up to the EC's first enlargement, but European integration went through trying times in the years ahead. The reason was not enlargement itself, but the worldwide economic downturn that coincided with enlargement. In the recessionary 1970s and early 1980s, the economies of the member states diverged rather than converged; the ambitious and not well-thought-out goal of monetary union was scrapped; nontariff barriers proliferated in member states; and EC decision making ground to a halt.

The EC's fortunes revived in the mid-1980s when national governments, reeling from years of poor economic performance and facing intense interna-tional competition, rediscovered the benefits of market integration. One of the main architects of the EC's revival was none other than British prime minister Margaret Thatcher. Though later dismissed as a Euroskeptic, or zealous opponent of European integration, Thatcher championed the importance of completing the single European market by ensuring the free movement of goods, services, capital, and people. Thatcher looked back to the future: to the original provisions of the treaty establishing the EC (the Treaty of Rome) as a means of breaking down economic barriers among member states in order to boost growth and employment. Thatcher was instrumental in forging a consensus across the political spectrum in favor of what became known as the single market program. Optimistic assessments of the likely economic impact of a borderless EC, notably the Cecchini Report of 1988, bolstered her position.

Whereas Thatcher did not think that completing the single market necessitated institutional reform in the EC, most of the other national leaders wanted to enshrine their commitment to the single market in a new treaty, which would include provisions for greater use of qualified majority voting, an instrument of supranational decision making. This was the genesis of the Single European Act, the first major overhaul of the Treaty of Rome. Negotiation of the Single European Act coincided with another round of EC enlargement, Greece having joined in 1981 and Portugal and Spain being about to join in 1986. In keeping with the recurring fear that wider would mean weaker, especially as the new member states were substantially poorer than the existing members, national leaders included in the Single European Act a promise to strengthen regional (cohesion) policy by substantially increasing spending on development projects in the EC's disadvantaged areas. Thatcher saw this as a betrayal of the liberal principles of the single market program and a shameful side payment to the EC's poorer member states. By contrast, most other national leaders, as well as Jacques Delors, the commission's new president, saw it as a manifestation of solidarity in a growing EC and an acknowledgement that, contrary to neoliberal belief, market

forces alone would not guarantee the equitable or eventual spread of economic growth from the rich core to the poor periphery.

Thatcher and Delors fought their ideological battles in a series of speeches on the nature and purpose of European integration, delivered in the late 1980s. Embittered by the acceleration of integration beyond the single market program, and especially by the renewed momentum for economic and monetary union, Thatcher became increasingly isolated within the EC. Undisguised opposition to German unification set Thatcher further apart from her European counterparts. Battling fierce opposition at home to a proposed poll tax and growing hostility in Europe, Thatcher was forced from office by her own Conservative Party in 1990. Thatcher's departure and Delors's preeminence symbolized the remarkable transformation of the EC by the end of the 1980s, a period of profound change in the international system. With the end of the Cold War and the imminent collapse of the Soviet Union, a united Germany and a uniting Europe seemed to portend the triumph of European integration. As if to prove the point, the Maastricht Treaty of 1991, another far-reaching reform of the original Treaty of Rome, subsumed the EC into the EU, while pointing the way toward monetary union by the end of the 1990s, strengthening cohesion policy, launching a fledgling Common Foreign and Security Policy, and setting the stage for close cooperation in the policy areas of justice and home affairs.

The Overreaching EU It soon became apparent that the single market program was the zenith of European integration and that the Maastricht Treaty marked a profound turning point. The rejection of the treaty by a narrow majority of Danes in a referendum in June 1992 symbolized the EU's troubles. The result astounded Europe's political elites: how could a majority of citizens in any member state have rejected a carefully negotiated treaty intended to deepen European integration? Although there were many reasons why people voted against the treaty, the result reflected widespread public concern about the rapid pace of integration and, especially, the so-called democratic deficit the seeming unaccountability and remoteness of EU institutions. Aware of the danger of the democratic deficit, EU leaders had already addressed the issue by giving more legislative power to the directly elected European Parliament and promoting the principle of subsidiarity or states' rights. Most Europeans were unimpressed by the European Parliament, however, as evidenced by the declining turnout in successive elections. Nor has subsidiarity, which is difficult to put into practice, grabbed the popular imagination.

Public disaffection with the EU has increased steadily since the early 1990s. Subsequent treaty changes Amsterdam in 1997, Nice in 2001, and the Constitutional Treaty, signed by national leaders in 2005 failed to allay concerns about the democratic deficit or to endear the EU to the people. At the same time, poor economic performance in the big, continental member states further undermined public support, although responsibility for sluggish growth lay primarily with national leaders rather than the EU itself. Indeed, national leaders agreed at an EU summit in 2000 to undertake a series of labor market and other reforms the so-called Lisbon Strategy but governments in France, Germany, and Italy, in particular, were loath to antagonize volatile electorates by following through with concrete measures. The road to economic and monetary union in the 1990s may have made matters worse, as governments strove to reduce deficits and debts in order to meet the criteria for participation in the third stage of the process: adoption of a single monetary policy and a single currency. Regardless of its economic or political merits, the advent of monetary union in 1999 followed by the introduction of the euro in 2002 lacked popular enthusiasm. Most people in the eurozone miss their national currencies far more than they value the euro.

Europeans are especially concerned about enlargement, fearing that further expansion of the EU, following the accession of 10 Central and Eastern European states in 2005 7, is unsustainable. Economic arguments about the long-term benefits of enlargement larger market size, economies of scale, increased competition run counter to widespread

worries about worker migration from east to west, downward pressure on wages, and possible job losses. Under the circumstances, Turkey's application for EU membership seemed doomed by late 2007. The accession negotiations, which formally began in 2004, were overshadowed in any case by disputes between both sides over the future of northern Cyprus and over the pace and durability of political reforms in Turkey. Lurking in the background was the generally unspoken but politically potent viewpoint that Turkey, a predominantly Muslim country located mostly across the Bosporus, is neither culturally nor geographically European.

The fate of the Constitutional Treaty, a political initiative to improve the EU's functioning and fortunes, illustrates the state of the EU itself. Drafted by a convention representing a wide range of political opinion from the existing members and candidate countries, the Constitutional Treaty included provisions to improve decision making in an enlarged EU, address concerns about the democratic deficit, and enhance the EU's ability to act internationally. Yet sizable majorities in France and the Netherlands, two of the EU's founding member states, rejected the Constitutional Treaty in referendums in mid-2005. Their reasons for doing so, like those of the Danes who rejected the Maastricht Treaty in 1992, were varied, but included a strong dislike of the EU's political pretensions. After a lengthy "period of reflection," EU leaders redrafted the Constitutional Treaty dropping the word "constitution" or "constitutional" from the title and text and making other symbolic changes and signed the Lisbon Treaty in December 2007. Until ratified by all member states, the Lisbon Treaty cannot come into effect. In the meantime, the EU is operating under the terms of the existing treaties, whose institutional provisions are hardly adequate for such a large and multifaceted organization.

Prospects The EU has been in existence, in one form or another, since 1952. During that time it has grown from 6 to 27 member states and in scope from a common market for coal and steel to a single market in goods, services, capital, and people, as well as a monetary union for countries that meet the convergence criteria. Managing and perfecting the single market facilitating free movement within its borders is the core activity of the EU. It is an activity that requires constant vigilance, regulatory fine-tuning, and occasional intervention by the Court of Justice. It is also an aspect of the EU that enjoys public support, as Europeans have come to appreciate the benefits of unimpeded cross-border travel and shopping. Europeans appreciate as well the need for their governments to cooperate closely in the fight against terrorism and transnational crime, and to maximize their leverage by acting collectively on the global stage. Beyond that, Europeans appear to have little appetite for further enlargement and for extravagant constitutional schemes. There is a growing consensus that, at this stage in its history, the EU needs to focus on first principles and strengthen its fragile legitimacy by demonstrating its effectiveness in those policy areas in which it provides obvious added value.

■ evolution of development thinking

In the international community, a focus on devel opment emerged in the 1940s and 1950s, follow ing the focus on reconstruction and development after World War II and the subsequent decoloniza tion of former empires. As academics and senior civil servants turned their attention to how the newly decolonized regions could catch up to their richer counterparts, the arguments of development think ers soon became caught up in the schisms of the Cold War.

In the heat of the postwar period, the spec trum of solutions offered by development thinkers ranged from solutions inspired by Marxist thought to those that advocated closer integration in the capitalist system. In the 1950s and 1960s, however, even the procapitalist economic orthodoxy placed the state at the heart of economic development, and the dominant paradigm across the spectrum was of state-led growth. For development thinkers, the lesson of the theories of John Maynard Keynes and the chastening experience of the Great Depres sion was that self-regulated markets could not be relied on to generate prosperity. This perception had been reinforced by what were regarded as the relatively effective planning processes of post World War II Europe. Meanwhile, the small size and often enclave- or state-dependent private sec tor in developing countries meant that develop ment thinkers had little evidence of, and heard only muted arguments for, more effective and open markets.

The broad aim of development thinkers was to raise growth in poorer countries to achieve the same income levels, on average, as developed countries. At first, even the non-Marxist development thinkers looked for universal models of development and theories that would initiate the growth process. The idea that growth, once initiated, would continue through virtuous circles or reinforcing effects gained wide currency. This was echoed in development thinkers' phrases that persisted into the 1960s, such as the "big push" (Rosenstein-Rodan), the "takeoff" (Rostow), and the "great spurt" (Gerschenkron) (see Hirschman 1981).

Development practitioners and thinkers observed that market failures were particularly prevalent in developing countries. The private sector, which was relatively poorly developed and driven by narrow interests, had shown itself to be an inadequate engine of growth. In newly decolonized Africa and in Asia and Latin America, new national states were determined to establish postcolonial models of development. Given that the majority of professionals were concentrated in public service and had limited knowledge of the private sector, and that the absence of democracy meant that the state exercised virtually all the levers of power, the preoccupation with the role of the state was not surprising.

Two strands of thought emerged, both of which reflected this heavy reliance on the state. The first was the dominant strand within developing countries, particularly on the political left. This was import-substitution industrialization (a policy intended to promote industrialization by protecting domestic producers from competition from imports), which informed government thinking in Latin America, Africa, and Asia. The second strand of thought was multilateralism (a policy of multiple nations working cooperatively to solve world problems), which was given added impetus in the strategic agenda of Western Europe and North America.

Industrialization plans aimed at getting around the problems of coordination of industry development became the dominant currency of development thinkers residing in developing countries and some developed countries, particularly the United Kingdom. Planning models, at times elaborated through input-output matrixes, provided a vision of an integrated chain in which domestically produced raw materials and local labor provided the building blocks of industries that met first domestic and then export requirements. To the extent that the concept of dynamic comparative advantage influenced thinking, it was within the constraint of perceptions regarding the unequal terms of trade and protectionism in rich countries, which were seen as effectively preventing the balanced integration of developing countries into a global trading system. Greater self-reliance and import-substitution indus-

trialization, reinforced by fixed exchange rates, import tariffs, and exporting cartels, were seen by many as the appropriate response. These would prime the pump for a virtuous circle of increased employment and incomes, which would be coupled with improved health and education as well as rising consumer demand and investment. To the extent that the rich countries were seen to have a role, it was primarily as providers of capital and technology.

These ideas reflected the view that the prices for agricultural goods, expected to be primarily exported by developing countries, would fall in the long run and that the technological spillover effects from manufacturing were greater than those from agriculture (Prebisch 1950). Raúl Prebisch not only exercised a powerful influence in the evolution of development thinking but also was instrumental in the establishment of institutions that continue to carry his ideas forward, notably the Economic Commission for Latin America (ECLA) and the United Nations Conference on Trade and Development (UNCTAD).

The oil price increases of the 1970s also had important impacts on ideas about trade policy and development. Many developing countries considered that cartelization, as used by the Organization of the Petroleum Exporting Countries (OPEC), could be extended to other commodities to ensure that the gains from trade were more equally shared with developing countries. Government intervention at the national and supranational levels in markets and trade became a key element of what some termed the "New International Economic Order." UNCTAD and an array of marketing boards at the national and international levels (including the international coffee, cocoa, sugar, and commodity bodies established in the 1960s and early 1970s) were seen as providing the means to rebalance the international trading system for the benefit of developing economies.

While some thinkers continued to pursue global solutions, by the late 1970s many development specialists saw the evident constraints faced by bankrupt governments and narrowed their ambitions. Focus shifted toward filling needs such as those

for food, education, and health and away from overall integrated frameworks that attempted to incorporate all sectors of an economy. This evolution largely reflected a lack of success in kick-starting growth and a growing realization that theories did not account for political economy factors related to institutions, governance, and conflict. There was also evidence that the benefits of growth were not necessarily trickling down to the poorest people in developing countries and that some types of growth were environmentally unsustainable.

Development thinkers recognized that state-led models, at least in the medium term, had failed to address poverty and that stubborn levels of high unemployment were endemic in many societies. Chenery and others argued that policies should be devised to specifically benefit the poor (Chenery et al. 1979). The Basic Needs Approach was adopted by the International Labor Organization and later by the World Bank. Rather than challenging the role of governments, it sought to ensure that governments adopted pro-poor policies that would ensure that minimum needs would be met to enable all citizens to lead productive lives. In the 1980s, the capability approach developed by Amartya Sen and others built on this understanding with the United Nations Development Program in its 1990 Human Development Report. This report went beyond the analysis of the World Bank's annual World Development Reports to provide a broad understanding of the issues and data required to address poverty (Stewart 2006). The shift in development aims was accompanied by an expanded set of measures by which to track development. In particular, the human development indicators published in 1990 covered poverty, health, education, and the status of women in many of the world's countries. A number of these indicators, as well as others covering environmental sustainability, are now part of the Millennium Development Goals.

Primacy of Markets By the late 1970s, the oil crises, interest rate hikes, and widespread macroeconomic instability had led to a reconsideration of the balance of state and market. Growing awareness that the pressure on public-sector finances was not politically sustainable led to a reconsideration of governments' roles. The tension between the informational requirements of central planning and the increasing complexity and integration of developing economies was also becoming more evident. Macroeconomic instability associated, at least in part, with spikes in oil and interest rates led to deep crises, which in turn were seen by a new wave of development thinkers as symptomatic of a deeper malaise. By the 1980s, the global economic slowdown and the debt crisis had increasingly constrained the potential for state action in initiating development, and the voices of those who argued that governments should "get out of the way of development" were being heard more widely.

In the late 1970s, a new cohort of development thinkers, based mainly in the United States, was in the ascendant. They argued that state planners could not possibly possess all the knowledge required to make decisions reflecting efficiency as well as people's differing preferences. An influential World Bank study (Krueger et al. 1988) argued that import substitution often resulted in inefficient industries and an antiagriculture bias, undermining both growth and poverty reduction. Moreover, governments had revealed themselves to be collections of interests rather than the benevolent arbiters of the collective interest that the import-substitution industrialization model required. The development thinkers at the fore in the 1980s eschewed state-led development and focused on the removal of regulations, tariffs, and other government-induced economic and trade distortions. Governments were now viewed as a barrier to entrepreneurs and development, rather than as initiators of development. It was argued that the private sector, left to its own devices, would be the engine of economic growth.

The increasing market focus of development thinkers and practitioners reflected in part the economic experiences and the broader political climate of the time. Global economic growth slowed following the oil price shocks of 1974 and 1979. The second oil price shock was followed by higher U.S. interest rates to control inflation, which pushed the United States into recession. With falling demand

for their exports and rising interest rates, many developing countries could not service the debts they had built up over the preceding ten years, resulting in the debt crisis that began in Mexico in 1982 and spread to other developing countries. The belief that government officials and bureaucrats would act in their own interest led many thinkers to push for rapid change. Jeffery Sachs and others argued that a crisis would provide only a limited amount of time for reform. Reforms would have to be pushed through quickly, despite attendant costs, to ensure that the rent seekers who sought to gain wealth through benefiting from the imbalances and lack of transparency in the legal and regulatory environment could not reestablish their interests (Sachs 1994; Lal 1997).

In the richer members of the Organisation for Economic Co-operation and Development (OECD), the oil shock and subsequent rise in interest rates and debt servicing costs also led to a growing appreciation for the need for fiscal adjustment. With the dominant political mood more open to the arguments of those economists who called for reductions in pubic expenditure, policies became more promarket in key developed economies.

The broader geopolitical context also contributed to this pendulum swing. The hardening of the Cold War caused a reaction against state-led growth models, with these models being seen as part and parcel of socialism. In this context, advanced economies such as the United States, Britain, and Germany began the wave of deregulation and privatization under the leadership of Ronald Reagan (United States), Margaret Thatcher (United Kingdom), and Helmut Kohl (Germany). Given the power that these governments exercised over the Bretton Woods institutions, and that the trend reflected a broad shift in economic thinking, it is not surprising that in this period the strongly promarket Anne Krueger replaced the long-serving development economist Hollis Chenery in the influential role as chief economist of the World Bank.

In this environment, Williamson (1990) identified a set of policies that he termed the "Washington consensus." These policies reflected the prevailing view of orthodox development thinkers, not least at the Washington-based World Bank and International Monetary Fund, in the 1980s and the first half of the 1990s. These policies included macroeconomic stabilization; liberalization of trade, exchange rates, and financial markets; deregulation of domestic industries; and privatization of government-owned businesses. What Williamson identified was not only the prevailing Washington view. It also was applied by a growing number of developing countries, often under the duress of fiscal adjustment, as these countries sought a prerequisite to sustainable growth.

The consensus broke down over the extent of liberalization required for growth. For the Washington-based multilateral lending institutions, this required the removal of regulations including trade barriers, freeing prices from controls, and the dismantling of marketing boards and similar state institutions to allow markets to work to achieve their reputed efficiency. Like the classical economists of the 19th century, these thinkers advocated a highly restricted role for the government involving the provision of public goods such as law and order, defense, and a sound currency, and when necessary, primary education, primary health care, and a social safety net.

The late 1980s saw improvements in macroeconomic stability and an opening to trade, financial, and other flows in much of the developing world. From the 1980s to 2005, trade barriers fell across developing economies from average levels of more than 30 percent to about 10 percent. The "tiger economies" of East Asia were held up as examples of the benefits of getting rid of government regulation and controls, promoting exports, and "letting markets work," and several studies appeared to confirm that these policies were responsible for the rapid growth of these economies (World Bank 1993). These studies were later shown to provide an inadequate explanation of the success of the "Asian Tigers." The interpretation of the industrialization of Asian economies has been challenged by a number of critics who argued that the state played a pivotal role in development (Amsden 2001; Wade 1990), and even the World Bank later developed a more nuanced

view of the East Asian experience (Stiglitz and Yusuf 2001).

Importance of Institutions By the late 1990s, the failure of the rapid transition from centrally planned to capitalist economies to deliver broad-based benefits in Eastern Europe, together with the Asian crisis of 1997, in which institutional weakness played a part, and a growing perception that the distribution of globalization's gains was inequitable, led to a widening acknowledgment of the shortcomings of a purely "promarket" approach to development. In particular, it neglected the importance of institutions and the provision of public goods, not least good governance, both at the national and at the global level. The pendulum shift in development thinking built on the work of the 1993 Nobel laureate Douglass North, who noted that individual behavior was constrained by numerous rules and social norms of the society in which the individual lives (North 1990). It was argued that without studying these constraints, including how they arise and their impacts, attempts to promote development would be unlikely to succeed.

The constraints provided by history became particularly obvious following the attempted shock therapy in the former Soviet states. In contrast, China continued to implement market-oriented reforms while nevertheless holding to its core commitment to a powerful state and with only partial reform of key macroeconomic and institutional levers.

Development practitioners began promoting stable and effective government institutions, strong enforcement of property rights, the absence of bureaucratic harassment, a lack of corruption, and protection from organized crime all things that matter for the functioning of markets and that had been previously neglected. In retrospect it was now considered naïve to think that the institutions that enable markets to work could evolve quickly and without state intervention.

The Asian crisis, Soviet transition, and Chinese experience highlighted the importance of sequencing, the order in which policies were put into effect. The orthodox position promoting liberalization of all aspects of the capital account was replaced by a heterodox view that highlighted the importance of sequencing and country specificity.

Complementarity of Markets and Governments By the mid-1990s, the dominant development discourse had begun to move away from market-led approaches. In its place, a consensus was forming around the complementarities between markets and governments. Attention focused on how government and the private sector may best work together. A vibrant private sector was now seen as the driver of economic growth, but this required properly functioning state institutions to build a good investment climate and deliver basic services competently. Investment climate analysis was focused on the ease and cost of starting legitimate businesses, including the bureaucratic costs and access to credit and basic infrastructure and utilities. Indicators based on World Bank surveys provide a comparison of the performance of different countries (World Bank Doing Business Project and World Bank Investment Climate Surveys).

Countries that combined institutional improvements with market-oriented policy reforms and greater engagement with the world economy saw their per capita incomes grow in the 1990s at the historically very rapid pace of more than 5 percent per year. Some countries have achieved even faster growth, with China's per capita growth averaging 8.7 percent from 1990 to 2005. That a sound state is required for solid growth was shown in the uneven development outcomes of the former Soviet countries. Promarket policies could not be expected to succeed without strong market-based institutional foundations.

Important too is local "ownership" of the development agenda rather than imposition from outside. The countries that have achieved rapid development, such as China and India, have done so through the actions of their own people and government, and with very little development assistance.

Growth Theory and Development Thinking Growth has been a concern throughout the history of development thinking, albeit with a general decline in expectations of what development assistance and policies can do. Yet growth theory and devel-

opment thinking diverged considerably in the 1960s, with growth theory identifying formal mathematical models these were mainly focused on growth in advanced economies. Underlying these models were assumptions of well-functioning markets and a system of economic incentives.

In contrast, development theorists typically eschewed mathematical models and focused on the failure of the assumptions used in growth theory. Interest in input-output and later general equilibrium analysis has provided a heavily quantitative seam within the development literature, but such methods remain a relatively minor feature of development thinking (Goldin, Knudsen, and Brandao 1994).

With increasing macroeconomic stability has come a greater recognition of the importance of microeconomic and institutional development. To the extent that the focus of many development thinkers today is mainly on how to affect the actions of individuals and firms rather than on macroeconomic aggregates, interest in models based on broad aggregates of national accounts has diminished.

Both growth theory and development theory have had a considerable influence on development policy. The simplistic stories that emerge from growth models have encouraged theories of missing components of production and policies that fill these gaps. These have variously included capital, foreign exchange, human capital, and technology. Development thinkers have been more active than growth theorists in exploring the reasons why these factors may be missing. In this sense, recent development thinkers have focused on the incentives for people to accumulate physical and human capital, and on an efficient use of these types of capital.

Questions regarding the sustainability of growth have only recently begun to enter the mainstream of development theory. The oil price shocks of the 1970s and the rapid recovery of the 1980s, not least in East Asia, led to a growing recognition of the need to focus on resource degradation and what was termed (by the Club of Rome) as the Limits to Growth. The United Nations Commission on Environment and Development in 1987 published the widely cited Brundtland report, which defined sustainable development as meeting the needs of the present without compromising the ability of future generations to meet their own needs (WCED 1987). It would be 20 years, however, until the evidence of climate change became so overwhelming that the largely grassroots movement influenced by the Brundtland report could see sustainability becoming central to development thinking.

No Single Model for Development Development thinking has evolved rapidly since the 1950s and is continuing to change. Different development concepts have emerged in response to specific economic and political conditions and problems, attempting to address these challenges, but typically only partially succeeding. Concepts have been less useful when they have been exported without accounting for different economic, social, and cultural conditions, or when they have continued to be applied after economic and political conditions have changed. Development strategies have been most successful when they addressed the specific challenges facing a country at a particular point in time. This requires that countries have the capacity for policy formation in terms of skilled researchers and the relevant data. Both are vital to policy reform. Since the mid-1990s, development thinking has continued to evolve. Increasingly, development is seen not through the lens of actual outcomes but through the outcomes that a person is able to choose. This concept gives greater prominence to empowerment of the individual and the expansion of individual freedom; and individuals are seen as agents for change rather than as passive recipients of assistance.

It has become clearer since the 1950s that there is no development panacea or universal path for development. Development thinkers and practitioners can benefit from understanding the experiences of different countries and by drawing on the latest theory. There is, however, no shortcut. If anything, the evolution of development thinking shows how today's truths are replaced by tomorrow's wisdom. The application of development thinking requires an arsenal of knowledge that includes economic theory and is informed by comparative and

historical analysis. The application also requires that the thinking respond to a country's specific priorities and circumstances. Greater investment in research is required to ensure that development thinking evolves even more rapidly in response to the enormous current challenges, many of which, such as global equity and climate change, go the heart of questions of sustainable development.

■ exchange market pressure
Foreign exchange market pressure (EMP) indexes are weighted schemes of variables designed to gauge

speculative pressure on a country's currency. These variables normally include the exchange rate, the domestic interest rate, and/or a measure of international reserves available to the monetary authority. Crisis incidents in recent years, including the severance of the British pound from the exchange rate mechanism in 1992, the Asian crisis in 1997, and the abolition of the Argentinean peg with the U.S. dollar in early 2002, have shown that the potential for foreign exchange market pressure to result in currency crises is significant, and hence monitoring informative variables is crucial.

Investors may put downward pressure on a currency for several reasons: for example, they may have spotted a fundamental imbalance and believe that a given exchange rate is unsustainable; or they may observe and follow the actions of other investors/ speculators. The reaction of policymakers depends on whether they want to accommodate the pressure and allow devaluation or, assuming a tough stance, they prefer to deter it. If the latter is the case, they may increase the short-term interest rate (hence offering a greater return than before on domestic currency investments) or spend international reserves (buying the domestic currency in the foreign exchange market with the aim of supporting its value). An EMP index is designed to capture this kind of activity in the foreign exchange market.

Theoretical Foundations The roots of the EMP index can be found in an analysis of demand and supply of national currencies in Girton and Roper (1977), where the term *exchange market pressure* was first used. A monetary model of the balance of payments is derived in which changes in the exchange rate and real international reserves for a small open economy are a function of changes in domestic credit expansion and real income, the money base and real income of a center currency country, as well as the inflation differential and the uncovered interest differential.

The widespread effects of the crises in the 1980s and the early 1990s highlighted the need to explain and predict such incidents. Girton and Roper's model provided the necessary insight for finding a solution to the problem of how to measure pressure

in the foreign exchange market. Whereas changes in the exchange rate can be easily used to capture the effects of a successful speculative attack, they cannot identify instances where in spite of speculative pressure being present no significant loss in the value of the currency has taken place. Furthermore, devaluation episodes may be voluntary on the part of policymakers attempting, for example, to boost exports. Clearly, in order to construct meaningful models of crisis prediction, also known as early warning systems, a robust definition of what constitutes a crisis needs to include a measure of international reserves.

Practical Issues The issue arises of how to weight the two variables exchange rates and reserves in an index of speculative pressure. One method commonly used is to employ the ratio of the standard deviation (σ) of the two components (Kaminsky and Reinhart 1999):

$$Index = \frac{\Delta e}{e} - \frac{\sigma_e}{\sigma_r}\frac{\Delta r}{r},$$

where $\Delta e/e$ stands for the percentage change in the nominal exchange rate and $\Delta r/r$ stands for the percentage change in the level of international reserves. The negative sign in front of the second term implies that losses in reserves are associated with a higher index value. Another weighting scheme could involve the inverse of the standard deviations. In addition, a third variable, namely, interest rate changes ($\Delta e \neq e$), is sometimes included in the computation. Thus another commonly used EMP index (Eichengreen, Rose, and Wyplosz 1995) is as follows:

$$Index = \alpha\frac{\Delta e}{e} + \beta\frac{\Delta i}{i} - \gamma\frac{\Delta r}{r},$$

where α is the inverse of the standard deviation of the percentage change in exchange rate divided by the sum of the inverses of the standard deviations of all three variables, β is the inverse of the standard deviation of the percentage change in the interest rate divided by the sum of the inverses of the standard deviations of all three variables, and γ is the inverse of the standard deviation of the percentage change in real reserves again divided by the sum of the inverses of the standard deviations of all three variables. This weighting scheme ensures that the most volatile

components do not dominate the index. The variables are expressed relative to a reference country.

Advantages and Problems The advantage of EMP indexes over simple measures of exchange rates is that even if the exchange rate does not move in the presence of speculative pressure, the pressure is registered through the policy response of the authorities, which might be an increase in interest rates and/or a reduction in reserve levels. Very often the indexes are converted into a discrete binary variable so that observations can be classified as either crisis or noncrisis. It is commonplace to allocate a one whenever a value of the index exceeds the mean of the index by three standard deviations. Otherwise, a zero is allocated. It needs to be noted that the definition of a critical threshold for classifying an observation as crisis is rather arbitrary; as a result, a wide range of critical thresholds has been used in the literature.

The identification of crisis episodes is also sensitive to other factors, for instance, sample selection and data frequency. Extending a given sample by, say, incorporating a period of excess volatility will push the critical threshold up (as a result of a higher standard deviation in the sample), which may lead to different results: observations that were characterized as crisis in the original sample may now turn into noncrisis observations. The frequency of the dataset used in the construction of the index is also of importance, as crises in the foreign exchange market can be short lived, with exchange rates, interest rates, and reserves assuming their precrisis values soon after an episode. It may be the case that if an annual frequency is selected, crisis incidents may be missed. Higher frequency data increase the likelihood of spotting a crisis but these are not always readily available for all the components of the index, especially data on interest rates. A further issue relates to the fact that different exchange rate regimes may be in place over the time span of the index (de jure or de facto). This can have implications for the index. For example, the switch from a fixed regime to a flexible one may be followed by a sustained depreciation of the domestic currency, with the index failing to readily convey this information (due to the lower variability in the interest rate and reserves changes).

Overall, despite their deficiencies, EMP indexes have been widely used in the context of early warning systems to inform policymaking. The absence of components relating to capital controls and exchange rate regimes implies that they should be used in conjunction with relevant information about the implementation of the prevailing exchange rate policies.

■ exchange rate forecasting
While exchange rate changes can lead to significant gains or losses to private entities involved in international transactions, from a macroeconomic perspective they can also have important impacts

on inflation and output growth. Exchange rate determination has therefore been a topic much researched by central banks and financial markets. Two broad methods of exchange rate determination fundamental analysis and nonstructural analysis have been used by economists. Based on the evidence, however, it appears that no single model can forecast exchange rates for all currencies or at all times.

Fundamental Analysis Since the mid-1980s, a multitude of fundamentals-based models have been used to assess the predictability of exchange rates. The host of fundamentals-based or structural exchange rate models includes monetary models, portfolio balance models, behavioral (fundamental) equilibrium exchange rate models, productivity differential models, the interest rate parity equation, and the purchasing power parity specification. One general observation is that there is no consistent evidence of a complex structural model outperforming a simpler one.

For economists, the monetary model, of which money market equilibrium is an important component, has been the workhorse model of exchange rate determination. In their seminal work, however, economists Richard Meese and Kenneth Rogoff (1983) forcefully show that forecasts from the monetary model do not outperform the naïve forecast from a random model that uses current exchange rates to predict future exchange rates. The result has largely withstood the challenge of sophisticated exchange rate models and elaborate econometric techniques developed after its publication. Consequently, the Meese and Rogoff study has greatly shaped the subsequent empirical studies on forecasting exchange rates.

More recent empirical work rejuvenates the monetary model by showing that its forecasting performance can beat the random walk's over long horizons (Mark 1995). The intuition is that, despite its large short-term volatility, an exchange rate's long-run value is determined by economic fundamentals (also see Chinn and Meese 1995). These long-horizon results are, nonetheless, not that persuasive once they are subjected to close scrutiny. Besides the choice of sample periods and the method of con-

structing fundamental values, an issue is the interaction between short- and long-horizon forecasts. If long-horizon forecasts are constructed from a sequence of short-horizon forecasts, then the performance of these two types of forecasts should be linked (Berkowitz and Giorgianni 2001). Further, forecasting into the distant future usually involves a high level of uncertainty. These considerations plus some more recent studies cast doubts on the results that long-horizon forecasts from structural exchange rate models are better than those from a random walk.

Despite some setbacks, long-horizon forecasts are still the focus of some foreign exchange forecast exercises. Efforts to revive the monetary model's forecast ability include the uses of long history data, panel data, nonlinear dynamics, and nonparametric techniques. Notwithstanding all of these efforts, an extensive study shows that, despite some evidence of forecast superiority, it is difficult to find a fundamentals-based exchange rate model outperforming a random walk specification for all the sample periods, evaluation criteria, and currencies under consideration (Cheung, Chinn, and Pascual 2005).

Nonstructural Analysis Given the dismal performance of structural exchange rate models, researchers have explored the forecasting ability of nonstructural time series models. Various time series techniques have been used to model exchange rate behavior. Some common ones are standard autoregression-moving-average models, vector autoregression models, vector error correction models, fractional integration models, threshold autoregression models, Markov switching models, and nonparametric models. Again, there are reservations about the positive results of using a time series model to forecast exchange rates.

Technical analysis that relies on price patterns is also commonly used to forecast exchange rates. Technical analysis uses a range of tools from the relatively simplistic moving average rules to complicated neural network based techniques. Despite the skeptics in academia, technical analysis is quite popular among professional foreign exchange traders (Cheung and Wong 2000). The performance of technical analysis has been quite unstable over time,

however, and there has been a debate on whether the observed profits from technical analysis are compensations for trading risk or excess (abnormal) returns (Menkhoff and Taylor 2006).

Summing Up Since Meese and Rogoff reported the failure to beat the forecast performance of a random walk, there have been serious efforts to determine the predictability of exchange rates. Sophisticated exchange rate models both structural and nonstructural and refined econometric techniques have been developed to challenge the random walk forecast. In the process of finding the real contender, various reasons have been offered to explain the difficulty in forecasting exchange rates. The most commonly cited reasons include the time-varying relationship between exchange rates and their fundamentals, bad data quality, and incorrect model specification.

With the intense investigation since the mid-1980s, we are still waiting for convincing evidence that an exchange rate model can consistently outperform the random walk. In sum, exchange rate forecasting is still an elusive exercise, and the extant evidence confirms the adage that no single model can forecast exchange rates for all currencies or at all times.

■ exchange rate pass-through

Exchange rate pass-through can be defined as the degree of sensitivity of import prices to a one percent change in exchange rates in the importing nation's currency. A closely related term is *pricing to market*, which refers to the pricing behavior of firms exporting their products to a destination market following an exchange rate change. More to the point, *pricing to market* is defined as the percentage change in prices in the exporter's currency due to a one percent change in the exchange rate. Thus the greater the degree of pricing to market, the lower the extent of exchange rate pass-through.

At one extreme, if import prices change by the same proportion as the change in the exchange rate, the result is full or complete pass-through and hence no pricing to market. At the other extreme, if exporters adjust prices in their own currency by the same proportion as the exchange rate change but in the opposite direction, the result is full pricing to market but no or zero pass-through of the exchange rate change to the destination market prices. More generally, if exporters alter the export prices in their own currency by a proportion smaller than the exchange rate change, then exchange rate pass-through is said to be partial or incomplete.

The degree of exchange rate pass-through and pricing-to-market behavior has important bearings on economic policy. If pricing to market is high and exchange rate pass-through low, then any exchange-rate-based adjustments to improve the trade balance for economies may be ineffective, as nominal exchange rate changes do not translate into real exchange rate changes.

Although these concepts have been well known to economists for a long time, they attracted particular interest following the Plaza Accord in 1985 and the subsequent sharp appreciation of the Japanese yen in relation to the U.S. dollar. Following this strengthening of the yen, other things being equal, one would have expected the unit price of Japanese products sold in the United States (in U.S. dollars) to have risen sharply. In reality, however, the price of Japanese cars and electronic items sold in the United States rose only marginally or remained constant, and in some cases actually declined (Goldberg and Knetter 1997). This suggested that the Japanese firms exporting products to the United States may have been absorbing a large part of the exchange rate changes in order to maintain market share. Given this important empirical observation, economists began trying to estimate the extent of exchange rate pass-through, as well as to analyze the determinants of exchange rate pass-through and the corresponding pricing-to-market behavior.

What Determines Exchange Rate Pass-Through? Among the most important factors that determine the extent of exchange rate pass-through are the size of the export market and the degree of competition the exporter faces in that market. If the export market for the product is large, then exporting firms are often willing to absorb a proportion of the exchange rate change so as not to lose market share. This is particularly true if the industry is highly competitive. The presence of a large number of suppliers selling similar goods in the market provides domestic consumers with a choice of many substitutes, making them relatively price sensitive. Conversely, if the industry is highly differentiated and exporters do not face much competition for their products, then exporter prices may be somewhat less responsive to exchange rate changes. In this situation, pricing to market will be lower and the corresponding pass-through will be higher. For example, exports to certain competitive industries in the United States, such as autos and alcoholic beverages, show relatively high pricing to market and corresponding lower exchange rate pass-through as exporters try to preserve market share (Knetter 1993).

The direction, duration, and magnitude of exchange rate changes also affect pass-through. If the currency of the destination market depreciates, then exporters may be willing to absorb this exchange rate change in order to keep local currency prices of their products stable and retain market share. In this situation, exchange rate pass-through may be low or incomplete. If the currency of the destination market strengthens, however, the exporter's product will be relatively cheaper and the exporting firm may engage in complete exchange rate pass-through. In other words, the response of exporters to exchange rate changes may be asymmetric, depending on whether the currency rate appreciates or depreciates.

The high costs of changing prices, as well as the possibility that frequent changes in unit sales prices (in the destination market's currency) can adversely affect a firm's reputation, may prevent firms from passing through temporary fluctuations in exchange rates. When exchange rate changes are large or appear to be permanent, however, exporting firms are more likely to pass through the changes to avoid a sharp reduction in their profit margins.

Low and Declining Exchange Rate Pass-Through Exchange rate pass-through generally has a greater effect on import prices than on a nation's consumer price index. This is because the latter includes nontradables that are less responsive to exchange rate changes. Regardless of the price index used, however, exchange rate pass-through was lower in the 1990s than in the 1980s, and has continued to decline. Although most of the research has focused on developed countries, where more data are available, some studies suggest that the conclusion holds for developing countries as well (Ghosh and Rajan 2006).

Exchange rate pass-through may also depend on a country's monetary and exchange rate policies. The more stable a country's monetary policy and the lower its rate of inflation, the lower the extent of exchange rate pass-through will be, as it is less likely that foreign exporters will pass through exchange rate changes (Taylor 2000). This in turn helps to sustain low inflation and makes monetary policy more effective. Thus there may be a "virtuous cycle" between stable monetary policy and low exchange rate pass-through.

If exports are invoiced in the currency of the importing nation known as consumer-currency pricing or local-currency pricing then exchange rate changes have little effect on the destination market import prices, which leads to low exchange rate pass-through. On the other hand, if exports are invoiced in the currency of the exporters referred to as producer-currency pricing then exchange rate changes have a greater effect on prices in the importing nation, leading to higher pass-through. It has been argued that if exporters set their prices in the currency of the country that has the more stable monetary policy (i.e., local-currency pricing as opposed to producer-currency pricing), then exchange rate pass-through into import prices in local currency terms will be correspondingly low (Devereux and Engel 2001).

In an important paper, the economists Campa and Goldberg (2005) test the significance of changes in macroeconomic variables and the extent of exchange rate pass-through into aggregate import prices for 25 industrial nations for the period 1975 99. The authors find that the lower the average rate of inflation and the less variable the exchange rate, the lower the corresponding extent of exchange rate pass-through will be. These macroeconomic factors play a minor role in explaining the low exchange rate pass-through, however, compared to the changing composition of a nation's imports away from raw materials and energy imports toward manufactured imports. This changing composition of the basket of imports toward manufacturing goods (which tend to be characterized as being more competitive industries) may be behind the low and declining rates of exchange rate pass-through.

Another factor that may have affected the extent of pass-through is cross-border "production fragmentation," which refers to the dispersion of the production process among different countries. A country might export the final product but at the same time import the corresponding parts and components from another nation. A depreciation of the currency of the nation exporting the final good makes its imported components more expensive. Therefore, an exchange rate change affects the exporter's costs, which leads the exporting firm to raise its price denominated in its own currency, and subsequently pass through less of the exchange rate changes into the partner nation's currency denominated prices. Moreover, with dispersion of production processes, often more than one nation supplies parts and components, thereby increasing competition and lowering exchange rate pass-through (Ghosh and Rajan 2006).

Policy Relevance The low exchange rate pass-through in the United States may explain the persistence of the U.S. trade deficit despite declines in the U.S. dollar. Conversely, low exchange rate pass-through implies that economies may be less concerned about the potential inflationary consequences of exchange rate fluctuations. Although the extent of exchange rate pass-through has important macroeconomic implications, it is predominantly a microeconomic phenomenon and depends significantly on the types of goods being traded.

■ exchange rate regimes

The exchange rate regime is the characterization of the way a government manages its national currency in the foreign exchange market. The different forms of exchange rate regimes relate to how actively the government manages the foreign exchange rate, and how its actions are supported by institutional arrangements. At one end of the spectrum is an independently floating currency; at the other, a fixed exchange rate system, sometimes referred to as a "hard peg." Many varieties of exchange rate regimes exist between these two poles.

Floating Rate Regimes With an independent floating exchange rate regime the exchange rate is market determined and there is no explicit exchange rate target level or institutional commitment to influence the path of exchange rates. The purest form of independent floating is the "free float," in which the government neither intervenes in the foreign exchange market (buying or selling foreign currency from international reserves) nor directs monetary, fiscal, or regulatory policies to an explicit exchange rate objective. In free float regimes, the government allows the market-determined exchange rate to prevail and does not attempt to influence its value. Instead, the government directs macroeconomic policy entirely toward domestic stabilization objectives such as output and inflation levels.

Few countries follow purely free floats; even those that are independently floating occasionally intervene in foreign exchange markets and take into account the value of the exchange rate in making macroeconomic policy decisions. The countries with regimes most closely approaching pure free floats are the United States and the euro area (European countries that share the euro as a common currency). The United States has intervened in the foreign exchange market on only a few occasions since the mid-1990s with the objective of countering "disorderly" market conditions. The Federal Reserve System also puts little weight on exchange rates in its policy deliberations. Similarly, the European Central Bank has intervened in the foreign exchange market only a few times since the introduction of the euro in 1999 (Fatum and Hutchison 2002).

Other countries with independently but not freely floating regimes include Japan, Canada, New Zealand, Sweden, and many more. Countries that follow independent floats intervene in foreign exchange markets occasionally and at times quite heavily, but have no explicit exchange rate target level. Japan, for example, intervened to an unprecedented degree in 2003 and 2004, buying more than $300 billion in the foreign exchange market in an attempt to support the value of the U.S. dollar

exchange rate against the yen (Fatum and Hutchison 2006).

Closely related to independently floating systems are "managed floating" exchange rate regimes. In these cases, the exchange rate is again largely market determined, with official foreign exchange market intervention aimed at slowing exchange rate movements or reducing volatility but without having a specific exchange rate path or target. These countries tend to undertake more active interventions in foreign exchange markets than independent floaters, with indicators for managing the rate being broadly judgmental (e.g., balance of payments position, international reserves, parallel market developments), and adjustments may not be automatic. In managed floating cases, however, the exchange rate is typically a secondary policy target with little constraint placed on the conduct of domestic monetary or fiscal policy. The International Monetary Fund (IMF) characterized 53 exchange rate regimes at the end of 2005 as "managed floating, with no predetermined path for the exchange rate." Most developing and emerging market economies fall within the managed floating group. Examples include the Czech Republic, Paraguay, and Indonesia.

National Legal Tender, Monetary Unions, and Currency Boards A "fixed" exchange rate regime is at the opposite end of the spectrum from an independent floating regime. In a fixed exchange rate system, the government is committed to maintaining a particular exchange rate value and pegs this rate by a combination of official foreign exchange market intervention, macroeconomic policies, and institutional arrangements such as international capital controls. The "hardest," or most durable and credible, exchange rate peg is supported by strong institutional arrangements, either by stringent controls on the flows of financial capital into and out of the country, when the country enters into a currency board arrangement, or when the national currency is replaced with a foreign currency ("dollarization").

Dollarization refers to a country's choice to circulate the currency of another country as its sole legal tender, without a separate national currency. The term *dollarization* does not necessarily refer to the

U.S. dollar; it is a generic term for any national currency that is the legal tender in a foreign country. Ecuador "dollarized" after currency turmoil, and the U.S. dollar has been in circulation in Panama for many years. Many small island nations are dollarized because it would be impractical for them to have independent national currencies. The IMF classified 29 countries (excepting members of the European Monetary Union) in the group "exchange rate arrangements with no separate legal tender" at the end of 2005. Dollarized countries have no control over the exchange rate, and typically little or no control over domestic monetary policy, since interest rates are largely determined abroad.

Countries that belong to monetary or currency unions have a legal tender that is shared by members of the union. As of 2006, 12 European countries had given up their national currencies since 1999, adopting the euro as a common currency. Previously separate (except in the case of Belgium and Luxembourg) national legal tenders have been replaced by one currency and one exchange rate, which is independently floating. Monetary unions have a common monetary and exchange rate policy. In the case of the euro, monetary policy is run by the European Central Bank (ECB) in Frankfurt. Unlike dollarized countries, however, countries in modern monetary unions participate in the exchange rate and monetary policy deliberations for their shared currency. The ECB has a decision-making structure representing all of the European Monetary Union (EMU) countries.

The "hardest" and most credible of the pegged rate systems (considering arrangements with no separate legal tender as a special case) is the currency board regime. Under this arrangement, all of the national currency in circulation is backed by the government's holding of foreign currency reserves, and the government stands ready to buy or sell as much foreign currency as necessary to maintain the exchange rate value. Currency boards are based on an explicit legislative commitment to exchange domestic currency for foreign currency at a fixed exchange rate. To enable the central bank to make this commitment, the board imposes restrictions on the is-

suance of domestic currency: new issuance of national legal tender is contingent on an inflow of foreign exchange reserves. The government has little or no control over monetary policy or short-term interest rates in a currency board institutional setting. The Hong Kong Special Administrative Region, China, has a long-standing currency board arrangement. Estonia, Lithuania, and several other countries also have currency board arrangements.

Pegged Exchange Rate Arrangements Pegged exchange regimes may take a variety of forms, including fixed peg arrangements, pegged rates in horizontal bands (e.g., the Danish krone vis-à-vis the euro), crawling pegs (e.g., Turkey), rates within crawling bands (e.g., Hungary, Israel, and Venezuela), and other fixed pegs (e.g., China, Egypt, and Malaysia). In a conventional fixed peg regime, the authorities attempt to maintain the value of the exchange rate within a narrow band (usually plus or minus 1 percent) around a central parity (or reference value) exchange rate. The authorities commit to intervene by buying and selling foreign exchange reserves, sometimes in cooperative arrangements with other central banks, or to adjust interest rates and other policies to maintain the exchange rate within the band. There is no legal or institutional commitment to maintain the central parity exchange rate irrevocably, and occasional adjustments to the central parity may occur. The central parity referenced exchange rate may be a single currency, a cooperative arrangement, or a currency composite. In the absence of capital controls, there is very limited monetary autonomy with a fixed rate peg, as foreign exchange interventions, and often interest rate changes, are necessary to maintain the value of the currency within a narrow range. Forty-five countries followed a fixed peg arrangement at the end of 2005, reflecting a wide range in level of development and geographic distribution. Examples include China, Malaysia, Nepal, and Saudi Arabia.

A pegged rate within horizontal bands is similar to a fixed peg but with more flexibility of the exchange rate around the central parity, typically plus or minus 2 percent. The wider band, compared to the fixed peg regime, allows somewhat greater monetary policy discretion. In general, the broader the band width, the greater the degree of monetary policy independence in principle, monetary policy discretion is possible until the limits of the band are reached. As in the case of conventional fixed pegs, reference may be made to a single currency, a cooperative arrangement, or a currency composite. Target zones, such as the former exchange rate mechanism (ERM) of the European Monetary System, are a form of pegged rates within a horizontal band. Only six countries followed a pegged rate within horizontal band arrangement at the end of 2005, four of which were in the context of the ERM II arrangement with the EMU (Cyprus, Denmark, the Slovak Republic, and Slovenia).

Two other common forms of pegged exchange rate regime are the crawling peg and crawling band systems. The crawling peg refers to a case in which the currency is adjusted periodically in small amounts, either at a fixed increment or in response to indicators such as domestic inflation relative to trading partners or perhaps to expected future inflation differentials. Maintaining a crawling peg imposes constraints on monetary policy in a manner similar to a fixed peg system. Similarly, the crawling band regime maintains the currency within a band but adjusts the central reference rate or margins periodically in response to quantitative indicators.

Exchange Rate Regimes, Monetary Policy, and International Capital Controls One key feature distinguishing exchange rate regimes is the extent to which they constrain the conduct of monetary policy. Generally speaking, the greater the fixity of the exchange rate, the less room there is for monetary autonomy. On one side of the spectrum is an independently floating exchange rate, in which conduct of domestic monetary policy is under little constraint. On the other side of the spectrum is a currency board arrangement or a country that has no separate national legal tender. In these latter two cases, there is little or no room for independent monetary policy. If there is no separate legal tender, there is no national money and therefore no national monetary policy. In the currency board arrangement, changes in monetary policy follow the balance of

payments and the rise and fall of official international reserves. Capital outflows that result in a decline of international reserves automatically trigger a contraction of the money supply, and the opposite is the case for capital inflows.

As the exchange rate regime moves along the spectrum from hard pegs toward independently floating, monetary authorities in principle have greater control over setting domestic interest rates and the path of monetary policy. The degree of international capital mobility, that is, the legal, institutional, or market-related constraints on the cross-border flow of financial resources, also affects a country's monetary policy. Monetary authorities frequently impose restrictions on capital flows in an attempt to gain more monetary autonomy in the face of constraints imposed, say, by fixed pegged exchange rates. The Bretton Woods system of fixed peg exchange rates (1946 71) lasted several decades because of pervasive capital controls, policies that led to low inflation in the United States, and the willingness of countries pegged to the U.S. dollar to accept limited monetary autonomy. Countries are more willing to give up monetary independence and link with the U.S. dollar if the monetary leadership of the reserve-currency country provides a stable macroeconomic environment.

The economics term *impossible trinity* means that countries cannot simultaneously follow an independent monetary policy, maintain a fixed peg exchange rate regime, and allow unrestricted international capital flows. Countries frequently face a dilemma if their domestic stabilization policy objectives and desired path of monetary policy (level of interest rates, for example) conflict with the monetary policy needed to maintain a pegged exchange rate. In these circumstances the country must abandon its desire to pursue its stabilization objectives, give up the exchange rate peg, or impose capital controls in the hope of gaining some flexibility in reconciling the two other objectives. Exchange rate regime changes frequently occur because of this dilemma, usually because countries cannot constrain monetary and fiscal policy effectively to curtail inflation and balance of payments imbalances. In a

system with freely mobile international capital, this policy dilemma is often exacerbated by a sharp capital outflow as domestic asset holders, both foreign and national residents, anticipate devaluation (and associated capital loss on domestic assets) and move to sell the domestic currency before it occurs. In this circumstance, devaluation of the exchange rate is commonplace.

Optimal Exchange Rate Regimes and Regime Collapses A basic question in discussing exchange rate regimes concerns which regime is best suited to the particular circumstances of a given country. This topic is often referred to as "optimal" exchange rate regime choice. Much of the work in this area focuses on the nature of disturbances facing the country, whether they be foreign or domestic in origin, real or monetary, permanent or transitory, combined with the choice made by authorities of a particular systematic approach to intervention in the foreign exchange market or monetary policy rule to influence exchange rate developments (Marston 1985). The exchange rate arrangement must be consistent with the degree of monetary independence and international capital mobility to be sustainable. Traditional theory suggests that an intermediate regime usually is preferable to either a hard peg, such as a currency union or currency board arrangement, or a completely free floating exchange rate. The structure of the economy, the nature of economic disturbances, and the degree of capital mobility are some of the standard criteria in the choice of an exchange rate regime.

The choice of exchange rate regime, however, is more constrained than the traditional view would suggest. Speculative international capital flows can cause regime collapses very quickly, even when current fundamentals appear strong. Concerns about future policy choices, vulnerabilities in the banking sector, and similar factors may start a run on the currency. Self-fulfilling crises are also possible, with a seemingly random speculative attack causing so much economic disruption that the policy authorities may change course entirely, devalue the currency, and end up with higher inflation than otherwise would be the case. Clearly, exchange rate regime

sustainability and choice are greatly complicated in an era of integrated financial markets and deregulated capital flows, and in response there has been a tendency for countries to move to one polar case or the other either hard pegs or independently floating exchange rates.

■ exchange rate volatility

One of the key facts in international finance is that when exchange rates are flexible they are also highly volatile. Such volatility manifests itself in two key ways: inter- and intraregime volatility. *Intraregime volatility* refers to the volatility of exchange rates in floating exchange rate regimes relative to the volatility of macroeconomic fundamentals such as money supplies, interest rates, and output levels. A common, although by no means universal, belief is that exchange rates are excessively volatile compared to macroeconomic fundamentals. *Interregime vola-*

tility refers to the behavior of real and nominal exchange rates in the move from fixed to floating exchange rates: as a country moves from fixed to floating exchange rates the volatility of standard macroeconomic fundamentals remains unchanged, but the volatility of both real and nominal exchange rates increases dramatically. The key question that arises from this kind of regime-dependent behavior is: Can such exchange rate behavior be explained in a manner consistent with a macroeconomic framework (that is, using a model that relies on macroeconomic fundamentals such as money supplies), or does such a framework have to be abandoned and an alternative framework, such as a market microstructure approach, be adopted?

The first part of this entry analyzes the issue of intraregime volatility and, specifically, different explanations for the volatility result. All the explanations rely on some variant of the monetary model of the exchange rate. The second part of the entry focuses on interregime volatility, starting with empirical evidence and then considering some theoretical explanations for this phenomenon.

Intraregime Volatility: Monetary Model In trying to explain intraregime volatility in terms of macroeconomic fundamentals, the monetary model of the exchange rate has become something of a workhorse. In essence this model posits that exchange rates are determined by the interaction of money supply (usually assumed to be exogenous, i.e., predetermined by the central bank) and money demand (which is a function of interest rates and income levels) terms between the home country and its trading partners. Other things being equal, an increase in the home money supply leads to a proportionate depreciation in the exchange rate.

In the flexible price version of the monetary model, exchange rate volatility is explained in terms of a "magnification effect" that arises because of the link in the model between the current (spot) exchange rate and the future expected exchange rate (Bilson 1978). The model may be written simply as:

$$s_t = f_t + E_t s_{t+1}, \qquad (1)$$

where s_t denotes the nominal exchange rate, f_t is a composite fundamental comprising home and for-

eign money supplies and income terms (suitably weighted with income elasticities), and $E_t s_{t+1}$ is the expected exchange rate in period t+1. The expected exchange rate in each future period of the life of the underlying asset (money) is determined by expected money supplies and expected income levels and so the current spot exchange rate in this model becomes a function of current fundamentals (money and income) in other words, period-t variables and the expected fundamentals in all future periods. More formally, the current spot price is the present discounted value of all expected fundamentals. To the extent that a current change in the money supply signals to agents an expected increase in future period fundamentals, this can cause the exchange rate to move by more than the current change in the period-t fundamentals, f_t. By simply observing the current exchange rate and the current change in fundamentals, a magnified response of the former with respect to the latter will be seen. This is the so-called magnification effect.

The monetary model has also been used to demonstrate the implications that speculative bubbles or, more generally, any nonfundamental factor can have for exchange rate volatility. A speculative bubble or nonfundamental factor can be added to equation (1) as:

$$s_t = f_t + E_t s_{t+1} + b_t, \qquad (2)$$

where b_t represents a speculative bubble term and can impart exchange rate volatility over and above that generated by the macroeconomic fundamentals. The speculative bubble can be a rational bubble, which means it is consistent with the underlying model (i.e., equation 1), or nonrational and therefore not necessarily consistent with any model. The introduction of a speculative term into the monetary model can generate excessive volatility of the exchange rate with respect to the fundamentals (see MacDonald 2007).

Intraregime Volatility: Dornbusch Overshooting Model Perhaps one of the best-known explanations for intraregime volatility is the seminal overshooting model of the economist Dornbusch (1976). This model is also in the monetary class, but assumes that consumer prices are sticky in the short run (although flexible in the long run) while asset

prices and yields (the exchange rate and interest rates) are continuously flexible. In the short run, income is assumed to be fixed. In this context, an increase in the domestic money supply upsets money market equilibrium and leads to a proportional depreciation of the long-run, or equilibrium, price level and exchange rate (which are flexible). In the short run, however, or in the immediate aftermath of the money supply increase, equilibrium can be restored only by a change in the interest rate (since the price level and income are held constant by assumption). But in a world of high, or complete, capital mobility the domestic interest rate is tied into the foreign rate through the uncovered interest rate parity condition and can change only if the expected change in the exchange rate is assumed to be nonzero.

The expected change in the exchange rate is, however, nonzero in the overshooting model because it is governed by a regressive expectations mechanism: a current depreciation of the exchange rate relative to its equilibrium, or long-run, value is expected to be reversed in the future. In other words, a current depreciation of the exchange rate produces the expectation of a future appreciation. So, in response to the increase in the money supply, what is required is the current exchange rate to move more than proportionally to the long-run, or equilibrium, exchange rate value (which moves in proportion to the increase in the money supply) to allow the domestic interest rate to fall below the world level: the exchange rate overshoots its long-run value and, by implication, the current change in the money supply. As in the magnification story, the current exchange rate is more volatile than current fundamentals. The extent of the overshooting is governed by how sensitive interest rates are to money supply changes (the less sensitive, the more the exchange rate will move) and the sensitivity of the expected change in the exchange rate with respect to the gap between the current and equilibrium exchange rates.

Intraregime Volatility: NOEM The variant of the monetary model used to derive both the magnification and overshooting results is regarded as ad hoc, in the sense that it is not based on an explicit microfoundations approach   that is, the starting point is

not an explicit utility function, maximized subject to a budget constraint. Both Stockman (1980) and Lucas (1982), however, present variants of the monetary model founded on an explicitly optimizing framework in which agents maximize utility subject to a budget constraint and a cash-in-advance constraint. In this model the current exchange rate is, as in the ad hoc approach, a function of relative money supplies and output levels and also the ratio of home to foreign marginal utility. In this context exchange rate volatility with respect to current information (in this case, period-t relative prices) arises because both preference and technology shocks   real shocks   are highly volatile. More recent explanations for exchange rate volatility using an optimizing approach have exploited the New Open Economy Macroeconomics (NOEM) model of Obstfeld and Rogoff (1995) and we now provide a brief summary of these explanations.

By introducing uncertainty into the basic NOEM, Obstfeld and Rogoff (2000) generate a variant of the forward-looking monetary model in which a "level" risk premium term features. There are two key insights here. First, the risk premium can affect the level of the exchange rate, and not just the predictable excess return, which has been studied extensively in the literature (see, e.g., MacDonald 2007). This is important because it means that higher moments of economic variables can affect the volatility of the exchange rate and not just the first moment   if the forward risk premium is quite volatile, this could have important implications for exchange rate volatility. Second, the effect of the risk premium on the exchange rate may potentially be very large in this model because it enters the forward-looking model with a scaling factor that puts a large weight on the premium.

In the Obstfeld and Rogoff (2000) model a rise in the level of home monetary variability leads to a fall in both the level exchange risk premium and the forward exchange rate risk premium, and, given plausible values of the scaling factor, imparts an exchange rate appreciation and considerable exchange rate volatility. The appreciation of the exchange rate and fall in the risk premium are contrary to the standard

intuition for the effect of increased monetary variability in which the common casual presumption is that financial markets attach a positive risk premium to the currency of a country with high monetary volatility. The effect is different in this model because in the sticky price variant, positive monetary shocks lead to increases in global consumption, which means that domestic money can be a hedge, in real terms, against shocks to consumption. Furthermore, higher monetary variability raises the expectation of the future real value of money (other things being equal) which is the convexity term (this effect also works in a flexible price model).

A further attempt to explain the excess volatility of exchange rates using a variant of the NOEM is made by Devereux and Engel (2001). They attempt to shed light on a conjecture of Krugman (1989) that exchange rate volatility is so great because fluctuations in the exchange rate matter so little for the economy. They use a variant of the NOEM in which there is a combination of local-currency pricing, heterogeneity in international price setting and in the distribution of goods (for example, some firms market their products directly in the foreign market and charge a foreign price while some exporters use foreign distributors, charging a price set in the exporter's currency), and crucially, the existence of noise traders (that is, traders who do not base their trades on fundamentals) who impart expectational biases into international financial markets.

Devereux and Engel (2001) demonstrate that in this setup the conditional volatility of the exchange rate depends on the volatility of the fundamentals (which in their case is the volatility in relative money supply terms) and the extent of local-currency pricing. With complete local-currency pricing, the conditional volatility of the exchange rate effectively rises without bound. This is because the combination of local-currency pricing, along with asymmetric distribution of goods and noise trading, implies a degree of exchange rate volatility that is far in excess of the underlying fundamental shocks.

Intraregime Volatility: Foreign Exchange Microstructure All of the foregoing research assumes that expectations are homogeneous. Bacchetta and

Wincoop (2003) build on the idea that the heterogeneity of investors may also be important for an understanding of exchange rate dynamics, however. In particular, they introduce two types of investor heterogeneity that have been associated with order flow into a standard variant of the monetary model. The first type is the heterogeneous information of market participants about future macro fundamentals a dispersion effect and the second is heterogeneity due to nonfundamentals. The latter includes noise traders and rational traders who trade for nonspeculative reasons, such as liquidity trades, or trades associated with differential access to private investment opportunities. Bacchetta and Wincoop demonstrate how information heterogeneity produces both a magnification effect on the exchange rate and endogenous persistence of the impact of nonfundamentals on the exchange rate. Using a simulation exercise and plausible parameter values, the authors demonstrate that there is a substantial magnification effect as a result of information dispersion, and a substantial part of this seems to be attributable to the role of higher-order expectations due to the infinite regress.

A number of economists have attempted to gauge the forward-looking monetary model as written in (1) and its speculative bubble variant given in (2) (e.g., see MacDonald and Taylor 1993). The evidence, in general, does not support the magnification story, although this could simply reflect the model specifications used. The research gives some support to the speculative bubbles hypothesis, although such tests could simply be picking up some other extraneous influence on the exchange rate (see, e.g., Engel and West 2004). More favorable empirical evidence has been reported for the overshooting model, while tests of the more recent NOEM variants of the monetary model have not yet begun. So, at best, we can conclude from this empirical evidence that the jury is still out on the validity of the various theoretical explanations for intraregime volatility (see also Arnold, MacDonald, and de Vries 2005).

Interregime Volatility Baxter and Stockman (1989) were the first to examine the variability of output, trade variables, and private and government

consumption across the Bretton Woods and post Bretton Woods experience, and they demonstrated that the behavior of macroeconomic fundamentals does not change in the move from fixed to floating exchange rates but that the behavior of the exchange rate (both real and nominal) does.

Flood and Rose (1995) reexamined the issue of interregime volatility using the monetary model. Specifically, they construct composite f terms using standard monetary and income variables and compare the conditional volatility of this term to the conditional volatility of the sum of the exchange rate and the interest differential for the Bretton Woods and post Bretton Woods periods. The countries studied are the United Kingdom, Canada, France, Germany, Holland, Italy, Japan, and Sweden. The results of Flood and Rose show that the volatility of the exchange rate term increases dramatically as countries move from fixed to floating, but the volatility of the composite fundamental term does not. In their view, the standard monetary fundamentals cannot explain the volatility of exchange rates in the move from fixed to floating exchange rates and attention has to be focused on what does change in the fixed to floating move, namely the market microstructure of the foreign exchange market.

A number of papers have attempted to understand the interregime puzzle without abandoning a macroeconomics-based approach. For example, Duarte (2003) uses a variant of the two-country NOEM model in which asset markets are incomplete and prices are set one period in advance in the buyer's currency (i.e., local-currency pricing) to address the interregime volatility issue. Duarte studies the properties of this model in the context of a simulation exercise in which the utility function is fully specified, along with technology and monetary shocks. This exercise clearly generates a sharp increase in the volatility of the real exchange rate following a switch from fixed to flexible rates, with no similar change in the volatilities of output, consumption, or trade flows. The intuition for this result is quite simple: because prices are set one period ahead in the buyer's currency, allocation decisions are disconnected at the time of impact from unexpected changes in the nominal exchange rate and so the volatilities of output, consumption, and trade flows are unaffected.

Arnold, MacDonald, and de Vries (2005) argue that to understand interregime volatility issues it is important to introduce distortions (such as trade and capital account restrictions and IMF support), which are likely to be prevalent in fixed rate regimes such as Bretton Woods, into the standard monetary exchange rate equations. Using a variety of measures for the distortion terms, the authors demonstrate that such terms can explain the interregime puzzle.

Reinhart and Rogoff (2002) argue that the interregime puzzle may not be such a puzzle after all. Specifically, they argue that empirical studies such as those of Flood and Rose (1995) and Baxter and Stockman (1989) use the IMF method of classifying an exchange rate regime as fixed or flexible. The de facto situation in the Bretton Woods and post Bretton Woods eras, however, was in fact very different, with the majority of countries in Bretton Woods having much more flexibility in their exchange rate behavior than that portrayed in the official statistics, and in the floating rate period there is in practice much more evidence of exchange rate fixity than that indicated in the standard classification. Perhaps the neatest explanation for interregime volatility is that when exchange rates are de jure fixed they are often de facto flexible, and when they are flexible they are in practice fixed or quasi-fixed.

■ exchange rate weapon

The concept of the *exchange rate weapon* refers to the use of the exchange rate by one state to secure policy change on the part of another. The weapon helps to explain important aspects of the international polit ical economy of monetary relations, such as the be havior of governments and central banks during adjustment conflicts and the distribution of the costs of adjustment among countries. When collective management of the adjustment process has been re-

quired, the use or threat of use of the exchange rate weapon often underpinned international agreements.

The exchange rate weapon can take two forms, one *passive* and the other *active*. In the passive form, officials of a leading state within the system can allow the exchange rate of its currency to shift, perhaps even overshoot, in the knowledge that a more vulnerable partner country is thus subject to incentives to adjust its fiscal and/or monetary policy. Authorities can also actively promote a shift in the rate to induce the partner to shift macroeconomic policy. The two forms are deliberate, often coincide empirically, and have similar coercive effects.

Adjustment Conflict and Causal Mechanism
The exchange rate weapon can come into play particularly when current account imbalances become unsustainable and key states enter into political conflict over measures to reduce them. A large, closed economy is less sensitive to changes in the exchange rate compared to its smaller, more open partner(s), other things being equal. Under these circumstances, the smaller state will be subject to greater pressures to change macroeconomic policies in the face of a large shift in the exchange rate. The presence of a substantial asymmetry enables the large country to alter the incentives that confront the small country when setting macroeconomic policy.

Consider the example of a large country with a current account deficit locked in an adjustment standoff with a small partner, which runs corresponding surpluses. Domestic politics in both countries have dictated the macroeconomic policy preferences (e.g., for employment, growth, and inflation) that have given rise to the imbalances. The large state could eliminate the imbalance by shrinking its government budget deficit, for example, and the smaller state could accomplish the same through a fiscal expansion. For domestic political reasons, however, each government prefers that the other undertake the policy change.

When the imbalance becomes unsustainable that is, private markets have become unwilling to finance it the governments are confronted with politically difficult choices. The large, less vulnerable state could allow or encourage its currency to depreciate with relative equanimity. The corresponding currency appreciation of the small, more vulnerable state, however, sets in motion a chain of events that alters that government's incentives with respect to its macroeconomic policy. Specifically, the appreciation of the small country's currency will reduce the domestic price of imports, reducing inflation, and will shift the current account balance toward deficit, reducing growth and employment prospects. The reduction in inflation eases a constraint on stimulating domestic demand and the reduction in growth provides an incentive to do so. A change in macroeconomic conditions within the small country thus shifts the domestic political equilibrium toward providing a stimulus.

An asymmetry in exchange rate vulnerability enables the more insulated states to exploit cross-border economic effects in applying political pressure on their partners for policy adjustment. This generalization holds across a broad range of open economy macroeconomic assumptions, such as the degree of capital mobility. Three additional factors can reinforce the strength of the exchange rate weapon. First, a large, less vulnerable country might press the small country for policy change through diplomatic moral suasion, offering its support for currency stabilization in return. Second, the large country could deliberately act to shift the exchange rate in order to secure policy change on the part of the small country. Third, the large country could be reinforced in this effort by the international role of its currency, as in the case of the United States.

The active use of the exchange rate weapon hinges on the "exogeneity" of the exchange rate that is, the ability of governments to influence currency values without altering underlying macroeconomic policies. Governments' scope for doing so is widely debated among international monetary economists. Professional consensus on the question has evolved over the decades. Recent studies generally find intervention to be more effective than did studies conducted during the 1980s. Suffice it to say that government action can be successful under a variety of circumstances, such as when it is publicly an-

nounced, conducted jointly by two or more central banks, and consistent with the underlying fundamentals, and when the exchange rate is far from equilibrium.

Historical Episodes The exchange rate weapon became a threat or a tactic during each of four episodes of conflict over international adjustment since the Bretton Woods regime: (1) the breakdown of that regime in the early 1970s, (2) the Bonn Summit of 1978, (3) the Plaza and Louvre accords of the mid-1980s, and (4) the early and mid-1990s. During each of these episodes, U.S. administrations pressed European and Japanese governments and/or central banks for expansionary measures and in some cases actively encouraged a depreciation of the dollar. U.S. authorities were more successful in some episodes, such as 1971–73, 1977–78, and 1985–87, than in others, such as during the 1990s.

Consider the Plaza-Louvre period as an example. During the first half of the 1980s, the U.S. current account deficit increased substantially under the macroeconomic and exchange rate policies of the first Reagan administration. In the summer of 1985, political pressure for trade protection in the U.S. Congress boiled over and Treasury Secretary James A. Baker III sought to defuse it with international policy coordination, among other measures. He and his counterparts among the Group of Five finance ministers signaled their support for dollar depreciation in the Plaza Accord of September of that year. A few months later, but prior to administering substantial stimuli to their economies, Japanese and West German officials indicated that the dollar had depreciated enough. By contrast, U.S. Treasury officials continued to "talk down" the dollar further and very large appreciations of the yen and mark occurred, prompting lobbying within Japan and West Germany for expansionary measures to offset the contractionary effects. At the meeting at the Louvre in 1987, U.S. officials agreed to stabilize currencies in exchange for European and Japanese policy stimuli. Changes in exchange rates and macroeconomic policy helped to nearly eliminate the U.S. current account deficit in subsequent years.

Structural Shift Because the effective use of this weapon hinges on the exploitation of an asymmetry by a large state, changes in the relative size and openness of the major countries could well affect the relevance of the weapon during adjustment conflicts in the future. Changes in the broad structure of the global economy structural shift derive from three main developments. First, the formation of the euro area in January 1999 created, in one fell swoop, a new monetary region of roughly equivalent weight to the United States the most important change in the structure of the international monetary system since at least the Bretton Woods regime. Second, in East Asia the adjustment problem has been regionalized by foreign direct investment and cross-border production networks, as well as the practice by governments within the region of shadowing Chinese exchange rate policy vis-à-vis the dollar in order to preserve trade competitiveness. East Asian governments are advancing potentially important projects of regional financial cooperation. Finally, the U.S. economy is increasingly internationalized as measured by trade relative to gross domestic product and foreign investment relative to total U.S. financial assets.

The combined effect of these developments is to make Europe potentially less vulnerable to dollar depreciation, give pause to American officials when contemplating use of the exchange rate weapon in East Asia, and reduce the asymmetry in the effects of exchange rate changes between the United States and its partners. The exchange rate weapon could therefore be less useful to U.S. policymakers in the future than it has been in the past. Nonetheless, the United States will probably retain residual power while Europe's monetary union, Japan, and China could conceivably begin to exercise a similar form of influence through their currencies in geographically contiguous areas. The exchange rate weapon is thus likely to have continuing relevance as an instrument of economic conflict.

Critiques Some analysts find the notion of the exchange rate as a weapon to be troubling. Three specific objections can arise: (1) governments' ability to manipulate the exchange rate is limited; (2) the

exchange rate should not be used coercively; and (3) the weapon is rarely used in practice. Consider each of these objections in turn.

First, the objection that governments are not generally effective in managing the exchange rate exogenously applies especially to the active form of the exchange rate weapon. But in the presence of high capital mobility, flexible exchange rates are often driven by herd behavior and expectations, and are thus frequently disconnected from the underlying economic fundamentals. In addition, the foreign-exchange markets often exhibit multiple equilibria more than one exchange rate can be consistent with underlying fundamentals and the market rate is determined by private expectations. When private expectations are easily swayed which is more often the case in the presence of large payments imbalances and conflicts over adjustment governments are more likely to be able to induce a shift from one equilibrium to another. Particularly when the rate moves far from equilibrium, authorities might well coordinate the expectations of private participants by articulating an emerging consensus on the direction of movement.

Government officials can influence financial market expectations about rates and underlying policies, depending on market sentiment, by signaling their desire for a stronger, weaker, or stable currency; forswearing intervention; and intervening. Under some market conditions, such as a profound current account imbalance, an official's "no comment" in the face of a significant exchange rate movement can be interpreted by the market as a clear signal of approval. Conflict over trade policy and market access can enhance the markets' sensitivity to official statements. Thus, even if policymakers have only partial influence over the exchange rate, that influence can be substantial at particular junctures.

The second objection that the exchange rate should not be used coercively springs from the notion of the exchange rate as an economic variable whose movements allow consistency of internal and external balance across national economies. The main response to this objection is that simply ac-

knowledging that the exchange rate is sometimes used coercively does not mean that we endorse its use. The exchange rate weapon is a positive, explanatory concept, rather than reflecting a recommendation or prescription. The normative merit of the instrument depends on the use to which it is put and has varied from one historical case to the next.

As a positive concept, the weapon is an analytical tool of political economic analysis rather than of economic analysis per se. While acknowledging the economic function of the exchange rate, political analysis places the exchange rate in a larger context: an international struggle over the distribution of the costs of balance of payments adjustment. The variable is thus intermediate between the national politics of countries' macroeconomic policy, rather than intermediate simply between their economies. The exchange rate weapon is, in this conception, one of several means by which some states alter the payoffs to policy choices on the part of others.

Finally, in response to the objection that the instrument is rarely used, the exchange rate weapon has been employed at especially critical junctures in modern international economic relations. During the crises of the early 1970s, late 1970s, and mid-1980s, for example, U.S. administrations confronted strong protectionist pressures that were defused in part by the use of the exchange rate to secure adjustment. Had the U.S. Treasury simply let market forces bring adjustment in their own good time and in their own good measure, U.S. trade policy could have slowed the pace of liberalization or even become protectionist. Decisions to deploy or withhold the exchange rate weapon, therefore, can cast a long shadow into the future.

■ exchange rates and foreign direct investment

One of the many influences on foreign direct in vestment (FDI) activity is the behavior of exchange rates. Exchange rates, the domestic currency prices of foreign currencies, matter in terms of both their levels and their volatility. Exchange rates can influence the total amount of FDI that takes place and the allo cation of this investment spending across a range of countries.

Understanding the effects of exchange rates on FDI is important for many reasons. For example, alternative exchange rate arrangements adopted by countries can reduce nominal changes in the rel ative values of currencies, sometimes even merging the currencies completely through a monetary union. For countries trying to attract more FDI, what roles do exchange rate levels and volatility play in determining the attractiveness of these countries for FDI? Can countries make themselves more or less attractive by manipulating the exchange rate?

Exchange Rate Levels When a currency depre ciates, meaning that its value declines relative to the value of another currency, this exchange rate move ment has two potential implications for FDI. First, it reduces that country's wages and production costs relative to those of its foreign counterparts. All else being equal, the country experiencing real currency depreciation has enhanced "locational advantage" or attractiveness as a location for receiving productive capacity investments. By this relative wage channel, the exchange rate depreciation improves the overall rate of return to foreigners contemplating an overseas investment project in this country.

The exchange rate level effects on FDI through this channel rely on a number of basic considerations. First, the exchange rate movement needs to be as sociated with a change in the relative production costs across countries, and thus should not be ac companied by an offsetting increase in the wages and production costs in the destination market. Second, the importance of the relative wage channel may be diminished if the exchange rate movements are an ticipated. Anticipated exchange rate moves may be reflected in a higher cost of financing the investment project, since interest rate parity conditions equalize risk-adjusted expected rates of returns across coun tries. By this argument, stronger effects of exchange rate movements on FDI arise when unanticipated and not reflected in the expected costs of project finance for the FDI.

Some experts dismiss the empirical relevance of the interest-parity caveat. Instead, some argue that there are imperfect capital market considerations, leading the rate of return on investment projects to depend on the structure of capital markets across countries. For example, Froot and Stein (1991) argue that capital markets are imperfect and lenders do not have perfect information about the results of their overseas investments. In this scenario, multinational companies that borrow or raise capital internationally to pay for their overseas projects will need to provide their lenders some extra compensation to cover the relatively high costs of monitoring their investments abroad. Multinationals would prefer to finance these projects out of internal capital if possible, since internal capital is less expensive than borrowed capital.

Consider what occurs when exchange rates move. A depreciation of the destination market currency raises the relative wealth of source country agents and can raise multinational acquisitions of certain destination market assets. To the extent that source country agents hold more of their wealth in own currency-denominated form, a depreciation of the destination currency increases the relative wealth position of source country investors. As the parent company's wealth rises, more financing out of internal capital occurs. The reduced relative cost of capital allows these investors to bid more aggressively for assets abroad. Empirical support for this channel is provided by Klein and Rosengren (1994), who show that the importance of this relative wealth channel exceeded the importance of the relative wage channel in explaining FDI inflows to the United States during the period from 1979 through 1991.

Blonigen (1997) makes a "firm-specific asset" argument to support a role for exchange rates movements in influencing FDI. Suppose that foreign and domestic firms have equal opportunity to purchase firm-specific assets in the domestic market but different opportunities to generate returns on these assets in foreign markets. In this case, currency movements may affect relative valuations of different assets. While domestic and foreign firms pay in the same currency, the firm-specific assets may generate returns in different currencies. The relative level of foreign firm acquisitions of these assets may be affected by exchange rate movements. In the simple stylized example, if a representative foreign firm and domestic firm bid for a foreign target firm with firm-specific assets, real exchange rate depreciations of the foreign currency can plausibly increase domestic acquisitions of these target firms. Again, this channel predicts that foreign currency depreciation will lead to enhanced FDI in the foreign economy. Data on Japanese acquisitions in the United States support the hypothesis that real dollar depreciations make Japanese acquisitions more likely in U.S. industries with firm-specific assets.

Exchange Rate Volatility In addition to levels of exchange rates, volatility of exchange rates also matters for FDI activity. Theoretical arguments for volatility effects are broadly divided into "production flexibility" arguments and "risk aversion" arguments. To understand the production flexibility arguments, consider the implications of having a production structure whereby producers need to commit investment capital to domestic and foreign capacity before they know the exact production costs and exact amounts of goods that will be ordered from them in the future. When exchange rates and demand conditions are realized, the producer commits to actual levels of employment and the location of production. As Aizenman (1992) demonstrated, the extent to which exchange rate variability influences foreign investment hinges on the sunk costs in capacity (i.e., the extent of investment irreversibilities), on the competitive structure of the industry, and overall on the convexity of the profit function in prices. In the production flexibility arguments, the important presumption is that producers can adjust their use of a variable factor following the realization of a stochastic input into profits. Without this variable factor — that is, under a productive structure with fixed instead of variable factors — the potentially desirable effects of price variability on profits are diminished. By the production flexibility arguments, more volatility is associated with more FDI ex ante, and more potential for excess capacity and production shifting ex post, after exchange rates are observed.

An alternative approach linking exchange-rate variability and investment relies on risk aversion arguments. The logic is that investors require compensation for risks, and that exchange rate movements introduce additional risk into the returns on investment. Higher exchange-rate variability lowers the certainty equivalent expected exchange-rate level, as in Cushman (1985, 1988). Since certainty equivalent levels are used in the expected profit functions of firms that make investment decisions today in order to realize profits in future periods, if exchange rates are highly volatile, the expected values of investment projects are reduced, and FDI is reduced accordingly. These two arguments, based on "production flexibility" versus "risk aversion," provide different directional predictions of exchange rate volatility implications for FDI.

The argument that producers engage in international investment diversification in order to achieve ex post production flexibility and higher profits in response to shocks is relevant to the extent that ex post production flexibility is possible within the window of time before the realization of the shocks. This distinction suggests that the production flexibility argument is less likely to pertain to short-term volatility in exchange rates than to realignments over longer intervals.

When considering the existence and form of real effects of exchange rate variability, a clear distinction must be made between short-term exchange rate volatility and longer-term misalignments of exchange rates. For sufficiently short horizons, ex ante commitments to capacity and to related factor costs are a more realistic assumption than introducing a model based on ex post variable factors of production. Hence, risk aversion arguments are more convincing than the production flexibility arguments posed in relation to the effects of short-term exchange rate variability. For variability assessed over longer time horizons, the production flexibility motive provides a more compelling rationale for linking FDI flows to the variability of exchange rates.

As explained earlier, the exchange rate effects on FDI are viewed as exogenous, unanticipated, and independent shocks to economic activity. Of course,

to the extent that exchange rates are best described as a random walk, this view is a reasonable treatment. Otherwise, it is inappropriate to take such an extreme partial equilibrium view of the world. Accounting for the comovements among exchange rates, monetary demand, and productivity realizations of countries is important. As Goldberg and Kolstad (1995) show, these correlations can modify the anticipated effects on expected profits and the full presumption of profits as decreasing in exchange rate variability. Empirically, exchange rate volatility tends to increase the *share* of a country's productive capacity that is located abroad. Analysis of two-way bilateral FDI flows between the United States, Canada, Japan, and the United Kingdom showed that exchange rate volatility tended to stimulate the share of investment activity located on foreign soil. For these countries and the time period explored, exchange rate volatility did not have statistically different effects on investment shares when distinguished from periods where real or monetary shocks dominated exchange rate activity. Real depreciations of the source country currency were associated with reduced investment shares to foreign markets, but these results generally were statistically insignificant.

Although theoretical arguments conclude that the share of total investment located abroad may rise as exchange rate volatility increases, this logic does not imply that exchange rate volatility depresses domestic investment activity. In order to conclude that domestic aggregate investment declines, one must show that the increase in domestic outflows is not offset by a rise in foreign inflows. In the aggregate U.S. economy, exchange rate volatility has not had a large contractionary effect on overall investment (Goldberg 1993).

Overall, the current state of knowledge is that exchange rate volatility can contribute to the internationalization of production activity without depressing economic activity in the home market. The actual movements of exchange rates can also influence FDI through relative wage channels, relative wealth channels, and imperfect capital market arguments.

■ exorbitant privilege

Exorbitant privilege refers to the ability of the United States to finance external deficits by printing its own currency. Countries incur external deficits by spending abroad more than they earn abroad. The conventional measure of this is a country's "current account deficit," which consists of three components: its export earnings minus its spending on imports; its earnings on foreign assets (interest payments on bank deposits and bonds, dividends on stocks, and profits on production abroad minus its payments to foreigners on their holdings of domestic assets), and its receipts of aid and private remittances from abroad minus its payments to foreigners for such aid and remittances.

Beginning in the late 1950s, the United States began running ever-larger external deficits: that is, it was "living beyond its means." By late 2007, the U.S. current account deficit was larger than ever before in its or any other country's history: about $850 billion per year, largely comprised of an excess of imports over exports.

Charles de Gaulle, ever envious of Anglo-American privilege, is widely credited with coining the term, but although he popularized it in speeches, it came, in fact, from Valery Giscard d'Estaing, de Gaulle's lieutenant during the 1960s.

The post World War II arrangements designed by Britain and the United States at the Bretton Woods conference in 1944 placed the U.S. dollar at the core of the international monetary system. Al-

most all noncommunist countries agreed to peg their currencies to the dollar, which was in turn pegged to gold. Not only was the dollar literally as "good as gold"; it was for two decades almost the only currency that was freely convertible into other currencies (Canadian and Australian dollars were exceptions). It was also in goodly supply, given America's near-hegemony in world trade and finance from 1945 until the late 1950s. America produced more than 80 percent of world GDP and exports, and America's trade surpluses were invested in dollar-denominated assets issued by foreigners running trade deficits. Hence U.S. dollars became the world's preeminent choice for both trade and finance.

In short, all countries outside the Soviet sphere that aspired to import or export, or to borrow or lend internationally, had little alternative but to use U.S. dollars. America's exorbitant privilege derived from worldwide demand for a financial asset that could be created at near-zero cost. This led to the complaint that America was able to live beyond its means by simply printing money.

In 2007 almost all of the world's central banks still held at least three quarters of their "foreign exchange reserves" in U.S. dollars, usually in the form of bonds issued by the U.S. Treasury. By the time the Bretton Woods system collapsed in 1971 73, the United States was running a large external trade deficit. This was financed by the trade surpluses of large countries like Germany and Japan. Under Bretton Woods arrangements, these countries had kept their currencies pegged to the U.S. dollar at undervalued exchange rates by directing their central banks to sell deutsche marks and yen, and in the process to buy dollars. Trade surpluses accumulated as foreign exchange reserves in the coffers of their central banks.

After the Bretton Woods system collapsed, Germany, Japan, and other countries allowed their currencies to rise to market values. Nevertheless, global demand for dollar-denominated bonds and other dollar-denominated assets continued to grow. Although flexible-exchange-rate countries did not necessarily accumulate international reserves as rapidly as when they had fixed their rates, most countries returned to fixed- or managed-rate regimes. For example, from 1979 to 1999 (before the introduction of the euro), core Western European countries fixed their rates against one another. International trade grew rapidly, as did central banks' appetite for foreign exchange reserves, mostly in the form of U.S. Treasury bonds. And in the 21st century, China's central bank has become the world's largest single buyer of U.S. Treasury bonds: since 1994, it has held its currency at a below-market exchange rate and has hence run current account surpluses that are mostly invested in U.S. government bonds, enhancing American "exorbitant privilege" as never before.

The United States has imported more than it has exported almost continuously since 1969. America enjoys the exorbitant privilege that it can finance part of this trade deficit simply by printing Treasury bonds, which are readily bought by the world's central banks. To be sure, the United States must pay interest on these bonds, but it is able to pay lower rates than on any other low-risk financial asset the world can offer. Because of the U.S. dollar's near-hegemony in international trade, and also because U.S. Treasury bonds are not only safe but quick and easy to sell (they are both default-risk-free and liquid), central banks and other investors are willing to hold Treasury bonds at rock-bottom interest rates relative to government bonds issued by other countries. This is likely to be true for the foreseeable future since no other country's government bonds are rivals for those of the United States in terms of both their default-free record and their sheer volume and hence liquidity.

Exorbitant privilege does not derive only from central banks' purchases of U.S. Treasuries. Private investors and institutions all over the world hold large parts of their portfolios in U.S.-dollar financial assets: in Treasury bonds, in corporate bonds, and in equities. This is partly because such assets yield good risk-adjusted returns, but it is partly also because the United States is a haven of free-market capitalism: it has never imposed currency controls, and (almost) never frozen funds (Iran's in 1978 79 were a notable exception).

In short, U.S. assets are virtually free from default risk and almost free from political risk. They are not, however, free from currency risk: the U.S. dollar can

and does fluctuate widely against other currencies. Implicit in the term *exorbitant privilege* is that the United States has less incentive than other countries to assuage expectations of currency depreciation because it is assured of a "privileged" market for U.S.-dollar debt and equity, even when such assets seem likely to decline in value against other currencies.

■ **expenditure changing and expenditure switching**

In an open economy setting, policymakers need to achieve two goals of macroeconomic stability: internal and external balances. Internal balance is a state in which the economy is at its potential level of output that is, a country's resources are fully employed and domestic price levels are stable. External balance is attained when a country is running neither an excessive current account deficit nor surplus (net exports are equal or close to zero). Attaining internal and external balances requires two independent policy tools: expenditure changing policy and expenditure switching policy.

Expenditure changing policy, which takes the form of fiscal or monetary policy, aims to affect income and employment with the goal of equating domestic expenditure, or absorption, and production. Expenditure switching is a macroeconomic policy that affects the composition of a country's expenditure on foreign and domestic goods. More specifically, it is a policy to balance a country's current account by altering the composition of expenditures on foreign and domestic goods. Not only does it affect current account balances, but it also can influence total demand, and thereby the equilibrium output level.

Internal and External Balances The interaction between internal and external balances can be demonstrated through a simple Keynesian model where consumption is a function of disposable income; the current account is related to the real exchange rate and disposable income (while foreign income that affects the domestic country's exports is assumed to be constant); and investment and government spending are exogenous. Internal and external balances are:

Internal balance (II):

$$Y = Y^f = C(Y^f - T) + I + G$$
$$+ CA(EP^*/P, Y^f - T)$$

External balance (XX):

$$CA = CA(EP^*/P, Y - T) = XX$$

where XX is a sustainable amount of current account deficit or surplus.

When the exchange rate is flexible, fiscal expansion either government expenditure increase or tax cuts raises output but worsens current account balances. Conversely, a fiscal contraction improves current account balances but lowers output. More specifically, if a country wants to raise its income level through fiscal expansion, it would have to experience a worsening in trade balances, because expansionary

fiscal policy would lead to a rise in imports through improved disposable income and, therefore, worsens current account balances. Alternatively, if a country with a current account deficit attempts to reduce it, it could achieve that by implementing contractionary fiscal or monetary policy, so that as to reduce imports. When a country wants to achieve both internal and external balances simultaneously, it is most effective if the country lets the value of its currency change, so that change in the real exchange rate can affect both the economy's total demand and the demand for imports. Such policy to achieve current account balances by manipulating the demand for domestic and foreign goods through changes in the value of the currency is called expenditure switching policy.

When expenditure switching policy is not available   that is, when an economy is under the fixed exchange rate regime   expenditure changing policy through fiscal policy becomes the only available policy tool for attaining internal and external balances. In the fixed exchange rate system, monetary policy becomes unavailable because it affects the interest rate and the exchange rate. However, fiscal policy is insufficient to achieve both internal and external balances in such an environment.

Effects of Expenditure Changing Policy Although it is expected that expenditure changing policy with fiscal policy changes can affect output in the short run regardless of whether the exchange rate is flexible or fixed, its effect, or the "multiplier of fiscal policy," is smaller in an open economy than in a closed economy. When fiscal expansion is implemented, money demand and thereby the interest rate increase. This rise discourages, or "crowds out," private investment. This outcome arises as long as some degree of price stickiness is assumed. Hence some of the effect of fiscal expansion will be offset by the crowding out of investment, which makes the overall effect on income and also net exports (i.e., $EX - IM = S - I$) smaller than what could have been if the interest rate were assumed to be constant. Also, the multiplier is smaller the more open to international trade the economy is, because a greater portion of income "leaks out" of the system in the form of demand for foreign goods.

Expenditure changing policy with monetary expansion, on the other hand, involves a reduction in the interest rate in the short run, which expands income and worsens net exports. Both types of expenditure-increasing policies function in the same way: income rises while current account worsens in the short run. However, while monetary expansion favors private investment, fiscal expansion favors government spending.

Under the fixed exchange rate system, while monetary policy becomes ineffective, the effect of fiscal policy can be larger than under the flexible exchange rate system. When expansionary fiscal policy is implemented, the interest rate would rise because of the crowd-out effect. At the same time, however, the central bank would have to implement accommodative, that is, expansionary, monetary policy to cancel the rise in the interest rate. The action of canceling the effect on the money supply or interest rate is called sterilization. Otherwise, the interest rate would be affected, and that would affect the capital flows across the border (given the unchanged foreign interest rate) and therefore the exchange rate. Because fiscal expansion must be accompanied with sterilization, the effect of fiscal expansion on output is larger than that under the flexible exchange rate system where the exchange rate is allowed to fluctuate to reflect the change in the interest rate.

Effects of Expenditure Switching Policies Among possible expenditure switching policies, devaluation, or revaluation, is the most focused policy to affect current account balances and the equilibrium level of output. Devaluation increases the domestic price of imports and decreases the foreign price of exports; therefore, it decreases imports and increases exports. However, whether devaluation leads to an improvement in current account balances depends on the elasticities of demand for exports and imports. According to the Marshall-Lerner condition, if the sum of the elasticities of demand for exports and imports is greater than one, depreciation of the domestic currency leads to a current account improvement.

When an economy attempts to attain both internal and external balance, expenditure switching

policy alone is insufficient. For example, if an economy is at the full employment level, in other words, internal balance is already attained, but if it is running current account deficits, policymakers in the economy could devalue its currency so that net exports rise. However, the improvement of current account balances would lead the economy to experience overheating so that internal balance would disappear. If an economy is experiencing an inflationary gap, or overheating, while maintaining a balanced current account, a revaluation policy may reduce total expenditure back to the full employment level, but lead to a current account deficit. Therefore, a mix of expenditure switching and changing policies is usually necessary to achieve both internal and external balances.

With the assumption that the Marshall-Lerner condition holds, for any given level of expenditure, devaluation leads to improvement of net exports, or current accounts, and therefore, a rise in output. However, when prices are assumed to be sticky in the short run, expenditure switching policy with devaluation involves the crowding-out effect. That is, the increase in output also raises the demand for money and consequently the interest rate, which discourages private investment. It is the crowding-out effect that offsets part of the income increase caused by devaluation. Hence, the new equilibrium income level will be a little lower than what could be achieved if the interest rate could remain constant.

Although devaluation policy is the most focused expenditure switching policy, it is not the only one. In general, expenditure policies take the form of trade (control) policy since they are aimed at affecting the volumes of exports and imports. Tariff policy can be implemented to discourage the inflow of imports, and export subsidy can be used to encourage exports, though these policies tend to be industry specific. The best-known tariff policy that has been actually implemented with macroeconomic ramifications is the infamous Smoot-Hawley Tariff Act of 1930. The goal of this policy was to switch demand for foreign goods to domestic ones at the expense of other countries to rescue domestic industries battered by the Great Depression. This policy, however, was followed by other countries that also tried to protect their domestic industries, eventually leading to rapid contraction of international trade.

■ export processing zones
Export processing zones (EPZs) are locations where host countries have established special incentives to

attract producers that import raw and intermediate components, process those items, and then export the final product. The regulatory structure governing EPZ operations in most zones is relatively straightforward. Participating firms are allowed to import inputs and equipment into the host country and export their final product duty free. Host countries may also provide zone firms incentives such as reduced income and property taxes, free or low-cost land, reimbursement for training expenses, and other benefits. In some countries, participating firms have to be located in a specific area. In others, producers qualifying for EPZ benefits can be located anywhere in the country. China, the Philippines, Malaysia, Mexico, Costa Rica, El Salvador, Honduras, Tunisia, Mauritius, and Madagascar are just a few of the many developing countries that have been able to dramatically increase exports through their EPZ initiatives. As a result, EPZs have become increasingly popular in the developing world. The International Labor Organization (ILO) reports that in 1997, 93 countries had established zones and total EPZ employment stood at 22.5 million. By 2002 these numbers had grown to 116 countries and 43 million jobs.

EPZs and Host Country Development EPZs are a controversial aspect of the global economy. On the positive side, they offer clear benefits to both producers and host countries. For producers, EPZs provide multinational companies (MNCs) and others easy access to a low-cost workforce in a developing country. For host countries, EPZs help create jobs, generate foreign exchange, and increase exports. EPZ opponents, however, contend that economic development strategies based on EPZ initiatives result in host countries voluntarily assuming an unattractive position within the global production system. MNCs have historically kept high-value-added, high-complexity links in the value chain close to the corporate center and delegated fragmented, low-value-added assembly tasks to their developing country operations. EPZ firms tend to be concentrated in labor-intensive industries such as apparel, footwear, toys, and electronics assembly, and to employ 18- to 25-year-old women with little education or formal training.

In developing countries where host country governments are struggling to provide the basic necessities of life to their population, low-value-added EPZ activity may represent a positive contribution to national development. To constitute a positive force in more advanced developing countries, the EPZ sector must transition toward a higher-value-added, higher-complexity production model. There are clear examples of countries where a significant percentage of EPZ firms have made this transition. This evolution can also include the transfer of knowledge-intensive support activities such as research and development and design engineering to the host country location. In other zones, the majority of firms have not evolved beyond basic assembly, and wages, especially for operating-level workers, have stagnated.

The quality of the jobs created through EPZ initiatives has been a consistent point of contention between EPZ proponents and their critics. The ILO, nongovernmental organizations, and academic researchers all express concerns about and actively monitor employment conditions in EPZs. In most countries it appears that zone firms provide at least equal if not better terms of employment than local companies, especially when compared to small businesses and the informal sector. There is, however, a clear need to develop appropriate regulatory structures and to aggressively monitor and enforce EPZ labor and environment standards. Of particular concern for the ILO, many developing countries restrict the opportunity for EPZ employees to join representative unions and engage in collective bargaining.

Critics also argue that the business model pursued by EPZ firms creates export enclaves with few if any linkages to other sectors of the host country economy. A closer look at day-to-day operations in successful zones shows that EPZs create numerous opportunities for construction companies, transportation firms, customs brokers, and a host of additional host country service providers. Local entrepreneurs also have the opportunity to supply raw and intermediate inputs that zone producers would otherwise import from global sources. For a variety of

reasons, however, local firms have been unable to take full advantage of these opportunities in many developing regions. In Mexico, for example, inputs from national suppliers represent less than 4 percent of all raw and intermediate components used by the EPZ sector.

EPZs and Their Impact on the Developed World The use of EPZs by producers in many industry segments creates clear benefits for consumers in the developed world. Through accessing an abundant, low-cost workforce, companies are able to sell products at relatively low prices while still generating a profit. A number of well-known retailers such as Wal-Mart and Home Depot have increasingly turned to sourcing goods from EPZ plants in China as a core component of their business model. China's emergence as the world's premier EPZ location is frequently cited as one of the main reasons inflation has remained low in the developed world over the last decade.

As with so many other aspects of globalization, these benefits come at a cost. The argument has been made that EPZs represent one of the primary forces resulting in a so-called race to the bottom in global labor and environmental standards. Critics typically support this contention with three main points. First, EPZs clearly facilitate the exodus of manufacturing jobs from high-wage developed countries to low-wage developing regions. Second, the EPZ option also reduces the power of organized labor to bargain for improved wages and working conditions in industries where it is possible for companies to shift production to low-wage EPZs. By contributing to reduced demand for workers and the disruption in the bargaining power between management and unions, EPZs may be partially responsible for the recent stagnation in blue-collar wages in the United States and elsewhere. Finally, critics also contend that MNCs frequently move environmentally risky operations to developing country EPZs where appropriate standards are lacking and/or enforcement is weak. There is considerable, primarily qualitative evidence for the first two points, but little if any sound support indicating that large numbers of MNCs have moved to developing country EPZs to avoid strict environmental standards.

China's New Role in the Global EPZ Industry The primary location of EPZ-style production was very different in the early 2000s compared to prior decades. Starting from a very low base in the late 1970s China has rapidly become the world's preferred EPZ location. In 1997, the ILO estimated 18 million people were employed in Chinese EPZs. In December 2001, China gained full membership in the World Trade Organization (WTO) and with improved market access to the world's primary industrial and consumer markets EPZ employment increased to 30 million by 2002. This total represents close to 70 percent of the world's EPZ workforce.

EPZ producers are the main force responsible for China's increased prominence in world markets. It is estimated that EPZ firms account for more than half of all Chinese exports and 70 percent of Chinese exports to the United States. China's attraction as a production location is due to several factors: the undervalued Chinese currency, the availability of large numbers of very low cost workers as well as skilled middle- and upper-level engineers and managers, generous incentives provided by the Chinese government, considerable investment in export infrastructure, and the opportunity for firms to simultaneously engage in EPZ-style production and sell a percentage of factory output to the country's 1.2 billion consumers.

China's success is forcing countries in both industrialized and developing regions to rethink their export promotion strategies. A study by Lall and Albaladejo (2004) found higher-cost Asian countries were losing market share to China in the 1990s primarily in low-technology segments and were increasingly focusing on the production of intermediate components that were then exported to China for final assembly. Lall characterizes the trade relationship between China and its East Asian neighbors as complementary rather than competitive. This may change as China upgrades toward more technology-intensive, high-complexity sectors.

China does represent a direct threat for many EPZ producers in Mexico and the Caribbean Basin. The brief recession in the United States and increased competition from Chinese EPZ exports contributed to the loss of close to 300,000 jobs in *maquiladoras*, as Mexican EPZs are known, from 2000 to 2003. Mexican policymakers have argued that China's low-cost advantages will force Mexico's EPZ industry to shift from labor-intensive to more capital- and technology-intensive activities. The available evidence indicates, however, that *maquiladoras* have responded by adopting business models in which competitive advantage is based on proximity to industrial and consumer markets in the United States, such as mass customization, just-in-time delivery, low volume high mix production systems, and remanufacturing centers.

Policy Implications The historical record clearly shows both positive and negative outcomes associated with EPZs. Using scarce development resources to establish a zone in which participating firms employ a very young, unskilled, primarily female workforce at subsistence wages to perform low-value-added assembly work may be worthwhile only in the poorest of countries. This type of participation in the global economy is useful only if it represents a starting point leading to something better. Governments in Asia, Mexico, and elsewhere have employed EPZs as an integral component of much larger and more comprehensive upgrading strategies. Global competition as well as the evolution of the organizational capacity of MNCs present interesting new challenges for host countries with EPZ programs. In search of efficiency and profitability, MNCs continue to migrate entire industries from high- to low-wage locations. Companies are also improving their ability to divide value chains into smaller and smaller segments and place activities around the world where they can be performed most efficiently. The world's largest MNCs are also much more willing than they were in the past to delegate knowledge-intensive functions such as design engineering to their developing country subsidiaries. The offshore outsourcing of service functions is a closely related phenomenon that represents significant new opportunities for developing countries. In Mexico there are now locations where traditional EPZ activity, engineering centers, and call centers are all located in the same industrial park. Based on both the historical record and new opportunities, EPZs have a place in the policy kit of those in developing countries attempting to create wealth through open engagement with the global economy.

■ export promotion

Governments often seek to promote exports from their country and to encourage national production of goods that might be exported. Export promotion can be viewed, therefore, as either an aim of economic policy (an export promotion strategy) or the set of policies and measures used by government agencies and the private sector to promote exporting and the production of exportable goods and services (export promotion policies).

Trade economists and policymakers have long been interested in how the trade policies, institutions, and trade strategy a country adopts affect its export and wider economic performance. The issues that generate this interest are controversial. Differences of opinion exist on the relationship between trade in general, and exports in particular, and economic growth; the influence of trade strategy in general, and an export-promoting strategy in particular, on export performance; and whether and how governments should interfere with market processes in general and in trade sectors in particular.

Traditional neoclassical theory represents trade as exposing domestic markets to greater competition, which induces efficient use and allocation of resources in line with relative world prices. In the absence of pervasive market failures, this representation provides a rationale for limiting government intervention and for adopting relatively neutral government interventions in the traded goods sectors. This resulting openness of the economy to international trade and competition implies in turn an outward orientation of the country's trade strategy, a will-ingness for as much specialization of domestic production and as much growth of imports and exports to occur as is consistent with the openness of the economy.

It is necessary, however, to recognize that the issues of trade orientation and degree of government intervention in markets are analytically separate. Outward orientation and export promotion can be led by markets or by policy intervention. An inward orientation can be removed by dismantling protectionist, import-substituting trade policies and moving to a free trade regime. The removal of import tariffs and other nontariff barriers can be seen as a market-led approach to export promotion. Alternatively, greater incentives to produce for export markets can be offered through additional government measures to subsidize exports and production in export sectors explicitly or implicitly. The relative merits of these alternative approaches to export promotion have been at the heart of the academic and policy debate in this area of international economics, in particular in the context of developing countries' policy options. Given the tendency of governments to use a mixture of import liberalization and direct export promotion measures to implement more outward-oriented trade strategies, controversy has developed over how to interpret the empirical evidence on the relationships among trade strategy, export performance, and economic growth or development.

The Case against Export Promotion There is a strong strand of the development economics literature that rejects the neoclassical focus on domestic supply conditions as an influence on export performance (see Evans 1990). This strand views the level of external demand as critical in influencing the export performance of developing countries. Pessimism about the growth of demand reflects the relatively low income elasticity of demand for primary products and the belief that the growth of manufactured imports by these countries would be met by protectionist responses in the industrial countries. Export pessimism provided a rationale for reducing reliance on external demand and export conditions

for growth and development and led in the post World War II period to the widespread adoption of interventionist and inward-looking policies.

Import restrictions were adopted to protect industries producing for the domestic market, with the aim of causing the demand for home goods to grow by replacing or substituting for imports. An import-substitution trade strategy was implemented through a range of direct and indirect means, which subsidized the production of importable goods, taxed the production of exportables, or did both. Taxes on imports, such as tariffs, or quantitative restrictions on importing (e.g., import licenses or quotas) implicitly subsidized importables production, while export taxes explicitly taxed exportables. Equivalent effects could be achieved also by less direct means. Export marketing boards might use their monopoly position to give commodity exporters less than the world price for their exports. Reluctance to alter a pegged exchange rate in the face of high inflation may cause currency overvaluation, reducing the price competitiveness of exports in foreign markets.

The Case for Export Promotion There are a priori arguments for encouraging outward orientation based on the benefits of more efficient allocation and use of resources due to greater competition. These may be one-time gains that raise per capita incomes but do not alter the steady-state or long-term growth rates of economies. More recently, theoretical support for export promotion has been provided by the so-called new or endogenous growth theories. In these, export growth may, in the presence of increasing returns and complementarities between physical and human capital accumulation, lead to permanent, positive growth effects.

It was not the advent of this new branch of theory, however, that caused most economists and policymakers to reject import-substituting trade strategies. In part they responded pragmatically to the revealed effects of import substitution and the evidence from developing countries of the resulting high costs of protection. Under import substitution, factories were underused, production technologies were often overly capital intensive, and the growth of

trade regulations created high returns to lobbying and other forms of rent-seeking. The move away from import substitution was also in part a reaction to the evidence that some developing countries, particularly in Southeast Asia, had developed an export capacity in manufactured goods and had brought about rapid growth and industrialization (Trindade 2005). This undermined the generality at least of the "export pessimism" arguments for inward orientation (Bhagwati 1990).

Finally, even where policymakers remained unconvinced by the relative performance of inward- and export-oriented countries or by the benefits of moving from one strategy to the other, the macroeconomic and debt problems of their economies forced them into accepting trade policy reform as part of the conditionality for the loans they needed from the World Bank. Structural adjustment programs that were required in order to access these loans were a major vehicle during the 1980s and 1990s in driving the import liberalization (reduction and/or elimination of nontariff barriers, and rationalization and lowering of tariff rates) and exchange rate adjustment (currency devaluation or depreciation). These reforms significantly lowered the large anti-export bias that had grown up in the trade regimes of many developing countries.

Export Opportunities and Mechanisms for Export Development Globalization and the growth of the global economy have brought increased export market opportunities. In addition, the successful newly industrializing and exporting countries demonstrate a "ladder of development" effect. There is evidence of the richer and more industrialized countries being displaced as exporters first of standardized labor-intensive manufactures and subsequently of less standardized and more capital-intensive products. This displacement has been by developing countries of varying size. The emergence of new, large-scale exporters such as China, India, and Mexico may cause other smaller, potential late entrants to worry that there are forces of agglomeration of international production that will make future entry into exporting more difficult. These new

exporting countries, however, also offer additional market opportunities for final and intermediate goods. Furthermore, the increasing fragmentation of international production increases these market opportunities in both developed and developing country markets. Indeed, the key focus of the literature on export development has shifted away from concern about the absence of export opportunities when all countries try simultaneously to promote exports (often referred to as the "fallacy of composition" problem) to identifying the internal and external constraints on export development.

In the 1950s and 1960s attention tended to focus on external constraints, including on the issue of market access to the industrial countries. High trade barriers, especially against labor-intensive imports such as textiles, clothing, and footwear, were seen as constraining export growth in the developing countries. This led to the incorporation of "special and differential" treatment principles for developing countries in the General Agreement on Tariffs and Trade, which allowed the industrialized countries to offer preferential access to their markets for developing country exports. The benefits of preferences (lower tariffs than those applied to exports from non-preference-receiving countries) have been weakened subsequently by the multilateral trade liberalization that the industrialized countries have implemented. They have lowered their tariff and nontariff barriers significantly in general, though market access can still be highly constrained in specific products where contingent protection measures (e.g., anti-dumping controls) and regulations (e.g., technical and health standards) restrict imports.

The continuing small share of world trade of the developing countries led to the shift of attention after the 1970s to the role of the developing countries' own trade policies in constraining export development. As outlined earlier, high import barriers and other protectionist measures created major sources of antiexport bias. Unilateral and regional trade reforms in recent decades have significantly reduced this constraint on export development. Before they liberalized their imports, however, many developing countries experimented with trying to simultaneously import-substitute and export promote, that is, to supplement existing import-substitution measures with fiscal incentives for exporting.

In broad terms simultaneous promotion of import-substituting and exportables production may well be mutually offsetting, moving the economy toward similar relative prices as under free trade if the incentives to both sectors are of similar magnitude. Taxing imports and subsiding exports will, however, absorb resources to collect and spend the taxes. The costs of policy administration can be avoided with free trade. Nonetheless, governments were often reluctant to liberalize imports for ideological and political economy reasons.

One strategy pursued by reforming governments was to continue with a general import substitution regime, while creating enclaves of production for export markets. Domestic and potentially footloose foreign firms within these enclaves, or export processing zones, often gained access to duty-free imported inputs and capital goods or to subsidized inputs and were subject to preferential profits tax arrangements not applied to firms in the rest of the economy. Such arrangements tend to give rise to monitoring problems associated with trying to avoid leakage of subsidized production into the domestic market (Warr 1990). It is also increasingly recognized that exporting requires access to reliable and low-cost inputs and services, which is more likely where exporters are integrated into competitive, open economies.

Recently, attention has shifted from trade policy constraints to other policy and nonpolicy constraints on export development. Increasingly advocates of outward orientation of trade policies recognize that trade policy reform may not be a sufficient condition for improved export performance. Export promotion may well require improved institutions (to support better export marketing or provide cheaper trade credits) and improved infrastructure (better roads for internal sourcing of inputs and distribution or cheaper and more reliable international transportation services). There is growing evidence that

the "taxing" effects on exports that arise from developing countries' own trade policies or from the trade policies of their trading partners are generally less important than those resulting from the inefficiencies or inadequacies of local services and input suppliers, of local institutions in both the private and public sectors, and of the national and regional communications and transport infrastructures (see Milner 2004). Export promotion is in fact recognized as being a much broader concept than that of the country's trade policy stance alone. It encompasses measures to reduce production costs in general and to reduce transportation (internal and international) costs in particular.

■ expropriation risk

See trade costs and foreign direct investment

■ factor endowments and
foreign direct investment

International factor endowment differentials (FEDs) between home and host countries of multinational corporations (MNCs) setting up affiliate subsidiaries are one of the key determinants of foreign direct investment (FDI) flows. One reason that some corporate operations are geographically separated from headquarters activities is to minimize production costs. Aspects of production that are intensive in a particular factor (such as labor or a natural resource input) tend to be located where that factor is abundant.

Ascertaining how FEDs affect FDI is important for achieving a general understanding of the determinants of FDI. There is a broad concern, in developed countries, that production is fleeing high-cost industrialized countries for low-cost developing countries such as China that FDI is motivated by firms trying to slash costs by shifting labor-intensive activities to countries where labor is cheap.

Yet it is important to recognize that to operate in a given host country, in addition to requiring abundant labor to make production costs low, the subsidiary of an MNC may also need to import machinery and employ engineers. Hence while relative labor abundance makes wage production costs low, the other production costs, such as for physical capital and human capital, cannot be exceedingly high for the country to be an attractive host for affiliate production. Moreover, the host location for affiliate operations must have nonproduction costs that also are sufficiently low. In fact, the poorest

countries attract almost no FDI. Considering all costs of bringing a good to market, not just labor production costs, poorer countries are often not cheaper locations.

This entry will consider theories of how FEDs affect FDI, and the empirical evidence. Understanding this issue will help form the basis for a better overall knowledge of why FDI occurs.

Global Firm Organization and Modes of FDI FDI occurs when a firm decides to locate production abroad and opts to maintain organizational, as well as financial, control over its foreign production. The first step in the choice to undertake FDI is the decision to relocate part of the production process offshore. The second step relates to organization whether the foreign production is to be organized within the confines of the corporation or at arm's length. In the former case, the corporation is multinational and sets up an affiliate subsidiary outside the country where its headquarters are located. If the costs of setting up the affiliate subsidiary are financed via the MNC's headquarters, there is a financial inflow into the host country in the form of FDI. When the overseas production is at an arm's length operation rather than a subsidiary, there is foreign outsourcing rather than FDI.

In pursuing FDI, MNCs deploy various modes of entry, with the traditional ones being vertical and horizontal. The mode of entry will impinge on the role of FEDs in determining FDI, as each mode of entry seeks to minimize a particular cost to the MNC. First, *vertical* affiliate entry breaking up stages across countries seeks manufacturing cost

minimization through production line fragmentation. Second, *horizontal* subsidiary entry creating duplicate plants abroad aims for transportation cost minimization by bringing production closer to customers. Third, using a host country as an *export platform* by a MNC building a plant abroad to serve a third market balances advantages emanating from FEDs enhanced by geographic location advantages minimizing trade impediments, including tariffs.

Vertical FDI involves different locations for the various parts of the production process of the MNC's final output. This type of organization involves international trade between the firm's subsidiaries with headquarters, and seeks to exploit international factor price differentials. As an example, a MNC might locate headquarters in a skilled labor abundant home country and engage in unskilled labor intensive production in an unskilled labor abundant host country. In this case, there are foreign affiliate exports of final output from the host to the home country of the MNC. Vertical FDI is expected to be more prevalent the greater the FEDs across countries. Greater FEDs give rise to greater differences in factor prices and thus greater incentive for vertical FDI.

Horizontal FDI minimizes the costs of serving the market by producing locally rather than trading. It is more likely when trade costs are relatively high (e.g., tariff-jumping FDI). Establishing a plant in the host country incurs additional plant-level fixed costs but avoids per unit trade costs (including both tariffs and transportation costs), and hence is preferable when the host country market size is sufficiently large. Using a monopolistic competition model, Markusen and Venables (2000) demonstrate that multinationals are more likely to arise when countries are more similar in both relative and absolute endowments. At the same time, a reduction in transportation costs for intermediates can lead to either vertical FDI (when upstream activities are labor intensive) or horizontal FDI (when downstream activities are labor intensive).

The vertical and horizontal modes of FDI have been combined in the "knowledge-capital" model of the multinational firm by Carr, Markusen, and Maskus (2001). Barriers to investment and trade between countries give rise to endogenous FDI modes. The higher the relative costs imposed by trade barriers relative to investment barriers, the more likely MNCs are to engage in horizontal rather than vertical FDI. At the same time, MNCs need not view horizontal and vertical FDI as mutually exclusive strategies. In some cases, a host FDI country may play the role of export platform to serve a regional market.

When there is possible geographic fragmentation in the stages of production into intermediate input manufacturing and assembly, interesting complementarities emerge that give rise to more complex organizational forms.

First, Yeaple (2003) identifies one complementarity that results when the lower cost attainment associated with production relocation induces a rise in overall output, which in turn will give rise to further production relocation. Moreover, Grossman, Helpman, and Szeidl (2003) show that when transportation costs for final goods are moderate, there is a complementarity associated with the source of components: the cost savings from locating assembly in the low-cost region are higher when components are also produced there. This complementarity implies that FDI in assembly responds to changes in the costs of FDI in components. When transportation costs for components are high enough, there is also an agglomeration complementarity in FDI: firms conducting assembly abroad want to locate component production nearby to reduce the costs of shipping components. In addition, the interest in hybrid integration strategies has led to models with more than two countries, with emphasis not only on FEDs but also trade and investment costs across regions of the world.

When producing overseas raises MNC profitability, FDI rather than offshoring will be more likely, the more contractual difficulties the multinational corporation faces in the country where component production is most efficient. Hence the decision to engage in FDI jointly minimizes production and transaction costs for the investor. In this context, Antras and Helpman (2004) show that,

other things equal, countries with a level of contractual frictions will receive more FDI inflows, the more abundant their endowment of the factor used intensively in production of intermediate inputs.

In terms of the financing of production once the offshoring decision is made, Antras, Desai, and Foley (2007) develop a model and provide evidence suggesting that the less developed investor protection is in a potential host country of FDI, the more of an outside stake by the MNC will be required in local capital markets to fund the affiliate subsidiary. More funding for the affiliate in the form of FDI will be forthcoming from headquarters, the less investor protection and financial development there is in the host country.

Thus given that relative factor abundance makes a country comparatively attractive to locate some stage of production activity, the inflow of FDI into that country should, controlling for other relevant country characteristics, increase with higher contractual frictions and lower investor protection. To some extent, FDI is a way to organize production within the confines of the MNC to substitute for poor institutions and incomplete markets in the host country where manufacturing can be most productive due to FEDs, or other motives for production relocation.

Evidence on FEDs and FDI Based on simple models of MNC behavior, FEDs should give rise to more vertical, but less horizontal, FDI. Brainard (1997) reports findings that are inconsistent with multinational activity depending on factor proportion differences. The finding is that increases in per worker income differences reduce affiliate sales (absolutely and relative to trade). Estimates of the knowledge-capital model of the multinational enterprise, which embeds both horizontal and vertical FDI, find support for horizontal FDI.

However, several recent studies do lend support to vertical FDI models based on FEDs. Hanson, Mataloni, and Slaughter (2005) find that demand for imported inputs increases when affiliates face lower wages for less-skilled labor. Braconier, Norback, and Urban (2005) find that more FDI is conducted in countries where less-skilled labor is relatively cheap.

Given the recent reductions in transportation costs, facilitating both international trade of goods and factor flows, traditional theories would predict that FEDs' importance in determining FDI would be mitigated. To the extent that FEDs play an important role in explaining recent FDI flows, this is likely to be due to the interaction, emphasized in more recent theories, of FEDs with some other determinant of FDI. For example, the complementarities discussed previously predict that a fall in transportation costs within an intermediate range may exacerbate the impact of FEDs on FDI flows.

More generally, theories on complex modes of FDI suggest that bilateral sales by MNCs between two countries are not determined solely by the characteristics of those two countries but are also affected by characteristics of other countries and regions. There is evidence consistent with bilateral FDI being complementary with exogenous bilateral and third-country determinants in the case of horizontal export-platform FDI. For vertical FDI, bilateral and third-country effects of changes in skilled and unskilled labor endowments tend to be substitutes for complex vertical FDI. Indeed, more recent evidence suggests that international FEDs matter for FDI not only at the bilateral level but in a more general sense.

Much of the recent expansion in trade flows would appear to be related to the growth of FDI. MNCs account for approximately half of U.S. exports. These are intrafirm transactions between the headquarters of U.S. MNCs and their foreign affiliates (Hanson, Mataloni, and Slaughter 2005). Helpman, Melitz, and Yeaple (2004) have shown that the effect of sector- and country-specific trade impediments in favoring FDI over exports is more pronounced under firm heterogeneity, both in theory and data. In addition, there is evidence that the most productive MNCs are able to atomize production facilities across countries and are not bound to central locations. In global markets, the organizational changes due to firm growth have overall been associated with higher FDI in response to international FEDs.

Taken together, these facts imply that the growth in tandem of FDI and exports reveals the increasing

global importance of MNC activities and their fragmentation across countries. The most productive MNCs have far reach across world markets both in intermediate input production organization and in assembly for global supply of final goods. The cost advantages conferred by certain locations due to FEDs are magnified for the select MNCs whose FDI flows, in their many modes, have global presence.

■ **fair trade**

The concept of fair trade carries an implicit critique of the *unfairness* associated with the conventional North-South trade system and the proposition that an alternative *fairer* trade system is possible. Fair trade advocates reject the assumption that an un regulated, comparative advantage based trade sys tem provides a viable avenue for sustainable devel opment with most artisans, small-scale farmers, and

workers. The persistent poverty among small-scale agricultural commodity producers and artisans in the global South demonstrates the need for a different type of trading system. Since the 1940s, fair trade organizers have worked to create and expand an alternative trade system that starts with a set of commonly held principles codified into standards intended to support empowerment, gender equity, long-term partnerships, transparency, and sustainable community development (FLO 2007; Barratt-Brown 1993). According to an alliance among several international fair trade associations, "Fair trade is a trading partnership, based on dialogue, transparency and respect, which seeks greater equity in international trade. It contributes to sustainable development. Fair trade organizations (backed by consumers) are engaged actively in supporting producers, awareness raising and in campaigning for changes in the rules and practice of conventional international trade" (Krier 2005).

In practice, fair trade is an uneven global movement and an expanding market. The twin strategies for implementing fair trade principles are the creation of a market that offers better prices to small-scale producer organizations and support from international development nongovernmental organizations (NGOs) for business and social development. Fair trade organizations have established an international labeling system (Fair Trade Labeling Organizations International) and international associations of alternative trade organizations (IFAT) to implement these practices, expand awareness among in Northern countries, and build demand.

Although fair trade accounts for 1 5 percent of the global trade in specific agricultural commodities and handicrafts, the markets have expanded rapidly. As of October 2006, the global fair trade certified network included 586 producer organizations and 1.4 million farmers, artisans, and workers in 58 developing countries from Latin America, Asia, and Africa (FLO 2007). Consumers worldwide spent U.S. $2.024 billion on fair trade certified products (FLO 2007). The expanding list of fair trade products includes coffee, cocoa, tea, fruits, wine, sugar, honey, bananas, rice, crafts, and some textiles (Krier 2005). Although artisans and craft producers helped to pioneer the fair trade movement, coffee has emerged as the economic backbone of the certified fair trade system (Bacon et al. 2008).

Fair Trade History The historical roots of the global fair trade movement, like those of many international social movements, extend into many lives, organizations, and landscapes. The primary partnership consisted of impoverished small-scale producers and artisans selling high-quality goods to Northern volunteers, NGOs, and, later, businesses. The risk was often shared between producing and consuming ends of the movement: producers and artisans sometimes provided their products months or even years before receiving full payment after volunteers and alternative trade organizations sold them to distant markets. On the other hand, fair trade organizers from the North provided producers with loans that would otherwise be unavailable and bought crafts and coffee before they had developed markets.

The early alternative trade organizations emerged around handicrafts, often connecting religious and politically motivated Northern groups with groups of women artisans in impoverished communities. In 1946, Edna Ruth Byler, a church volunteer working with the Mennonite Central Committee in Pennsylvania, started buying quilts directly from seamstresses in Puerto Rico. Several years later, the church assumed this project and later created Ten Thousand Villages, an alternative trade organization that as of 2006 connected to some 100 artisan groups and had annual sales in excess of $20 million (DeCarlo 2007). Another early alternative trade organization, called SERVE International (Sales Exchange for Refugee Rehabilitation and Vocation), began as an income generation project in 1949 through the sale of wooden clocks carved by refugees in Germany. In 1959, Oxfam, UK, launched the Helping-by-Selling project to import and sell handicrafts (Oxfam 2007). Later that same decade, the first Worldshop opened in the Netherlands. By 2005, there were more than 2,800 Worldshops throughout Western Europe selling mostly fair trade products with annual sales of about $151.8 million (Krier 2005).

Coffee led the rise of fairly traded agricultural products, which followed a path similar to crafts until alternative trade organizations united with other NGOs and traders to create an international certification system in 1988. The emergence of a product certification system allowed the participation of more conventional companies, expanded fair trade markets, and shifted the ratio of global fair trade goods from crafts to foods and beverages. Dutch fair trade advocates were connected to fair trade coffee cooperatives from Guatemala and Mexico by the early 1970s. In the 1980s, two U.S.-based companies, the Equal Exchange workers cooperative and the Thanksgiving Coffee Company, imported Nicaraguan coffee through Canada in protest against the Reagan administration's embargo against the Sandinista government. During the same decade, a large cooperative of small-scale indigenous farmers in southern Mexico called the Unión de Comunidades Indígenas de la Región del Istmo began working with Frans VanderHoff Boersma, a liberation theology inspired Jesuit priest from Holland (VanderHoff Boersma and Roozen 2003). VanderHoff Boersma and others soon identified that a core bottleneck in the fair trade movement was the lack of demand in Northern countries. The small volumes traded through these alternative networks limited revenue generation and community development impacts for small-scale producer organizations.

In response to the problem of how to expand fair trade product demand and distribution without compromising consumer trust, producer groups and Dutch organizers created a *product* certification and labeling system called Max Havelaar. Max Havelaar later united with European and North American NGOs to create Fairtrade Labeling Organizations International (FLO) in 1997. FLO is an international nonprofit multistakeholder association that seeks to establish fair trade standards; support, inspect, and certify disadvantaged producers; and harmonize the fair trade message across the movement (FLO 2007). The combination of activist push, the availability of a credible third-party product certification program (that adheres to ISO 65 standards), consumer demand, and growing public awareness

about the low commodity prices contributed to several large mainstream companies' decision to sell fair trade certified products (Bacon et al. 2008). In an effort to support the alternative aspects within the fair trade movement and distinguish themselves from the large multinational companies, which include Starbucks, Procter and Gamble, and Nestlé, the International Fair Trade Association created a certification for alternative trade *organizations* that implemented fair trade principles throughout their operations.

Impacts, Debate, and Paradox Total sales figures, certification programs, and organizational histories tell us little about the ability of fair trade to deliver on its stated empowerment and sustainable development goals. A primary consideration in assessing fair trade impacts is the fact that as of 2006 only 20 percent of the agricultural goods produced by fair trade certified organizations are sold according to generally accepted fair-trade terms (FLO 2007). Producers generally sell the remaining 80% of their products into lower-paying domestic and international markets. An important percentage is consumed within the household or traded locally. Furthermore, many producers have participated in this market for less than seven years. Most scholars agree that small-scale producers linked to fair trade are better off than producers that lack these connections (Jaffee 2007; Raynolds 2002). Many producers have advanced their sense of collective empowerment by building stronger organizations, and they have also conserved biological and cultural diversity through their farming practices (Bacon et al. 2008). However, the combination of fair trade sales and additional support from allied international development NGOs is not a panacea for eliminating poverty or stopping out-migration even within fair trade organizations (Bacon et al. 2008; Jaffee 2007; Hernández Navarro 2004). The minimum coffee prices are especially important when conventional market prices fall. Cooperatives used their links to fair trade networks to strengthen their capacity and grow as they outcompeted private exporters and transnational trading companies and helped to buffer small-scale farmers from consequences of the coffee

crisis in 1992 and again in 1999 2004 (Bacon et al. 2008). Artisans have generally been able to sustain their crafts and cultures and partially support their livelihoods even as they have improved their organizations' business capacity through direct connections to better markets for their products (Leclair 2002).

Although fair trade has proven itself a useful tool for Southern producer organizations to strengthen their collective influence and for Northern social justice activists leading campaigns to declare fair trade towns and college campuses, it has yet to make significant contributions to international trade and development policy. Fair trade advocates have won voluntary support from the United Nations and the European Commission, and certified fair trade coffee is even served in the U.S. Capitol. No standards have been clearly adopted into global trade regulations, however. Small-scale producers have also used their participation in fair trade to strengthen their alliances and increase their visibility and negotiating power (Renard 2005). For example, the Latin American and Caribbean Network of Small-Scale Fair Trade Producers (CLAC), which represents more than 200,000 producer families, has used its participation in fair trade to win a seat on the FLO board of directors, to gain partial ownership of the certified fair trade system, and to advocate for minimum prices that keep up with inflation and cover the costs of sustainable production (CLAC 2006).

As a voluntary third-party certification system, fair trade contributes to debates about corporate social responsibility and the role of consumers, big business, and more cooperative economies in international sustainable development. One of the certified fair trade system's central paradoxes is that it sets out to achieve social justice and environmental sustainability within the same market that many believe impoverished small producers in the first place. There is also competition with a rapidly expanding array of sustainable product certification programs, such as the Rainforest Alliance and Utz Certified. Although this hybrid approach causes fair trade activists, producer organizations, NGO administrators, and business leaders to live in ideologically

uncomfortable spaces, it may hold the potential to transform market-centered relationships from the inside out.

■ fear of floating

Since the end of the Bretton Woods system of fixed exchange rates in the early 1970s, the number of countries claiming to be running a flexible exchange rate regime has steadily grown. However, many of these countries appear to actively limit fluctuations in the external value of their national monies. Econo mists Calvo and Reinhart (2002) dubbed this be havior "fear of floating" and argued that this phe nomenon appears pervasive in so-called "emerging markets" (middle-income countries with some ac cess to global financial markets). Indeed, many self-proclaimed "floaters" often accumulate vast war chests of international reserves, which would not be necessary if their currencies were truly floating. In other words, many countries float with "a large life-jacket." Such behavior is puzzling not only because it does not match official pronouncements by pol icymakers, but also because emerging market econ omies are typically buffeted by larger and more frequent external shocks, which in theory necessitate more (not less) exchange rate flexibility.

Why Is Floating So Fearsome? Several inter-locking factors underlie "fear of floating." First, while many industrial countries have operated fairly flexi ble exchange rates quite effectively, they have well-developed and diversified financial systems that are able to minimize real sector disruptions due to transitory exchange rate variations. Most important, industrial countries are able to borrow overseas in their domestic currencies. In contrast, many emerg ing economies are unable to do so, leading to an accumulation of foreign currency debt liabilities that are primarily dollar-denominated and unhedged (i.e., "liability dollarization"). This is commonly re ferred to as the "original sin" problem. In these countries, sharp depreciations in their currencies al ter the domestic currency value of their external debt and therefore the net worth of the economies, with calamitous real sector effects. This in turn may ex plain why exchange rate stability is so important to emerging economies, and why many of these econ omies have an acute "fear of floating."

The inability to borrow overseas in one's own currency is related to the lack of hedging in a number of emerging economies. Even if a country has the ability to hedge, the transaction costs can be too high to make it an attractive option, especially in the short term. In view of this, it may be reasonable to expect some smaller domestic firms in emerging economies to be affected by exchange rate volatility (Bénassy-Quéré, Fontagné, and Lahrèche-Révil 2001). How-

ever, many economists argue that multinational firms can protect themselves from exchange rate fluctuations by maintaining diversified production facilities in different countries and by sourcing from a number of different countries.

Second, policymakers in emerging markets suffer from a chronic lack of credibility. They often have a poor track record in monetary and fiscal policy as a result of, for example, resorting to the inflation tax too often in the past. Consequently, an emerging economy might experience large and frequent shocks to exchange rate expectations or to interest rate risk premiums. A true floater would allow the spot exchange rate to absorb these shocks, while a true pegger would allow the interest rate to adjust in a way to keep the spot exchange rate stable. Governments struck by "fear of floating" allow for some flexibility in both variables, but by and large it is the interest rate that absorbs most of the shock. This might be why various empirical studies have found that emerging economies with officially floating exchange rates have domestic interest rates whose volatility is considerably higher than that in the developed world. Policymakers in these countries might be limiting exchange rate volatility as a way to gain credibility and in order to signal to financial markets their commitment to monetary discipline.

A third reason for "fear of floating" is that small and open economies are relatively more susceptible to exchange rate pass-through effects in domestic prices.

Fourth, countries with flexible regimes have experienced "excessive" volatility over the last few decades. It is difficult to define "excessive" with any precision, but evidence of excessive exchange rate variability comes in a number of forms. For instance, a number of surveys of foreign exchange ("forex") market participants clearly indicate that short-term/high-frequency exchange rate movements are caused by "speculative" or "trend-following" behavior rather than by underlying macroeconomic fundamentals. Indeed, destabilizing speculation is a particular problem in developing countries with thin markets (Indonesia's postcrisis experience since 1999 is a case in point). Of course, even if flexible exchange rates exhibited greater volatility than would be warranted by underlying fundamentals, why might such excessive volatility be of concern? Studies suggest that institutionally fixed exchange rate regimes (i.e., common currency, currency boards, or dollarization) stimulate trade, which in turn boosts income. Proponents of the European Monetary Union (EMU) have used such an argument extensively in support of a single regional currency.

Fifth, some economists argue that access to global financial markets for developing countries is conditioned on currency stability. A sharp depreciation in the nominal exchange rate will often trigger an abrupt pause or even reversal of capital flows into the country (the so-called "sudden stop"). Empirically, such a reversal is associated with a sharp adjustment in the current account (from deficit to surplus), an output contraction, and a collapse in credit ratings.

Finally, there are political reasons behind "fear of floating." Sharp fluctuations in the nominal exchange rate combined with sticky prices translate into unstable relative prices for traded versus nontraded goods. This might cause political disruption in a country in which both the traded and nontraded sectors are large and have powerful lobbies.

Significance Given these explanations for fear of floating, it is reasonable to ask why emerging economies do not fix their currencies explicitly. One reason is that pegging the exchange rate constrains monetary independence. To be sure, some research casts doubt on the extent to which floating regimes in emerging economies provide insulation from foreign interest rate shocks (see Frankel, Schmukler, and Serven 2004; and Hausman, Panizza, and Stein 2001). However, a more recent study using de facto exchange rate regimes for 100 developing and industrial countries between 1973 and 2000 finds that the interest rates of the countries that operated pegged regimes followed the base country far more closely than nonpegs (Shambaugh 2004). There is also some evidence that emerging economies "learn to float" in the sense that as they adopt more flexible exchange rate regimes, they tend to adopt stronger monetary and financial frameworks (Hakura 2005). China appears to be a good example of a country

engaging in this "learning to float" behavior. For example, as the Chinese authorities gradually allow for greater volatility of the currency, they are also putting in place the necessary infrastructure and institutions to ensure that the foreign exchange market functions well (i.e., is liquid) and that agents are able to hedge themselves against volatility. The loss of monetary-policy autonomy can have significant costs that must be carefully considered by policymakers.

■ Federal Reserve Board

The Board of Governors of the Federal Reserve System (or the Federal Reserve Board, or "Fed," as it is more commonly known) is the central bank of the United States. It was created by an act of Congress, commonly known as the Federal Reserve Act, in 1913. It is a federal system, with its principal central entity, the Board of Governors, in Washington, DC,

and 12 regional Federal Reserve Banks, one for each of the 12 Federal Reserve Districts, in Boston, New York, Philadelphia, Cleveland, Richmond, Atlanta, Chicago, St. Louis, Minneapolis, Kansas City, Dallas, and San Francisco.

The Federal Reserve System has five main sets of responsibilities: (1) the conduct of monetary policy, (2) bank supervision, (3) addressing systemic risk, (4) acting as the agent for the U.S. government and for foreign official institutions, and (5) operating the payments system of the United States. Generally, the goals of monetary policy, as established by Congress in a number of statutes passed since 1913, include economic growth, price-level stability, high employment, and moderate long-term interest rates.

The Board of Governors is intended to be an independent government agency as well. The board is not funded by congressional appropriations, and governors, once appointed, can be removed from office only "for cause." The Federal Reserve's decisions are not subject to approval by the executive branch, and its funding comes largely from the interest earnings of its portfolio of Treasury debt instruments.

Independence, however, does not mean isolation: members of the Board of Governors testify frequently before congressional committees, and the chairman is required by law to report in February and July of each year. The board has regular contact with the president's Council of Economic Advisors, and the chairman meets regularly with the secretary of the treasury and at times with the president.

Board Responsibility and Composition The Board of Governors has a staff of professionals (about 1,800) who analyze domestic and international economic and financial conditions. The board oversees the Federal Reserve Banks, regulates the operations of the nation's payments system, and administers laws regarding consumer credit protection.

The Board of Governors has seven members, appointed by the president subject to Senate confirmation, for nonrenewable terms of 14 years staggered so that one term would normally expire January 31 of each even numbered year. (A governor appointed to fill the balance of an unexpired term may still be appointed to a full 14-year term.) The chairman and the vice chairman are nominated by the president from the membership of the existing board, subject to Senate confirmation, for four-year terms, renewable through the end of their term as governor. The chairman is the chief executive of the board and is the public face and the spokesperson of the system.

The board and the system are meant to be apolitical: the law governing the board's composition allows for no more than one governor from any Federal Reserve District and calls on the president to make appointments with "due regard to a fair representation of the financial, agricultural, industrial, and commercial interests, and geographical divisions of the country." The staggered terms and fiscal independence provide a substantial measure of insulation from short-run political influence, as a president in the normal course of events would appoint only two governors during each four-year term in office.

Federal Reserve Banks The regional Federal Reserve Banks, which are the operating arms of the Federal Reserve System, include both public and private elements. Each Federal Reserve Bank has a separate board of nine directors, by law chosen from outside the bank. The boards are intended to represent a cross-section of interests within the district: commercial, agricultural, industrial, and public. Some are elected to their posts by the commercial banks in the district that are member banks in the Federal Reserve System, while others are appointed by the Board of Governors.

Conduct of Monetary Policy Responsibility for the conduct of monetary policy lies with the Federal Reserve System, using four mechanisms:

1. Open market operations—the purchase and sale of securities to raise or lower balances held by depository institutions at Federal Reserve Banks;
2. Reserve requirements: the percentage of deposits that depository institutions must hold in reserve as cash or as deposits at Federal Reserve Banks;

3. Contractual clearing balances: amounts that depository institutions agree to hold at Federal Reserve Banks in addition to required reserves; and

4. Discount Window lending: loans by the Federal Reserve Banks to depository institutions.

The Board of Governors is responsible for setting reserve requirements, and it must approve changes in the discount rate initiated by a regional Federal Reserve Bank. Open market operations are the province of the twelve-member Federal Open Market Committee (FOMC), which includes the seven members of the Board of Governors, the president of the New York Federal Reserve Bank, and 4 of the remaining 11 Federal Reserve Bank presidents. Those banks are arranged into four groups of districts   (1) Boston, Philadelphia, and Richmond; (2) Cleveland, Chicago, and Atlanta; (3) St. Louis, Dallas, and Minneapolis; and (4) Kansas City and San Francisco and one Federal Reserve Bank president from each group serves a one-year term in rotation with the others from that group. The nonvoting presidents participate in the Open Market Committee deliberations and evaluation of the economy. Open market operations are conducted by the New York Federal Reserve Bank.

In deploying the tools of monetary policy, the Federal Reserve affects the demand for and supply of deposits held by depository institutions at the Federal Reserve Banks, and thus the federal funds rate, which is the interest rate depository institutions charge one another for overnight loans of deposits at the Federal Reserve banks. The most frequently used   daily, in general   instrument of monetary policy is open market operations, an activity that entails, in simple terms, the purchase (or sale) of U.S. Treasury securities by the Federal Reserve to increase (or decrease) aggregate deposits held by depository institutions at the Federal Reserve, and cause the federal funds rate to fall (or rise). Since 1995, the Federal Reserve has announced its target for the federal funds rate.

The discount rate applies to loans made via the Discount Window, a facility available to virtually all depository institutions that maintain reserves. The rate is usually set about 1 percentage point above the target federal funds rate for what is called primary credit, available to sound institutions for short periods, often overnight. All Discount Window loans are backed by collateral. The facility is an important supplement to open market operations when the supply of balances is less than demand. Further, in cases of natural disaster or other market disruption, the Discount Window provides an avenue for assuring credit availability in the financial system.

Bank Supervision The Federal Reserve Board supervises state-chartered banks that are member banks of the Federal Reserve System, bank holding companies, and the foreign activities of member banks. The board and the Federal Reserve Banks together supervise about 900 state banks and about 5,000 bank holding companies. Bank supervision is also provided by the Comptroller of the Currency (for national banks), and the Federal Deposit Insurance Corporation (for state banks that are not member banks of the Federal Reserve System).

International Responsibilities The chairman has international responsibilities, which include serving as the alternate U.S. member of the board of governors of the International Monetary Fund, a member of the board of the Bank for International Settlements, and a member of the National Advisory Council on International Monetary and Financial Policies. The chairman regularly attends the meetings of central bankers and finance ministers of the G7, and meetings of the Organisation for Economic Co-operation and Development in Paris. The board is also represented at international meetings such as the Finance Ministers' Process of the Asia Pacific Economic Cooperation Forum, meetings of the G20, and meetings of the Governors of Central Banks of the American Continent.

The Federal Reserve's foreign currency transactions are done under the direction of the FOMC and in consultation with the U.S. Treasury, which is responsible for U.S. international financial policy. The manager of the System Open Market Account at the Federal Reserve Bank of New York is the agent for both the Treasury and the Federal Reserve in conducting foreign exchange transactions. Since 1995,

the Federal Reserve has only rarely intervened in foreign currency markets, though in principle it is ready to do so to counter disorderly market conditions. In 1985, when the governments of the five major industrial countries crafted an agreement on exchange rates known as the Plaza Accord, the United States began using foreign exchange market intervention more frequently than it had previously. That intervention, sometimes in concert with other countries' central banks, continued for about a decade, whenever the movement of dollar exchange rates against foreign currencies was deemed excessive.

Publications The board publishes information about the economy and its activities in publications such as the *Federal Reserve Bulletin* (quarterly) and the *Statistical Supplement* (monthly), the semiannual *Monetary Policy Report to the Congress,* and an *Annual Report.* The Federal Reserve Banks provide the board a variety of information from across their districts, used by the board to compile its assessments of the economy and by the FOMC in arriving at its decisions. This information is summarized and made publicly available in a document, popularly known as the Beige Book, issued about two weeks before each FOMC meeting.

■ Feldstein-Horioka puzzle

There is a widely held perception that the world economy is highly financially integrated in other words, a global finance village exists. However, the accumulated evidence suggests that national markets for physical capital (for example, plant and equipment) are much less integrated than national markets for financial capital (for example, bonds and equities). Martin Feldstein and Charles Horioka, in a well-known article of 1980, were among the first to challenge the view of an international capital market. Using data from 16 industrial countries for the period 1960 74, these authors showed that national investment in physical capital is primarily financed by national saving. Feldstein and Horioka used the following cross-section regression to test market segmentation:

$$I_i = \alpha + \beta S_i + u_i, \qquad (1)$$

where I denotes the ratio of national investment to gross domestic product (GDP), S the ratio of national saving to GDP, and the subscript i the country. If national markets are perfectly segmented, the estimated β is unity. National investment is fully financed by national saving, and capital is not mobile among countries. If, instead, national markets are perfectly integrated, the estimated β is zero. High national investment relative to national saving is financed by capital inflows; low national investment relative to national saving prompts an outflow of capital. Feldstein and Horioka tested and failed to reject the null hypothesis of $\beta = 1$ of zero physical capital mobility.

Interpreting the Feldstein-Horioka Results The Feldstein-Horioka finding instigated a vast empirical literature, which found values of β lower

than unity but larger than zero, especially for the 1980s, but did not disprove the basic conclusion that the markets for physical capital are segmented. Just as important, this literature raised many questions and much criticism on what equation (1) means for capital mobility; three of the most significant criticisms are reviewed here.

The first pertains to the interpretation of parameter β. Consider a classical model in which investment and saving depend exclusively on the real rate of interest, r: r affects negatively I and positively S. In an open economy, an excess of saving over investment implies a net capital outflow or a current account balance surplus, denoted by B. In this model, β is the ratio of the interest sensitivity of investment to the sum of the interest sensitivity of investment, saving, and the current account balance:

$$\beta = I_r/(I_r + S_r + B_r), \qquad (2)$$

where I_r, S_r, and B_r are the slope coefficients of I, S, and B with respect to r (Coakley et al. 1998, 172 73). A simple inspection of equation (2) reveals that complete segmentation of national markets, meaning $\beta = 1$, occurs when both S and B are insensitive to the real interest rate. On the other hand, perfect capital mobility, meaning $\beta = 0$, occurs when either S or B is infinitely sensitive to r. What drives perfect capital mobility: an infinitely elastic saving rate or an infinitely elastic capital account? If we cannot discriminate between alternative causes of high or low β, the test suffers from what is known in jargon as an identification problem. The latter becomes more complex as the underlying models acquire more complexity.

The second criticism concerns the relationship between β and the size of the country. Recall that an excess of saving over investment spills over in a net capital outflow or in a current account surplus in a world of perfect capital mobility. Assume that an unforeseen increase in national saving takes place in a small open economy. The critical assumptions of a small open economy are that its real rate of interest is equal to the world rate of interest and that domestic events cannot influence the world rate of interest. It follows that the world rate of interest and the national investment demand will remain unchanged. The

increase in national saving spills over into larger net capital outflows; the relationship between I and S in equation (1) is such that β is zero. Suppose, instead, that the increase in saving occurs in an economy large enough to influence the world rate of interest. In this case, national I will rise because of the decline in r, and the relationship between I and S in equation (1) is such that β is positive. In sum, β is positively correlated with the size of the economies (Harberger 1980).

The final criticism deals with the use of cross-section data. In the Feldstein-Horioka test and in several subsequent studies, observations are averages of long annual time series. Given that the current account tends to be balanced over long periods of time, I and S tend to equal each other. It follows that the use of time series averages biases the estimate of β toward unity.

Persistence of the "Puzzle" Notwithstanding these criticisms, study after study has confirmed the positive association between investment and saving, to the point that the finding has been elevated to the rank of a "major puzzle" in international macroeconomics (Obstfeld and Rogoff 2001). It is a puzzle because our strong prior, or belief, is that capital is mobile, and our prior has been fed by the evidence on the integration of national markets for financial capital, especially short-term securities issued by industrial countries. Arbitrage tends to quickly eliminate yield differentials. But this parity does not hold for long-term portfolio capital or physical capital (Dooley et al. 1987, 522 23). For national markets of physical capital to be fully integrated, ex-ante real rates of interest in different national markets would have to be equalized; in other words, the following real interest rate parity would have to be satisfied:

$$\begin{aligned} r - r^* = (i - i^* - fp) + (fp - \Delta e) \\ + (\Delta e - \pi + \pi^*) = 0. \end{aligned} \qquad (3)$$

The new symbols in (3) are Δe = the expected depreciation of the home currency and π = the expected rate of inflation. The evidence overwhelmingly rejects (3), and not surprisingly. For (3) to hold, three conditions need to be simultaneously satisfied: covered interest rate parity (the first term in paren-

theses in the equation, the difference in national interest rates adjusted for the premium in the forward exchange market); the forward premium as an unbiased estimate of the expected depreciation (second term, the difference between the forward premium and the expected change in the future spot exchange rate); and expected purchasing power parity (third term, the difference between expected changes in national price levels adjusted for the expected change in the future spot exchange rate). The first of these three conditions, as we have noted, has empirical corroboration for selected currencies and a very narrow set of assets. The second and third conditions fail miserably. In sum, the failure of equation (3) supports the basic contention of Feldstein and Horioka that β is not zero.

Other Home Biases The Feldstein and Horioka finding seems to be consistent with two home biases, one in equities and the other in consumption. The domestic bias in equities is measured relative to the asset diversification predicted by the international capital asset pricing model. Given historical mean returns and variances, the model predicts that the weight of foreign equities should be much higher than the observed weight. The discrepancy between predicted and actual weight remains large even under the assumption of infinite relative risk aversion (Lewis 1999, table 2). The bias could stem from the failure of the capital asset pricing model to predict diversification, or from the failure of purchasing power parity, which is a standard assumption of the international capital asset pricing model, or from the failure of both; there is no way to distinguish between the two. Various attempts to justify the equity home bias have also failed.

The domestic consumption bias is measured relative to the prediction made by a model where markets are complete in the Arrow-Debreu sense and countries diversify risks due to idiosyncratic shocks (Obstfeld and Rogoff 1996, chapter 5). In this setting, the growth rate of domestic consumption is equal to that of foreign consumption. The data clearly refute the implication of complete markets (Lewis 1999, table 1).

In sum, financial capital is more mobile than physical capital. There is an obvious parallel between finance capital and traded goods, and between physical capital and nontraded goods. National borders are just as much an obstacle for the cross-border flows of many goods and services as they are for the flows of physical capital.

■ financial crisis

The financial system is a set of institutions and markets that provides financial intermediation by transferring savings into productive investment. In most developing countries the bulk of financial intermediation has been done via the banking system, with the stock market gaining importance in countries with more advanced institutions. Financial intermediation entails maturity transformation funding a longer-term tangible investment with shorter-term savings. As such, financial intermediation is exposed to financial fragility, in which heightened perceived risk may lead to liquidation, putting the financial system at risk.

Financial crisis refers to a rapid financial disintermediation due to financial panic. In practice, this involves a "flight to quality," where savers attempt to liquidate assets in financial institutions due to a sudden increase in their perceived risk, moving their savings to safer assets, such as foreign currency and foreign bonds in open economies, or currency, gold, and government bonds in closed economies. The ultimate manifestation of financial crises includes bank failures, stock market crashes, and currency crises, occasionally leading to deep recessions.

The economist Hyman Minsky (1964) theorized that financial fragility which is related to the business cycle and to leverage is a typical feature of any capitalist economy. These considerations are at the heart of the large literature propagated by the stock market crash of 1929 and the Great Depression (Bernanke 1995).

Financial Crises and Financial Integration
During the last quarter of the 20th century, observers focused attention on the growing role of international triggers for financial crises an outcome of the collapse of the Bretton Woods system (the post World War II framework for international trade and financial stability), the rapid increase in the importance of emerging markets in the global economy, and the growing financial integration of countries with the global financial system. The resumption of capital flows to developing countries in the early 1990s led to waves of "sudden stops" (the abrupt cessation of foreign capital inflows) and reversals of capital flows, starting with the Mexican crisis of 1994 95, continuing with the Russian and the East Asian crises in the second half of the 1990s, and culminating with the Argentinean meltdown in the early 2000s (Calvo 1998; and Edwards 2004).

Most of the financial crises in the 1990s and early 2000s affected developing and emerging markets, leading to a heated debate regarding their causes and the needed remedies. There is solid evidence that financial opening (that is, the dismantling of capital controls) increases the chance of financial crises. There is more tenuous evidence that financial opening contributes positively to long-run growth. Hence there may be a complex trade-off between the adverse intermediate run and the beneficial long-run effects of financial opening. These findings pose a challenge to policymakers: how to supplement financial opening with policies that would improve this intertemporal trade-off.

To place this issue in a broader context, the debate about financial opening is a reincarnation of the earlier immiserizing growth literature in economics. In particular, while financial opening increases a country's overall welfare when the only distortion is restricting intertemporal trade across countries, financial opening may be welfare-reducing in the presence of other distortions (an economic distortion occurs when an inefficiency prevents an economy from reaching its full potential). An example of such a distortion is moral hazard, which frequently acts as an implicit subsidy to borrowing and investment, ultimately leading to overborrowing and crisis

(McKinnon and Pill 1999; and Dooley 2000). Moral hazard arises when investors believe that they will be bailed out of their bad investments by the taxpayer and, therefore, have little incentive to undertake proper monitoring of their investments. This bailing out may be carried out by the treasury, the central bank, or by international agencies. In these circumstances, the taxpayer subsidizes the investment. A frequent rationale for the bailing out is the "too big to fail" doctrine the fear that allowing large borrowers to go under will trigger a systemic crisis.

Key factors contributing to an exposure to financial crises are balance-sheet features in the form of maturity and currency mismatches between the assets and the liabilities of the banking system, leading to financial fragility. A currency mismatch occurs when residents of the country are not adequately hedged against a change in the exchange rate. This is frequently the case in countries with few foreign assets, serving large external debt denominated in foreign currency, so that a large depreciation generates a large increase in the domestic valuation of the foreign liability, inducing a fall in the economy's net worth, usually accompanied by a large fall in output and insolvencies on the part of firms and banks. Maturity mismatch occurs when the average duration of the liabilities differs from that of the assets. Frequently, banks' liabilities have shorter maturity than banks' assets; hence large withdrawals by consumers may lead to a bank run. Developing countries are more susceptible to balance sheet fragilities and are characterized by debt intolerance: the inability of emerging markets to manage levels of external debt that are manageable for developed, high-income countries (Reinhart, Rogoff, and Savastano 2003).

This literature has led to a spirited debate concerning the wisdom of unrestricted capital mobility between high-income countries and emerging markets. Advocates of financial liberalization in the early 1990s argued that external financing would alleviate the scarcity of savings in developing countries, inducing higher investment and thus higher growth rates. The 1990s experience with financial liberalization suggests that the gains from external financing are overrated the bottleneck inhibiting economic growth has less to do with the scarcity of saving and more to do with other factors, such as the scarcity of good governance (Rodrik 1998; Gourinchas and Jeanne 2003).

Notwithstanding this debate, the strongest argument for financial opening is the pragmatic one. Like it or not, greater trade integration erodes the effectiveness of restrictions on capital mobility (see Aizenman 2004). Hence, for successful emerging markets that engage in trade integration, financial opening is not a question of if, but of when and how. Instead, the hope is that proper sequencing of policies (see McKinnon 1991) and improved coordination will reduce the severity of financial crises, thereby improving the odds of a positive long-run welfare effect of financial opening.

Financial Opening and Financial Crises: The Evidence The recent research has two common themes: it validates empirically the assertion "Goodbye financial repression, hello financial crash" (Diaz-Alejandro 1985). Yet it also has found tenuous evidence that financial liberalization tends to increase growth over time. Both observations suggest an intertemporal trade-off. In the short-run, the fragility induced by financial opening leads frequently to crises. Yet, if these crises force the country to deal with its structural deficiencies, financial opening may induce a higher growth rate in the long run (see Ranciere, Tornell, and Westermann 2005).

Kaminsky and Reinhart (1999) found that problems in the banking sector typically precede a currency crisis; that a currency crisis deepens the banking crisis, activating a vicious spiral; and that financial liberalization often precedes banking crises. Glick and Hutchison (1999) investigated a sample of 90 countries during 1975 97, covering 90 banking crises, 202 currency crises, and 37 twin crises. They found that banking and twin crises have occurred mainly in developing countries, and their number increased in the 1990s. Twin crises are mainly concentrated in financially liberalized emerging-market economies. The costs of these crises are substantial currency (banking) crises are very costly, reducing output by about 5 percent 8 percent (8 10 percent)

over a two- to four-year year period (Hutchison and Noy 2005).

A useful survey of financial liberalization is found in Williamson and Mahar (1998), which focused on 34 countries that undertook financial liberalization between 1973 and 1996. Overall, the authors found a mixed record of financial liberalization the gains are there, but the liberalization carries the risk of a financial crisis. Financial liberalization has yielded greater financial depth and increased efficiency in the allocation of investment. Yet it has not brought the boost in saving. The main recommendations emerging from their study are akin to those in Hellman, Murdock, and Stiglitz (2000) start with macroeconomic stabilization, improve bank supervision, while delaying capital account convertibility to the end of the process. Maintaining high spreads may be needed in a transition until banks are able to work off the legacy of bad debt inherited from the period of financial repression, preventing moral hazard associated with a "gamble for resurrection."

The overall effect of financial opening on growth remains debatable. Rodrik (1998) failed to detect any positive effects of financial opening on investment, growth, and inflation. Bekaert, Harvey, and Lundblad (2001) found that equity market liberalizations, on average, lead to a 1 percent increase in annual real economic growth over a five-year period. The investment/gross domestic product ratio increases postliberalization, with the investment partially financed by foreign capital, inducing worsened trade balances. The liberalization effect is enhanced by a large secondary school enrollment, a small government sector, and an Anglo-Saxon legal system.

In summary, recent financial crises affecting developing countries are the outcome of financial fragilities, reflecting the downside of growing financial integration. The challenge is mitigating the pain in ways that enhance growth and economic welfare.

■ financial liberalization

Financial liberalization, or *financial reform*, in the most general sense, refers to the transition away from a financial system characterized by state intervention and ownership and toward a more market-oriented system. Not only does financial liberalization need to be considered in discrete historical phases that differ by region and level of development, it also can and should be understood as it applies to the domestic and international spheres. Sometimes this distinc tion boils down to the difference between banking reform and capital market reform. Outward, or ex ternally oriented, financial liberalization involves lifting state controls on the flow of finance between the country in question and international financial markets, including allowing for competition from international banks operating within the country. Internally oriented financial liberalization focuses on removing restrictions on competition and other business practices within the domestic financial markets.

Internally Oriented Controls and Liberal ization One of the most common forms of restric tions placed on domestic banks in both developed and developing countries has been interest rate ceil ings that is, restrictions on the interest rate banks are allowed to pay depositors in order to compete for their deposits, and/or limits on the interest rate banks are allowed to charge borrowers on their loans. De regulation or liberalization in this case entails re moving such ceilings.

Another form of interest rate regulation takes a more microeconomic form. Governments can set different interest rate ceilings depending on the economic sector of the loan. In this way, govern ments gain control over where banks choose to direct financial resources and who has access to credit. This is sometimes referred to as sector-specific allocation of finance, which has been much more common among newly industrializing economies (NIEs) in Asia than in Latin America or advanced industrial countries. Another method of sector-specific alloca tion is the manipulation of marginal reserve re quirements on bank deposits. For example, mone tary officials could control the allocation of private investment by altering the level of reserves private banks are required to hold in the central bank. Sometimes the reserve requirements would be ad justed depending on the sector of the economy to which loans were destined. (For a more detailed discussion of how this worked in Mexico, see Auer bach 2001). Especially in Asia, directed finance was part of a broader industrial policy strategy of state-led industrialization.

The most direct way that governments have controlled the flow of domestic finance, particularly in developing countries, is through ownership of banks. Thus privatization, that is, the process of selling off these banks to the private sector, often becomes the cornerstone of financial liberalization for the domestic market. Even after the domestic banking sector has been privatized, however, gov ernments often and to varying degrees retain some control over where private sector banks direct their

financial resources. This phenomenon, often called "window guidance," was mostly practiced in Asian economies by heavily interventionist developmental states such as South Korea and Japan that were unwilling to give up complete control over the allocation of finance despite the intense pressure to liberalize.

Another of the mechanisms by which governments have retained control over privatized banking sectors is through the authority to charter new banks. While this authority, much like the authority to print money, falls naturally under the purview of the state and would not necessarily be considered interventionist, the level of restrictions on new charters and the form that those restrictions take do fall under the umbrella of state intervention. Thus when restrictions on chartering are lifted altogether, or when preferential charter policies are replaced with neutrally applied charters that treat foreign and domestic owners alike, these policy reforms would be considered a form of financial liberalization.

Restrictions on banking competition have taken multiple and specific forms often related to particular national histories. In the United States, for example, legislation once mandated that banks could not take deposits in more than one state and that banks could not directly own stock in industrial firms. The repeal of this legislation in 1999 represented for the United States one of the last steps in a financial reform process that began in the 1970s with the lifting of interest rate ceilings.

External Financial Liberalization Externally oriented liberalization aims to remove restrictions of financial flows or price controls between the domestic financial market and international finance. The removal of capital controls in advanced industrial countries took place mostly by the 1970s primarily because of the ineffectiveness of these controls in the context of new technologies that allowed banks to transfer capital internationally at the touch of a button. Yet there have been notable exceptions to this rule. Chile imposed a significant tax on capital outflows, known as the "Chile tax," in the 1990s that effectively controlled the outflow of capital.

The second major type of external liberalization came in the form of allowing the entry of foreign banks into domestic banking markets that had been previously restricted to domestic ownership. This type of liberalization has been slow and piecemeal given the politically charged role that banking plays in most economies.

Liberalizing exchange rates has resulted in part from the pressures of increasingly mobile international capital. Most experts have agreed that managing exchange rates has become increasingly difficult and risky given the tendency for exchange rate speculation in international currency markets. While governments have continued to see the exchange rate as a key economic variable affecting trade competitiveness and foreign investment flows, their ability to manipulate that variable waned considerably in the 1990s.

Waves of Financial Liberalization Historically and globally, financial liberalization has come in waves. The 1970s saw a major wave of financial reforms among advanced industrial countries. Some authors frame the wave of market-oriented reforms among advanced industrial countries as part of the breakdown of the Bretton Woods system, which promoted state intervention through tight control over international financial flows. The end of the Bretton Woods system resulted in an immediate shift from pegged, or fixed, to floating exchange rates for most advanced industrial countries. Most attempted to maintain capital controls, but rapidly increasing financial flows aided by new computer technologies rendered these policies increasingly costly and difficult to monitor. Capital controls in the United States were permanently removed in 1974, and in Britain in 1979. The last European countries to lift controls were Portugal and Ireland in the early 1990s.

In contrast to the advanced industrial country experience, developing countries, especially the NIEs, maintained more state interventionist or what some have called "repressed" financial systems until the 1980s. Here the catalyst for the wave of reforms came as a result of the Latin American debt crisis. Again, interpretations of this wave of financial liberalization differ widely among proponents and

opponents of financial liberalization. Proponents are apt to suggest that the debt crisis was the natural result of years of inefficient financial intervention or repression of financial markets. Opponents of financial liberalization, on the other hand, argue that the debt crisis put developing countries between a rock and a hard place: under international pressure from the United States and the International Monetary Fund (IMF), they had little choice but to liberalize their financial markets or face being permanently cut off from international capital flows. As a result, most Latin American countries and some Asian countries, to varying degrees, lifted interest rate ceilings, stopped using marginal reserve requirements to direct finance to specific sectors, loosened capital controls, and began privatizing the banking sector as part of the first rounds of financial reforms in the 1980s.

With the 1990s came a new set of financial crises that precipitated a new round of financial liberalization, this time focused on external capital markets and domestic banking. Lively debate over the pros and cons of financial liberalization has arisen among economists and political scientists as well. Particularly after the Asian financial crisis of 1997, proponents of financial liberalization blamed insufficient liberalization in the previous decade as the primary cause, while opponents blamed overly rapid and extensive liberalization, particularly the liberalization of external capital flows (see, e.g., Furman and Stiglitz 1998; and Rodrik 1996).

Most of the political economy literature on financial liberalization has focused on the causes of liberalization without differentiating between perverse and benign forms of liberalization. A growing political economy literature now rejects the notion that financial liberalization is either inherently beneficial or harmful, but instead describes the political conditions under which liberalization will promote growth and efficiency as opposed to perverse outcomes.

■ financial repression

Financial repression refers to the notion that a set of government regulations, laws, or other nonmarket restrictions prevents an economy's financial intermediaries such as banks and security markets from functioning at their full capacity. The policies that cause financial repression include interest rate ceilings, liquidity ratio requirements, high bank reserve requirements, capital controls, restrictions on market entry into the financial sector, credit ceilings or restrictions on directions of credit allocation, and government ownership or domination of banks. Economists have commonly argued that financial repression prevents the efficient allocation of capital and thereby impairs economic growth.

The economists McKinnon (1973) and Shaw (1973) were the first to explicate the notion of financial repression. While theoretically an economy with an efficient financial system can achieve growth and development through efficient capital allocation, McKinnon and Shaw argue that historically, many countries, including developed ones but especially developing ones, have restricted competition in the financial sector with government interventions and regulations. According to McKinnon and Shaw's argument, a repressed financial sector discourages both saving and investment because the rates of return are lower than what could be obtained in a competitive market. In such a system, financial intermediaries do not function at their full capacity and fail to channel saving into investment efficiently, thereby impeding the development of the overall economic system.

Rationale for and Types of Financial Repression The control of fiscal resources is a key reason for the implementation of financially repressive policies by governments. By having a direct control over the financial system, the government can funnel funds to itself without going through legislative procedures and more cheaply than it could when it resorts to market financing. More specifically, by restricting the behavior of existing and potential participants in the financial markets, the government can create monopoly or captive rents (that is, economic profits that can arise from market imperfection) for the existing banks and also tax some of these rents so as to finance its overall budget, which may be economically attractive to both the existing banks and the government. Existing banks may try to collude with one another and to interrupt possible liberalization policies as long as they are guaranteed their collective monopoly position in the domestic market.

In some countries, governments require banks to meet high reserve ratios and seize some of these reserves as government revenues. Because reserves earn no interest, reserve requirements function as an implicit tax on banks and also restrict banks from allocating a certain portion of their portfolios to productive investments and loans. When high reserve ratios are required, the lending and borrowing rate spread must widen to incorporate the amount of no-interest reserves, which can reduce the amount of funds available in the financial market. If high reserve requirements are combined with interest ceilings and protective government directives for certain borrowers, savers who are usually unaware of the requirement policy become the main "taxpayers" because they face reduced rates of interest on their savings. Inflation can aggravate the "reserve tax" because it reduces the real rates of interest. Thus high reserve requirements make the best use of the government's monopolistic power to generate seigniorage revenue (the revenue monetary authorities can create by issuing currency) as well as to regulate reserve requirements. A variant of this policy includes required liquidity ratios banks are required to allocate a certain fraction of their deposits to holding government securities that usually yield a return lower than could be obtained in the market.

Governments often impose a ceiling on the interest rate banks can offer to depositors. Interest ceilings function in the same way as price controls, and thereby provide banks with economic rents. Like high required reserve ratios, those rents benefit incumbent banks and provide tax sources for the government, paid for by savers and by borrowers or would-be borrowers. The rents borne by the interest ceiling reduce the number of loans available in the market the real interest rates on loans and deposits are higher and lower, respectively, thereby discouraging both saving and investment. In return for allowing incumbent banks to reap rents, the government often requires banks to make subsidized loans to certain borrowers for the purpose of implementing industrial policy (or simply achieving some political goals). Interest ceilings in high inflation countries can victimize savers because high inflation can make the real interest rates of return negative.

Financial repression also takes the form of government directives for banks to allocate credit at subsidized rates to specific firms and industries to implement industrial policy. Forcing banks to allocate credit to industries that are perceived to be strategically important for industrial policy ensures stable provision of capital rather than leaving it to

decisions of disinterested banks or to efficient securities markets. It is also more cost effective than going through the public sector's budgetary process. Government directives and guidance sometimes include detailed orders and instructions on managerial issues to financial institutions to ensure that their behavior and business are in line with industrial policy or other government policies. The Japanese Ministry of Finance (MOF) is a typical example of government's micromanagement of the financial industry. Till the 1980s, for example, the MOF segmented the banking industry into different types of banks and specified what kind of borrowers and depositors banks in each type can deal with, along with other specific directives and "administrative guidance" about the banking business allowed for each type of banks. The extreme example of direct state control of banks is the nationalization of banks as was observed in Mexico in the 1980s, when the government took control of all the banks to secure public savings.

Capital controls are restrictions on the inflows and outflows of capital, and are also financially repressive policies. Despite their virtues, the use of capital controls can involve costs. Because of their uncompetitive nature, capital controls increase the cost of capital by creating financial autarky (that is, restricting access to cheaper capital available outside the domestic market), limit domestic and foreign investors' ability to diversify their portfolios, and help inefficient financial institutions to survive by protecting them from international competition.

Impacts of Financial Repression Because financial repression leads to inefficient allocation of capital, high costs of financial intermediation, and lower rates of return to savers, it is theoretically clear that financial repression inhibits growth (Roubini and Sala-i-Martin 1992). The empirical findings on the effect of removing financial repression, that is, financial liberalization, on growth support this view. These findings suggest that liberalization spurs growth through various channels.

The possible negative effect of financial repression on economic growth does not automatically mean that countries should adopt a laissez-faire stance on financial development and remove all regulations and controls that create financial repression. Many developing countries that liberalized their financial markets experienced crises partly because of the external shocks that financial liberalization introduces or amplifies. Indeed, financial liberalization can create short-term volatility despite its long-term gains (Kaminsky and Schmukler 2002). Also, because of market imperfections and information asymmetries (in which one party to a financial transaction has better information than the other), removing all public financial regulations may not yield an optimal environment for financial development. An alternative to a financially repressive administration would be a new set of regulations to ensure market competition as well as prudential regulation and supervision.

■ financial services

A nation's financial system provides an essential infrastructure for the functioning of the entire economy. A sound and efficient financial system is therefore imperative for economic growth and development. A sound financial system also increases the resiliency of a nation's economy, thereby helping it to withstand external shocks such as movements in exchange rates or a major increase in global interest rates.

International trade in financial services in combination with enhanced prudential regulation and supervision and other basic structural reforms can play an important role in helping countries build financial systems that are more competitive and efficient and therefore more stable. Trade in financial services can enhance capital market efficiency and improve the quality, availability, and pricing of financial services. Especially when a foreign financial firm operates through a commercial presence in a host country, trade in financial services can stimulate innovation through the dissemination of new technologies, know-how, and skills. Trade in financial services can also promote the use of international good practices for example, with regard to risk management and disclosure of financial information.

Trade liberalization and strengthening domestic financial systems the two major dimensions of the international framework for financial services are complementary and mutually reinforcing. Indeed, in order to obtain the maximum benefits of liberalization while minimizing the risks, a host country must ensure adequate prudential regulation and supervision and put in place other elements of the institutional and legal structure necessary for a sound financial system. International work on strengthening domestic financial systems takes place in a variety of forums, ranging from the International Monetary Fund (IMF) to specialized bodies such as the Basel Committee on Banking Supervision.

Liberalization of trade in financial services is dealt with in the World Trade Organization (WTO) under the General Agreement on Trade in Services (GATS) and also in regional and bilateral trade arrangements.

International Trade in Financial Services Major financial firms now provide a wide range of services to customers in other countries. The GATS defines a financial service as "any service of a financial nature . . . including insurance and insurance-related services and all banking and other financial services" and provides a list of activities included in this definition. The list includes commercial banking activities such as lending and deposit-taking; investment banking activities, such as underwriting securities and advising on mergers and acquisitions;

trading activities, that is, brokering and dealing in securities and other financial instruments; and asset-management activities, including management of mutual funds and pension funds. Other noninsurance financial services on the list comprise financial information and data processing services; investment advisory services; payment and money transmission services, including credit cards; settlement and clearing for financial assets; and financial leasing. Insurance services on the GATS list include "direct" life and nonlife insurance, that is, insurance sold to the public and to noninsurance businesses; reinsurance and "retrocession" (reinsurance by reinsurers); and commercial insurance. The list also includes services auxiliary to insurance such as actuarial, risk assessment, and claims settlement services.

"Trade in services" as defined in the GATS covers both foreign direct investment (FDI) as well as cross-border trade, which is broadly analogous to trade in goods. FDI includes services provided through a "commercial presence" in a host country, such as a branch or subsidiary of a foreign bank. The GATS definition of commercial presence also includes representative offices, which are basically a marketing device and do not constitute FDI. Trade in services as defined in the GATS also includes services provided in a host country by "natural persons" (individuals) who are residents of another country. In the financial services sector, however, individuals usually provide services as employees of financial firms; exceptions are financial advisers and, in insurance, independent sales intermediaries.

A cross-border financial services transaction could be carried out in a number of ways. For example, a representative of a foreign bank might visit the customer's country to arrange a loan. Alternatively, the customer might travel abroad to visit the office of the foreign bank. Or, the transaction might take place via telephone, fax, or, increasingly, the Internet, which in this context is another technological means of carrying out a transaction. Although the GATS distinguishes between cross-border services provided to nonresidents "from" and "in" the country of the service supplier (referred to as "cross-border supply" and "consumption abroad," respectively), for financial services the line dividing these two modes of supply is not always clear.

Wholesale financial services   that is, services provided to "sophisticated" customers such as corporations and institutions, other financial services firms, and, under some definitions, wealthy individuals   are provided internationally both through FDI and across borders. Electronic transactions play a major role in the cross-border provision of wholesale financial services, including traditional financial services as well as newer types of services designed to facilitate business-to-business e-commerce activities. When wholesale financial services are provided through FDI, foreign financial firms typically prefer to use the branch form of organization. Branches, unlike subsidiaries, are not separately incorporated in the host country and, unless restricted by host-country regulations, operate using the firm's consolidated worldwide capital.

Retail financial services are still provided internationally primarily through FDI. Although the provision of some financial services over the Internet and through Web-enabled technologies, such as mobile telephony, is expanding dramatically *within* a number of countries, the cross-border provision of financial services to retail customers through these methods is still in its infancy. The lack of widespread development of cross-border retail banking and other financial services   whether through electronic transactions or more traditional methods   reflects host-country regulatory requirements aimed at ensuring adequate consumer protection, consumer preferences, and tax considerations. Some countries actually require the establishment of a commercial presence to provide retail financial services. Perhaps even more important, consumers may prefer dealing with a local commercial presence, particularly because redress against a local establishment is usually readily available through the domestic legal system. In addition, in a number of countries, consumers receive more favorable tax treatment on financial products that are provided through locally incorporated entities.

Strengthening Domestic Financial Systems
The financial services sector has an elaborate and intensively used framework of international forums that are used to address overall financial and regulatory policy issues, to promote cooperation and co-ordination among supervisors, to set voluntary but widely accepted international minimum standards and codes of good practices, and to provide "surveillance" of domestic financial systems. This international framework, which has been constructed over three decades and is still evolving, is a response not only to the internationalization of banking and other financial activities but also to the special characteristics of the financial sector, especially the phenomenon of "systemic risk" whereby problems with one financial firm can be transmitted to unrelated financial firms, both within and beyond a single country.

International minimum standards and codes of good practices for sound financial systems have been established in three broad areas: (1) transparency of macroeconomic policy and data; (2) institutional and market infrastructure, which covers insolvency, corporate governance, accounting, auditing, market integrity and functioning, and payment and settlement systems; and (3) prudential regulation and supervision, which covers both financial firms and regulatory and supervisory systems. Examples are the Code of Good Practices on Transparency in Monetary and Financial Policies promulgated by the IMF, the Principles of Corporate Governance issued by the Organisation for Economic Co-operation and Development (OECD), and the Core Principles for Effective Banking Supervision developed by the Basel Committee on Banking Supervision.

The international work on strengthening domestic financial systems includes financial sector surveillance conducted by the IMF and the World Bank under a joint Financial Sector Assessment Program (FSAP). The FSAP is designed to provide a "comprehensive health check-up of a country's financial sector" by identifying the strengths and vulnerabilities of a country's financial system, determining whether effective risk-management techniques are being used, and evaluating the observance of internationally accepted minimum standards and codes. A continuing challenge for the IMF is to integrate its financial sector surveillance more effectively into its so-called Article IV surveillance of the economic policies of its member countries. Technical assistance for a country that wishes to enhance its regulatory and supervisory capabilities is available under the auspices of the IMF and World Bank, or through programs established by national regulatory authorities.

Liberalization in the GATS The GATS, which was negotiated in the Uruguay Round (1986–94), is the first global trade agreement to cover financial and other services. The GATS has two major components. First, it establishes overall rules and disciplines for trade in services, both in the main text and in various annexes; the Annex on Financial Services deals with rules specific to financial services. Second, the GATS contains each WTO member's schedule of specific commitments and list of exemptions from the most-favored-nation (MFN) obligation. The results of the financial services negotiations—which were not concluded until December 1997, several years after the end of the Uruguay Round—are incorporated into these schedules and lists by the Fifth Protocol to the GATS. Although the expression "agreement on financial services" is widely used to refer to the results of the 1997 negotiations or, more broadly, to the GATS as it applies to financial services, from a legal point of view, a separate multilateral agreement for financial services does not exist.

The inclusion of the financial services sector in a multilateral trade agreement was a major milestone. Because of the special characteristics and sensitivity of the financial sector—in particular, the role of banks in monetary and payment systems and the phenomenon of systemic risk—finance officials in a number of countries were concerned about allowing financial sector issues to fall within the domain of trade officials and the multilateral trading system. Financial regulators made it clear that the inclusion of financial services in the GATS would be unacceptable without a specific carve-out from the obligations of the agreement for prudential

435

measures. The regulators emphasized that such a carve-out was necessary to ensure that the agreement would not interfere with their ability to carry out their responsibilities for prudential regulation and supervision. Financial regulators also insisted that any dispute settlement panel dealing with financial services must have the appropriate expertise regarding the specific financial service at issue. Ultimately, provisions addressing both of these issues were included in the GATS Annex on Financial Services.

The prudential carve-out allows a country to take prudential measures "to ensure the integrity and stability of the financial system" or "for the protection of investors, depositors, policy holders or persons to whom a fiduciary duty is owed" even if the measures are inconsistent with other provisions of the GATS. The carve-out also contains an anti-abuse provision. As a result, not only the question of whether a particular measure is prudential in the first place but also the question of whether a seemingly "prudential" measure is being misused to avoid a country's obligations and commitments could be brought before a WTO dispute settlement panel. However, as of October 2007, there had been no dispute settlement proceeding and no request for consultation on a financial services issue. Therefore the scope of the prudential carve-out and its antiabuse provision remain untested in WTO jurisprudence.

A GATS commitment is permanent in the sense that it cannot be withdrawn without compensation of trading partners. Failure to honor a GATS commitment could open a country to a WTO dispute settlement proceeding and, ultimately, to WTO-sanctioned retaliatory measures by its trading partners. Thus backsliding in the face of domestic political pressures could be extremely costly. The GATS calls for periodic negotiating rounds to improve commitments for financial and other services to achieve "a progressively higher level of liberalization." The Doha Round, which was launched in November 2001 but as of October 2007 remained stalled, includes a new set of negotiations on trade in services.

Ideally, GATS negotiations can both reinforce and build on market and political forces that are creating pressures for liberalization within a host country. In this regard, a country's "readiness" for reform is critical. Indeed, undertaking commitments in the GATS can be an integral part of a country's longer-term policy reform agenda. For example, China's WTO accession commitment to open its banking market to FDI within five years (i.e., by December 11, 2006) in effect set a domestic political deadline for substantial progress in reforming China's banking system. During the 1997–98 Asian financial crisis, making commitments in the GATS to permit FDI in their domestic financial sectors offered an additional opportunity for Asian governments to try to reassure markets that they were committed to longer-term policy reform.

In the 1997 agreement on financial services commitments, most of the WTO members participating in that agreement "bound" the levels of liberalization for FDI that existed as the negotiations entered their final phase in late 1997. For a number of emerging market economies and other developing countries, such liberalization represented a substantial improvement over the liberalization that existed a few years earlier. Moreover, capturing existing levels of liberalization in binding commitments subject to WTO dispute settlement is important in its own right. In contrast to the commitments for FDI, the 1997 commitments for cross-border services provided "from" the country of the service supplier ("cross-border supply") were, even for OECD countries, relatively limited and did not always reflect existing liberalization. Most countries that have acceded to the WTO since its inception in 1995 have made strong financial services commitments, including new liberalization, for FDI and, in some cases, cross-border services.

Three Pillars of Liberalization The inclusion of financial services in the GATS and the negotiation of the 1997 agreement on financial services commitments constitute a significant step in the larger process of achieving international contestability of markets for financial services and strengthening domestic financial systems. "International contest-

ability of markets" refers to the creation of markets that are competitive and efficient on a global basis a goal that can be achieved by removing all types of barriers to foreign participation in host-country markets. International contestability is, in effect, based on three pillars of liberalization namely, (1) opening markets by ensuring "national treatment" and "market access"; (2) removing nondiscriminatory structural barriers (domestic structural reform); and (3) liberalization of capital movements.

For financial services, the GATS has so far dealt mainly with first-pillar liberalization, that is, liberalization aimed at opening markets to foreign services and service suppliers and ensuring that they enjoy substantially the same treatment as their domestic counterparts. First-pillar barriers of particular importance for financial services include limitations on foreign ownership interests in domestic financial firms; restrictions on juridical form, for example, prohibiting a foreign financial firm from establishing a branch as opposed to a subsidiary; and prohibiting branches or subsidiaries of foreign financial firms from engaging in all of the activities that are permissible for their domestic counterparts.

One question for future negotiations on financial services is whether, or to what extent, they should extend into the second pillar. Second-pillar liberalization deals with nonquantiative structural barriers that do not discriminate between domestic and foreign services and service suppliers. In contrast to national treatment and market access which ensure that foreign services and services suppliers can enter a host-country market as currently structured and enjoy equality of competitive opportunities vis-à-vis their domestic counterparts second-pillar liberalization represents an effort to create maximum potential competitive opportunities in a host-country market. It may therefore require major domestic structural reform. Second-pillar barriers can be created by anticompetitive domestic policy measures, the inadequacy or absence of domestic regulation, differences in national rules that make it difficult to conduct operations on a global basis, or lack of regulatory transparency. Moreover, second-pillar barriers to trade in financial services are not limited

to financial sector regulation. They also include, for example, a host country's lack of an effective legal framework for corporate governance or insolvency; both of these areas are part of the international work on strengthening domestic financial systems.

The European Union's single-market program represents the most far-reaching effort to date to remove nondiscriminatory structural barriers among a group of nations. Predicated on political agreement on goals for economic liberalization, that effort is being carried out in the context of the unique supranational legislative, judicial, and administrative structure of the European Community. Even within the European Union, however, important nondiscriminatory structural barriers to trade in financial services among the member states still exist, especially with regard to retail financial services.

At present, the GATS addresses certain types of second-pillar barriers, including lack of transparency and barriers created by domestic regulation, in very general terms. Some second-pillar barriers are also dealt with in countries' schedules of commitments. For financial services, most of these commitments are simply "best efforts" commitments. Many believe that it is not realistic or appropriate to negotiate and bind in the GATS additional second-pillar liberalization for financial services. However, one type of second-pillar liberalization that involves procedural as opposed to substantive barriers namely, regulatory transparency is being discussed in the Doha Round for possible inclusion in the GATS. Disciplines on regulatory transparency, which might be designed to apply to all service sectors or only to financial services, would strengthen current GATS disciplines on transparency for example, by requiring WTO members to establish a meaningful procedure for interested parties to comment on a proposed regulation prior to its adoption in final form. Such a requirement, together with other transparency disciplines, was included in China's Protocol of Accession to the WTO; similar disciplines have been included in the financial services chapters of bilateral free trade agreements to which the United States is a party.

The GATS deals with third-pillar liberalization only insofar as it affects countries' specific commitments to liberalize trade in services; in general, liberalization of capital movements is a matter of concern for the IMF. In particular, the GATS prohibits a WTO member from imposing restrictions on certain capital movements that would be inconsistent with its specific commitments to provide national treatment and market access. As a result, if a country makes a commitment to liberalize trade with respect to a particular financial service in the GATS, it is also making a commitment to liberalize most capital movements associated with the trade liberalization commitment. The country is not, however, making an across-the-board commitment to freedom of capital movements. The GATS provisions dealing with capital movements, like GATS-specific commitments to liberalize trade in services, are subject to a balance-of-payments safeguard. Both the capital movements and balance-of-payments safeguard provisions of the GATS refer to and are consistent with the IMF's responsibilities in these areas.

Trade Liberalization and Sound Financial Systems The financial services sector including international trade in financial services plays a vital role in the modern world economy. The adoption of international minimum standards and codes for sound financial systems and their implementation by individual countries make an important contribution to financial stability, both nationally and globally. These standards and codes also provide a strong foundation for liberalization of trade in financial services in the GATS and in regional and bilateral trade agreements. As the GATS explicitly recognizes, liberalization of trade in financial and other services is an ongoing process. For financial services, this process is being driven in large part by market forces and new technologies. It also reflects a growing recognition among policymakers that opening markets to foreign suppliers of financial services can both benefit host-country consumers and contribute to the resiliency of domestic financial systems.

■ **fixed costs and foreign direct investment**

Fixed costs are production costs, such as research and development (R&D) expenditures and rent of pro duction facilities, that do not vary by the quantity of output. The existence of fixed costs often suggests increasing returns to scale in the production process: the average fixed cost borne by each unit of output decreases as output expands.

Fixed costs are a key element in a firm's decision to invest abroad and set up foreign subsidiaries. How motivated firms are to invest in a foreign country can be altered by the existence of fixed costs. Firms may decide to establish plants in foreign countries to avoid trade costs or to take advantage of lower factor prices. The former strategy leads firms to duplicate production across countries and undertake a horizontal type of foreign direct in vestment (FDI), while the latter motivates firms to locate different stages of production in different countries and engage in a vertical type of FDI. When fixed costs arise at the level of a plant, they create a disincentive to have duplicated plants, and thus a disincentive for horizontal FDI.

Firm-Level versus Plant-Level Fixed Costs Fixed costs may exist at the firm and/or the plant level. This distinction is particularly important to multi-plant firms. Plant-level fixed costs include any fixed costs that accrue based on the number of plants, such as the cost of renting production facilities and the cost of equipment. These fixed costs provide physical capital for a specific plant and increase with the number of plants. By implication, they discourage firms from maintaining multiple plants and encour age geographic concentration of production.

Firm-level fixed costs, in contrast, include any fixed costs that accrue based on the number of firms, such as R&D and advertising costs. This type of fixed cost does not increase with the number of plants and thus raises firms' incentive to expand horizontally and spread the cost across multiple plants.

More specifically, the role of fixed costs in a firm's decision to invest abroad depends on whether the costs involve the supply of knowledge capital or physical capital. Knowledge capital such as technology know-how can be simultaneously supplied to multiple production locations and thus does not have to increase with the number of plants a firm operates. Physical capital such as production facility, however, is exclusively supplied to one location and thus requires additional investments when a firm establishes new plants. FDI is more likely to arise in industries where knowledge-based assets are important and scale economies in physical capital are less critical that is, where firm-level fixed costs are important relative to plant-level fixed costs. In industries that are both knowledge- and physical-capital intensive, firms invest abroad when the benefit of proximity to consumers or lower factor prices in the host country dominate the plant-level diseconomies of scale.

Theoretical Considerations Numerous theoretical studies, led by the seminal work of Markusen (1984) and Horstmann and Markusen (1987, 1992), have investigated the role of these two types of fixed costs in a firms' decision to undertake FDI. Markusen (1984) was one of the first authors who showed from an international trade perspective that multinational enterprises may arise endogenously in equilibrium. In his model, firms may separate headquarter activities such as R&D from production. The headquarter activities require an up-front fixed cost and in turn provide knowledge-based assets, such as patents, blueprints, and trademarks. These assets then serve as a joint input that can be supplied to all the production facilities of a firm without lowering the value of the input. This approach is extended by Horstmann and Markusen (1987, 1992), who show, for instance, that two-way investment flows between pairs of countries can arise in equilibrium. These studies find that firm-level scale economy implies that it is best to have one firm produce for all markets as doing so avoids the need for duplication in headquarter services. A multiplant multinational firm with plants in both countries or a firm with a plant in one country that exports to the other would have cost efficiency over a single-plant firm in each country selling locally. Furthermore, firms are motivated to set up local production plants in foreign countries rather than export from headquarters when the trade costs are high or the variable production cost in the foreign country is low.

The existing theoretical literature also shows that plant-level scale economies give rise to export-platform FDI. Ekholm, Forslid, and Markusen (2007), for example, find in both their model and empirical results that, in the presence of large plant-specific fixed costs, firms tend to adopt an export-platform strategy in which they concentrate their production in a low-cost country and export to other markets. A reduction in trade costs between the low-cost country and other countries would further augment firms' incentive to undertake geographically centralized FDI and achieve economies of scale.

Empirical Assessment The effect of fixed costs on multinational firms' decision to invest abroad has also been investigated empirically. In particular, Brainard (1997) and Yeaple (2003) examine the extent to which multinational production location decisions can be explained by a trade-off between maximizing proximity to consumers (or exploiting countries' difference in comparative advantage) and concentrating production to achieve economies of scale. Their analyses consider both firm-level and plant-level economies of scale. Firm-level scale economies are measured by the number of non-production workers in the average U.S.-based firm in each industry, while plant-level scale economies in each industry are measured by the number of production workers in the average U.S. plant. As predicted by the theory, these studies find that overseas production by multinational firms increases relative to exports when the scale economies at the plant level are lower than those at the firm level.

Ekholm, Forslid, and Markusen (2007) also confirm the role of scale economies in multinationals' investment decisions. They examine specifically export-platform FDI, a product of significant plant-level fixed costs and declining trade costs. They find that since the removal of trade barriers within the European Union and the North American Free Trade Area, multinational firms are increasingly

motivated to concentrate their production in a low-cost member of the integrated region and supply the rest of the region through exports.

In sum, theories of the multinational firm suggest that firm-level fixed costs give rise to increased FDI, while plant-level fixed costs encourage export-platform FDI but deter horizontal FDI. Broad empirical support exists for these predictions.

■ **footloose production**
Multinational firms are increasingly important in the world economy. Since multinationals are usually firms with plants in more than one country they are considered "footloose" since they can shift their ac tivities more easily from one country to another. At the end of 1997 the added value of all multinational enterprises (MNEs) in the world was approximately a quarter of the total added value in the world. In 2002, the stock of foreign investments worldwide was on average 22 percent of the gross domestic product of each country, and the corresponding percentages for West European countries were still higher, between 31.4 and 42.7 percent.

Increasingly, worldwide, more and more trade is in the hands of MNEs. The amount of intrafirm trade within MNEs accounts for almost one third of all worldwide trade. The number of MNEs also has increased substantially. Since the mid-1990s the amount of worldwide foreign direct investment has increased more rapidly than exports.

By the very act of becoming a multinational, the production of MNEs is potentially footloose in na ture. A distinction can be made between horizontal MNEs, which produce the same goods and services in multiple countries, and vertical multinationals, which fragment production geographically by stages. While theoretically this distinction is easy to make, it is much harder to analyze empirically how much horizontal versus vertical MNE activity is involved

(Carr et al. 2001). Nonetheless, both types of multinational activity enable MNEs to shift production across countries.

MNEs are flexible in terms of geographically organizing their production structure. Optimizing their activities over different countries often results in vertical fragmentation of production, with activities of R&D, design, marketing, and distribution usually located in high-income developed countries and the production of intermediate inputs and assembly located in low-wage/low-tax countries (Hanson et al. 2005). This fragmentation of production results from endowment differences and falling transportation, tariff, and information costs across countries. In response to changes in any of these causes, MNEs may respond by shifting more (or less) production abroad. For example, improvements in information technology or increases in domestic wages may cause an MNE to shift the production of intermediate components abroad.

MNEs also often establish plants undertaking similar activities in multiple countries. A typical MNE may have several similar plants, with one in each major market, such as one in Asia, one in North America, and one in Europe. This duplication of plants is generally undertaken to avoid transportation costs, tariffs, and other trade restrictions. Although these plants are intended primarily to serve the immediate market (the country where located and neighboring countries), they can also be used to supply other markets if needed. A shock in demand or supply in one region could be offset by adjustments in production throughout the global network of plants.

How Footloose Is Production? Although all MNEs have the potential to shift production across countries, how easy it is to do so can differ. The ownership share that MNEs have in affiliates with plants abroad varies. While some studies consider ownership of 20 percent or more, other studies consider a higher cutoff for MNE ownership in the affiliate. For an MNE to be really footloose, however, arguably ownership in the affiliate by the MNE should exceed 50 percent or more of the shares. Only when the MNE has majority ownership in its affiliate

can it easily decide to "pack up and go" as typical for footloose production. Also, the higher the number of majority-owned affiliates, the more footloose the MNE is since it can relocate production activities from one affiliate to another.

There are two main reasons that production is becoming increasingly footloose. First, the production of MNEs is more footloose than that of domestic firms, so as the degree of multinational activity increases, production overall becomes more able to be moved across national borders. Second, changes may be occurring that make production by MNEs more flexible. New markets are joining the world economy and opening up to the inflow of foreign capital. This growth in market opportunities implies that MNEs geographically expand the scope of their networks with more plants in more countries.

Implications of Footloose Production The footloose nature of multinational production has implications for local product, labor, and capital markets. Whatever the type of MNE involved, its presence in the host country tends to increase the volatility of the local economy. MNEs' production tends to respond more quickly to upswings or downswings in economic conditions than does the production of domestic firms. Due to their footloose nature, MNEs are usually the first firms to come when conditions are favorable and the first to exit the market when fortune reverses. The increase in the number of MNEs worldwide therefore makes local economies more subject to shocks and volatility. Countries with flexible labor markets, that is, with low hiring and firing costs, are better equipped to cope with this new challenge since they can more quickly and at lower costs adjust to shocks.

In terms of local labor markets, MNEs usually have a stronger bargaining position with labor unions than domestic firms do, since MNEs always have the outside option of relocation. This does not imply that MNEs necessarily pay lower wages, however. Empirical evidence seems to suggest that MNEs pay higher wages and provide better working conditions than local firms in developing countries (Brown et al. 2003). In developed countries, wages in MNEs also tend to be higher. One reason is that MNEs tend to be

larger and more productive; they also produce higher-quality goods than their local rivals, which gives them greater market power in product markets and allows them to charge higher prices. Higher product market rents are likely to result in higher wages. MNEs on average employ better-skilled workers to guarantee higher quality in production and a higher level of productivity. They often invest substantially in internal training. All these elements offer explanations for the wage gap between MNEs and local firms in the same country or region.

Theory suggests that MNEs in high-income countries export unskilled jobs to their affiliates in low-wage countries. There is some empirical confirmation; however, Braconier and Ekholm (2000) and Konings and Murphy (2006) find evidence of substitutability of labor among high-wage countries, but not between high-wage and low-wage countries. Employment effects may depend on the type of activity that is outsourced. Some suggest that in the long run the outsourcing of unskilled activities could create more job opportunities in developed countries. This subject is hotly debated, but more research is needed to understand the dynamic effects of MNEs on the labor markets of parent and host countries.

MNEs rely less on local capital markets. Typically MNEs and their affiliates benefit from internal capital markets. Recent evidence suggests that MNEs are less subject to credit constraints than other firms (Harrison et al. 2004). Hence MNEs suffer less from incomplete capital markets in developing countries than local firms since they can always turn to intrafirm financing. They depend less on local banking conditions and on the competition in the banking sector.

The footloose nature of multinational production implies that MNEs usually also have a strong bargaining position vis-à-vis governments that host their affiliates. Prior to choosing where to locate a plant, MNEs are often able to negotiate financial incentives with host governments. In recent years national governments have increasingly been using the corporate tax instrument as a tool to attract MNEs into their region. Small countries and countries that are

otherwise less attractive may have to offer more favorable tax treatment to MNEs than to local firms. Vandenbussche and Tan (2005) found that in a small country such as Belgium, foreign-owned firms on average have lower effective tax rates than purely domestic firms.

In sum, the increasing prevalence of MNEs has caused production to become increasingly footloose in nature, with important implications for the world economy.

■ foreign direct investment (FDI)

Foreign direct investments are defined as investments in which a firm acquires a majority or at very least a controlling interest in a foreign firm. Foreign investments not involving a majority or controlling stake are typically referred to as portfolio investments. Firms making foreign direct investments (FDI) are referred to as multinational enterprises (MNE) and the two terms are used somewhat interchangeably. A direct investment may involve creating a new foreign enterprise, often referred to as a greenfield investment, or acquiring an existing foreign firm (sometimes referred to as a brownfield investment, though that term is much less common; *acquisition* is the typical label).

Historically, there are three strands of literature that see the multinational and FDI in different ways: the international business tradition, the trade-theory tradition, and the macroeconomic tradition. This entry will focus heavily on the trade-theory tradition, where the biggest developments in the last twenty years have occurred.

The international business approach is very individual-firm oriented. It details the determinants of the decision of firms to go abroad and the mode they chose for doing so. In addition to FDI, the firm considers exporting, joint ventures, licensing or contracting with arm's-length foreign firms, and so forth. The international business literature has been far more interested than the other streams of literature in the choice-of-mode decision.

It is probably accurate to say that until the late 1980s the microeconomic trade-theory approach to FDI and the macroeconomic tradition were pretty much the same. These two traditions did not really distinguish between direct and portfolio investments: there was no real attempt to model the "D" in FDI. Both schools modeled FDI as the movement of homogeneous capital from locations where its return was relatively low to where its return is higher. The simple approach to capital flows had a natural intersection with Heckscher-Ohlin trade theory, in which factors are expensive where they are scarce and cheap where they are abundant. The consequence is the obvious hypothesis that capital should flow from capital-rich to capital-scarce countries.

There was no sense of individual firms in this literature, and certainly no modeling of mode choice. Even trade theory, with its better-developed sense of general-equilibrium than macroeconomics, was dominated by perfect-competition, constant-returns-to-scale models in which individual firms had no real meaning. But trade theory did have advantages over the international business approach in that it had a basic general-equilibrium structure that did at least give some predictions as to the pattern of capital flows we should observe.

Macroeconomics has more or less continued in the tradition of restricting analysis to aggregate capital flows generated by international rental-rate or cost-of-capital differentials. It is not easy to fit a rich structure for individual firms into macro models, and hence that stream of literature continues to make no real distinction between FDI and portfolio investments.

International trade theory, on the other hand, began to move sharply away from the macro approach in the 1980s, and to draw a clear distinction between FDI and portfolio investments. It began to move more toward the international business literature in that it included meaningful treatments of individual firms, yet the trade approach retained the general-equilibrium roots of its tradition. The split with macro seems to have been driven by some important statistical evidence that casts considerable doubt on the suitability of cross-country differences

in the cost of capital as a driving and motivating force for FDI.

Troubling Statistics The first statistical difficulty confronting the traditional theory is that the high-income developed countries are not only the major source of FDI but also the major recipients. FDI does not primarily flow from capital-rich to capital-poor countries; it flows primarily from capital-rich to other capital-rich countries. Firms from high-income countries are mutually invading one another's markets. In addition, the FDI that does flow to developing countries is highly concentrated in the most advanced of those countries.

Many statistics are found in Caves (2007), Markusen (2002), UNCTAD, OECD, BEA, and other publications. One simple way to measure this source/recipient pattern is to simply compute the shares of total world FDI inward and outward stocks that are found in different countries or groups of countries. UNCTAD statistics for 2003 indicate that the developed countries accounted for 89 percent of the outward stock in this year, but also accounted for 69 percent of the inward stock. Of course, the developed countries also account for the overwhelming share of world income, so we can instead divide the inward share of a group by its share of total world income. This yields the results shown in table 1. The high-income countries are close to a share of inward FDI equal to their share of income. Developing countries are higher on this score, as the simple capital-scarcity macro approach would suggest, but it turns out that this is highly concentrated in the more advanced of the developing countries. The least-developed countries (a UN-defined group of 44 countries) have a share of inward FDI only slightly greater than their share of world income.

A second statistic that led to a rethinking of trade theory is that there is very often a disconnect between the act and amount of FDI and the sources of financing for new investments or acquisitions. There is much less systematic evidence on this point since published data rarely comment on the source of financing for individual foreign projects. Yet the international business literature documents a great variety of financing choices: retained earnings of the parent firm, equity or bonds issued in the parent-country market, equity or debt issued in the host-country market, or third-country financing. Apparently, many FDI projects in China are financed with Chinese capital, although systematic data are not known to this author. If we think of Chinese debt financing an American direct investment, we have in fact a portfolio and a direct investment flowing in opposite directions.

A third relevant statistic is that FDI is attracted to large markets. Inward FDI divided by GDP should not display any particular pattern in a simple cost-of-capital macro approach. The data shown in table 2 are from 1993 and thus somewhat dated (Markusen 2002), but there is no reason to think that the basic message has changed. They show that not only is FDI attracted to rich countries, it is clearly attracted to large markets.

A fourth statistic that called for a new approach to FDI is that a very large proportion of the actual output of FDI projects is for local sale in the host country. Firms were often replicating their home

activities, goods or services, in foreign markets. These are now generally known as "horizontal" investments, although the term "market-seeking" is also used. The latter term emphasizes that the FDI is not motivated by cost-side considerations as it would be in a cost-of-capital-differential approach, but rather by the demand-side motive of serving the local market. Table 3 presents a few statistics from BEA data. Perhaps 60 percent local sales does not seem terribly high for the sample as a whole. But more interesting is the fact that only 12 percent of sales are back to the United States; 28 percent of the sales are to third countries, often referred to as "export-platform" production and sales.

Closer inspection of the data suggests that third-country sales are most important for affiliates located in large regionally integrated trade areas: the exports are destined for the other regional members. In an important sense, this represents horizontal production in which one location within the region is chosen. United States affiliates in Ireland, for example, export 71 percent of their total production to third countries, and apparently almost all of this is horizontal production destined for other European Union markets. For U.S. affiliates in Canada and Mexico, exports are similarly directed to other members of the North American Free Trade Agreement, and so the overwhelming portion of their exports are to the United States. Thus is it clear that the overwhelming portion of affiliate output is destined for local or regional sale. Note that Canada and Mexico

exhibit remarkably similar statistics in spite of the large difference in per capita income, and that local sales have shares close to the world average for U.S. affiliates. While many investments in Mexico are surely chosen to access cheap labor for production for the United States market, the general notion that multinationals are firms seeking cheap production abroad for sale back home is at best a minor phenomenon.

The consequence of these observations was that trade theory needed to move away from the old macro approach and adopt a firm-based approach, yet one still rooted in the general-equilibrium tradition. Trade theory began to think of and indeed measure FDI not in terms of the value of investments (inputs), but in terms of the outputs of foreign affiliates, the destinations for those outputs, and the trade patterns with the parent firm. But the old bias is still very evident in data sources: it is much easier to get data on FDI stocks and flows than on affiliate outputs, sales destinations, and intrafirm trade.

The International Business Approach As suggested earlier, researchers in the field of international business have produced a rich set of theory and empirical analysis, though little is formalized and few testable hypotheses emerge. Nevertheless, the newer formal models owe a great debt to these scholars. An early approach was by Dunning (1973) with his ownership-location-internalization (OLI) framework. Dunning suggested that three conditions must be met before a firm will want to establish an owned production facility. Subsequent researchers have assembled a great body of evidence, though very little of it formal econometric work, about the form that these advantages take.

The first condition is ownership advantage. Given a disadvantage relative to local firms in a host country, a foreign firm must own a propriety asset such as a superior product, production process, patent, trademark, or asset that gives it a compensating advantage over local firms in the host market. This focuses the theory on the assets of the individual firm and away from some general return to homogeneous capital. Caves (2007) has written much on this idea, using the term *intangible assets* to label these proprietary assets.

Empirical analysis established that multinationals tended to be firms that are intensive in knowledge-based assets (Markusen 2002) rather than physical capital. Multinationals are associated with patents, research and development (R&D) intensity, skilled white-collar and technical workers and engineers, new and complex products, and product differentiation variables such as advertising, trademarks, and brand names. Multinationals have a high value of intangible assets, which can be measured as a sort of Tobin's Q: the ratio of the market value of the firm to the book value of capital. There are good reasons why multinationality should be associated with knowledge-based assets, but a discussion of this is temporarily postponed.

But ownership advantage is not sufficient. For example, if the purpose of the investment is to serve local markets, then the firm can exploit its asset through exporting. The second condition is therefore location advantage. This is some factor that leads the firm to prefer to actually produce abroad rather than export. Location advantages tend to depend in large part on whether the purpose of the investment is to serve local markets or to export from the host country. For the first type, termed horizontal or market-seeking investments as noted earlier, location advantages are (1) a large host-country market to compensate for set-up costs and plant-level scale economies, and (2) trade costs in the form of tariffs or transportation costs (time as well as money) that make serving the host country by exports expensive. For investments that are more directed at using the host country as an export platform, termed vertical or resource-seeking investments, location advantages are more in the form of low input costs and low trade costs to get intermediate and final goods into and out of the country.

The third condition is internalization advantage. The firm must have a reason to own the foreign production facility rather than simply to license its asset or contract with a local firm to produce on its behalf. Internalization is often contrasted with its mirror image, outsourcing. These are the two alternatives to one decision: the firm must choose between internalizing and outsourcing.

Internalization advantages are the most abstract of the three. For some authors, the principal issue derives from properties of knowledge capital, which are discussed a bit more below. The firm needs to maintain tight control over knowledge-based capital or the value can be easily dissipated through copying and other forms of agent opportunism. Many threats of asset dissipation arise from the lack of strong legal institutions in host countries, such as intellectual property protection and contract enforcement. Other determinants of the internalization/outsourcing decision are familiar from more general discussion of the boundaries of the firm and are not focused on anything particularly international in scope (i.e., strictly domestic firms face decisions on what activities to outsource and which to internalize).

In what follows, we will focus on ownership and location issues in discussing both theory and empirical evidence. The goal is to explain the statistics presented earlier. Internalization is attacked with a very different set of tools and, to date, empirical evidence is scarce.

Early Trade-Theory Models Two very different papers appeared in 1984. Helpman (1984) is a model in which a firm can decompose a production process into a headquarters activity and a production activity. Headquarters and production have different factor intensities and firms can choose to geographically separate these activities. A multinational is a firm that has its headquarters in one country and a plant in the other; in other words, this is a model of vertical multinationals. There are no trade costs in the model and multinationals arise only when countries are sufficiently different in relative factor endowments (i.e., countries must be outside the factor-price-equalization set in the Edgeworth box). In particular, in this model multinationals cannot arise between identical countries, and there are no multiplant firms. Helpman's model is very much in the older tradition of factor-price difference driving FDI discussed earlier.

Markusen (1984) is a model in which there is also something like a headquarters activity and a production activity that can be geographically separated, but these activities do not have different factor intensities.

The whole focus of this model is different from Helpman's. The key idea in the Markusen paper is that headquarters activity, such as R&D, has a "jointness" or "public-goods" property, in that it can yield the full value of its productivity in two locations: adding a second production facility does not reduce the value of the R&D asset in the first location. A blueprint, formula, or procedure can be jointly and fully used in multiple locations. The focus of Markusen's paper is on multinational, horizontal or market-seeking firms that produce in two locations to exploit the value of their knowledge capital. Multinationals can arise between two identical countries, marking a clear break with the old capital-flows literature.

Subsequent Theoretical Developments Important refinements of the horizontal approach are in Horstmann and Markusen (1992) and Brainard (1993). These papers solve for equilibrium market structure between two countries and show that two-plant horizontal multinationals arise when firm-specific fixed costs (knowledge capital) are important relative to plant-level fixed costs, when trade costs are high, and when the two markets are large and similar in size. The result that FDI is expected between large, similar countries provided a theoretical underpinning for the empirical finding that most FDI occurs between large, high-income countries as discussed earlier.

The general-equilibrium structure of the problem was later fleshed out in several papers by Markusen and Venables (1998, 2000). Markusen and Venables use the world Edgeworth box. They concentrate on horizontal two-plant firms and do not consider vertical structures in which a single plant and headquarters are located in different countries. There can be single-plant national firms and two-plant multinationals located in each country, or four potential firm types in all.

They solve the model over a grid in the Edgeworth box, where countries different in size and/or in relative endowments occur at each point in the box (they are identical in the center of the box). Solutions indicate which types of firms are active in equilibrium (termed the "regime") and the pattern of foreign affiliate sales and exports. They show that affiliate production is most important when the two countries are similar in size and in relative endowments. The intuition is found by considering what happens when the two countries are quite dissimilar in either of these dimensions. If one country is quite large relative to the other, the dominant firm type will be single-plant firms located in that country serving the small country with exports: it does not pay to incur a plant-specific fixed cost in a small market. If the two countries are quite dissimilar in relative factor endowments, the dominant firm type will be single-plant national firms located in the country which is abundant in the factor used intensively in the multinational's industry.

An integrated treatment of horizontal and vertical multinationals was developed in Markusen's knowledge-capital model (Markusen 2002). Specifically, the model rests on three assumptions relating to knowledge-based assets. First, the services of these assets are easily used in foreign production facilities (transportability or fragmentation). Second, the production of knowledge-based assets is skilled-labor intensive (skilled-labor intensity). Third, knowledge-based assets can yield their full productivity in multiple locations at the same time (jointness). The first two properties support vertical firms while the third supports horizontal multiplant firms.

The contribution of this model is that it yields clear, testable predictions about how foreign affiliate production and trade should be related to the size, size differences, skilled and unskilled labor endowments, and trade and investment cost barriers for two countries. An important extension to include physical capital as a third factor and a third country is found in Bergstrand and Egger (2007).

Empirical Evidence Once again, a good deal of empirical evidence is found in Caves (2007) and Markusen (2002). Brainard (1997) gave convincing evidence for the first time that FDI is not closely related to factor endowments (further discrediting the simple cost-of-capital approach), but much more closely related to country similarity. The ratio of foreign affiliate production to home exports to the host market is increasing in trade costs, increasing in corporate scale economies, and decreasing in plant

scale economies. Only that proportion of affiliate production that is destined for export is related to factor endowments, but that makes sense given the vertical motive for foreign production.

Carr, Markusen, and Maskus (2001) found strong support for the knowledge-capital model. In subsequent work, Markusen and Maskus (see Markusen 2002) found strong support for the horizontal model and virtually no support for a pure vertical model, and could not reject the pure horizontal model in favor of the more complex knowledge-capital model.

Combined with the Brainard paper, these results give strong confirmation to simple summary statistics that the vertical model, the most natural incorporation of the cost-of-capital approach, is a very poor fit indeed. Somewhat later and more sophisticated work by Braconier, Norbäck, and Urban (2006) has discovered more evidence in favor of vertical production, and has found it where the knowledge-capital model suggests it should be found. The addition of physical capital and a third country in Bergstrand and Egger (2007) clears up a number of issues. Finally, readers can find an empirical analysis of the horizontal model extended to heterogeneous firms in Helpman, Melitz, and Yeaple (2004).

The Way Forward There seems no clear direction to the research agenda at this time. Both theoretical and empirical work on multicountry models is needed. Most affiliate activity is directed at local markets as we have noted, and for this part of FDI studying bilateral relationships is fine. But the phenomenon of export-platform production is quantitatively important, and there are only a few papers on this topic. Competition among host countries for inward investment is also interesting and important for development economics.

Research integrating models of internalization/outsourcing into the ownership/location models would be valuable. There is some clear link in models that focus on knowledge capital: the same property that makes knowledge easy to transfer makes it easily dissipated through agent opportunism. There is much less of a link with some newer literature on the property-rights, hold-up approach.

While much has been done on country characteristics (size, endowments, trade and investment costs) as determinants of FDI, somewhat less has been done on the converse question: the effects of inward FDI on host countries. There certainly has been good work on the effect of inward FDI on local labor markets and local firms, but this literature remains disjoint from much of what is covered here. The relationship between host-country governments and multinationals deserves more work. Weak results on taxes as determinants of FDI may reflect the fact that, while multinationals don't like taxes, they value strong physical, educational, and institutional infrastructure that taxes bring.

A few papers have interfaced the so-called New Economic Geography with the theory of the multinational. It seems clear that results from the geography literature on the instability of diversified (or dispersed) equilibria in the presence of moderate trade costs break down when multinational firms are added: horizontal multinationals arise precisely when countries are similar and trade costs are moderate to high, and equilibria in the presence of horizontal multinationals are stable. But much more remains to be done. Similarly, the strategic-trade policy literature focuses almost exclusively on single-plant nationally-owned firms, yet it is precisely in those industries in which scale economies and imperfect competition dominate that we find multinationals.

Individuals working in theory would do well to revisit the international business literature as indicated above. That literature, while frustratingly informal and lacking in testable hypotheses, contains a great richness of insights and data that should be fertile ground for new theoretical ideas.

■ foreign direct investment and exit of local firms

The exit of local firms refers to the discontinuing of operations by firms owned by local shareholders (i.e., not affiliates of foreign-owned multinationals, which represent foreign direct investment, or FDI). This

cessation of activities might involve firms closing down completely and exiting the industry, or firms discontinuing their current operations but continuing activities in other guises (e.g., under a new name in the same or a different industry). The former situation is the one more frequently studied and is the focus of this entry. Empirical data show that firm exit (in the sense of complete shutdowns) is a fairly frequent phenomenon. In a comprehensive overview paper Caves (1998) provides evidence that in the United States around 7 percent of all firms shut down annually, accounting for about 3 percent of market share in the economy.

Economists have long debated whether there is a link between the large and growing activities of foreign multinationals and the exit of local firms in host countries (e.g., Lall 1978; McAleese and Counahan 1979). The question became even more topical at the end of the 20th century with the increasing concern about globalization and the fears this has sparked for domestic economic activity, in particular the jobs associated with it (Barba Navaretti and Venables 2004). There are three interrelated yet distinct parts to this question: first, whether there are differences in exit patterns between affiliates of foreign-owned multinationals and local firms; second, whether a foreign acquisition affects exit probabilities of the local takeover target; and third, whether the presence of foreign-owned multinationals affects, either positively or negatively, the exit and survival prospects of unrelated local firms.

Comparison of Exit in Foreign and Local Firms
When comparing the incidence of shutdown across foreign affiliates and local firms one may subscribe to one of three views. The first contends that affiliates of multinationals have shallower roots in the domestic economy than local firms and therefore are more likely to shut down production and move to another location, especially when the economy is hit by a negative shock (such as, for example, an economic downturn). A second perspective is that multinationals incur substantial costs for investing abroad, not all of which can be retrieved if they leave; hence, affiliates of multinationals are more likely than domestic firms to stay in the economy in order not to

lose the sunk investment costs. A third view contends that both affiliates of multinationals and local firms are purely profit-maximizing operations and, therefore, there is no strong case that either should behave differently from the other.

Analyzing these possible differences in the incidence or probability of exiting is hampered by a number of difficulties. Perhaps the most important of these is the issue of choosing the right comparison group. Affiliates of multinationals are, on average, quite different from the typical local firm — they are larger, more productive, more skill-intensive, and more technology-intensive. Firms that have these attributes are generally less likely to exit than others, irrespective of the nationality of their ownership. Then the question becomes whether one should compare the incidence of shutdown among foreign affiliates with that of an average local firm, or with that of a local firm that is as similar as possible to the average foreign affiliate.

A study by Görg and Strobl (2003a), using data for the Republic of Ireland, illustrates this issue. In a comparison of the total incidence of exit for all foreign affiliates and all local firms they find that local firms are, on average, significantly more likely to cease operations. This finding would, hence, support the optimistic view described earlier. It does not, however, take account of the fact that affiliates of foreign multinationals based in Ireland are, for example, larger and in more technology-intensive industries than the "typical" local firm and the difference in exit rates could be due to only these differences, rather than to the nationality of ownership per se. To deal with this issue, Görg and Strobl use an econometric technique that allows them to calculate the effect of nationality on the exit rate, abstracting from the effect of firm size and characteristics of the industry. When doing that, they find that affiliates of foreign multinationals are in fact more likely to exit than local firms. A similar analysis is undertaken by Bernard and Sjöholm (2003) for affiliates of foreign-owned multinationals in Indonesia, with results that are strikingly similar in qualitative terms, if not magnitude. Comparing foreign multinationals to a typical local firm shows that the former are less

likely to exit. This difference can be explained by firm characteristics other than nationality, however. Once these are controlled for using econometric techniques, affiliates of foreign multinationals are found to be more likely to exit than a comparable local firm.

Foreign Acquisition and Exit These differences between affiliates of foreign multinationals and local firms raise the question of what would happen if a domestic firm were taken over by a foreign multinational. Would one expect these takeover targets to become more or less likely to face shutdown? Theoretically, the result could be either way. First, since multinationals are generally found to be more likely to exit, a change in ownership may also lead to a higher incidence of plant shutdown for the domestic takeover targets. Second, foreign acquisition may be a device to acquire market access, distribution channels, skills, and so on for a new foreign market entrant. Once these resources/capabilities have been ingested, the acquiring firm may divest itself of the acquired establishment and source its requirements from its plants elsewhere. Foreign acquisition may also lead to a lower threat of exit, however, if the foreign acquirer transfers technology, knowledge, or skills to the acquired plant and hence contributes to an improvement in its performance.

Empirical research into this issue poses some challenges, most important that of constructing a valid counterfactual. While one observes what happens to a local takeover target once it has been acquired by a foreign owner, the important question is what would have happened otherwise in order to identify the effect the acquisition has had. Of course, the latter scenario is unobservable as it did not materialize. Advances in statistical and econometric techniques allow researchers to deal with this problem in various ways, and most recent empirical work uses econometric techniques allowing one to essentially compare local takeover targets with a carefully chosen group of similar local firms that have not been taken over. Based on such econometric techniques, findings for the United States and the United Kingdom using data for the 1980s and 1990s suggest that a takeover by a multinational

increases the chances that the takeover target will be closed (see Bernard and Jensen 2007; Girma and Görg 2004).

Impact of FDI on Exit of Local Firms The presence of foreign firms in an economy can also have an impact on the exit performance of unrelated local firms. The early pessimistic view is that foreign multinationals increase competitive pressure in the economy and therefore make it more difficult for local firms to survive, hence increasing the threat of shutdown for these firms. For a given market size, expansion of output by foreign affiliates attracts demand away from local firms. This shift will cause these domestic firms to cut their production, which, if they face fixed costs, will raise their average cost, reduce profitability, and therefore ultimately make them more vulnerable to shutdown. In fact, regardless of cost structure, increased production by foreign affiliates may lead to a reduction in output price (at least in the short run), which will reduce profitability for local firms and, thus, increase their exit threat.

Although this argument is still powerful, a more recent alternative view takes a more benevolent stance on foreign multinationals and asserts that foreign affiliates may transfer some of their technology to unrelated local firms (either voluntarily or involuntarily). This technology transfer allows local firms to improve their production processes and produce at lower average cost. Hence technology transfer can improve domestic firms' performance by lowering cost and increasing profitability and, thus, also lower the chance of shutdown. This positive effect provides a counterbalance to the possible negative influence through increased competition, and the net impact of foreign affiliates on the exit of local firms may hence be positive, negative, or neutral (the last if the positive and negative effects offset each other).

Empirical evaluation of this issue also is hampered by the challenge of constructing a valid counterfactual. One is able to observe what happens to a local firm in a given industry with a certain level of foreign affiliates operating in it; however, what is unobservable is what would have happened in the absence of

these. Most recent empirical work uses econometric techniques to compare local firms in industries with different levels of presence of foreign affiliates, controlling for possible differences in other firm and industry characteristics in order to deal with this problem.

A study of Ireland by Görg and Strobl (2003b) finds that the presence of foreign affiliates has an exit-reducing effect only on local plants in high-tech industries, while it has no impact on local firms in low-tech industries. This suggests that in the former industries, domestic firms benefit from foreign firms through technology transfers that allow them to improve their performance and reduce the threat of exit. By contrast, if anything the results for firms in low-tech industries indicate that the negative and positive effects offset each other. Whether these findings hold for other countries is an issue for further research.

Policy Implications Foreign direct investment is an important feature of the globalized world economy. The impact of FDI on economic development, in particular the interplay between local firms and foreign affiliates of the countries involved, is an important issue for policymakers. Although studies have identified general trends and possible effects, it remains to be seen what lessons can be learned from these for particular economies at different levels of development.

■ **foreign direct investment and export performance**

The foreign direct investment export link focuses on the role of foreign direct investment (FDI) in export performance. FDI represents international capital flows through which a firm in one country (the home) creates a subsidiary or acquires control over a business enterprise in another country (the host). The firm with FDI is thus a multinational enterprise (MNE), which must have firm-specific advantages (technology or brand name) and choose a host country with location advantages (cheap labor or growing markets). Export performance has many facets, including export volume, technological composition, growth rate, and global competitiveness. FDI plays a significant role in world exports. Broad estimates indicate that MNEs account for two-thirds to three-quarters of world exports, and foreign affiliates of MNEs account for more than one fifth of world exports and one third of developing country exports (UNCTAD 2002). The paucity of data, however, makes quantitative assessments of the effect of FDI on export performance difficult.

Theoretical studies generally identify two types of FDI: vertical and horizontal (Markusen 1995). A manufacturing MNE usually engages in three activities: firm activities producing headquarters services; upstream-plant activities producing components; and downstream-plant activities of assembling. Headquarters with firm activities are located in home countries, while cross-country relocation of downstream- and/or upstream-plant activities results in vertical and horizontal FDI.

Vertical (efficiency-seeking) FDI is associated with relocation of labor-intensive downstream-plant activities to host countries with cheap labor, while in horizontal (market-seeking) FDI, another set of production facilities (including both upstream- and downstream-plant activities) is built in host countries to serve local markets. Motivated by cheap labor and other resources, the vertical FDI firm may export capital-intensive components and headquarters services to its host-country affiliates for assembling, and ship finished products back to the home country or third-country markets (Helpman and Krugman 1985). Horizontal FDI tends to overcome trade barriers such as tariffs and transportation costs in order to maintain or expand market shares in host countries (Markusen 1984).

The sharpness of the distinction between the two types of FDI may be best explained by MNEs in semiconductors and automobiles. In the 1970s, U.S. chip firms made substantial investments in assembly and testing facilities in Southeast Asia, motivated by cheap labor there. Semiconductors were shipped from the U.S. design and manufacturing complexes to the assembly and testing facilities in Southeast Asia, and then shipped back to sales destinations in the United States and elsewhere. In contrast, Japanese automakers in the 1980s established production lines in the United States in order to avoid local protection threats by replacing existing exports with local production.

How Does FDI Affect Home-Country Exports?
FDI affects home-country export performance through direct effects on trade as well as indirect effects through various channels. The direct effects depend to a large extent on the type of FDI. Vertical FDI could enhance the home country's exports of intermediate products (parts and components) required for assembling. This intrafirm trade is called a complementary effect of exports. Horizontal FDI may lead to an increase in exports of capital goods and intermediate products in the short run, but its long-term impact turns out to be export reduction (so-called substitution effects).

Empirical evidence from developed countries (e.g., the United States, Japan, and Sweden) indicates the FDI-export link to be one of complements at country and industry levels, but of "substitution" at the product level (Blonigen 2001). When activities of foreign affiliates can be classified as vertical and horizontal, evidence is consistent with the theoretical prediction that vertical FDI complements exports and horizontal FDI substitutes for exports. FDI from high-income developing economies (e.g., Hong Kong, Korea, Singapore, and Taiwan) to other developing countries (e.g., China) has been found to be a contributory factor

for expanding home-country exports (UNCTAD 2002).

In the long run, FDI may indirectly affect home-country exports by improving the competitiveness of parent companies; upgrading industrial structure; and creating spillovers to the rest of the home economy.

How Does FDI Affect Host-Country Exports? Effects of FDI on the host country's exports may differ, depending on the MNE's motives. Horizontal FDI is oriented primarily to the host-country market, so it does not directly contribute to host-country exports. Vertical FDI directly boosts host-country exports, since output resulting from FDI is typically intended for export. Most vertical FDI is hosted in developing countries in labor-intensive industries such as textiles, garments, and home electronics. China, for example, attracted a significant amount of vertical FDI, which contributed 57 percent of its total exports in 2004 (Zhang 2006). While the overall impact is export-promoting, the real increase in host-country exports depends on the local content of value-added with exports. If local firms supply intermediate products to MNE affiliates, host-country exports would be much greater than in cases where the inputs are imported from outside the host economy.

A popular form of vertical FDI is located in export processing zones (EPZs), in which materials are imported duty free and transformed for exports, with strictly controlled trade with the rest of the host country. EPZs allow exploiting the location-specific assets of a host country while avoiding the restrictions imposed by its trade regime, providing good infrastructure, and offering fiscal incentives. Many countries (such as Costa Rica, China, Haiti, Mauritius, Bangladesh, Singapore, Malaysia, and Sri Lanka) have enjoyed spectacular growth in manufactured exports from EPZs. The most successful exports have been garments and semiconductors.

Theories and evidence suggest that FDI may have several potential mechanisms to influence host export performance. Its contribution may derive from additional capital, technology, and managerial know-how; training for the local workforce; and access to global and especially home-country markets. These resources and market access may complement a host country's own resources and capabilities, and may provide some of the missing elements for greater export competitiveness. The host country may build on these to enter new export activities and improve its performance in existing ones (UNCTAD 2002). Many studies emphasize the role of FDI in building host export competitiveness in manufacturing goods. Three positive effects of FDI may be identified: helping transfer of technology and new products for exports; expanding market access for exports; and building dynamic comparative advantages. On the other hand, some negative effects of FDI on host exports have been observed. FDI may (1) lower or replace domestic savings and investment; (2) transfer technologies that are low level or too complicated for the host country to absorb due to lack of human capital; (3) target primarily the host country's domestic market and thus not increase exports; (4) inhibit the expansion of indigenous firms that might become exporters; and (5) neglect the host country's dynamic comparative advantages by focusing solely on local cheap labor and raw materials (Zhang 2006).

While potential benefits of FDI to host exports exist, they do not automatically accrue. To what extent a host country can capture them depends largely on its own strategies and efforts. Opening up to FDI is only the first step, and host countries need to realize existing comparative advantages based on initial capabilities. For countries with weak industries and exports, FDI may well lead only to a short-lived boost in export performance. To build a more sustainable and dynamic export base, host countries have to use proactive policies, including selective liberalization to reconcile efforts to attract vertical FDI with the need to protect particular industries; attracting FDI by targeting investment conducive to export competitiveness and upgrading; and strengthening domestic enterprises, as well as the skills, capabilities, and institutions necessary for successful export-oriented strategy.

■ foreign direct investment and innovation, imitation

Following successful innovation of a new process or product technology, production can be shifted abroad through a variety of channels: firms can li cense their technologies to foreign firms, undertake foreign direct investment (FDI), or may find that their technologies are transferred abroad through imitation by foreign firms. With FDI, the incumbent firm establishes a plant in another country, whereas with imitation, production in the other country is done by a rival firm (or firms).

FDI, innovation, and imitation each typically requires the investment of resources. Most innova tion results from intentional efforts to develop new varieties of products, higher-quality levels of existing products, or lower-cost methods of production (process improvements). These efforts require firms to bear significant costs with an uncertain outcome. While there may be some products for which imi tation is straightforward, in most cases imitation, like innovation, is also a costly and uncertain activity. Mansfield, Schwartz, and Wagner (1981) find that imitation costs average two-thirds of innovation costs for firms in the chemical, drug, electronics, and machinery industries. Undertaking FDI also incurs costs (prior to production), such as fixed costs of establishing new plants, adapting technologies to new economic environments, finding local suppliers, and the like.

Each of these activities FDI, innovation, and imitation must yield a reward in the form of an expected stream of profits sufficient to offset the initial costs or else firms would have little incentive to undertake them. Properly discounted, the total ex pected profits from an innovation must at least cover the costs of generating the innovation for firms to be willing to invest resources in the innovation. As the costs of a successful imitation tend to be lower than for the original innovation, the profits of a successful imitator can be lower (or shorter in duration) than for an innovator, but again imitators need to rewarded, through the expected profits from a successful imi tation, for their imitation expenses. For FDI, the expected profits must rise by enough to compensate for the up-front costs of shifting technology abroad.

Additionally, these activities may be constrained by the availability of factors such as skilled labor. In countries where firms innovate, there must be enough resources for both R&D and production

uses; in countries where firms imitate, there must be enough for imitation efforts, production by successful imitators, and production by multinational firms. Thus FDI, innovation, and imitation are all affected by incentives and resource availability the two key factors that determine practically all economic activity.

How FDI Affects Innovation The costs of innovation need to be offset by the expected stream of profits from selling the product. As FDI is undertaken to enhance profits, it would seem that the opportunity to undertake FDI should accelerate innovation by enhancing the reward for innovation.

Suppose FDI involves shifting production to a lower-cost location. If the opportunity to shift production abroad arrives at a higher probability, then the higher profits under FDI should begin sooner, all else being equal. Glass and Saggi (1999), however, show that the effect of faster arrival of FDI opportunities on innovation can be essentially zero due to increased exposure to imitation. The faster arrival of higher profits under FDI is offset by a shorter duration of profits before imitation, when FDI opportunities are beyond the control of firms.

Why then are FDI opportunities commonly believed to stimulate innovation? Perhaps FDI occurs not in response to increases in opportunities to shift production abroad, but rather in response to other influences. Instead of a faster arrival of fixed FDI opportunities, suppose that FDI increases in response to variations in the underlying economic environment. For example, suppose the labor supply abroad increases to provide more labor for production there. In response, FDI increases to shift production from home to abroad, and innovation also increases, as shown in Glass and Saggi (2002). Other changes, such as a reduction in the difficulty of adapting technologies for production abroad, can also increase FDI and innovation. Crisuolo, Haskel, and Slaughter (2005) provide evidence that firms that are globally engaged do innovate more.

How FDI Affects Imitation By shifting production abroad, FDI typically generates technology spillovers through demonstration effects. More can be learned about a technology when it is produced

locally than when only the final product can be seen. Although inspecting the final product can yield useful insights, full knowledge of the production process is hard to determine from the end result. When production occurs locally, however, workers at the multinational firm observe the production process firsthand. Workers who have been exposed to the technology, and perhaps specially trained, may leave the multinational to work for local firms or even start their own firms. Local suppliers of intermediates may also serve as sources of information. These knowledge flows act to lower the cost and difficulty of imitation. Hence, by reducing the cost of imitation, FDI should encourage imitation through incentive effects.

On the other hand, FDI vies with local production for local resources such as skilled labor. In some circumstances, FDI might deter imitation if multinationals bid up prices for scarce resources. Furthermore, when FDI is motivated by cost savings, multinationals have lower production costs than firms that export the good from elsewhere, so the profit margins earned when producing an imitation of a multinational's product should be less than that earned when producing an imitation of a product produced elsewhere. Due to the reduced profit margins for imitators, FDI could deter imitation. Glass and Saggi (1999) show that a faster arrival of opportunities to shift production abroad through cost-saving FDI can leave the aggregate rate of imitation essentially unchanged. So even though FDI makes imitation easier, there is no guarantee that FDI spurs local imitation.

How Innovation Affects FDI Multinational firms need to possess an ownership advantage in order to overcome the inherent difficulties of operating in multiple countries. Innovation yields the technological expertise that often provides the source of ownership advantage for multinational firms. As innovation is, in a sense, a necessary precondition for FDI, innovation should spur FDI.

Who is conducting the innovation matters, however. Doing more innovation should lead the innovating firm to do more FDI. But to the extent that innovation is being done by rival firms, FDI may be

deterred. Innovation by rivals poses a risk that the profit stream that rewards innovation may be terminated (or reduced) by a successful innovation by another firm. In some industries, the existing leaders have significant advantages from successful past innovations and therefore have a greater incentive to innovate, whereas in other industries, firms are on more equal footing and innovation is spread across many firms. This distinction suggests that the relationship between innovation and FDI may differ across industries.

For the newest technologies, firms usually opt for FDI over licensing on account of large transaction costs that arise due to the presence of asymmetric information. At the moment when a new technology is first created, only the innovating firm is well informed about its key attributes. Thus transferring such technologies to independent firms in other countries via arm's-length contracts might be rather difficult since such firms would typically not have a reliable estimate of the value of the technology. Under such a scenario, the innovating firm might choose to undertake FDI by establishing a fully owned subsidiary as opposed to licensing the new technology to a foreign firm. By impeding arm's-length contracting, transaction costs can induce internalization on the part of an innovating firm.

Furthermore, such internalization might also be motivated by strategic considerations: a firm may be unwilling to share its newest technologies with foreign firms that could become future competitors. It may be difficult, or perhaps even impossible, to prevent a licensee from terminating the contract and undertaking independent production after it has mastered the new technology. A further worry is that a current licensee might use the technology to invent a future technology that would make it an even fiercer competitor. Both the transaction cost perspective and strategic considerations suggest that firms will typically transfer their newest technologies through FDI and relatively more mature, and less valuable, technologies through licensing and other arm's length arrangements. A wealth of econometric and case-study evidence supports this hypothesis.

How Imitation Affects FDI When FDI brings about higher profits through costs savings, imitation poses the risk that the enhanced profit stream under FDI will be terminated. Thus imitation would seem to deter FDI. To determine how imitation affects FDI incentives, however, Glass and Saggi (2002) have argued that, as multinationals need not be the only firms targeted by imitation, the relative risk of imitation for a multinational must be compared to the imitation risk of producing in the home country. Even though FDI lowers the cost of imitation, it also lowers the multinational's production costs and therefore the profit margin earned by an imitator targeting the multinational's product. So there is reason for both types of imitation to exist: easier imitation targeting multinationals and more difficult imitation (that is more richly rewarded in terms of profits) targeting products produced elsewhere. When imitators target technologies regardless of whether FDI has occurred, increased risk of imitation need not deter FDI if the imitation risk also increases for firms that produce back in their home countries. What matters is how much more exposed to imitation multinationals are relative to firms that export. Glass and Saggi (2002) demonstrate a tendency for the relative risk of multinationals to remain constant, so the increased risk of imitation for a multinational does not vary as many other parameters of the model change.

For example, if imitation becomes more difficult, the rate of imitation falls, which one might think would encourage FDI. But both imitation targeting multinationals and imitation targeting nonmultinationals decrease, and they decrease in equal proportion, so the relative imitation risk for multinationals is essentially unchanged. In addition, there are effects operating though the labor constraint: due to the increased difficulty of imitation, the labor needed for imitation can increase, even though imitation falls. The increased use of labor for imitation crowds out FDI, as there is less labor left for production by multinational firms. In this case, less imitation (due to increased difficulty) leads to less FDI.

Imitation can be thought to encourage FDI in some settings. Glass and Saggi (1998) construct a

model with two types of FDI: FDI that transfers state-of-the-art technology and FDI using older technology. In that model, successful imitation of the older technology is required before FDI transferring state-of-the-art technology becomes feasible. The initial imitation is needed to establish a knowledge base in order for the technology transfer costs for the new technology to become reasonable. In this setting, although imitation of the latest technology could deter FDI, some initial imitation of older technologies is necessary for more advanced FDI to occur.

The impact of imitation on FDI can also depend on whether imitation is varied or whether imitation changes in response to other parameters of the model. Glass and Wu (2007) contrast the results for the effects of imitation on FDI when imitation changes on its own or in response to changes in other parameters of the model, as well as depending on whether imitations are quality improvements or new varieties, and whether innovations are done by leaders or rival firms (followers). Mostly, imitation and FDI move together in quality ladder models, except when innovations are done by followers. Increases in imitation may decrease FDI when innovations are new varieties (see Helpman 1993; Lai 1998). There are also models with R&D having decreasing returns to scale (see Dinopoulos and Segerstrom 2005; Sener 2006).

In sum, the interrelationships between FDI, innovation, and imitation are quite complex. Claims that may seem intuitively obvious, such as that innovation spurs FDI or even that FDI spurs innovation, need not be generally true. Similarly, FDI need not spur imitation and imitation need not always deter FDI. Given the many possible scenarios uncovered by theory, there is a great need for empirical work to sort out which outcomes are predominant. A better sense of what is happening in the data will lead to a better understanding of how imitation, FDI, and innovation matter to firms.
