A perplexing and well-known empirical regularity is that real exchange rates display both a high level of persistence and an intense amount of short-term volatility (Rogoff 1996). If one attributes large short-term volatility to some dominating nominal shocks, then the observed persistence is too high to be explained by price stickiness. This phenomenon is labeled a "PPP puzzle." Several attempts have been made to explain the puzzle. One study shows that, when sampling uncertainty is taken into consideration, the estimated persistence parameter gives only a very imprecise measure of the true persistence (Cheung and Lai 2000b). Thus the observed persistence puzzle may not be a well-defined puzzle. Subsequent studies also point out that the estimated level of persistence can be reduced to a "nonpuzzling" level when, say, nonlinearity adjustment mechanisms are considered.

Economic Factors So far the discussion has mainly drawn from studies based on the time-series (à la intertemporal) properties of exchange rate and price data. What economic factors affect the behavior of the real exchange rate, which is a measure of PPP deviations?

The Balassa-Samuelson effect is perhaps the most discussed economic force shaping real exchange rate behavior. The hypothesis is related to the observation that, when measured in the same unit, price levels in high-income countries are higher than those in low-income countries. The price differential is due to the difference in productivities in the tradables and nontradables sectors. The Balassa-Samuelson effect is a supply-side factor. A demand-side factor is government spending. It is perceived that nontradables account for a large fraction of government spending. Thus government spending tends to have a positive impact on a country's real exchange rate.

Other economic factors that affect real exchange rates include net foreign asset position, distribution sector, and market structure. Since the turn of the 21st century, the net foreign asset position has been introduced to a real exchange rate equation via portfolio-balance channels (Lane and Milesi-Ferretti 2002). The role of net foreign asset position is related to the effect of current/trade account balances articulated in the 1980s and 1990s. The effect of net foreign asset position is verified in a number of empirical studies. It is noted, however, that the construction of data on national net foreign assets involves approximations and these data are all in U.S. dollars.

The prices faced by consumers are affected by distribution costs. The productivity and efficiency of the distribution sector will have an impact on the price structure and, thus, on real exchange rate behavior. Intuitively, the distribution activity occurs within a locale and is likely to be a "nontradable" service. In the Balassa-Samuelson effect parlance, improved distribution sector productivity should be associated with a depreciation of the real exchange rate. Nonetheless, the extant empirical evidence points in a different direction   a result that may be driven by tradable components in the distribution sector (MacDonald and Ricci 2005). One caveat is the paucity of data on productivities of distribution sectors.

The implication of market structure for the adjustment of relative prices to exchange rate movements was recognized in the 1980s. A model with, say, a markup pricing strategy that is a function of the degree of monopolistic power offers an easy illustration of the market structure effect on real exchange rate behavior. Indeed, the market structure has implications for both the persistence and volatility of real exchange rates. As always, the availability of proper data is a challenge for the empirical valuation of the market structure effect. Since the turn of the 21st century, some positive evidence of market

structure effects has been reported using sectoral data (Cheung, Chinn, and Fujii 2001).

Inter- and Intracountry Analysis Usually, both LOP and PPP are stated with the implicit assumption that prices in different countries are being compared. There is no reason, however, that the two parity conditions should not apply to prices of the same goods within a country. Indeed, the study of relative price behavior within a country avoids a few problems that plague the cross-country analysis.

For instance, the procedures for compiling price data and constructing indexes can differ across countries. Within a country, however, price data are likely to be collected and recorded in one unified system. Thus data compatibility should not be a significant issue in comparing the prices of same goods across cities and regions within a country.

There are a few other reasons why results based on intracountry data are easier to interpret than those from intercountry data. First, intracountry relative prices are subject to similar fiscal and monetary policies, whereas intercountry relative prices are subject to possibly different policies. Second, the trade barriers within a country are usually less severe than those across countries. Third, the intracountry relative prices are literally linked via an exchange rate that is credibly fixed at the one-to-one level and, thus, are free from uncertain exchange rate variability. Indeed, Engel and Rogers (1996) have shown that there is an enormous increase in relative price variability across national borders. These factors imply that intracountry relative prices of identical goods are more likely to meet the parity condition.

Given these considerations, it is perhaps not too surprising to find that intracountry data, compared with intercountry data, display a faster convergence rate and are more likely to satisfy the parity condition. The result is supported by studies using either individual goods prices or price indexes.

YIN WONG CHEUNG

■ quantity theory of money

The classical equation of exchange as it is applied today equates the money supply multiplied by the velocity of circulation (the number of times the average currency unit changes hands in a given year) with the economy's gross domestic product (the quantity of output produced multiplied by the price level). Although the American economist Irving Fisher originally included transactions of previously produced goods and assets as part of the output measure, only newly produced goods are included in present-day calculations of gross domestic product. If the velocity of circulation and output are both constant, there is a one-to-one relationship between a change in the money supply and a change in prices. This yields a "quantity theory of money" under which a doubling of the money supply must be accompanied by a doubling of the price level (or, when the rate of money supply growth doubles, the rate of inflation also doubles). The Nobel Prize winning economist Milton Friedman (1956) restated this quantity theory of money by modifying the assumption of constant velocity, allowing velocity to adjust in response to changes in expected inflation and the returns available on other assets such as bonds and equities.

The tendency for velocity to rise as expected inflation rises reflects people's incentive to unload a depreciating currency before its purchasing power erodes. This reinforces the effects of faster money supply growth on inflation because, at the same time that more money is being printed, people want to hold even less of it than they did before the inflationary process began. There is, in fact, an exact inverse relationship between the proportion of income held as money and the velocity of circulation with, say, a halving of average money holdings requiring that the currency circulate at double the old rate in order to buy the same goods as before. In the extreme case of "hyperinflation" (broadly defined as inflation exceeding 50 percent per month), money holdings plunge and the inflation rate significantly outstrips the rate of money supply growth. Conversely, under deflation, velocity is likely to fall: people hold onto their money longer as they recognize that the same funds will buy more goods and services over time if prices continue to decline. Thus money demand rises as money supply falls, again exaggerating the effects of the money supply change on the aggregate price level.

The demand for money is also influenced by the economy's output level. If output rises, money demand should rise too, as increased production generates more income and spending power. This would put downward pressure on prices. Just as sustained inflation is possible only when the rate of money growth rises above the rate of growth of output (and money demand), so too does sustained deflation occur under conditions of insufficient money growth. According to the monetarist school, which emphasizes the importance of the money supply as a long-run determinant of prices and gross domestic product, stable prices could be achieved by simply tying the rate of money supply growth to the

long-run rate of growth of output. This would keep money demand and money supply in balance so long as velocity is stable.

Critics, such as those of the Keynesian school, which views the effects of monetary policy as unreliable and uncertain in practice, argue that such a policy rule would have undesirable consequences because velocity historically has been subject to fluctuations that require offsetting movements in the money supply. On the other hand, Friedman (1960) argued that velocity has been unstable only because policy has been unstable and that adoption of a constant growth rate rule for the money supply would keep inflation expectations, along with velocity, steady.

Friedman's restatement of the quantity theory of money tempers the classical prediction that money supply increases exert one-to-one effects on prices even in the short run. Under the restatement, velocity is allowed to adjust to a new level if the inflation environment changes. However, once real money holdings have adjusted to their new lower equilibrium level following a rise in inflation, the rise in velocity should end with a one-to-one relationship between money growth and inflation. Such a pattern is typically observed over extended periods. Moreover Friedman's (1992) famous proposition that inflation is always and everywhere a monetary phenomenon receives support from the fact that it is hard, if not impossible, to find any episodes of significant inflation that have not been accompanied by accelerating rates of monetary expansion. The importance of this link is further illustrated by the fact that, while a one-third money supply reduction in the eastern Confederate States in April 1864 dramatically reduced inflation there, inflation continued to run rampant in the western portion where the monetary cutback was postponed.

Criticisms of Quantity Theory Critics of the quantity theory approach have questioned not only the stability of velocity and money demand but also the determination of the money supply itself. That is, a link between money and prices does not necessarily prove that money supply movements are driving price movements. The economists Sargent and Wallace (1973) argue that such "reverse" causation could arise when a government is dependent on the revenue earned by inflating away the value of its outstanding money issues. Here, higher inflation produces faster rates of monetary expansion, and not the other way around. As higher expected inflation leads individuals to reduce their real money balances, this reduces individuals' exposure to the inflation tax and reduces the government's revenue from inflation. To keep inflation tax revenue at its old level, the government must accelerate the rate of monetary expansion so as to increase the inflation tax rate and offset the decline in the inflation tax base as real money balances fall. This novel, albeit controversial, perspective could not apply in the more usual situation where governments are able to finance their expenditures through conventional taxes and bond issues.

The quantity theory's predictions have also been questioned by adherents of "backing theory." Under this view, it is the quality rather than the quantity of money that matters. Whereas unbacked paper money may well be as inflationary as the standard quantity theory assumes, this need not be true of money that is credibly backed by future taxes or other provisions for their future retirement from circulation. Pioneering analysis of the American colonies prior to the Revolutionary War by Smith (1985) suggests that even large money issues might be willingly held rather than spent   implying a fall in the velocity of circulation and an absence of the inflationary pressures predicted by the quantity theory provided that they were properly backed. The case of Maryland stands out because that colony undertook to accumulate funds set aside for future purchases of pounds sterling that would retire the colony's paper money at a predetermined rate of exchange. Data limitations make it hard to conclusively determine the practical extent to which backing reduced the inflationary effects of the Maryland currency issues and those of other colonies, but recent work suggests that Pennsylvania enjoyed the long-run constancy of velocity, and proportional relationship between money and prices, implied by the quantity theory (Grubb 2005).

Excess Monetary Creation Whatever predictive power the quantity theory approach may have over the long term, even its strongest adherents would accept that short-run dynamics and adjustments militate against a one-for-one relation between money and prices in the short run. Excess money creation will eventually lead to inflation, but extra liquidity may well initially push down interest rates and encourage greater output and employment. Until these beneficial effects are reversed, the extra money issue may "buy" at least the illusion of greater prosperity. This, in turn, may produce a temptation to inflate. While the continued ratcheting up of the money supply will eventually lead to hyperinflation, such an extreme outcome usually occurs only when a government finds itself unable to obtain funding from any source other than the printing press. Such episodes, while unfortunate, have nevertheless provided economists with ample opportunity to observe not only the inflationary consequences of such rampant excess money growth but also the surge in the velocity of circulation as individuals become progressively less willing to hold the depreciating currency.

RICHARD C. K. BURDEKIN

■ quotas

Quotas in international trade are government-imposed maximum amounts of a product that can be imported into or exported from a country during a specific period of time (usually a year). The maximum can be a quantitative limit specifying the maximum tons or units or square yards that can be traded, or it can be a maximum in value terms, denominated in either domestic or foreign currency. A *global* import quota sets a single maximum amount

that can be imported, regardless of the country of origin. Import quotas are frequently subdivided among exporting countries, specifying a maximum amount that can be imported from each trading partner.

Use of Quotas Governments have used import and export quotas to achieve a number of different policy objectives. Governments often used import quotas to protect domestic producers from import competition or to encourage domestic production. An example would be the import quotas on petroleum in the United States from 1959 to 1973, intended to promote domestic exploration for oil and oil production to enhance national security. The United States relied on import quotas to prevent lower-priced imports from undermining price supports for domestic agricultural products, or from increasing the cost of the support program. Countries with fixed exchange rates and escalating balance of payments deficits often resorted to import quotas to limit payments for imports and prevent large losses in international reserves. In a balance of payments "crisis," governments often chose quotas because of the certainty that a quota ceiling would limit imports.

Governments sometimes impose export quotas to ensure sufficient supplies of a product for domestic consumption or processing. Romania, for example, used export quotas on logs, lumber, and plywood to ensure a supply of inputs for domestic furniture producers. Another objective is to keep domestic prices of sensitive goods below world market prices. The United States, for example, imposed export quotas on logs in the mid-1970s in an attempt to prevent increases in the price of lumber from driving up the cost of homebuilding. For countries that are major suppliers of an export commodity, export quotas reduce supply to the world market and keep world market prices high. An example would be the Organization of the Petroleum Exporting Countries' (OPEC's) export quotas on petroleum. Voluntary export restraints (VERs) are export quotas that were imposed by an exporting country on shipments of a good to a particular importing country *at the request of the importing country.* They allowed importing countries to protect struggling industries without

violating international trading agreements by imposing their own import restrictions.

Administration of Import and Export Quotas Governments have used many different rules or mechanisms to determine which international traders effectively receive the right to import or export under quota systems.

"First come, first served." One method of administering a quota restriction is to simply allow traders to import or export the restricted product starting at the beginning of the quota period until the quota ceiling is reached and then close the border to additional trade for the rest of the time period. This method can cause a chaotic situation as traders "stampede to the border" at the beginning of the quota period. Countries that attempted to administer quotas under a first-come, first-served rule in the 1930s found that quota limits were often exceeded because information flows to the authorities were too slow to close the border quickly enough to prevent the quota from being overshipped. Governments began to allocate the rights to import under quota to firms or individuals according to sets of rules or allocation mechanisms.

Allocation by "traditional trade shares." This method allocates shares of the quota among traders on the basis of their trade volumes during a specified base period. A firm that had imported 10 percent of total imports during the historical base period would be allocated 10 percent of the total amount allowed in under the quota restriction. This method excludes traders who did not happen to be trading in the base period, so governments often reserve a small portion of the quota for "new" or "nontraditional" importers or exporters. The United States Department of Agriculture allocated import quotas for cheese to importing firms on the basis of historical trade shares.

Allocation in proportion to domestic production. During the period in which the United States used import quotas to restrict petroleum imports, import licenses were allocated to domestic refineries in proportion to refinery output (Bohi and Russell 1978). McCulloch and Johnson (1973) discuss the efficiency properties of this allocation rule in the face of a set of different noneconomic objectives. They point out

that a proportionally distributed quota tends to produce an additional subsidy to production and a reduced tax on consumption relative to a tariff or standard quota.

Allocation by political decision. In some instances quota allocation is determined on the basis of politics. The U.S. Congress decided the distribution of sugar import quota allocations among sugar exporting countries and the secretary of agriculture sent "certificates of eligibility" to bring sugar into the United States to the governments of the exporting countries. Cuba, which had been the major exporter of sugar to the United States, lost its sugar quota allocation due to disapproval of Fidel Castro's government.

Quota auctions. Australia and New Zealand were two of the very few countries that auctioned quotas to the highest bidders. Auctions provide a market-oriented method of allocating quotas and also raise revenue for the government (Bergsten, Elliott, Schott, and Takacs 1987).

Economic Impact of Import Quotas An import quota is "binding" if the quantity that would be imported without the quota restriction exceeds the quota ceiling. A binding import quota reduces the supply of the product on the domestic market of the importing country and drives up its price. Domestic producers benefit from the quota restriction because the higher price encourages them to produce a larger quantity, which they sell at the higher price. Domestic buyers of the product are worse off because they pay a higher price and buy a smaller amount.

The increase in price of the restricted good in the internal market creates a gap or wedge between the higher internal price and the price of the good on the world market. Traders who can import under the quota system earn a windfall profit, called a "quota rent," because they can buy the product at the going world market price, import, and resell at the higher internal price. The choice of the allocation method for quotas is thus important because it determines who can import and thus who receives the windfall gains from the quota rents.

Import quotas also create net losses in total welfare for the country that imposes them because of resource misallocation and efficiency losses in both production and consumption. On the production side, the quota encourages expansion of domestic production of the restricted good, but the extra production takes place at a higher cost than the price of the good on the world market. The cost of the domestic resources used up to expand domestic production exceeds what it would cost to buy the imported goods that they replace. On the consumption side, buyers lose welfare because they pay a higher price and cut back their purchases of the restricted good in response to the artificially high price. Quotas often cause additional inefficiencies because an overall quota limit on imports of a general product category is often subdivided into smaller quotas for particular varieties of the product, and often further subdivided to specify the country of origin of the imports. For example, the U.S. import quotas on cheese were subdivided into subquotas on different types of cheese (Swiss, provolone, parmesan, cheddar, etc.) and those subquotas were further subdivided to impose upper limits on imports from each exporting country. Thus the quota system arbitrarily determined the distribution of cheese imports by type and source, without regard to cost or consumer preferences (Anderson 1988).

Economic Impact of Export Quotas A binding export quota constrains the amount of a good that can leave the country, forcing more of it onto the domestic market. The larger supply on the domestic market reduces the internal market price. Domestic producers of the restricted good lose because they produce a smaller quantity that sells at a lower price. Domestic buyers or users gain because they obtain the good at a lower price and buy more of it.

Export quotas cause distortions on the production and consumption sides that create overall welfare losses for the economy as a whole. On the production side, artificially constrained exports preclude domestic firms (and thus the economy as a whole) from capturing the gains from selling in the world market at a price above production cost. On the consumption side, the decrease in price encourages domestic buyers to expand purchases, but the extra units they buy could have been sold in the world market at a price higher than the value to domestic users.

Export quotas also generate quota rents because the decrease in the domestic price of the restricted good due to the export quota creates a wedge between domestic and world market price, so whoever can export the good receives a windfall gain equal to the difference between the world market and domestic price. VERs also involve quota rents because the restriction in supply will push up the price of the restricted good in the domestic market of the importing country. Exporters who receive quota allocations to ship to the importing country are likely to receive the quota rents. De Melo and Tarr (1992) calculated very large losses to the United States due to the transfer of quota rents to exporting countries under VER agreements on textiles and apparel, automobiles, and steel.

Comparison of Quotas to Tariffs Quotas influence international trade flows by directly limiting the quantity of a product that can be imported or exported. An import tariff, in contrast, reduces imports through the price mechanism by making imported goods more expensive. A major question in the analysis of international trade barriers is the equivalence of quotas and tariffs (Bhagwati 1968). The question is, "Under what conditions will an import tariff and an import quota that result in the same amount of imports have exactly the same economic impact?" If market conditions remain unchanged, and the product markets are perfectly competitive, an import quota and a tariff that result in the same import quantity will also result in the same domestic price, quantity produced, and quantity consumed. The literature on the equivalence of tariffs and quotas has identified a number of ways in which the impacts of tariffs and quotas differ, however (for detailed explanations see Vousden 1990).

Government revenue. The government collects revenue from an import tariff or an export tax, but import or export quotas generate quota rents, which do not directly go to the government. Governments could in principle attempt to capture what would be quota rents by auctioning quota licenses, but quota auctions are rare (Bergsten, Elliott, Schott, and Takacs 1987). Quota rents may be captured by the nationals of the country imposing the quota: for

example, if import licenses are allocated only to domestic firms importing the good. But if import licenses or permits are given to exporters (as in the case of the U.S. sugar import quotas or under VERs), the quota rents are very likely to be captured by nationals of the exporting country and thus represent an additional loss to the importing country, in addition to the welfare losses from production and consumption distortions. The possibility that quota rents may be lost to the quota-imposing country is one reason to favor tariffs over quotas as a policy instrument to reduce imports or protect a domestic industry.

Noncompetitive market structure. If the domestic industry producing the good in the importing country is not perfectly competitive, the economic impact of a quota and a tariff can differ. If only one domestic firm produces an imported good, that domestic monopoly faces quite different demand conditions for its product under a tariff than under a quota. If the monopoly firm is protected by a tariff, it can sell its product at a price above the world market price, but it cannot control the price at which it can sell. If it attempts to raise its price above the world price plus tariff, buyers can simply buy from foreign suppliers and pay the tariff. The monopoly has no ability to control the domestic price with a tariff. It has no "market power." But if the monopoly is instead protected by an import quota set to allow in the same quantity of imports as the tariff, the firm will raise its selling price because buyers no longer have the option of importing more from abroad than is allowed by the quota. An import quota gives a domestic monopoly "market power" that it would not have under the tariff, which it will exploit by reducing output and charging a higher price. This extra distortion that arises from a quota when domestic industries are highly concentrated is another reason to favor tariffs over quotas.

Changes in market conditions. A tariff and a quota also lead to different outcomes if market conditions change after the tariff or the quota is imposed. The difference arises because a tariff allows imports to increase if market conditions change, whereas a quota does not. Assume a small country that is too small to influence world prices by the

amount that it imports. If a binding quota restricts imports to the quota ceiling and domestic demand for the product subsequently increases, imports cannot increase to satisfy the extra demand, so the domestic price of the product will rise and domestic production will increase. In contrast, if a tariff had restricted imports to the same initial level (resulting in the same initial domestic price, production, and consumption) an increase in domestic demand simply would increase the quantity imported, without any increase in the price, which would remain equal to the world market price plus the tariff.

A tariff and an import quota also lead to different outcomes if international market conditions change. If the world market price of an imported good falls, but domestic demand and supply conditions remain unchanged, the import quota prevents imports from increasing even though their price is falling. The external price decline will not be transmitted into the domestic economy. If a tariff had been used to control imports, falling world prices would make imports less expensive, and the quantity of imports would increase. The world market price decline would be transmitted into the domestic economy. This difference between tariffs and quotas is the main reason governments used quotas to control imports of products subject to domestic price supports.

Upgrading of product quality. If a product category contains varieties of different qualities that sell at different prices, the composition of imports will differ under a tariff regime and a quota regime. Import quotas result in "upgrading," or a shift toward imports of higher-quality, higher-priced varieties, rather than lower-quality, lower-priced varieties. The quota creates a wedge, or price gap, between the domestic price and the world price of the imported products. The given price gap represents a larger percentage price increase for lower-priced goods than for higher-priced goods, so lower-priced goods become more expensive relative to higher-price goods and there is a tendency for buyers to substitute higher-quality goods for lower-quality goods.

Directly unproductive activities. The quota rents earned by those individuals or firms who receive the rights to import under quota provide a powerful incentive to engage in activities to influence quota allocation decisions. Thus quota regimes encourage individuals to spend time and use up real resources in their attempt to influence quota allocation decisions in their favor (Krueger 1974). Tariff revenue accrues directly to the government, so a tariff regime does not promote similar unproductive activities.

Quotas have long been a feature of global trade policies. While the role of quotas has diminished somewhat with recent progress in liberalizing trade in the textile, clothing, and agricultural sectors under the auspices of the World Trade Organization, the analysis of quotas remains an important area in theoretical and applied trade policy research. As such, it informs a preference in the trade policy community for tariffs as a more appropriate trade policy intervention.

Also discusses the effects of quotas in the presence of retaliation by trading partners, the rent seeking costs of tariffs and quotas, product upgrading when quotas are imposed on differentiated products, and a discussion of the comparison of quotas with tariffs when the protected sector is a monopoly.

WENDY TAKACS

real exchange rate

The real exchange rate, a linchpin of international economics, tells us about the overall costs in one country compared with another. Defined as the cost of a bundle of goods in one country relative to the cost of the same bundle of goods in another country, it is conventionally written as the nominal exchange rate adjusted for international differences in prices levels:

$$Real\ Exchange\ Rate \equiv$$
$$Nominal\ Exchange\ Rate \times \frac{Domestic\ Prices}{Foreign\ Prices},$$

where the nominal exchange rate is specified here in terms of foreign currency units per unit of domestic currency.

From this expression, one sees that if the nominal exchange rate fluctuates widely while the price indexes are relatively stable, then the real exchange rate will move with the nominal exchange rate. This indeed has been the pattern under floating exchange rates: real exchange rates have been nearly as volatile as nominal exchange rates have been. Moreover changes in the real exchange rate seem to persist for a very long time. Explaining the behavior of real exchange rates therefore requires both an understanding of why nominal exchange rates are so volatile under floating exchange rate arrangements and an understanding of what keeps prices from fluctuating proportionately.

Theoretical Approaches Most theoretical approaches to understanding real exchange rates focus on the price of goods. These explanations generally fall into two categories. The first category emphasizes the importance of international borders, particularly those aspects of borders that prevent the law of one price from holding internationally. The second category emphasizes what goes on within countries, especially what happens to the relative prices of traded and nontraded goods within an individual country. International failures in the law of one price and international differences in relative prices within countries are related, but they each capture different ideas of what is important in determining real exchange rates.

Across international borders, the law of one price fails for many goods, and its failure is particularly notable for final goods. Its failure can occur most obviously because of transportation costs and official trade barriers, but it also can occur because of noncompetitive market structures, in which prices resist change. In many new open economy macroeconomic models, firms have monopoly power and prices are set as a markup over marginal cost. In these models, the law of one price can fail, at least in the short term. Failures of the law of one price represent impediments to the adjustment of the real exchange rate.

Looking within countries, explanations of real exchange rate behavior emphasize distinctions between different sectors of the economy, such as the traded and nontraded sectors, or the intermediate and final sectors. These explanations tend to rely either on differential changes in productivity across the sectors or on changes in the relative demands across the sectors. All such changes affect the relative prices and the composition of what is produced and consumed in each country. Such changes, in turn, affect

the real exchange rate via the price indicators that we see in its definition. The most prominent of these explanations is the Balassa-Samuelson effect.

The other explanations of real exchange rate behavior are primarily shorter-term explanations. Changes in preferences across an economy's traded and nontraded sectors whether due to changes in consumption or government expenditures will affect relative prices for as long as it takes for the factors of production to move across the sectors within a country. (Some of the new open economy models fit into this category as well.) In the short run, the supply of nontraded goods is inelastic, and the demand for nontraded goods matters. So changes in the consumption of nontraded goods will affect relative prices, and real exchange rates will change.

Empirical Challenges Despite much work, little is known about the empirical determinants of real exchange rates. A large number of econometric studies have attempted to determine whether the exchange rate converges over time to an equilibrium value that is, whether it is stationary. The focus on this particular issue arises in large part because it is equivalent to knowing whether relative purchasing power holds, in which case nominal exchange rate changes and inflation differences eventually offset each other. The persistence of real exchange rate changes, however, means that tests even of this fairly clear-cut hypothesis lack statistical power, even with long time series or with panel data.

Econometric work that attempts more broadly to discern the real exchange rate's most important determinants and thereby to distinguish among competing theories has had only limited success. The real exchange rate's volatility and persistence are not matched by observations of its theoretical fundamentals, and it is difficult to generate endogenous persistence in real exchange rate models without introducing other counterfactual implications.

Thus empirical studies have been able to tell us only a few things. First, real exchange rates tend to move with nominal exchange rates, and their behavior correspondingly depends on prevailing nominal exchange rate arrangements. Second, real exchange rates are volatile. Finally, their changes are persistent.

Even this last conclusion is subject to the criticism that it may be an artifact of poor measurement.

Measuring the Real Exchange Rate Empirical work on real exchange rates involves many judgments about how to construct real exchange rate measures. Most important, appropriate price indicators and suitable aggregation methods must be selected. Typically, price indexes, such as the consumer price index or the producer price index, are used. Just as those indexes show price changes rather than price levels, real exchange rates so constructed will gauge real exchange rate changes, rather than their levels. These measures tell us what the real appreciation or depreciation has been relative to some point in time, but they do not provide the real exchange rate's actual value. Calculation of the real exchange rate's level requires information about price levels, information that is not always readily available. Such distinctions between *indexes* and *levels* can be important in debates about exchange rate policies and trade policies. For example, an index can tell how much the value of the Chinese currency has changed since the Asian financial crisis in 1997 98, but only a measure of the real exchange rate's level can tell us if it is weak or strong relative to another currency or relative to a theoretical value.

One also faces the question of what categories of prices to use. Consumer prices are used most often. Producer and wholesale price indexes, and even export price indexes, are sometimes chosen over the consumer price index because they better represent the notion of export competitiveness, which often is of particular interest. As the set of prices narrows increasingly toward including only actually traded goods, however, it also becomes increasingly like a measure of the terms of trade the relative price of imports and exports and less a measure of the real exchange rate.

Finally, since currency values so often diverge, real exchange rate measures can be sensitive to the set of countries included and to their weights. A country's real exchange rate often is measured bilaterally, that is, against only one other country. A broader multilateral measure can differ markedly from a bilateral one, however. For example, a country that

pegs its nominal exchange rate against that of a single trading partner is likely to have a relatively stable bilateral real exchange rate against that country. Against other countries, however, its real exchange rate could be very unstable, either rising or falling. A multilateral or effective real exchange rate will capture those broader movements.

Whether one is interested in questions about the fundamental determinants of the real exchange rate or has questions about the experience or policies of a single country, all of the measurement choices affect the measures and thereby shape the conclusions.

regional development banks

Regional development banks (RDBs) play a critical role in the international financial architecture. They provide development finance to their poorer member countries on highly concessional terms, mobilizing between U.S. $15 billion and $20 billion a year, compared with about U.S. $20 billion for the World Bank. By comparison, foreign direct investment flows represent more than U.S. $300 billion per year, albeit concentrated in a few emerging markets.

RDBs are central components of the constellation of the 20 or so multilateral development banks that emerged after World War II: the World Bank; five RDBs, four dealing with transition and developing countries (the African Development Bank, the Asian Development Bank, the European Bank for Reconstruction and Development, and the Inter-American Development Bank) and one, the European Investment Bank, dealing mainly with members of the European Union, although the level of its operations in developing countries is significant at around U.S. $3 billion a year; and 13 subregional development banks of varying size, such as the Council of Europe Development Bank, the Caribbean Development Bank, and the West African Development Bank.

Lending for Development The RDBs' mandate has evolved over time, as has the rationale for development finance. They are multilateral organizations mobilizing development finance to their member countries to promote growth, encourage development, and reduce poverty. They act as financial intermediaries, leveraging resources from international capital markets that they lend-on at advantageous conditions to their members, which often have limited and volatile access to those markets. Each of them has built up a corpus of economic and technical expertise, and in 2004, their combined outstanding loans were more than U.S. $1 trillion, of which U.S.

$128 billion was for the RDBs operating in transitional and developing countries (compared with U.S. $225 billion for the World Bank).

Two general characteristics distinguish RDBs from private financial institutions and bilateral donors: their multilateral shareholding structure and preferred creditor status, and a subsidized capital base and access to other subsidies. Their financing model is similar to that of the World Bank, with which there is a certain degree of competition. They are perceived as generally less efficient and more politicized, imposing less stringent conditions than the World Bank. Their comparative advantage resides in their regional constituency, governance structures, and closeness to their members, as well as the low interest rates they charge their borrowing members.

Features The financing model of RDBs consists of three main features: a financial leverage mechanism, a preferred creditor status, and a soft-lending window. RDBs borrow on international capital markets, backed by a capital structure with a low paid-in amount (direct cash contributions representing between 4 and 20 percent of subscribed capital, or issued share capital). They are thus able to borrow in international capital markets at lower rates than their borrowing members could individually, and the RDBs pass on to their members the low interest rates they pay. Their preferred creditor status is anchored in the support of their shareholding governments, reflected in capital contributions and pledges to soft-lending windows providing loans with extended grace periods, longer amortization and lower interest rates than conventional bank loans, and the incentives for borrowing countries to service their debt in order to secure continued access to concessional sources of development finance. Their membership typically includes regional borrowing members, as well as regional and nonregional nonborrowing countries.

Members contribute to the authorized capital, partly paid-in but mainly in the form of callable capital should an RDB become unable to meet its obligations to bondholders. Each member's financial contribution is a function of its relative affluence and determines its voting rights as a shareholder. Nonborrowing members contribute grant resources to their soft-lending windows, which they replenish every three to five years, allowing them to lend-on at highly concessional rates and on a very long-term basis to poorer members.

Functions RDBs provide nonconcessional loans and concessional credits, as well as nonrepayable grants, technical assistance, and policy advice. They also generate and disseminate knowledge, through advisory and analytical work, which shapes public policies and informs policy reform. Typically, they have four main lending instruments: a window providing nonconcessional loans to its wealthier members, financed with ordinary capital and with a repayment period typically of 15 30 years; a soft-lending window established as a separate development fund providing long-term concessional credits to poorer members with low creditworthiness, essentially in Africa and Asia, with a large grant element and a repayment period of up to 40 50 years; a private sector lending window operating on a commercial basis and providing a mix of financing instruments (loans, equity finance, risk management, intermediary finance); and a guarantee window promoting foreign direct investment.

Instruments RDBs provide two main types of sovereign loans or credits. Policy-based loans (also called adjustment or programmatic loans) provide general budget support against a program of reform and are linked to disbursement conditions, at times earmarked to specific sectors such as health, education, or social protection. Investment loans are designed to support specific development projects in sectors such as water, sanitation, infrastructure, or energy utilities. The banks increasingly support subnational governments and large municipalities, sometimes without sovereign guarantee from the central government. They are also prompted to increase their support to the private sector in better-off regions, especially small and medium enterprises, directly or through commercial banks (lines of credit).

Stepping Up to the Future The RDBs, like most multilateral development banks, are confronted with multifaceted challenges from a changing environment and the evolving financing needs of their members, especially middle-income countries. The

rapid development of international capital markets and recent financial crises have prompted many reassessments of the role of multilateral finance, including by the G7 since 2001. Key challenges evolve around the RDBs' corporate mandate, comparative advantage, and lending strategies.

Corporate Mandate Many attempts are being made to redefine the banks' mission, as part of a gradual rethinking of the purpose and effectiveness of multilateral lending. RDBs are to focus more narrowly on reducing poverty and inequality and address a broader set of development challenges, including governance and anticorruption strategies. They are pressed by their richer shareholders to deliver results, and by civil society to show greater corporate social responsibility in their sovereign loans and equity investments in sensitive sectors such as extractive industries. They are under external pressure to increase transparency and accountability in their internal governance and modus operandi and are often criticized for operating as foreign policy extensions of powerful shareholders, especially the United States.

Strategic Selectivity RDBs are pressed to act more strategically and selectively, concentrating in those countries with sound institutions and good governance where aid has been found to be more effective. Calls for more selective engagement are part of the broader debate on the balance between grants and loans, lending instruments and pricing policies. Shifting to grant aid, it is argued, would help avoid the reaccumulation of unsustainable levels of debt. A

major debt relief initiative for highly indebted poor countries was launched in 1996 (enhanced in 1999), amounting to about U.S. $100 billion in nominal terms. In 2005, the Multilateral Debt Relief Initiative agreed to cancel the eligible debt of 22 poor countries, in particular in Africa, owed to the concessional lending arms of the African Development Bank and Inter-American Development Bank (as well as the World Bank and the International Monetary Fund).

In addition to pressuring the RDBs for greater reliance on grants in low-income countries with limited fiscal capacity, observers often question the banks' relevance and effectiveness in middle-income countries, partly as a result of developing countries' increased access to capital markets. In 2000, the U.S. Congress's Meltzer Commission recommended that the RDBs essentially end nonconcessional lending to middle-income countries and that their assistance to low-income countries be mainly in the form of grants. The commission also suggested that RDBs should assume most of the lending to their respective regions, except for Africa. Nevertheless, the emerging markets crises of the late 1990s showed that middle-income countries' access to private capital remains volatile and precarious.

Changing Context In a changing environment, the RDBs' importance as a source of development finance is declining, overtaken by private sector flows and remittances. Moreover grant financing from bilateral donors is set to increase sharply. New actors, especially China, are emerging as alternative sources of development finance, with fewer strings attached. In addition, the RDBs' loan portfolios are maturing, resulting in transfers out of developing countries as repayments and prepayments are made. In 2005, for example, net lending was nil, if not negative, reflecting patterns of "defensive lending," whereby new loans are made to ensure that past loans are repaid (see table 1).

Repositioning Efforts The RDBs are thus seeking to reposition themselves along different directions, through a more selective approach in middle-income countries, a sharper poverty focus in lower-income countries, and greater synergies with the private financial sector. They are concentrating on good performers with sound economic policies in order to improve portfolio performance, tackling global public goods, and restricting their balance of payment support, especially emergency lending in crisis situations. Borrowers see competition among the multilateral development banks as providing them with greater choice and therefore improving loan quality, but specialization and cooperation between the World Bank and regional and subregional development banks are areas for further improvement.

■ regionalism

Enshrined in Article I of the World Trade Organization's (WTO's) General Agreement on Trade and Tariffs (GATT) is the key principle of the multilateral trade system the principle of nondiscrimination which prevents member countries from discriminating against imports based on the country of origin. In an important exception to this central prescript, however, the GATT (Article XXIV) permits WTO members to enter into preferential trade agreements (PTAs), provided these preferences are complete. In so doing, it sanctions the formation of free trade areas (FTAs), whose members are obligated to eliminate internal import barriers, and customs unions (CUs), whose members additionally agree on a common external tariff against imports from nonmembers. In addition, the Enabling Clause allows tariff preferences to be granted to developing countries (in accordance with the Generalized System of Preferences) and permits preferential trade agreements among developing countries in goods trade. Among the more prominent existing PTAs are the North American Free Trade Agreement (NAFTA), the European Economic Community (EEC), and the European Free Trade Association (EFTA), all formed under Article XXIV, and Mercosur (the CU encompassing Argentina, Brazil, Paraguay, and Uruguay) and the ASEAN (the Association of Southeast Asian Nations) Free Trade Area (AFTA), both formed under the Enabling Clause. Other forms of integration, such as the formation of a common market, involve the further elimination of barriers to factor mobility, as in the Common Market for Eastern and Southern Africa (COMESA) and the use of a single currency to form a common currency area (as in the European Union). Since preferential integration has often (but not always) involved geographically proximate countries, the term *regionalism* has been used to describe such regional groupings and sometimes to describe the broader phenomenon of preferential integration itself.

Economic Analysis Motivated by ongoing discussions concerning optimal trade arrangements in the postwar period, especially over the possibility of a European customs union, Viner (1950, 41 50) developed a seminal analysis of the economics of preferential trade. Viner's analysis disputes the presumption that cutting tariffs necessarily improves welfare. On the one hand, because of discriminatory liberalization, there will be commodities that a member country may "newly import from the other but which it formerly did not import at all because the price of the protected domestic good was lower than the price of any foreign source plus the duty." Viner calls this shift from a high to a lower cost point "trade creation" and associates it with welfare improvement for the importing country. He also argues that, on the other hand, "there may be other commodities, which one of the members will now newly import from the other," whereas before the PTA it "imported them from a third country, because that was the cheapest possible source of supply even after the payment of duty." He calls this shift in imports from a low-cost third country to a higher-cost member country

"trade diversion," associating it with an increase in the cost of imports and, thus, welfare losses for the importing country.

The demonstration that preferential trade liberalization may be welfare decreasing stimulated a substantial theoretical literature on the "static" welfare effects of PTAs. Post-Vinerian analysis of the welfare effects of preferential trade developed examples of both welfare-improving trade diversion and welfare-decreasing trade creation in general equilibrium contexts broader than those considered by Viner (see Panagariya 2000 for a comprehensive discussion). The intuitive appeal of the concepts of trade creation and trade diversion and supporting empirical findings, however, have ensured their continued use in the economic analysis of preferential trade agreements, especially in policy analysis.

It has sometimes been argued that countries entering into preferential arrangements with geographically proximate countries are likely to do better than in agreements with distant countries, because the former are more likely than the latter to be trade creating. The theoretical literature has provided a number of examples, however, in which, between two otherwise identical potential partners, a country achieves a superior outcome by granting trade preferences to the distant partner (see Panagariya 2000). Moreover empirical analysis of this question has not found any support for the hypothesis that regional trading partners should be considered "natural" partners in the context of preferential trade (see Krishna 2005).

The generally ambiguous welfare results provided by the theoretical literature raised an important question relating to the *design* of necessarily welfare-improving PTAs. A classic result by Kemp and Wan (1976) provided a welfare-improving solution for the case of CUs. Starting from a situation with an arbitrary structure of trade barriers, if two or more countries freeze their net external trade with the rest of the world through a set of common external tariffs and eliminate the barriers to internal trade (which implies the formation of a CU), the welfare of the union as a whole necessarily improves and that of the rest of the world does not fall. A Pareto-improving

CU is thus achieved. Panagariya and Krishna (2002) have provided a corresponding construction of necessarily welfare-improving FTAs where, in analogy with Kemp and Wan, external trade is frozen for each FTA member country. Common to these analyses of welfare-improving preferential trade blocs is the elimination of trade diversion achieved in each case by freezing external trade. To ensure this outcome, the trade barriers imposed on nonmembers must generally be less restrictive than before. Since existing GATT rules require only that external barriers not be raised, some trade diversion is likely in practice.

Recent analysis in the literature has focused on issues concerning the effects of preferential agreements on the multilateral trade system. Will PTA membership encourage governments to expand their agreements to include new countries or will there instead be political-economy incentives to keep new countries out? (Or, as Bhagwati 1993 has phrased it, will trade blocs serve as "building blocs" or "stumbling blocs" in the path to multilateral free trade?) Does the answer depend on the (trade-creating or trade-diverting) nature of the PTAs involved?

Modeling the endogenous determination of trade policy while emphasizing the role of powerful domestic interests in influencing policy, it has been argued that PTAs that divert trade are more likely to win internal political support. This is so because the political costs of liberalization are alleviated when gains to domestic firms of member countries come largely at the expense of outsiders. It follows that such PTAs will lower the incentives for any subsequent multilateral liberalization due to the fact that producers in trade-diverting PTAs may oppose multilateral reform since this would take away the gains from benefits of preferential access that they enjoyed in the PTA that diverted trade to them. Indeed, the incentives for further multilateral liberalization may be completely eliminated. The literature has obtained similar results when trade policy is determined by majority voting. If bilateral agreements occur between similar countries, so that there are gains from trade but no major income distributional shifts, bilateral agreements could render multilateral liberalization infeasible, as the latter may involve income
Figure 1

PTAs in force by date of entry into force. Source: World Trade Organization.

distributional changes that worsen the lot of the median voter. These analyses demonstrate the possibility that preferences in trade may have a negative impact on multilateral liberalization incentives for member countries. On the other hand, nonmember countries may see their incentives for multilateral liberalization increased. Thus, it has been argued that PTA expansion could have a "domino" effect increasing the size of a bloc increases the incentive for others to join it (as they then gain preferential access to increasingly large markets). Assuming open membership rules (i.e., insiders do not oppose the entry of new members who abide by the same rules as the members), it has been shown that the successive expansion of a PTA could then lead to multilateral free trade, but this desired outcome is not achieved under alternative membership rules (see Krishna 2005 for a survey discussion).

A half century of research has significantly advanced our understanding of the implications of trade discrimination even if the frequently equivocal theoretical and empirical results have established among economists and policymakers an ambivalent attitude toward preferential trade agreements. Concerns regarding the fragmentation of the world trade system, however, have grown with the rapid proliferation of preferential trade in recent years (see figure 1). Several hundred PTAs were in existence in 2007 (with many countries belonging to multiple PTAs), and several more were in process. With this inexorable erosion of nondiscriminatory disciplines within the trade system, research on preferential trade is certain to remain central to the field of international trade policy for many years to come.

■ remittances

International remittances, the sums of money and goods that immigrants send home, have recently captured the attention of bankers, economists, and policymakers. Previously, little effort was expended
Figure 1

World receipts of workers' remittances. Source: World Bank, World Development Indicators.

to measure and analyze these flows because they were thought to be small in magnitude and of little significance for most countries. Evidence to the contrary has motivated policymakers and others to pay closer attention to the measurement, determinants, and impact of remittances.

Trends and Geography Using a broad definition of international remittances — workers' remittances and compensation of employees — we find that these flows increased from U.S. $37 billion in 1980 to U.S. $249 billion in 2005 (World Bank Indicators). This almost sevenfold increase (see figure 1) exceeds the growth of many macroeconomic variables, including world trade. Although some of the growth in remittances is simply due to better tracking and reporting of these flows at the aggregate level, microeconomic surveys also indicate that there has been brisk growth in the flows of resources from immigrants to their families. It is likely that this growth will persist as an important by-product of world migration.

Figure 2 reports on the worldwide distribution of remittance receipts, revealing that 50 percent of total receipts flow to Latin American, East Asia, and the Pacific regions. South Asia, the Middle East, and North Africa account for about another quarter of flows, while 14 percent flows to Europe and Central Asia. Sub-Saharan Africa, the region most in need of resource inflows, has the smallest share — only 4 percent.

Data Sources Individuals interested in obtaining yearly country-level data on international remittances can consult *The Balance of Payments Statistics Yearbook*, a publication of the International Monetary Fund (IMF). Since these data originate from reports submitted by member nations, more detailed information on remittances can sometimes be obtained directly from reporting agencies of individual countries. For example, Mexico provides monthly data on remittances on its Web site (www.banxico .org.mx). These are disaggregated by transmission method — whether the receipts arrived by money order, check, electronic transfer, or cash. In contrast, understanding how remittances affect household behavior (e.g., schooling, labor force participation) requires obtaining microeconomic data that report on both the household receipt of remittances and household characteristics. Many national income and expenditure surveys, a handful of censuses, and some specialized migration surveys provide this information.

Definition and Measurement of International Remittances At the time of this writing, the term *remittances* is used to refer to one or a combination of three separate concepts: workers' remittances, compensation of employees, and migrants' transfers. The first of these, workers' remittances, are current transfers by nonresidents to resident households, for example, the sums of money that a Dominican national with *U.S. residency* sends to her family in the Dominican Republic each month. In contrast, if the Dominican had been hired to work in the United States for five months only, her earnings net of travel expenses would be classified as compensation of employees. The main distinction in this latter case is her classification as a *Dominican resident* due to the temporary (less than one year) nature of her stay in the United States. The third category, migrants' transfers, are the changes in asset designations that take place when an individual changes residency. Take the case of an individual moving from the United States to Thailand. His U.S. saving account changes from being owned by a *U.S. resident* to being owned by a *Thai resident* and would be recorded under migrants' transfers. In practice there is considerable confusion and practical difficulties regard-

Share of world remittance receipts. Source: World Bank, World Development Indicators.

ing the three designations of remittances. Efforts to change and simplify the reporting and categorization of these international money flows were under discussion as of 2005 (see International Monetary Fund 2005).

Aside from these definitional difficulties, the researcher is likely to be challenged by the noncomparability of data across countries and over time. Although annual data on remittances are derived from standardized reports submitted to the IMF, countries still use different methodologies to collect the data. Some countries measure remittances by aggregating reports of inflows by the banking system and by money transfer firms such as Western Union. Different country-specific reporting requirements and thresholds make for variations in the scope of these reports, however. In other cases, central banks estimate flows using household surveys. Reliability, in these cases, rests with the ability of the survey instruments to capture all flows. Furthermore some surveys ask only about monetary remittances while others collect information on both monetary and in-kind transfers.

Nonuniformity of series across time can cause additional problems. There are variations in the abilities of statistical agencies to track different methods of transmission. It may be relatively easy for central banks to account for transfers made through officially regulated channels (e.g., banks and money transfer firms). Informal transfers those that are hand carried, mailed as cash, or transmitted through hawalas are harder to track (a participant in the hawala system provides a sum to a hawaladar who, in turn, directs a counterpart in another country to pay out that same sum of money to the intended recipient). Variations in policies and regulations can affect the choice of transmission method of immigrants remitting money home, which, in turn, affects the officially reported flows but not the actual flow of money across borders. For example, in 2002 a number of large banks chose to recognize the Mexican *matricula consular* (identification card issued by Mexican consulates to Mexicans residing outside of Mexico) as a valid form of identification, thereby facilitating the opening of bank accounts by many unbanked Mexican immigrants in the United States. An observed surge in *recorded* remittances following the policy change was likely due to shifting from harder to track informal transmission methods to more easily measured formal bank channels.

Determinants of Remittances To appreciate the impact of remittances it is helpful to understand why migrants remit. What motivates remittances? Do remitters respond to economic variables in both the host and home communities? Do incentives to remit change with policy? If we can describe their determinants, we can better predict and influence remittances.

Various motives for remitting have been put forth and tested (Rapoport and Docquier 2006). The motive most commonly cited is altruism — to facilitate higher levels of consumption by the family left in the home country. In fact, the prospect of earning higher wages abroad and sharing those with family back home is thought to be at the heart of much migration. But migration may also be motivated by a desire to accumulate assets, to purchase housing, land, or capital goods, to begin or expand a business in the origin community, or to cover for risky ventures away from home.

Many find it useful to think of migration and remittances as an overall strategy to permit the family to gain from the geographic dispersion of its members (Lucas and Stark 1985). Rosenzweig and Stark (1989) provide a good example of this, demonstrating how marriage with migration takes place to diversify income streams. Total household income remains more stable in these geographically dispersed households as members suffering from income shortfalls are compensated with income transfers by those in preferable situations, lowering consumption variance for all.

Isolating the determinants of remittances is helpful for predicting how remittances may respond to policy and to changing economic conditions. If migration and remittances take place to diversify income, remittance flows may rise and fall with economic shocks. If migration takes place to take advantage of higher earnings to purchase large-ticket items, remittances may subside once the purchase is made. If remittances are purely altruistic in nature, we can expect to observe that they flow and ebb with crisis situations in the home community. If remittances are undertaken to invest in the community of origin, local economic conditions and exchange rate policy are apt to have impacts on the volume and timing of flows.

Impacts of Remittances While many argue that remittances are beneficial, raising living standards, others emphasize negative effects of remittance inflows. This has led to confusion regarding appropriate policy. Should remittances be supported and encouraged or should we impede and slow growth in these money transfers? As with many phenomena, the issue is complex with both viewpoints earning currency.

Macroeconomic impacts: In an often-cited report, Ratha (2003) lauds remittances as more stable and reliable than foreign direct investment or foreign aid and thus an important source for financing development. Chami, Fullenkamp, and Jahjah (2005) take issue with this view, finding remittances to be negatively correlated with economic growth, compensatory in nature, and sent to families during hard times. As such they do not view remittances as a source of funding for investment and growth. Fajnzylber and López (2007) find that remittances contribute to surprisingly modest economic growth, while Adams and Page (2005) credit remittances with reducing both the rate and depth of poverty in developing countries.

The scorecard on remittances becomes even more difficult to interpret when we consider that remittances have uneven, time-sensitive, and redistributive effects. For example, given that international migration is costly, the benefits from remittances often bypass the poorest, who lack the means to finance migration. But this is found to change over time because as migration networks become more widespread, individuals lower in the income distribution obtain the means to migrate and in turn benefit from remittances too (McKenzie 2005).

Additional redistributive impacts may result when remittance spending patterns cause the relative prices of nontraded goods to increase, causing real exchange rate appreciation. This places the export sector in a less competitive position and results in an additional set of gainers and losers. If national policy

is set on fueling economic development via export growth, changing real exchange rates due to remittances may thwart those efforts.

Microeconomic impacts: Understanding the microeconomic impacts of remittance inflows might help settle some of the controversy regarding their macroeconomic impacts. Are remittances all "squandered away" on consumption and thus have no chance to contribute toward longer-term economic growth? Or are these flows invested, increasing the physical and human capital stock? Surveys that simply ask senders what the transfers are intended for have sometimes been consulted to determine the share invested and the share consumed. But while senders claim to transfer money for specific purposes, it lies with the recipient to actually allocate the inflows.

Many researchers use microeconomic-level surveys that link remittances with household characteristics. Using such, Cox Edwards and Ureta (2003) found that remittances positively affect the level of schooling in children. Others, however, have found only very modest increases in schooling levels due to remittances. Differences in research outcomes are likely due to difficulties in separating the "migration effect" from the "remittance effect." Remittances are often a by-product of migration by a household member. Although remittances may loosen liquidity constraints, facilitating school attendance, the absence of a family member may force children to assume the role of an absent member in home or market work, reducing time available for school.

What is the impact of remittances on work behavior? Do remittances promote dependency by inducing individuals who would otherwise work to refrain from supplying their labor? Amuedo-Dorantes and Pozo (2006) find that women remittance recipients in Mexico appear to work fewer hours, perhaps because the additional income allows the women to tend to children instead. Men also appear to change their behavior but not in terms of hours of work. They appear to move away from formal sector work and toward informal sector work much of which is self-employment. Perhaps

remittances facilitate self-employment by providing resources to acquire the necessary capital stock or a "backup fund" to permit the recipient to engage in riskier entrepreneurial ventures. Evidence that remittances are used for the acquisition of physical capital is furthered by Woodruff and Zenteno (2007), who find that attachments to migration networks in Mexico are associated with increases in investments in microenterprises.

Since migrants are complex individuals facing a variety of choices, circumstances, and constraints, it stands to reason that there are many different motives for remitting. Differing motives will result in varying impacts of remittances. In many cases the impacts will benefit recipients, but in other circumstances they might not. Nevertheless, remittances will likely continue to grow and take on greater importance. Continued research to further our understanding of remittances will permit the tailoring of policy to better unlock their potential to do good for recipient households and nations.

■ **reserve currency**

A reserve currency is a foreign currency held by central banks or monetary authorities for the purpose of exchange intervention (to influence the exchange rate of the national currency) and the settlement of intergovernmental claims (debts). A reserve currency is also used in the pricing of goods, services, and assets entering international trade and finance. A reserve-currency status allows the nation issuing the currency to pay a somewhat lower price for imports (because it need not incur the small cost of exchanging its cur rency for another to pay for its imports), borrow at marginally lower rates, and earn seigniorage (the difference between the minimal cost of printing money and its face value).

The U.S. dollar is by far the largest vehicle cur rency in the world today. The euro (the currency of the European Monetary Union, or EMU) has in creasingly been used as a vehicle currency since its creation in 1999. To be a vehicle currency, a national currency must (1) be stable in value; (2) belong to a nation that occupies a central, or at least a very im portant, position in world production, trade, and finance; and (3) be fully convertible into other cur rencies and freely tradable in a viable foreign ex change market.

Table 1 shows that the share of national currencies in official holdings of foreign exchange reserves in the

form of U.S. dollars rose from 62.1 percent in 1996 to 71.0 percent in 1999, declined to 65.8 percent in 2004, then rose to 66.5 percent in 2005. The Japanese yen was 6.7 percent of the total in 1966 but declined to 3.6 percent in 2005; the British pound was 2.7 percent in 1996 and rose to 3.7 percent in 2005; the Swiss franc's share was very small (0.3 percent) both in 1996 and in 2005 (0.1 percent). The euro accounted for 17.9 percent of official holdings of foreign currency reserves in 1999 (the year of its

[a] Includes foreign exchange reserves whose currency composition could not be determined.

creation) and rose to 25.3 percent in 2003; it was 24.4 percent in 2005. This was less than the EMU's share of world output and trade but much larger than the sum of the share of the deutsche mark, French franc, Netherlands guilder, and ECU foreign currency reserves that it replaced. The ECU (the European Currency Unit) was introduced in March 1979 by the European Monetary System (EMS), a forerunner of the EMU. On December 31, 1998, ECUs were unwound into gold and dollars. Table 2 gives the dollar amount of the various foreign exchange reserves from 1996 to 2005.

Before World War I, gold was the only international reserve held by nations and the British pound was the only important international currency. Under the Bretton Woods system, which operated from 1947 until 1971, the value of the U.S. dollar was fixed in terms of gold and the international value of other currencies were then fixed in terms of dollars. The fact that U.S. dollars held by foreign central banks were redeemable in gold made the dollar "as good as gold." In time, a few other currencies joined the dollar as international currency reserves. Thus the Bretton Woods system was a gold-exchange standard, with both dollars and international currency reserves held as official reserves by nations' central banks and monetary authorities.

After World War II, the dollar replaced the British pound as the most important international reserve currency, to reflect the much greater importance of the United States than the United Kingdom in world output, trade, and finance, and also because the dollar better satisfied the other conditions for serving as an international reserve currency. The British pound, however, remained a significant international reserve currency after World War II because of tradition (recognition) and inertia, but its importance declined sharply after the mid-1970s when the pricing of petroleum and other primary commodities switched from British pounds to U.S. dollars.

In August 1971, the dollar was devalued (the dollar price of gold increased) and its convertibility into gold was abolished, thus ushering the world into a pure paper (essentially a de facto dollar) standard.

Early in the 21st century, foreign exchange reserves constitute the bulk of international reserve assets, with the dollar by far the largest and the euro second largest. Although gold remains an important international reserve asset, its relative importance has greatly diminished. Other official reserve assets are nations' net IMF positions (the amount that a nation could borrow without questions asked by the International Monetary Fund, or IMF) and special drawing rights, or SDRs.

In the present managed exchange rate system, the importance of international reserves ought to be less than under the previous fixed exchange rate system because a nation facing a balance of payments deficit can allow its currency to depreciate, thus correcting its deficit without the need to continuously finance it with international reserves unless more drastic forms of adjustment become necessary, such as a devaluation of the currency or import restrictions.

■ revealed comparative advantage

Revealed comparative advantage (RCA) is an empirical measure of the extent to which a given country specializes in the export of a particular product or range of products, compared with a reference set of countries. It is usually computed from trade data.

International trade theory starts from the premise that production specialization across different countries, followed by exports of the goods specialized in and imports of goods specialized in by other countries, leads to overall welfare gains for all economies. The pattern of specialization is called "comparative advantage," which is the result of relative advantage in access to materials, energy, or technological skills that are crucial for the efficient production of the exported good. Other countries would establish relative advantages in other goods that they export. The patterns of exports and imports would then derive from this relative or comparative advantage in production.

Trade theory begins by predicting patterns of trade from the existence of relative or comparative differences in natural resource endowments or capability acquired from production experience or technological change. The RCA approach starts from the other end of the production-trade chain, that is, the empirically observed patterns of export and import specialization revealed by the trade data. The explanation of the pattern of specialization is treated as a secondary matter to be inferred from the observed data on trade. Thus if the proportion of wine in France's exports is higher than the ratio of wine to all exports in the Organisation for Economic Co-operation and

Development (OECD) group as a whole, France is said to have revealed comparative advantage in the export of wine relative to the OECD reference set. Note that this does not imply that France would have RCA with respect to some other set of countries.

Origin and Mathematical Formulation The index most commonly used to measure RCA is the Balassa index (BI), which was developed and popularized by Bela Balassa (1965, 1989), though the concept of a specialization index was first proposed by Liesner (1958). If we wish to examine whether country i has manifest advantage in the export of product line j (at some level of product aggregation) over a set of reference countries represented by the symbol w, we construct the following simple Balassa index:

$$BI_{ij} = \textit{share of j in country i's exports/} \atop \textit{share of j in set w's exports} \quad (1)$$

If BI_{ij} is greater than 1.0, then country i would have RCA in product line j with respect to reference set w, since a proportionately greater share of its exports consist of j. If BI_{ij} is less than 1.0, the country is said to have revealed comparative disadvantage in good j. If we wish to be precise, we would have to specify the set w in the index as well, say as BI_{ijw}, since the index depends on the particular set of countries chosen. Exports are measured as total export values to the rest of the world expressed in a particular year's currency units. Clearly this index is very simple to compute from the actual trade data for any level of aggregation of export lines and is intuitively meaningful.

The index can also be extended from a single country i to a set k within a larger reference set w. For example, if we wish to compute the RCA of advanced industrial countries (AIC) in the export of capital goods, we would need to first aggregate all capital goods exported by all AICs and compute the share of these in total exports. This ratio would then have to be divided by the share of aggregated capital goods in total world exports. The index can be similarly modified to track the relative strength of any given trading region with respect to any particular characteristic of

exports, provided that it can be quantified, measured, and aggregated across a range of product lines.

In formal terms the Balassa, or revealed comparative advantage, index is often defined as follows for exporting region i, export line j and reference region w, where X_{mn} stands for export value of good n from region m and t stands for all exports from the particular region. The reference set w is often taken as the whole world:

$$RCA_{ij} = (X_{ij}/X_{it})/(X_{wj}/X_{wt})$$
$$= (X_{ij}/X_{wj})/(X_{it}/X_{wt}) \qquad (2)$$

Practical Issues Since its initial formulation, RCA indexes have been widely used to track specialization with regard to participation in the international economy. Starting from specialization in particular goods or ranges of goods, RCAs have been calculated for goods intensive in capital or labor, intermediate products, energy, a wide range of agrobased exports, and exports that use particular technologies. It is often the "first cut" analytical tool in export competitiveness studies carried out by academics and international consultants.

RCAs are even worked out for the generation of patentable innovations (Laursen 1998). The RCA concept has turned out to be a very flexible tool of analysis and the original formula has been modified in a wide variety of ways, a few of which are outlined in the next section. It is also clear that the formulation can be adapted easily for import specialization as well and there are indexes that use both export and import data.

RCAs must be used with some care. They are useful to identify sectors that are strong and have the potential to be built up further. But the index cannot be used to infer competitive strength vis-à-vis another country in the same reference set. A large country with a more diverse range of exports will have a smaller RCA than a small nation that concentrates on a much smaller set of exports but has comparable competitive strength. Nor do relative values of different products for the same country say much about the relative importance of these products for the economy. For example, tobacco has the highest Balassa index for the United States over a long time

span, but this is hardly its most important export product (Marrewijk 2002).

RCA measures are also affected by trade barriers or subsidies since these could distort exports or raise production costs by raising the price of imported inputs. Reexports and a high degree of intraindustry trade also pose special problems, which can be handled by the use of alternative measures (Laursen 1998; Utkulu and Seyman 2004).

Extensions One problem with the basic Balassa index is that it is not symmetrically distributed around the neutral value 1.0, ranging from 0 to 1 for comparative disadvantage and indefinitely upward from 1.0 for comparative advantage products. This problem is easily corrected by taking natural logarithms of the ratios with the index defined as follows:

$$RCA_{ij} = \ln(X_{ij}/X_{it}) - \ln(X_{wj}/X_{wt}) \qquad (3)$$

The revised index is now symmetric around 0. This form is particularly useful for econometric studies. An alternative transformation, which yields RCA values between 1 and +1 around 0, is given in Laursen (1998), but it is probably less useful than the log form for econometric work.

Vollrath (1991) proposed the following alternative index of trade specialization, which brings imports into the calculation:

$$RCA_{v1} = RXA - RMA \qquad (4)$$

Where $RXA = (X_{ij}/X_{it})/(X_{wj}/X_{wt})$, the original export specialization index, and $RMA = (M_{ij}/M_{it})/(M_{wj}/M_{wt})$, which is a similar import specialization index.

An alternative formulation of the Vollrath index takes the following form:

$$RCA_{v2} = \ln RXA - \ln RMA \qquad (5)$$

The Michaely index MI (see Laursen 1998) for country i and product j is defined as the difference between the share of sector j in total exports minus the share of sector j in total imports. There is no reference set of countries, so the index ranges from 1 to +1 and is 0 if import shares are perfectly balanced with export shares:

$$MI_{ij} = X_{ij}/X_{it} - M_{ij}/M_{it} \qquad (6)$$

A particularly useful measure of normalized revealed comparative advantage (NRCA), proposed by Yu et al. (2008), is defined in equation 7, where w

refers to the entire world and t to total exports. This index can be interpreted as the deviation of the normalized value of country i exports of product line j with respect to total world exports (the first term) from its expected comparative advantage neutral value (the second term).

$$NRCA_{ij} = X_{ij}/X_{wt} - X_{wj} \cdot X_{it}/X_{wt}^2 \qquad (7)$$

The equivalent form of equation 8 shows an alternative deviation kernel (term one) normalized by the relative weight of country i exports in world exports (term two).

$$NRCA_{ij} = [X_{ij}/X_{it} - X_{wj}/X_{wt}]\{X_{it}/X_{wt}\} \qquad (8)$$

This index has some useful properties: it is symmetrical about zero and displays additive consistency across product lines and country groupings. It just needs to be scaled up by an arbitrary factor to facilitate numerical comparisons, since both terms in equation 7 yield very small values; but this is no problem since RCA is a relative measure in any case. Furthermore the sum of NRCA across all commodities for any one country is zero as is the sum of NRCA across all countries for any one commodity.

Overall the RCA concept has proved to be an enduring and easily computable measure that can be used to track patterns of trade and production specialization. It has been used to study the performance of individual countries or groups of countries with respect to a larger set or even to comprehensively compare countries with one another, as in Batra and Khan (2005), which compares the evolution of India and China. RCA is therefore a very useful and powerful tool of trade analysis, used by academics and economic consultants to study evolving patterns in the world economy.

G. CHRIS RODRIGO

■ Ricardian model

The Ricardian model is the simplest and most basic general equilibrium model of international trade that

we have. It is usually featured in an early chapter of any textbook on international economics. Historically, it is the earliest model of trade to have appeared in the writings of classical economists, at least among models that are still considered useful today.

It is indeed still useful. In spite of being superseded over the years by models with much more complexity (more factors of production, increasing returns to scale, imperfect competition), the Ricardian model often provides the platform for the introduction of today's new ideas. Dornbusch, Fischer, and Samuelson (1977) examined a continuum of goods first in a Ricardian model. Eaton and Kortum (2002) incorporated an ingenious and elegant treatment of geography into a Ricardian model. Melitz (2003) started a small revolution in trade theory by modeling heterogeneous firms within what was essentially a Ricardian model.

The Ricardian model itself, as a new idea, came many years after Ricardo. According to Ruffin (2002), in 1816 David Ricardo introduced only a portion of the model that now bears his name, focusing primarily on the amounts of labor used to produce traded goods and, from that, the concept of comparative advantage. The first appearance of the Ricardian model, according to Ruffin again, was in Mill (1844).

The Simple Ricardian Model The simple Ricardian model depicts a world of two countries, A and B, each using a single factor of production, labor L, to produce two goods, X and Y. Technologies display constant returns to scale, meaning that a fixed amount of labor, a_g^c is needed to produce a unit of output of each good, $g = X,Y$, in each country, $c = A,B$, regardless of how much is produced in total. All markets are perfectly competitive, so that goods are priced at cost in countries that produce them, $p_g^c = w^c a_g^c$, where w^c is the competitive wage in country c. Labor is available in fixed supply in each country, L^c; it is immobile between countries but perfectly mobile within each. The Ricardian model typically leaves demands for goods much less fully specified than supplies, though a modern formulation may specify for each country a utility function, $U^c = U^c(C_x^c, C_y^c)$, which the representative con-

sumer maximizes subject to a budget constraint. Utility functions may, or may not, be assumed in addition to be identical across countries, or to possess other regularity properties, although most properties of the model's solution do not require any of these assumptions.

The most basic use of the model compares the equilibriums in autarky (that is, complete self-sufficiency without trade) with those of free and frictionless trade. In autarky, since both goods must be produced in each country, prices are given immediately by the costs stated above, and further analysis is needed only if one wants to know quantities produced and consumed. If so, the linear technology implies a linear production possibility frontier (PPF) that also serves as the budget line for consumers in autarky. The autarky equilibrium is as shown in figure 1, where $\tilde{~}$ indicates autarky and Q represents production.

Comparison of the two countries in autarky depends primarily on their relative costs of producing the two goods, which in this model defines their comparative advantage. For concreteness, assume that country A has comparative advantage in good X: $a_X^A/a_Y^A < a_X^B/a_Y^B$, so that $\tilde{p}_X^A/\tilde{p}_Y^A < \tilde{p}_X^B/\tilde{p}_Y^B$. Without further assumptions about preferences, little more can be said about autarky, but with addi-
Figure 1
Ricardian model equilibrium in autarky

tional assumptions about preferences, one can infer that $\tilde{Q}_X^A/\tilde{Q}_Y^A > \tilde{Q}_X^B/\tilde{Q}_Y^B$.

With free and frictionless trade, prices must be the same in both countries. Two kinds of equilibrium are possible, depending on the supplies and demands for goods in the two countries. One kind of equilibrium has world relative prices, denoted here by ˇ, strictly between the relative prices of the two countries in autarky: $\tilde{p}_X^A/\tilde{p}_Y^A < \check{p}_X/\check{p}_Y < \tilde{p}_X^B/\tilde{p}_Y^B$. In that case, each country must specialize in producing only the good for which its relative cost is lower than the world relative price, thus the good in which it has comparative advantage. Each must necessarily export that good.

With such complete specialization, outputs of the goods are determined by labor endowments and productivities, so equality of world supply and demand must be achieved from the demand side. That is, world prices are determined such that the two countries' demands sum to the quantity produced in one of them. These demands derive from the expanded budget constraints of each country's consumers, reflecting the value at world prices of the single good that the country produces. Consumers can now, unless they wish to consume only that single good, consume more of both goods than they did in autarky. Whether they choose to do so depends on the extent to which they substitute toward the cheaper good now imported from abroad, but in any case they reach a higher indifference curve and are better off. All of this is shown in figure 2. For this to be an equilibrium, the quantity of each good exported by one country must equal the quantity imported by the other, so the heavy arrows showing net trade in each panel of the figure must be equal and opposite.

Such an equilibrium with specialization will arise only if the two countries' capacities to produce their respective comparative-advantage goods correspond sufficiently closely to world demands for the goods. If this is not the case   if one country's labor endowment is too low and/or its labor requirement for producing its comparative-advantage good is too high for it to satisfy world demand   then while that country will specialize, the other country (call it the larger one, although that is not strictly necessary) will not. Instead of world relative prices settling between the two autarky levels as described earlier, prices will exactly equal the autarky prices of the larger country, and that country will produce both goods. At those prices, producers in the larger country will be indifferent among all output combinations on the PPF,
Figure 2

Free trade equilibrium with complete specialization

and output in the large country will be determined instead by the need to fill whatever demand is not satisfied by the smaller country.

Such an equilibrium is shown in figure 3, where in comparison to figure 2 country B's labor endowment has been made smaller and both countries' preference for good Y has been increased. As a result, country B is too small to meet world demand for good Y, even at country A's autarky prices. Therefore the free trade equilibrium has country A consuming where it did in autarky, while its production, $\breve{Q}^A$, moves down along its PPF so that, again, its trade vector can be equal and opposite to that of country B. Note that, in this trading equilibrium, the larger country neither gains nor loses from trade.

The following are some of the implications of this simple model, some of which have been illustrated above, while others can be derived rather simply:

Effects of trade:

- Each country exports the good in which it has comparative advantage, as defined by having a lower relative autarky price than the other country.
- Trade causes each country to expand its production of the good it exports, with labor being reallocated to it from the import-competing industry.

- Trade causes the relative price of a country's export good to rise, except in the case of a "large" country, defined here as one whose trading partner is too small to meet its demand for imports.
- Consumption and welfare are unchanged by trade in a large country; in any country that is not large, consumers buy more of one or both goods and welfare increases.
- Because all income accrues to labor, which earns the same wage in both industries due to mobility, conclusions about welfare or utility apply equally well to the real wage.

Effects of changes in trading equilibriums (assuming a bit more about preferences):

- An increase in the labor endowment of a country, holding other labor, technology, and tastes constant, hurts the growing country and benefits the other.
- A fall in the labor required by a country to produce its export good, holding other technology, endowments, and tastes constant, benefits the other country but may either benefit or harm ("immiserize") the growing country.
- A rise in the labor required by a country to produce its import good has no effect if it does not produce that good; if it does pro-
Figure 3

Free trade equilibrium with country A incompletely specialized

duce it (like country A in figure 3), the world price of that good rises, that country is harmed, and the other country gains.

- A change in preferences, in either country, in favor of one of the goods has no effect on prices or production if one of the countries is incompletely specialized. If both are specialized, however, then the relative price of that good rises, improving the terms of trade of the country that exports it.

Extensions of the Simple Ricardian Model Before considering several extensions of the simple model described here, it is reasonable to ask what extensions would *not* be acceptable, in that they would lead to a model that would no longer be "Ricardian," as trade economists understand the term. Ricardo himself might disagree, were he alive, but the essential features of a Ricardian model seem to be two: that production uses only homogeneous labor as a primary input and that comparative advantage arises from differences across goods and countries in the technology for producing goods from that labor. Both of these requirements distinguish a Ricardian model from the other principal model of trade theory, the Heckscher-Ohlin or factor-proportions model. With primary factors other than labor (including different kinds of labor based on skill and/or industry of location), a model takes on features that differ in essential ways from the Ricardian model. On the other hand, with only homogeneous labor as a factor of production, if technologies do not differ across countries then there is no scope for comparative advantage based trade.

More Goods and/or Countries Therefore, keeping the number of factors at one, the most obvious things to extend in the simple model are to add to the numbers of goods and/or countries. This is relatively easily done, as long as one does not try to do both.

With two countries and many goods, the goods can be ranked in a chain of comparative advantage based on the ratios of their unit labor requirements in the two countries. That is, if one numbers N goods such that $a_1^A/a_1^B < a_2^A/a_2^B < \cdots < a_N^A/a_N^B$, then country A has comparative advantage in the low end of this ranking while country B has it in the high end.

Further one can show that under free trade, each country will specialize in and export goods in its respective end of the chain, with at most one good (and perhaps no good) being produced in common by both countries. The division between A's exports and B's exports depends on country sizes, technologies, and tastes, much as in the choice between figures 2 and 3. For example, the larger the labor endowment and/or efficiency of country A compared with B, the further up the chain will A produce and export.

Similarly, with two goods and many countries, the countries can be ranked in a chain of comparative advantage based on the ratios of their unit labor requirements for producing the two goods. That is, if one numbers M countries such that $a_X^1/a_Y^1 < a_X^2/a_Y^2 < \cdots < a_X^M/a_Y^M$, those countries in the low end of this ranking will specialize in and export good X to those in the high end, which export good Y. Again there will be at most one country (and perhaps no country) that produces both goods. And the division between X-exporters and Y-exporters depends on country sizes, technologies, and tastes.

Unfortunately, extending to more than two of both goods and countries is not so simple or intuitive. Jones (1961) seems to have done about as well as one can, showing that an efficient assignment of countries to goods will minimize the product of their unit labor requirements. This certainly suggests the importance of comparative advantage, in the form of low relative unit labor requirements, which is perhaps all that one should hope for from a many-good, many-country Ricardian model (though see Eaton and Kortum's solution to this problem, which we discuss later).

A Continuum of Goods A less obvious, but much more useful, extension of the Ricardian model was provided by Dornbusch, Fischer, and Samuelson (1977) hereinafter DFS who took the number of goods to infinity, in the form of a continuum. Indexing goods by the continuous variable j on the interval [0,1], they specified technologies for each of two countries as $a^c(j)$ representing the amount of labor required in country c to produce one unit of good j. The ratio of these in the two countries of the model, ordered monotonically in a function $A(j)$,

then plays the same role as the chain of relative labor requirements mentioned earlier for the many goods case. But with a continuum of goods, the good at the dividing line between a country's exports and its imports is of negligible importance for labor markets, since it employs a negligible amount of labor, and this removes the need to consider whether a good is produced in both countries. Such a good now always exists, as the dividing line between one country's exports and its imports, but it is of negligible importance for employment.

This simplicity is helpful in itself, but the more important advantage of the continuum model is that it facilitates the analysis of the range of goods that a country will export and import, something that the two-good model could not usefully address. One finds, for example, that an expansion of the labor endowment of one country relative to the other will cause it to expand its exports, not just by exporting more of what it already exported (though that happens too), but by exporting goods that it previously imported.

The model in its simplest form is depicted in figure 4, which is taken directly from DFS's figure 1. The downward sloping function $A(j)$ is the ratio of the two countries' unit labor requirements, ordered so that country A's comparative advantage declines with rising j. Letting $\omega = w^A/w^B$, for any given value of this relative wage, free and frictionless trade will lead to country A producing and exporting all goods with $A > \omega$ and importing goods with $A < \omega$. To determine the equilibrium value of ω one needs assumptions about demand, which are reflected in the upward sloping curve $B(j; L^B/L^A)$. Assuming that preferences are identical and that constant shares of expenditure are spent on each good, this curve measures the relative wage at which demands for each country's range of goods produced would equal their supplies (or, equivalently, the relative wage at which values of a country's exports and imports will be equal). This requires simply that the ratio of expenditures on the two sets of goods equals the ratio of the incomes of those who produce them. As the definition of this market-clearing relative wage shown in figure 4 indicates, it depends positively on $\vartheta(j)$, the

fraction of income spent on the goods produced by country A, which in turn rises with the fraction of goods that A produces. It also depends positively on the relative size (labor force) of country B, since the larger that is, for a given division of goods between the two countries, the higher must be the relative wage in A to keep the expenditure ratio constant.

Figure 4 immediately yields the result mentioned earlier, that as a country's labor force rises relative to the other country (shifting the B curve up or down), its share of goods produced increases as well, while its relative wage falls. Likewise, if a country becomes more productive in producing all goods (its $a^i(j)$ shifts down, shifting the A curve up or down), it also produces more goods but its relative wage increases. Other exercises are possible with the simple model, and DFS extend the model in a variety of directions to illuminate many issues that could not be readily addressed in models with a finite number of goods.

Most notably, they incorporate transportation costs, giving rise to a third endogenous range of goods, in addition to those exported by countries A and B: nontraded goods, whose costs differ too little between countries to overcome the barrier of transportation costs. This is particularly useful, since it
Figure 4

Ricardian model with a continuum of goods

implies that as a country's relative productive capacity rises, some of the goods it previously imported become nontraded, while it begins to export some of the goods that were previously nontraded.

Multiple Countries with Random Technologies A limitation of the DFS model is that it applies to a world of only two countries, and because of its reliance on ratios of values in those countries it is not readily extended to more, although some (e.g., Wilson 1980) have had some success. A breakthrough was provided by Eaton and Kortum (2002), however, who extended the DFS model to an arbitrary number of countries by assuming that, in effect, the labor productivities of each good and country are determined randomly. Specifically, they let labor productivity, $z^i(j) = 1/a^i(j)$, be determined by a random draw from a probability distribution, such that each country has some probability, regardless of its overall technical ability and its wage, of having a lower cost than any other country. This probability, then, translates into the fraction of the continuum of goods that the country is able to produce and export under free and frictionless trade. More important, by including transportation costs for each pair of countries, each country has a fraction of goods that it will be able to produce even without necessarily having the lowest costs, since they only need to cost less than goods from other countries inclusive of transportation cost. Furthermore if transportation costs are low enough that a country imports anything, then it will also export some fraction of goods, since if necessary the wage will fall until some fraction of goods can be exported to one or more countries for delivered prices below those countries' domestic prices. This formulation therefore extends the Ricardian model not only to multiple countries but to a context that can account for bilateral trade.

The Eaton-Kortum model generates equations for prices and trade shares that provide the basis for empirical estimation as well as being susceptible to solution and comparative static analysis by numerical methods. The model provides an elegant and parsimonious theoretical justification for the gravity model of bilateral trade flows while illustrating the interaction between the forces of comparative advantage that give rise to trade and the geographical resistance to those forces in the form of transportation and other costs of trade that limit trade and direct it over particular geographical routes.

The Role of the Ricardian Model in Understanding the World Economy The Ricardian model was introduced long ago to explain one of the most basic concepts of economics, comparative advantage, but it continues to be useful as a framework for understanding how countries interact in trade. Countries continue to differ in their abilities to produce goods and services, and the extent of these differences varies across products. This is not the only reason for international trade, but it is surely the most basic. Modern extensions of the Ricardian model are essential for understanding this trade and anticipating its effects.

ALAN V. DEARDORFF

■ **rules of origin**

Rules of origin (ROOs) specify the conditions under which a good is deemed to originate from a country and hence is eligible for preferential treatment. Such treatment could involve zero or preferential tariffs in a free (or preferential) trade area (FTA), or the right to export under a country-specific quota as under the old Multifiber Arrangement regime in textiles and clothing. Since there are zero (or preferential) tariffs on goods imported from member countries of an FTA, but tariffs on nonmembers differ across coun tries, the opportunities for arbitrage are obvious: imports into the area as a whole should take the path of least resistance, that is, enter through the country with the lowest tariffs on them and flow freely from there into other FTA member markets. As a result the lowest-tariff country would gain tariff revenue at the cost of other members. This suggests that countries would compete to set the lowest tariffs in order to attract such trade flows (see Richardson 1995). This seems to have actually happened in the United States after the colonies obtained independence from the British but before they fully integrated and set a common tariff (see McGillivray and Green 2001; Viner 1950). ROOs are seen as limiting such arbi trage possibilities.

Defining ROOs There are four common criteria for defining rules of origin.

1. Domestic content: content can be defined in terms of value added or in physical terms.
2. Change in tariff heading (CTH): a product must change its tariff heading (i.e., where it is classified in the tariff code) in a specified way within the FTA or customs union (CU) to obtain origin and hence be eligible for the preferential treatment reserved for the country.
3. Specified process: this outlines the processes that must be performed within the FTA or CU to obtain origin. Restrictiveness de pends entirely on the steps prescribed and the nature of the production technology. The difference between this and the CTH criterion is only that the latter is based on some commonly used descriptions such as the tariff code, whereas the specified process definition is defined in terms of production processes specific to each industry.

4. Substantial transformation: this is more loosely defined. In the United States the term *substantial transformation* has come to mean the determination of origin based on common law, reasoning from case to case. This process results in a commodity-specific ROO that falls into one of the first three categories.

Origin requirements can be made more restrictive by requiring more than one criterion to be met. Exceptions can also be used to make the origin requirement more restrictive. For example, under the North American Free Trade Agreement (NAFTA), transformation from any other chapter (two-digit classification level) of the harmonized system to tomato catsup, chapter 21, confers origin *except* transformation from tomato paste, which falls in chapter 20!

Effects of ROOs Although it is tempting to think of ROOs as necessary bureaucratic nuisances, they are often far more. First, ROOs raise the costs of exports when they force a firm to use a particular process or input to obtain origin. This cost increase can significantly erode the benefits supposedly offered to developing country exports through special trade preferences. For example, Mattoo et al. (2002) argue that the value of concessions by the United States under the African Growth and Opportunity Act are cut in half by stringent ROOs. In addition, ROOs are often quite expensive to document, as detailed records need to be kept and certification procedures may need to be followed. As a result, even if a product satisfies origin, an importer may prefer to pay the tariff rather than bother with the documentation needed. Herin (1986) shows that the cost of proving origin seems to have led more than a quarter of European Free Trade Area (EFTA) exports to pay the tariff despite the possibility of not having to do so. These costs are a pure waste of resources and work to reduce aggregate income and welfare.

Second, ROOs are, in themselves, a form of hidden protectionism: they provide an incentive for regional producers to buy intermediate goods from regional sources, even if their prices are higher than those of the identical import from outside the FTA, in order to make their product originate in the FTA and qualify for preferential treatment. This, in effect, protects FTA suppliers. As a result, trade patterns and investment flows needed to sustain them can be profoundly affected by a FTA. Consider a producer of shirts in Bangladesh. If he uses imported fabric the shirt would not meet the ROOs under the EBA (everything but arms) initiative and be eligible for zero tariffs in the European Union (EU). Only when cloth made from Bangladeshi yarn (the so-called yarn forward rule) is used is origin granted. Otherwise, the most-favored-nation tariff (of about 12 percent to 15 percent) is applied. As a result, the shirt maker is better off using more expensive Bangladeshi cloth, so long as the Bangladeshi cloth does not raise his costs by more than the amount he saves by avoiding the tariff. In this manner, the ROOs act as a hidden subsidy for domestic cloth and a tax on imported cloth; small wonder that Bangladeshi textile producers support such ROOs, while apparel exporters oppose them (Demidova, Kee, and Krishna 2006).

Third, as ROOs are negotiated industry by industry during the negotiations for the agreement, they are both hard to change ex post and allow enormous scope for well-organized industries to essentially insulate themselves from the effects of the FTA by devising suitable ROOs. The fact that ROOs are negotiated in such an industry-specific manner may be exactly why FTAs are so popular; however, they allow organized interest groups to evade the FTA by setting strict ROOs, thereby removing their opposition to the FTA. Grossman and Helpman (1995), for example, argue that being able to exclude certain sectors (what appropriately constructed ROOs will do) can make an FTA viable.

That ROOs may be protectionist does not prove that they are. Work by Estevadeordal (2000) suggests, however, that ROOs are being used to prevent trade deflection, as the sectors that have large differences in tariffs between the partners are the ones where ROOs are strongest. The work of Anson et al. (2005) on NAFTA also suggests that ROOs negate the effects of tariff reductions due to an FTA. They show that while the severity of ROOs reduced

Mexican exports, tariff preferences raised them, and the net effect was close to zero.

As ROOs are extremely opaque and arcane, they are easily overlooked, and given that there is much potential for abuse, the cost of overlooking them may be substantial.

S

▪ safeguards

The term *safeguards* refers to trade intervention by national governments to address the injurious effects of import surges on import-competing industries. Trade intervention for this purpose has been subject to discipline under the General Agreement on Tariffs and Trade (GATT) since its inception in 1947 pursuant to GATT Article XIX. During the Uruguay Round of GATT negotiations, which culminated in the creation of the World Trade Organization (WTO) in 1994, discipline over safeguard measures was expanded and deepened through a new WTO Agreement on Safeguards. In addition, Article X of the General Agreement on Trade in Services authorizes negotiations over the possibility of safeguards in service sectors, but those negotiations have not yet resulted in any agreement. Consequently, safeguards are confined to goods sectors.

The Legal Foundation for Safeguards and Its Evolution in the WTO GATT Article XIX(1) provides:

> If, as a result of unforeseen developments and of the effect of the obligations incurred by a contracting party under this Agreement, including tariff concessions, any product is being imported into the territory of that contracting party in such increased quantities and under such conditions as to cause or threaten serious injury to domestic producers in that territory of like or directly competitive products, the contracting party shall be free, in respect of such product, and to the extent and for such time as may be necessary to

> prevent or remedy such injury, to suspend the obligation in whole or in part or to withdraw or modify the concession.

Article XIX thereby establishes four prerequisites for the use of safeguards. First, imports of the good(s) in question must have increased. Second, the increase must be a result of "unforeseen developments" and the "effect of the obligations incurred" under GATT. Third, the import-competing domestic industry must be suffering "serious injury" or a threat of such injury. Finally, a causal linkage must exist between the import surge (or the underlying developments that precipitated it) and the present or threatened injury.

Paragraphs two and three of Article XIX further provide that a party invoking its right to suspend or modify concessions must negotiate with adversely affected parties over the possibility of compensatory trade concessions. If these negotiations are unsuccessful, safeguards may be imposed nonetheless, but adversely affected trading partners then have the right to suspend "substantially equivalent concessions" in response. Thus the original structure of Article XIX permitted the use of safeguards but only at a price the GATT bargain was to be rebalanced either through an offer of trade compensation (the preferred outcome) or through a retaliatory withdrawal of substantially equivalent concessions.

Over the years, formal reliance on Article XIX within the GATT system diminished. Safeguard measures were largely replaced by what came to be known as "gray area" measures, such as voluntary restraint agreements and orderly marketing

agreements. These agreements were typically negotiated on a bilateral basis with major suppliers.

The proliferation of gray area measures was viewed as a serious problem by many observers. Gray area measures were not time-limited in the manner contemplated by Article XIX(1) and were employed regardless of whether the prerequisites for safeguards under Article XIX were met. In addition, gray area measures were often discriminatory in their impact, as less significant or less competitive suppliers were often exempted. A constituency thus developed for reform, which culminated in the Agreement on Safeguards in the Uruguay Round.

A key achievement of this agreement was a prohibition on gray area measures in Article XIII, coupled with a requirement for the phase out of existing gray area measures. In addition, to make reliance on formal safeguards more attractive, Article VIII(3) eliminated the rebalancing requirement (compensation or retaliation) for the first three years of any safeguard measure imposed in compliance with the agreement following an absolute increase in imports (as distinguished from a mere increase in their market share).

Other significant features of the agreement include a general prohibition on discriminatory safeguard measures, along with numerous transparency and procedural requirements applicable to any decision by national authorities to employ safeguards. The agreement limits the duration of safeguards to a maximum of eight years and provides that members proposing to employ them for more than four years must demonstrate anew that the prerequisites for safeguard measures are satisfied. It also requires progressive liberalization of safeguards over the course of their application.

The Agreement on Safeguards appears to have achieved its central objective. Preexisting gray area measures have been abolished, and WTO members have not sought to introduce new gray area measures. Likewise, formal reliance on GATT Article XIX is now far more common than in the waning years of GATT.

Safeguards have been a frequent target of litigation in the WTO system, however, and in every case to date that has reached the point of a formal ruling, the challenged measure has been ruled illegal. In some instances, national governments using safeguards have ignored obvious requirements under the law, but the litigation has also revealed some fundamental problems with the treaty text and with the ability of WTO members to implement it faithfully. The most difficult issues arise in connection with the requirement that import surges be attributed to "unforeseen developments" and with the requirement of a causal linkage between import surges and serious injury or threatened injury. We consider these issues further after reviewing the state of economic thinking about the proper role of safeguards in the international trading system.

The Economic Function of Safeguards The standard economic case for free trade counsels against the use of safeguards. They create the deadweight costs of protection while delaying the redeployment of resources in declining industries to more productive uses. Only if safeguard measures were routinely coupled with compensatory trade concessions would there be any basis for hope that their direct welfare effects are reasonably benign, but compensation has been the exception rather than the rule in practice.

Why, then, do nations employ safeguards, and why does the WTO/GATT system permit them? The answers to these questions are not entirely clear, although they have sparked a considerable amount of political and academic commentary.

Perhaps the most often invoked arguments for safeguard measures are those recited in U.S. national legislation. Section 201 of the U.S. Trade Act of 1974 indicates that safeguards may have one of two objectives   to restore the competitiveness of a declining industry or to facilitate its orderly contraction. Both of these possible justifications are problematic.

The notion that safeguards can be used to "restore competitiveness" presupposes that governments can accurately identify, and will choose to protect, only those industries that can become competitive again. But politically organized industries may seek and obtain trade protection irrespective of the impact that

it is likely to have on long-term competitiveness because of the short-term profits that it brings. Moreover even if governments were able to identify appropriate candidates for assistance and would properly exclude poor candidates, protection is not necessarily the best way to provide such assistance. Direct loans or subsidies to the troubled industry are in theory superior to protection. Finally, and most important, government intervention to restore competitiveness is simply unnecessary in countries with reasonable access to private capital markets. Private lenders will finance efforts to become "competitive" as long as the returns from such investments justify the apparent risk. Their unwillingness to do so is a strong signal that the investment is not justified, and there will often be little basis for governments to second guess the judgment of the capital markets.

The suggestion that safeguards can facilitate "orderly contraction" is also suspect. Beyond question, safeguards can slow the rate of industrial contraction in response to import competition, or end contraction altogether. But such delay is ordinarily an economic vice, not a virtue. Absent some market failure, resources will move to alternative uses at an appropriate pace without safeguards. To be sure, market failures are possible, and an important possibility in this regard is downward wage stickiness, perhaps due to unionization or to subsidies to the unemployed. But trade protection is likely to be an inferior policy instrument for addressing an unemployment problem that results from wage stickiness. Direct intervention in the labor market, through employment or retraining subsidies, targets the wage stickiness problem without introducing the costs of protection. Moreover safeguards are temporary and may thus do little more than postpone the unemployment problem to a future period.

For these reasons, modern economic commentary emphasizes alternative explanations for the existence of safeguards in the WTO/GATT system, generally grounded in political economy considerations. These accounts fall into roughly three categories. The first is the notion that safeguards afford a domestic political "safety valve" for protectionist pressures, deflecting them into an administrative process that ultimately affords less protection than would be put in place by the legislature absent the safety valve (see Lawrence and Litan 1986). Whatever the merits of the safety valve hypothesis as a justification for an administrative route to protection in a domestic political system such as that of the United States, however, it affords a questionable basis for safeguards in the WTO system. If the putative policy goal is to create obstacles to domestic interest groups seeking new or renewed protection, inescapable international commitments to eschew trade protection would seem helpful, which would themselves allow legislatures to "deflect" protectionist pressures by insisting that their hands were tied.

A second political economy account of safeguards is that of Bagwell and Staiger (1990, 2002), who argue that the function of a safeguard mechanism in the WTO/GATT system is to legalize behavior that might otherwise count as "cheating" and cause the system to unravel. A temptation to "cheat" arises in their framework because nations are "large" and can use tariffs to improve their terms of trade. The desire to cheat on tariff commitments increases in the face of import surges because cheating then yields more tariff revenue. If cheating occurs, Bagwell and Staiger assume that nations will revert to their preferred tariff policies in the absence of cooperation. To avert this prospect, it may be in the interest of the parties to a trade agreement to permit temporary deviation from tariff commitments in response to temporary import surges.

Although Bagwell and Staiger's account of safeguards is clever and rigorous, it has some difficulty explaining the structure of safeguard rules in practice. Among other things, nothing in their theory makes the condition of the import-competing industry relevant to the use of safeguard measures—any import surge suffices for the temptation to "cheat" to arise. Yet, the requirement of "serious injury" or threat thereof to an import-competing industry is central to the prerequisites for safeguards under WTO law. In addition, it is not clear that safeguards are needed to address the problem of "cheating" in a system with a well-functioning dispute resolution

system and calibrated retaliation such as that of the WTO.

A third political economy account of safeguards, first suggested by Dam (1970) and elaborated by Sykes (1991, 2006), posits that safeguards reduce the political risk of trade concessions under conditions of uncertainty. The analysis builds on Hillman (1982) and Baldwin (1982), which explain why declining industries will invest more resources than other industries (ceteris paribus) in lobbying for protection. Because it may be difficult for trade negotiators to predict the trade impact of concessions on their constituent industries, they may discover ex post that an import-competing industry is more harmed by concessions than expected and is clamoring loudly for relief. Temporary protection for that industry while its sunk capital depreciates may ameliorate heavy domestic pressures for protection. Because trade negotiators know that they can deviate from the bargain under these circumstances, they may be more willing to grant concessions ex ante. The welfare effects of safeguards then depend on whether safeguards do more to facilitate additional trade concessions ex ante or to allow renewed protection ex post.

Legal Issues If safeguards have any useful role to play in the trading system, their ability to play that role going forward is in some jeopardy. As noted, every safeguard measure that has been challenged to date since the inception of the WTO, and that has reached the stage of a formal ruling, has been found to be illegal. The problem is not simply a matter of WTO members failing to comply with clear obligations. Rather, the treaty text as interpreted by the WTO Appellate Body contains some confusing and illogical requirements that members have great difficulty interpreting (see Sykes 2006).

GATT Article XIX requires a linkage between the import surge and "unforeseen developments." This obligation raises two challenging issues what "counts" as an "unforeseen development," and how do members demonstrate a linkage between it and the import surge? The difficulties here have led to findings of illegality in several cases. It remains unclear how members are to determine what is "foreseen" and whether every "unforeseen" shock that leads to a rise in imports is a permissible predicate for safeguards (consider an unforeseen domestic supply shock, for example, that precipitates an import surge). Further, once an appropriate unforeseen development has been identified, the task remains to show how that development has affected import volumes. To do so convincingly may require elaborate econometric modeling, an exercise that is difficult to undertake given the time and data limitations in safeguards cases.

Article XIX also requires a causal linkage between increased imports and injury. The interpretation of this requirement has proven problematic, among other reasons, because import quantities are endogenous. It is thus difficult to treat import quantities as a causal variable at all. Moreover the Agreement on Safeguards requires national authorities to ensure that injury attributable to "other factors" is not erroneously "attributed" to imports. The task of defining the "other factors" has proceeded quite incoherently, even to the point of deeming an underlying cause of increased imports to be an "other factor." It then becomes impossible to distinguish the causal effect of "imports" from the causal effect of "other factors." It remains unclear how members can undertake the requisite nonattribution analysis in a fashion that will withstand legal scrutiny.

The future role of safeguards in the WTO system is thus in some doubt. An obvious concern is that if nations cannot employ safeguards legally, they will drift back toward the extralegal measures that motivated the Agreement on Safeguards during the Uruguay Round, and the key achievements of that agreement may be undermined. As of 2007, the larger trading entities such as the United States and the European Union whose safeguards are almost certain to be subject to legal challenge have simply stopped using them. The long-term systemic effects of this state of affairs remain to be seen.

■ sanctions

International economic sanctions are often favored by nation-states and by international organizations as a means of projecting power or influencing another government's behavior without resorting to military conflict. The utility of sanctions as an instrument of foreign policy is attested to by their growing popu-larity since the end of the Cold War. Economic sanctions include trade sanctions, which restrict imports from or exports to a target country; investment sanctions, which include restrictions on capital flows to the target and, in some cases, mandatory disin-vestment; and more narrowly targeted so-called smart sanctions, such as asset freezes and travel bans on individual members of the target nation's ruling elite.

A common argument against sanctions is that they are ineffective tools of foreign policy because of the relative ease with which target countries can find al-ternative markets and suppliers. In a study of 116 sanctions episodes imposed since 1914, for example, Hufbauer, Schott, and Elliott (1990) concluded that only 34 percent were successful in achieving their political objectives. Even this estimate may be opti-mistic, however, especially if success is interpreted to mean that sanctions were the *primary* factor con-tributing to the desired outcome (Pape 1997). An alternative view is that sanctions are necessarily suc-cessful as long as they impose costs on the target's behavior or enhance the sanctioner's international reputation. Galtung (1967) was one of the first to point out that sanctions are often imposed not pri-marily for instrumental purposes that is, to induce the target to comply with the sanctioner's demands but instead for expressive or demonstrative purposes. Thus one reason for sanctions' inefficacy is that they may not be designed to be effective in the first place: economic sanctions that are costly to a target are also costly to the sanctioner and are therefore likely to be avoided in favor of less costly, sometimes merely symbolic, measures.

Economic and Political Effects of Sanctions Both the sanctioning nation(s) and the target nation are, in general, made worse off by a trade embargo. The degree to which trade sanctions reduce welfare in these nations depends on the sanctions' terms-of-trade effects, which are larger in the case of multi-lateral than unilateral sanctions. Moreover any price distortions caused by sanctions inevitably create opportunities for nonsanctioning third parties to capture rents by continuing to trade with the target. Under multilateral sanctions, much sanctions-busting activity is likely to involve traders in the target

nation itself, thereby channeling some of the rents into the very country that is supposed to be punished (Kaempfer and Lowenberg 2007). Sanctions rents might even, perversely, enrich the target country's own rulers if they are able to participate in sanctions-busting trade. Empirical studies have confirmed that multilateral sanctions, despite, and indeed because of, their greater terms-of-trade effects, are typically less successful than unilateral sanctions.

Financial and capital sanctions, too, can have unintended consequences. In the case of disinvestment, the physical plant and capacity previously owned by foreigners is purchased by domestic capital owners at reduced prices, which increases their rate of return. The resulting windfall gain to domestic capital owners potentially increases the tax base available to the government to finance its objectionable policy (Kaempfer and Lowenberg 2007). Of course, in the long run, a decrease in the inflow of new capital and technology from abroad is likely to limit the target's growth potential.

Even if sanctions impose substantial economic damage on a target nation, there is no guarantee that the target will reform its behavior in conformity with the sanctioner's demands. In his classic study, Galtung (1967) noted that sanctions are often followed by increased levels of political integration in the target country, the so-called rally-around-the-flag effect, which has since captured the attention of many observers.

Sanctions have distributional effects. For example, an embargo on exports to a target country benefits domestic producers of importables in the target country at the expense of consumers. There are similar distributional effects within the sanctioning country. It follows that interest group politics in both countries are important in explaining the political origins and outcomes of sanctions. Thus the level of sanctions imposed by a sanctioning country depends on the relative political influences of prosanctions and antisanctions groups within that nation's domestic polity. In the target state, sanctions that are successful in bringing about a change in policy in the desired direction will generally do so by diminishing the political influence of the regime's supporters

relative to that of its opponents (Kaempfer and Lowenberg 2007). There is considerable consensus on the utility of smart sanctions that pinpoint those groups most responsible for the objectionable policy while minimizing "collateral damage" to innocent citizens (Cortright and Lopez 2002).

Game-theoretic work on sanctions demonstrates that, given perfect information, sanctions would never be implemented: if a threatened sanction were sufficiently effective, the target would comply immediately, obviating the need to impose the sanction, while if the sanction were ineffective, the sanctioner would not threaten it in the first place (Eaton and Engers 1992). Thus the sanctions that are most likely to succeed will often do so as threats, without having to be imposed at all. It has also been shown that the success of sanctions depends on conflict expectations: target states that anticipate future conflict with a sanctioner are relatively unlikely to comply with the sanctioner's demands, although these are precisely the countries that are most likely to be sanctioned (Drezner 1998).

Empirical Findings on Sanctions Many studies have attempted to identify the correlates of sanctions success. The most common findings are that the success of sanctions is positively correlated with political instability and economic weakness in the target country and with close, cordial ties between sanctioner and target prior to sanctions. Some scholars also find a significant positive relationship between the cost of the sanctions to the target, measured as a percentage of the target's gross national product, and the success of the sanctions.

Most of the empirical literature uses the data compiled by Hufbauer, Schott, and Elliott (1990), which include only those sanctions that were actually applied, despite the fact that successful sanctions often end at the threat stage. Consequently empirical studies of actually implemented sanctions are likely to be biased against sanctions success. Such selection bias is part of a broader problem, namely, that the factors determining whether sanctions are used are intrinsically linked to the factors determining their success. Recent empirical work therefore uses simultaneous equations techniques to estimate models

of jointly determined policy choice and sanctions outcome.

Another focus of empirical inquiry is the role of political regime type in determining sanctions usage and success. The interest of sanctions scholars in regime type stems from the literature on the democratic peace, which is the theory that democracies typically do not go to war against other democracies. Lektzian and Souva (2003) investigate whether there is an analogous "economic peace" among democracies. They find that, although democracies impose sanctions more often than other regime types, democracies are indeed less likely to sanction other democracies than they are to sanction nondemocracies. However, others have found evidence that sanctions are more successful when imposed against democracies than nondemocracies, suggesting that democracies make more attractive targets (Nooruddin 2002).

■ sanitary and phytosanitary measures

Since the 1990s, attention to agricultural trade policy has widened to include issues related to technical barriers to trade, particularly sanitary and phytosanitary (SPS) measures that regulate movement of products across international borders. SPS measures protect plant, animal, and human health from hazards such as pests, diseases, contaminants, and toxins that might be found in imported agricultural and forestry products. Unlike most nontariff measures, they are potentially welfare increasing because they may correct market failures stemming from externalities that arise from importing goods that may be accompanied by these hazards. But like other regulations, they arise from an equilibrium process of policy determination. The observed levels of intervention emerge from the interaction of the demands for measures by various domestic interest groups (including producers, processing industries, and

consumers) and the supply of these barriers by policymakers. That regulatory processes can be captured by interest groups with a vested interest in a particular regulatory outcome is well recognized in the economic theory of regulation, and cases involving the promulgation of SPS measures are no exception. Since the 1990s, objective economic analysis and international trade rules have provided the basis for reform of some SPS regulations that lowered net social welfare by restricting imports that posed negligible risks.

Measurement of Economic Effects Although traditional trade barriers have been extensively studied, informing policy trade-offs and negotiating priorities in the Uruguay and Doha trade rounds, far less is known about the impacts of SPS measures on trade. The analytical complexity and scant data available for quantifying the economic effects of SPS measures pose significant challenges for analysts. Conceptual difficulties stem from the heterogeneous nature of SPS measures, the fact that multiple measures are aimed at a particular product, and that measures are difficult to aggregate.

Data scarcity is perhaps an even more significant challenge. No registry for SPS measures comparable to tariff schedules exists at either national or international levels. The UN Conference on Trade and Development is leading an effort to update its Trade Analysis and Information Systems database, an international inventory of nontariff barriers, to fill this data gap. At present, however, direct measures of the economic effects of SPS and other technical regulations are limited to the evidence from business surveys. Surveys by the Organisation for Economic Cooperation and Development and the World Bank indicate that these regulations can significantly increase costs or limit market access for exporters of selected products in developing and developed countries alike.

Indirect methods of measuring the effects of SPS measures on trade are important because of the paucity of direct measures. These methods rely on comparison of prices or are inferred from trade quantities in the context of a well-specified model of trade flows. Many studies in the literature have used partial equilibrium simulation models or gravity models to estimate the costs of specific measures, including Australia's ban on banana imports, the European Union's (EU's) ban on growth hormones in beef production, Japan's restrictive fire blight measures for apple imports, and the EU's aflatoxin standards for dried nuts and fruits. A smaller number of case studies have integrated risk and economic assessment in the analysis of SPS measures under alternative risk scenarios to inform specific policy changes for example, the gradual lifting of the United States' long-standing ban on imports of Mexican avocados. These studies have made important contributions to the development of methodology and policy formulation, but their results are not easily generalizable to other products or sectors in other countries.

More recently, a few econometric studies have examined the effects of SPS and other nontariff measures on food trade at a more aggregate level, finding that their effects are larger than tariff effects for product categories, including fruits and vegetables as well as meats. This emerging body of literature, which is still in its early stages and fraught with measurement, endogeneity, and other econometric difficulties, reinforces the perception that SPS barriers have a substantial influence on agricultural trade.

International Trade Rules Although it has been difficult to assess the aggregate effects of SPS regulations on trade in agricultural goods, or to evaluate their relative importance in the world trading system, there has long been broad recognition that these measures can significantly impede trade. Disciplines on SPS measures and other technical regulations were included in the original General Agreement on Tariffs and Trade (GATT) adopted by the Contracting Parties in 1947. The GATT treaty recognized the need to subject domestic regulations to international scrutiny so that the strategic application of these measures would not subvert the commercial opportunities created by other trade policy reforms.

The original GATT rules for SPS and other technical measures were expanded in the Tokyo

Round (1973 79) of multilateral trade negotiations and again during the Uruguay Round (1986 93) when a separate agreement for SPS measures was established. The challenge before the negotiators of the World Trade Organization (WTO) Agreement on the Application of Sanitary and Phytosanitary Measures (the SPS Agreement) was to create a set of rules that would strike the proper balance between allowing health and environmental protection while disallowing mercantilist regulatory protectionism. In broad terms, the SPS Agreement recognizes the right of each WTO member to adopt measures that achieve its "appropriate level of protection" but requires such measures to be based on a scientific assessment of the risks and to be applied only to the extent necessary to achieve the country's public health or environmental goals. As a benchmark, the SPS Agreement recognizes the international standards promulgated by the *Codex Alimentarius*, the International Organization of Epizootics, or the International Plant Protection Convention to be " safe harbor" standards. Members adopting these standards are " rebuttably presumed" to be in compliance with the agreement.

The compliance of countries with the SPS Agreement is reinforced by the WTO's formal dispute settlement procedures. Only a few conflicts over SPS measures have led to the establishment of dispute panels, but these few cases have played a critical role in establishing how trade rules place bounds on national sovereignty in this policy area. Of 30 requests for formal consultations on SPS measures from 1995 to 2006, 11 have advanced to dispute settlement proceedings. Landmark SPS disputes included the EU ban on hormone-treated beef and the EU's regulations for approval and marketing of biotech products.

The EU's defense of its hormone ban rested on its claims that existing international standards for hormone use in beef cattle did not meet its public health goals, and that the ban represented a precautionary approach to managing uncertain risks. In their rulings, the WTO affirmed the right of WTO members to establish a level of consumer protection that was higher than international health standards. The ban

was nonetheless judged to be in violation of the SPS Agreement because it was not backed by a scientific risk assessment. The WTO likewise ruled against the EU and some individual member states in the more recent biotech case because risk assessments did not support the disputed measures. These results remove a degree of national political sovereignty for regulations in cases in which evidence has not been marshaled to demonstrate any risk from trade. But the limits to what the WTO can achieve in this policy area is seen in the fact that the formal rulings have triggered additional scientific assessments rather than meaningful policy changes leading to increased trade in these two long-running disputes.

Prospects for Regulatory Reform of SPS Measures Although current international trade rules curb the protectionist abuse of SPS measures, they still allow countries to adopt measures for which global or even national costs outweigh their national benefits. Economic analysis that examines the benefits (reduced risks) and costs (reduced trade) of SPS regulations is important for regulatory reform efforts that seek to identify the most efficient policy instruments to manage SPS risks. Failure to work through the challenges of data and methodology will create the potential for anecdote and allegation to play a larger role in SPS policy formulation, which would likely result in increased costs to consumers and increased tensions between trading partners.

■ seigniorage

Seigniorage is profit from money creation, a way for governments to generate revenue without levying conventional taxes. In the days of commodity money, seigniorage revenue was the difference between the face value of the minted coins and the actual market value of the precious metal they contained. When this markup was insufficient for the government's revenue needs, the authorities might substitute less valuable base metal for some of the precious metal that was supposed to be in the coins. Such a practice has a long history, dating back at least to Roman times. Although this allowed the government to issue more coins without acquiring more precious metal, the coins quickly depreciated as agents became aware of their less valuable content. The continued partial precious metal backing still placed some limit on the possible issuance.

With the demise of the gold standard in the early 1930s, almost all nations abandoned commodity-backing for their currencies and adopted a fiat money standard under which the paper issued is backed by nothing more than faith and confidence in the issuer. Under this system, the cost of issuance declines close to zero and there is no longer any limit on the quantity of money that can be issued. Under a fiat

money system, seigniorage revenue is given by the product of the inflation rate and the inflation tax base. This inflation tax base reflects the purchasing power of the public's money holdings and is the level of *real* money balances (nominal money holdings divided by the price level). Undertaking more rapid monetary expansion causes the inflation rate to rise, but the revenue effects are partially offset as individuals attempt to quickly spend the extra money before it depreciates further. If people spend money faster than it is being printed, the rate of price increase comes to exceed the rate of money issuance.

Hyperinflation A government that is unable to fund its expenditures through conventional taxes or bond sales may become dependent on seigniorage revenues to maintain its existence. Attempts to raise seigniorage revenues are, however, not only inflationary but eventually self-defeating. Under circumstances where the decline in real money balances becomes proportionately larger than the rise in the inflation rate, the inflationary policy actually backfires and lowers seigniorage revenue. The economist Phillip Cagan's classic analysis of hyperinflations, with inflation rates exceeding 50 percent per month, suggested instances where the process had, in fact, been pushed beyond the revenue-maximizing point. It is possible that lags in the adjustment of inflation expectations may actually have allowed continued seigniorage gains, however, and subsequent analysis of the 1921 23 German hyperinflation points to seigniorage levels rising year by year (see Cukierman 1988).

Whatever success the German government may have attained in raising seigniorage revenues, such surging, and highly volatile, inflation rates interfere with the price mechanism and cloud production and employment decisions. Meanwhile attempts to economize on money balances require devoting more and more time to simply turning over the currency. By the end of the German hyperinflation, workers were being paid more than once a day because otherwise the value of the money would fall too much between the beginning and end of the shift! Other innovations, such as the indexation of bank deposits to inflation or establishing deposits de-

nominated in a stable-value currency, require even faster rates of note issue to maintain seigniorage revenues, given that part of the money supply is now insulated from the inflation tax. This factor was particularly evident in the record-breaking post World War II Hungarian hyperinflation. Negative effects on economic growth emerge well before such extreme circumstances, however. Recent work suggests that significant negative effects of inflation may emerge below the 10 percent level in both industrial and developing economies (Burdekin et al. 2004).

Certainly, even though conventional taxes impose their own distortions on the economy, few would argue that this justifies reliance on seigniorage as a deliberate policy choice. Dependence on seigniorage revenue seems, in practice, to be highly correlated with the degree of political instability. Vulnerability to this effect tends to be greatest in developing economies that are less democratic and/or more socially polarized (Aisen and Veiga 2005). High indebtedness is another common factor. In this respect, even a government that is initially able to fund its deficit through selling bonds to the public may eventually resort to inflation finance as the amount of debt approaches the saturation point. Thomas Sargent and Neil Wallace argue that such "unpleasant monetarist arithmetic" implies that, in the face of continued budget deficits, tighter monetary policy today simply implies more inflationary policy tomorrow once the limit on bond issuance is reached (see Sargent 1993). Furthermore the greater the outstanding stock of bonds, the greater the potential governmental gains from inflating away the real value of these obligations through inflation which, in turn, likely limits the demand for such bonds unless inflation protection is built in.

The typical mechanism of inflation finance is for the government to sell bonds to the central bank, which then immediately "monetizes" the debt with new money emissions. This is therefore properly characterized as money finance rather than true bond finance and provides the government with new funds to spend only via excess money creation. Conversely selling bonds to the public, rather than the central bank, is likely to be far less inflationary and has no direct effect on the money supply.

Making the central bank independent of the fiscal authority would seem to be a way of ending automatic government access to the printing press, and nations with independent central banks have historically tended to have lower inflation rates. But even in the United States, large deficits such as those incurred under the Reagan administration put considerable pressure on the central bank to at least partially monetize them insofar as very large bond issues push down bond prices and put upward pressure on interest rates. Moreover in a developing economy where the market for government bonds is much thinner, it is unrealistic to expect the central bank, nominally independent or not, to resist monetization pressures when no other financing options exist. Instituting central bank independence is probably better thought of as a way of discouraging future fiscal profligacy rather than something that alone can end an ongoing reliance on deficit monetization and seigniorage.

Reducing Reliance on Seigniorage Revenue A more drastic way of weaning a government away from reliance on seigniorage revenue is to dollarize the economy, following the example of countries like Panama (since 1904) and Ecuador (since 2000), which abandoned domestic currency issuance and adopted the U.S. dollar as their monetary standard. Another option is to maintain the domestic currency but link it to the U.S. dollar or another currency via a currency board arrangement, whereby the monetary authority commits to exchange local currency for the foreign currency on demand at a predetermined, fixed rate of exchange. Such a strategy still allows for some seigniorage revenue on interest-bearing dollar-denominated assets held to back the local currency. Although Hong Kong's currency board arrangement with the U.S. dollar has been maintained since 1983, Argentina's link with the U.S. dollar collapsed in 2001 in the midst of soaring unemployment and political unrest. The Argentinean case not only illustrates the potential dangers of tying the domestic currency to the dollar but also serves as a reminder that no such announced commitment is truly

irrevocable. Another alternative is to enter into a currency union, such as the euro zone, that eliminates the scope for domestic inflation finance by dispensing with the national currency entirely yet allows participating nations to share in seigniorage revenue earned by the group as a whole.

Chapter 5 covers the "unpleasant monetarist arithmetic" when tight monetary policy is combined with continuing budget deficits, and chapters 2 and 6 assess the implications of the Reagan deficits and their possible rationale.

RICHARD C. K. BURDEKIN

■ sequencing of financial sector reform

Sequencing of financial sector reform is concerned with the ordering of reforms in the financial system and with designing a path for these reforms that will improve economic welfare. Economists generally acknowledge that liberalized or market-based financial systems enhance the mobilization and allocation of financial resources and, therefore, economic growth and welfare more than repressed financial systems in which allocation of financial resources is subject to administration. History has shown, however, that when a country moves from a repressed to a market-based system, it risks its financial and economic stability and can face an economic and financial crisis. Liberalization of certain financial transactions before the necessary financial infrastructure is in place can contribute to the incidence of these financial crises. The sequencing of the financial sector reforms is intended to ensure an orderly

transition from repressed to market-based financial systems that avoids serious economic and financial crises.

Policy Issues Surrounding Sequencing The earliest literature on sequencing financial sector reform addressed the reform of financial systems as part of broader programs of economic reform that included, for example, trade liberalization and labor market reforms. The prevailing belief was that financial liberalization should occur late in the reform process since financial sector variables were seen as responding to relative prices and savings and investment decisions. Liberalizing financial systems before successful economic reforms that set the "correct" relative prices would lead to a less-efficient allocation of financial resources and could be destabilizing, as observed among some countries in Latin America during the 1970s.

A second strand of research addressed the speed of reform: whether it would be better to follow a gradualist approach or to have a rapid "big bang" program that reformed several sectors simultaneously. The arguments for "big bang" reform programs were motivated largely by political economy considerations, especially the need for a critical mass of reforms to break entrenched inertia and vested interests and to provide domestic and international credibility to the reform program. Financial sector reforms were seen as a key component of the "big bang" reform programs since they were often easier to implement than other components, such as labor market reform.

A third strand of the work on sequencing has focused on the design of the programs of financial sector reform. This strand identifies the major risks as well as benefits of the financial sector reform and seeks to mitigate these risks through the design of the financial liberalization. The emphasis is not on the speed of the reform but instead on putting in place a consistent set of polices that takes into account each country's unique circumstances.

A fourth related strand has focused on the liberalization of the capital account and, specifically, on the question of when countries should liberalize capital flows. This issue received additional attention following the Asian financial crisis of the mid-1990s, which was viewed as the result partly of a premature or an inappropriately sequenced liberalization of short-term capital flows.

Key Policy Insights As countries reform their financial systems, it is essential that they have instruments that allow them to exercise effective monetary control in a liberalized environment. The liberalization of financial systems is typically associated with significant initial expansions in monetary and credit aggregates and capital inflows. The expansions are largely the result of portfolio adjustments to the liberalized financial systems, but they can also have potentially destabilizing macroeconomic effects through increasing inflation or weakening of the balance of payments. Thus the authorities need to have flexible monetary instruments to manage these effects and avoid the buildup of potential fragility in the financial system that can result in financial crises. Typically, this has involved adopting techniques of indirect monetary control and following a consistent mix of monetary and exchange rate policies. For example, if countries seek to follow a restrictive interest rate policy to limit the credit expansions, they may need to adopt a flexible exchange rate regime.

Financial institutions typically need to be restructured early in the process of financial sector reform. Many of the financial crises that followed financial liberalizations can be traced to imprudent lending by weak banks. The bank restructuring programs include elements such as writing down the value of bad and doubtful debts and recapitalizing the banks to achieve a minimum level of capital at the beginning of the reform programs; reorganizing bank management and developing skills in risk assessment and management; introducing regulations of banks to limit large credit and currency risk exposures; and developing an effective system of prudential oversight. Experience has shown that banking failures can be costly to economies: they result in a loss of confidence in the currency and require significant government interventions to clean up bank balance sheets.

Implementation of the monetary and prudential elements of the reforms normally requires giving

some urgency to strengthening official institutions specifically, the central bank and the supervisory authorities   in the early stages of the financial sector reforms.

Reforms to develop longer-term capital markets and nonbank financial intermediaries have tended to occur at a later stage of financial sector reform. It usually is easier to develop the markets in longer-term instruments, the bond and securities markets, after those in short-term instruments are in place. Reforms of auditing and accounting, legal frameworks, bankruptcy, and payments and settlement systems generally should accompany these reforms. Derivative financial markets are normally the last to emerge since they rely on well-functioning markets in the underlying instruments on which the derivatives are based.

Payments and transfers on current international transactions have conventionally been liberalized ahead of capital movements. The former are important elements in the growth of trade in goods and services. The elimination of restrictions on current international transactions has often depended on foreign exchange market reforms.

A more controversial issue has been how to sequence the liberalization of capital movements with the domestic financial-sector reforms. One of the lessons of the Asian financial crises in the mid-1990s is that capital account liberalization should be approached cautiously with special attention to avoiding reliance on short-term capital flows. These crises were attributed in part to a premature opening of the capital account to short-term capital inflows. These flows were potentially destabilizing since, in the event of a loss of confidence, they could be withdrawn quickly, resulting in a balance of payments crisis. At the same time, capital movements can be beneficial as part of the financial-sector reform program. For example, allowing foreign direct investment (FDI) in financial institutions can help in their restructuring and in strengthening local technical and management skills. Notwithstanding the well-founded concerns about an overreliance on short-term capital movements, liberalization of certain short-term capital transactions is a key element in developing

efficient foreign exchange and domestic money markets. Hence capital account liberalization involves various complex elements, making it difficult to generalize on the optimal approaches.

Although it is neither desirable nor possible to have a one-size-fits-all approach to sequencing, some important technical and policy lessons have emerged on how to sequence reform measures to avoid major pitfalls. A key lesson is that at the beginning of the reform program, the authorities need to develop monetary instruments to maintain macroeconomic control. They will also probably need to restructure or recapitalize their commercial banks to avoid a major failure that could disrupt the domestic financial system and lead to a loss of international confidence. Finally they should approach the liberalization of short-term capital movements cautiously to avoid an overreliance on this source of capital.

■ shipping

Shipping, the movement of people and commodities by ship, has long been the dominant form of transportation for the movement of bulk commodities, especially over long distances. Many of the major

cities in the world have grown because of their sea-ports or access to good inland navigation. Physically, some 90 percent of world trade (nearly 7 billion tons) is carried by the international shipping industry, although because of the nature of the goods moved, the proportion is considerably less in terms of value. Shipping also is a growth industry, with the amount of seaborne trade in terms of tonne-miles (the amount carried, measured in metric tonnes, multiplied by the distance moved) rising from less than 6,000 in 1965 to nearly 30,000 in 2005.

As of 2006 there were about 50,000 mercantile vessels in the world, totaling some 650 million gross tons, engaged in international trade, and many more providing domestic coastal and ferry services. The merchant fleet consisted mainly of general cargo vessels (38 percent of the ships), oil tankers (25 percent), and dry bulk carriers (14 percent). It is, however, the container fleet that has expanded most rapidly, not only in relative numbers but also in size the average capacity rising from 1,944 twenty-foot equivalent units (TEUs) in 2002 to 2,108 in 2004. It is also a newer fleet: the average age of the overall merchant fleet is 12.5 years, but only 9.2 years for container ships. Passenger ships accounted for about 7 percent of the fleet. The majority of vessels register in developed countries (27 percent) or in the major open-registry ("flag-of-convenience") countries that allow foreign ships to register under their flag and offer attractive financial and other incentives to shipping companies to do so (Panama, Liberia, and the Bahamas, which register a total of 250 million gross tons). More than 97 percent of the world's merchant fleet was registered in just 35 countries.

The world's shipbuilding industry delivered 2,129 new ships, amounting to a record 70.5 million tons of new shipping capacity, in 2005, up from 49.4 million tons in 2004. This increased global net capacity by 7.2 percent. The major shipbuilding nations include South Korea, Japan, China, Germany, and Russia, with China taking an increasingly important role. Structurally, the shipbuilding industry tends to be more fragmented in Europe than in Asia where it is concentrated in a limited number of countries.

Although, because of technological advances, shipping is becoming more capital intensive and crews levels are getting smaller for any given size vessel, its overall size and growth rate means that it remains a major employer of labor. There are 466,000 officers and 721,000 sailors serving merchant ships that trade internationally with Organisation of Economic Co-operation and Development (OECD) countries. East Asia provides the majority of merchant ships' officers and developing countries the majority of sailors. Indirectly, the shipping industry creates much greater employment than these numbers indicate because ships need labor for their building, maintenance, chandelling (fitting out vessels), and vittling (supplying food for vessels).

Although there has been volatility over time, the costs of shipping have never been cheap and have varied considerably across markets. The cost of international freight transportation, for example, was 5.8 percent of the import value for developed countries in 2002 but ranged from 8.8 percent for developing nations overall to 12.4 percent for African countries. Although estimates of the income earned from international shipping are imprecise, the approximate figure is about $380 billion annually.

Structure of the Shipping Industry The shipping industry is segmented in a number of ways. The largest part of the industry involves the movement of cargo, with more limited transportation of people by ferries and cruise ships. A small number of passenger liners still provide scheduled services on oceanic routes, but this type of traffic has largely transferred to air transportation. The cargo part of the industry is divided into coastal activities and deep-sea shipping. The former serves point-to-point short-haul routes and acts as a distributor for large consolidating ports that collect and dispatch larger ships on deep-sea routes. Coastal shipping serves a key function in many countries where, for economic or geographical reasons, land transportation is of poor quality. For example, more than 70 percent of maritime activity in China is cabotage (coastal water transportation) traffic and accounts for nearly 55 percent of the total domestic ton-miles transported in the country.

Sliced another way, shipping offers regular, scheduled services ("liner services") and irregular sailings ("tramp shipping"). Liner services cater to customers who have partial shiploads often involving container shipments and who need to incorporate their cargo into a predetermined supply chain. Modern, just-in-time production demands reliability as well as speed in maritime logistics. To improve service, liner operations generally involve some form of cooperation between shipping companies to ensure regular sailings offering common-carrier services at frequent intervals. Traditionally, since the 1870s, when steam power made for reliable schedules with published rates, "conferences" have offered this service, although these have become refined into more integrated "consortia" and "alliances" that, for example, involve operating agreements allowing liners to share space on one another's ships. Containerization has provided scope for this interoperability by which ships from any line can carry standard containers. Although these agreements among shipping companies offer benefits in terms of coordinated, more stable rates and more frequent service, they also raise concerns about the concentration of market power that they may foster. Since the early 1990s, partly because of the wider use of long-term leases, greater competition for high-value cargo from air transportation, and tighter regulatory controls, but also because consolidation of liner operations has taken place, the number of conference type arrangements has declined.

Tramp shipping companies are often as large as their liner counterparts but are usually hired to carry entire shiploads of cargo, especially dry bulk or liquids. They often operate specialized vessels. In many cases these markets may involve the long-term leasing of vessels to a single customer, especially if they are for specific cargoes over a single route. The market for tramp shipping is highly competitive both for spot hires and for long-term leases. Rates tend to be highly volatile, reflecting the prevailing demand in the markets being served combined with the high degree of rigidity in short-term capacity. The rates are, at a macro level, highly correlated with international business cycles.

Economics of the Industry Shipping forms part of a more extensive supply chain. The industry directly interacts with ports, canals, and navigation systems and less directly with the operational surface modes (road, rail, and inland waterways) that service ports. This requires coordination of technology and of institutional structures if seamless service is to be provided to users, and so the industry has always been at the forefront of adopting up-to-date communications technology such as global positioning systems.

On the supply side, the technical peculiarities of the industry mean there are considerable economies of scale involved in the physical provision of individual ships. Simply put, a vessel 150 feet long, 20 feet high, and 20 feet wide has a capacity of 60,000 cubic feet and, assuming it is fully decked, has 12,800 square feet of steel plating. In contrast, a vessel 300 feet long, 40 feet high, and 40 feet wide has a carrying capacity of 480,000 cubic feet but requires only 51,200 square feet of plating. A doubling of dimensions increases capacity eightfold but the material needed to build the vessel rises only fourfold.

As engine technology and maritime engineering have allowed, the trend has been for larger cargo and passenger vessels for example, super-post Panamax (50,000 to 79,999 deadweight tons [dwt]) and Cape-size (more than 80,000 dwt) vessels used in the international movement of dry-bulk, ULCC (more than 300,000 dwt) crude oil tankers, and mega cruise liners. This challenges ports that do not have the depth or docking capabilities to handle such ships and water transit facilities, such as the Panama Canal, that do not have the width. Container traffic has grown considerably, especially in developing countries, and for this to be fully efficient ports also require specialized handling equipment that has to be upgraded as vessels get larger.

Institutionally shipping has always been seen as a risky activity, involving relatively large sums of capital and the commitment to tie up inventories for extended periods. Historically the sector expanded during the Classical Greek period only with the emergence of primitive insurance and later, in the Italian Renaissance, as more sophisticated

banking developed. Today the insurance market at Lloyds of London and financial markets around the world provide the lubricant for a multibillion-dollar industry.

The aggregate demand for shipping services is strongly tied to the state of the international economy. The worldwide recession of the early 1980s led to marked downturns in demand, and growth slowed during the Asian financial crisis of the late 1990s. But there can be wide variations in specific geographical and commodity markets. The demand for oil tankers, for example, can vary considerably according to the price of crude. Economic expansion in India and China has spurred rapid growth in those particular markets, with accompanying high freight rates. There are also spatial imbalances in demand, with significant difference in the demand for outbound and inbound services. Many developing countries, for example, are major exporters of bulk ores but are recipients of high-value, less bulky manufacturers. Tankers usually return from refineries to oil-producing countries in ballast (that is, empty of cargo, carrying only ballast to provide stability and maneuverability). This situation often leads to ships serving an "interconnected" network rather than a simple back-and-forth, "connected" routing. The American slave trade of the 18th century, for example involved a triangular pattern of service, with vessels taking European manufactures to Africa, collecting slaves in Africa for transportation to America, and bringing raw materials from America such as cotton and sugar back to Europe. This type of complex network is more difficult for specialized fleets such as tankers.

International trade cycles, combined with the time it takes to build new capacity and the competitive nature of much of the industry, often mean that there is a mismatch between supply and demand. In particular, given the costs of mothballing vessels during downturns in the business cycle, there is a tendency for excess capacity to exist over the full cycle. Estimates by the United Nations suggest, for example, that globally there was a residual (excess) fleet capacity amounting to some 21.7 million dwt (2.6 percent of the world fleet) in 2002, falling to 10.3 million dwt (1.2 percent) in 2003.

Regulating Shipping Markets Institutionally, long-standing debates have focused on the appropriate economic regulation of shipping to ensure that overall logistics chains are not distorted and on the social regulation of shipping to ensure safety and security. The shipping industry is thus subject to a wide range of laws and agreements, but the size and diversity of the sector make analysis and subsequent policy formulation difficult. The International Maritime Organization, an arm of the United Nations, provides broad global oversight, although other agencies, such as the United Nations Conference on Trade and Development (UNCTAD), become involved in maritime affairs when shipping is seen as a tradable service in its own right. At the macroregional level, national groupings such as the European Union play a role in determining the structure of the industry within more limited spatial markets.

Many developing countries have felt disadvantaged because their trade has been carried on ships from wealthier nations. Seeking to safeguard the position of developing countries, UNCTAD initiated in 1974 a "40/40/20 rule" whereby the freight being moved is shared between ships from the developed countries (40 percent), the developing country (40 percent), and cross-traders from third states (up to 20 percent). Developing countries often do not have the maritime capacity to handle their share of traffic and, because far more tonnage leaves most primary goods producing developing countries than is moved to them, efficiency drops.

Most nations allow free movement of shipping through their territorial waters and access to their ports, although there are limitations on the types of activity that may be pursued. Fishing and the extraction of minerals within territorial waters tends to be highly restricted. Many counties also limit maritime trade between their own ports (cabotage), even if international trade is allowed. The 1920 Merchant Marine (Jones) Act, for example, permits only U.S.-owned, -registered, and -built vessels, manned by citizen crews, to conduct cabotage between U.S. seaports.

Much of the economic regulation has focused on defining ownership and responsibilities for shipping and on ensuring that potential monopoly forces do not distort the market to the detriment of consignors or the public interest more broadly defined.

The growth of merchant shipping has always been vulnerable to attacks, and even in the early part of the 21st century there were more than 400 acts of piracy a year. Naval protection has thus often been seen as an important requisite of civilian shipping. Conversely merchant shipping has also been closely entwined with military operations, being a major part of many army and naval logistics operations. As a result, there are strong links between the merchant and military sides of shipping.

Despite the efforts of international bodies such as the World Trade Organization to remove tariffs and other institutional barriers to trade, the major factor that has facilitated the vast increase in the physical volume of goods trade has been technical improvements in the shipping sector. Without the advent of modern oil tankers, the energy required for production would not be available; without massive bulk carriers, food and raw materials could not be moved to places of production; and without the capabilities of container vessels, final products could not be moved to market. Shipping is the facilitator that allows the world economy to realize much of the division of labor so important for global economic growth.

■ **Smithsonian Agreement**

The Smithsonian Agreement was the understanding by which the Organisation for Economic Co-operation and Development (OECD) economies agreed to suspend the Bretton Woods system of fixed exchange rates in December 1971. The Bretton Woods conference had established a system of fixed exchange rates in 1944, encompassing nearly all the currencies of the free world, in which each currency was pegged to within a band of ±1 percent around a fixed parity against the U.S. dollar, and the dollar itself to a fixed price against gold. These systems had worked well and, with the exception of a few parity realignments in Europe in the 1960s, most countries had successfully kept to their parity values.

In the early 1960s, the United States still had a strong reserve position in which its gold holdings and foreign assets were larger than its liabilities to foreign institutions. But increasing balance of payment deficits later in the decade reduced those gold holdings, raised the United States' foreign liabilities, and weakened its reserve position. By the beginning of 1970, it was clear that the exchange rate regime was under threat when the U.S. balance of payments deficit sharply widened again and the (net) reserve position turned negative. In the first instance, these changes were the result of expansionary fiscal policies in Washington, driven mainly by President Lyndon Johnson's Great Society program and the expenditures of the Vietnam War. The result was a persistent tendency to large balance of payments deficits and a shortage of international liquidity, as the United States showed itself unwilling to restrain growth,

employment, and the expansionary pressures that were starting to increase inflation as well as aggregate demand. The initial response by foreign governments was to buy dollars and sell their own currencies in an effort to support the Bretton Woods system although some bought gold instead, which added to the American difficulties.

The United States meanwhile wanted to avoid devaluing the dollar (raising the dollar price of gold), not only to retain the support of the governments that had agreed to hold dollars but also, and more importantly, because such a move would achieve nothing if the other governments did not revalue against the dollar at the same time. However, as the American reserve position worsened and as inflation and unemployment began to increase, a change of policy leading to a general devaluation became inevitable. On August 15, 1971, President Richard Nixon temporarily froze wages and prices, imposed a 10 percent tariff on imports, and suspended dollar transactions in gold. This was designed to force a devaluation of the dollar on the existing system, while also cooling down the inflationary pressures within the U.S. economy.

The next step was to get the foreign governments to accept a revaluation of their own currencies against the dollar: a general realignment of the parities upward. The idea at this stage was not to create a regime of flexible exchange rates, but to force a general realignment in the parities before they were fixed again. The agreement that finally emerged after several months of hard bargaining at the Smithsonian Institution had to accommodate a 9 percent devaluation of the dollar versus gold and a continued suspension of gold transactions in order to force revaluations in the other currencies. Foreign governments also agreed to undertake a thorough review of the monetary system to achieve a suitable degree of flexibility and a significant liberalization of trade policies that would be acceptable to both sides.

The latter components of the agreement eventually led to the creation of the Committee of Twenty (of the leading OECD economies), which oversaw the attempt to design a system of "stable but adjustable" exchange rates, which was then used to legalize the float that followed under the International Monetary Fund's articles of agreement. The trade liberalization agreement, meanwhile, led to the Tokyo Round of trade negotiations in the later 1970s. The Smithsonian Agreement itself, however, proved to have been too little, too late, as the U.S. trade deficits and reserve position failed to respond. The U.S. economy continued to expand, other countries got into balance of payments difficulties too and floated, and dollars continued to flow into Germany and Japan. In 1973 the United States decided to devalue the dollar again, and one by one the other countries bowed to the inevitable and allowed their currencies to float beyond their new parities. The dramatic increase in energy prices that followed ensured that there was no going back to a regime of fixed parities, although the European Community did manage to create a system of stable but adjustable exchange rates among themselves six years later. In that sense, the Smithsonian Agreement did lead to the flexible exchange rates that we have today and to the European monetary system of 1979 99.

■ smuggling

Smuggling is the surreptitious import or export of goods in violation of domestic or international law. Export smuggling is relatively rare and is mainly relegated to products involved in a multilateral boycott, such as a United Nations embargo on diamonds from African war zones, or state-subsidized products that consequently can be sold for higher prices abroad. Most commonly, smuggling involves the illegal import of banned goods or goods that face import quotas, significant tariffs, or other high taxes.

The preponderance of literature dealing with smuggling in the field of economics focuses on its impact on the welfare of the nation. In the mid-1970s, many believed that smuggling was beneficial, at least to a small country, because smugglers circumvented tariffs that undermined free markets. Consequently smuggled goods (or contraband) could be sold for lower prices and therefore enhanced welfare. Bhagwati and Hansen (1973) challenged this commonly held belief, arguing that the level of prices resulting from smuggling was not the only issue relating to national welfare. Smuggling could be welfare reducing when it undermined government policies of establishing tariffs to protect local industries. Subsequent writers also noted that smuggling could corrupt and demoralize a society as smugglers normally undermined law enforcement through bribery, intimidation, and even murder.

Recent Trends in Smuggling Prior to trade liberalization at the end of the 20th century, most developing countries placed significant tariffs on imports to protect local industries, raise taxes, and/or restrict local demand for scarce supplies of foreign exchange. Although these policies were designed to enhance national welfare, they in fact resulted in higher prices for many products sold in these countries as well as limited product choice. Such policies promoted the growth of widespread smuggling of consumer products into developing countries. Many smugglers proved adept at physically evading law enforcement agents or co-opting them through bribery. Smugglers also found a convenient distribution channel among the many unlicensed street vendors of the developing world's informal economy.

For many in the growing middle classes in these countries, smugglers were seen as benign if not heroic actors. By the mid-1990s, the impact of smuggled goods was substantial in many markets. Contraband in Poland was estimated to equal 20 percent of legally imported goods, and half the computers sold in Brazil were smuggled into the country. In one year alone, Chinese authorities confiscated nearly half a billion dollars in contraband. In developed countries, too, smuggling of certain products thrived. A study by Albers-Miller (1999) observed that consumers of smuggled cigarettes in the United Kingdom considered their actions to be a reasonable response to high cigarette prices.

Widespread trade liberalization in developing countries in the last quarter of the 20th century raised expectations that smuggling would disappear as import quotas were abandoned and tariff levels diminished. However, the relationship of trade liberalization to smuggling proved more complex than originally believed. Gillespie and McBride (1996) studied the impact of trade liberalization on smuggling in Mexico during the 1980s and 1990s. They concluded that 15 years into trade liberalization smuggling had diminished but remained significant.

One reason for the persistence of smuggling after trade liberalization was the continuation of certain cost advantages to smugglers over legitimate importers. Tariffs had been lowered by trade liberalization but still existed, allowing smugglers to profit from circumventing them. For example, in 2006 the Indonesian tire industry was threatened by a surge of smuggled tires from China despite the country's relatively low 15 percent tariff on tires. In addition to tariffs, smugglers could avoid other taxes that their legal counterparts had to pay. In postliberalization Mexico, smugglers who switched to legitimate importation faced paying income tax as well as a 15 percent value-added tax on the products they sold.

In addition, many smugglers protected their low-cost position by increasingly forgoing the smuggling of legitimate goods in order to smuggle stolen or counterfeit goods. Stolen automobiles became especially popular. Cars stolen in the United States were not only smuggled into Mexico but shipped as contraband to China. Counterfeits were another way smugglers lowered the cost of smuggled products by stealing the brand equity of the brand owner. The trend toward smuggling counterfeit goods was exacerbated by greater scrutiny by law enforcement regarding counterfeits crossing borders. Customs authorities of many countries improved their ability to identify and confiscate shipments of counterfeits, thus forcing counterfeiters to seek out smuggling channels.

The diversification of smugglers into other criminal activities signified another disturbing trend. Smuggling was becoming less a business of Robin Hoods who were arguably providing consumers with good products at good prices and more the domain of organized crime. Smuggling activities appeared to be consolidating in the 1990s with contraband gangs involved in moving large shipments of goods. Violence, long associated with organized crime, appeared among these gangs. In Colombia and the United States, smugglers played a new role in the black market peso exchange. After a crackdown on the money laundering of illicit drug profits through U.S. banks, Colombian drug dollars in the United States were used to purchase products that were subsequently smuggled into Colombia. There they were sold for the pesos necessary to support the cartels' production operations. In the late 1990s, Colombian officials estimated that as much as 45 percent of the imported consumer products sold in their country had arrived via the black market peso exchange.

In light of smuggling's failure to disappear with trade liberalization and its increased consolidation and violence, many governments began to attack the problem with more vigor. Penalties, aimed at both smugglers and government employees who accepted bribes from smugglers, were increased. China and Vietnam threatened participants with a newly enacted death penalty. In some countries, such as Mexico, customs authorities were overhauled. Nonetheless, smuggling often remains hard to eradicate due to its organized nature, government corruption, and a lack of resources for law enforcement.

Smuggling and Legitimate Economic Actors
The role in smuggling of legitimate economic actors remains obscure. Legitimate importers and distributors are put at a cost disadvantage when required to compete with contraband. This has led to conflict in the past. In the early 1990s, violent altercations occurred in Mexico City when store owners attempted to evict informal vendors selling contraband outside their stores. However, smugglers and legal distributors need not always constitute two mutually exclusive groups. Several researchers have

proposed that smugglers could camouflage their smuggling with some legal imports and legal distributors could decrease their costs by including some contraband.

There are both benefits and disadvantages for producers of legitimate products that are smuggled. Smuggling works to their advantage when their products are barred from entering markets or when prohibitive taxation discourages purchase of those products. However, multinational corporations can suffer when smugglers undercut legitimate distributors, since legitimate distributors can provide greater oversight of product quality and deliver after-sales service. Relationships with strategic allies, such as licensees or joint venture partners in local markets, can be undermined when contraband enters a partner's market and diminishes legal sales.

The advantages and disadvantages of firms cooperating with smugglers are well illustrated by the case of the cigarette industry. In 1999, internal documents of the five largest tobacco companies were made public as part of a litigation settlement in the United States. These documents revealed a variety of ways in which cigarette producers cooperated with smugglers. These included sending cigarettes to known smugglers, destroying records related to smuggled cigarettes, discussions of how to disguise contraband shipments, setting up international financial accounts to camouflage contraband earnings, and buying air time on transnational media to provide advertising support for smuggled brands.

These revelations spurred a number of national and provincial governments to sue tobacco companies in U.S. courts. Besides seeking compensation for lost taxes and law enforcement costs related to the smuggling, some governments sought compensation for increased health costs due to greater cigarette consumption attributed to the lower price of contraband cigarettes. One suit brought by the European Union (EU) sought compensation of up to $1.7 billion a year. Another suit brought by Colombia charged Philip Morris employees with knowingly participating in the black market peso exchange, using cigarettes to help launder illicit drug money.

Despite the strong evidence of the public record, the plaintiffs were stymied by the U.S. Revenue Rule, which disallowed U.S. courts from assisting foreign governments in their collection of taxes. However, the EU won a ruling that allowed it to present its case anew as one involving money laundering. Subsequent to this decision, Philip Morris agreed to pay the EU more than $1 billion to settle the complaint.

Faced with increased public scrutiny, the multinational tobacco companies began to curtail supplies to distributors involved with smuggling. To the dismay of these multinational companies, smugglers who once helped them sell more of their branded cigarettes in high-tax countries quickly turned to smuggling counterfeit cigarettes instead. Practically overnight, smuggling ceased to be a major contributor to the profits of cigarette companies and became instead a substantial threat to their sales and brands.

Smuggling continues today to undermine public policy and challenge legitimate distribution channels. Trade liberalization has proven to be no panacea. For many governments, the increased association of smuggling with organized crime, counterfeiting, and money laundering only increases the urgency for its eradication.

■ social policy in open economies

Globalization and other forces are creating increased demand for social policies at the same time as they are restricting the ability of governments to supply such policies. Some observers see in this combination of increased demand and restricted supply a recipe for disaster in which globalization increasingly undermines the ability of governments to provide for the social well-being of their citizens. Both the theory and evidence available to date, however, suggest the glass is more half-full than half-empty: effective social policies remain alive and well in open economies, and the positive effects of the restrictions on governments' ability to provide social policy outweigh the negative effects.

The purpose of this entry is to outline the forces that increase the demand for social policies, the forces that restrict the ability of governments to supply such policies, and the conditions under which social policies can be provided. The concept of social policy as used here refers to the range of government policies that provide a social safety net, including employment standards involving factors such as minimum wages, hours of work, and terminations; health and safety regulations and programs, including workers' compensation, human rights and antidiscrimination legislation, and transfers such as unemployment insurance and welfare. Particular attention is paid to the United States and Canada, given the greater openness that has occurred in those countries after a number of recent free trade agreements.

Forces Increasing the Demand for Social Policy Initiatives The demand for social policy initiatives is increasing in part because of the interaction of three sets of interrelated forces: those affecting the demand side of the economy, especially the labor market; those affecting the supply side, especially related to demographics; and those affecting institutional changes.

On the demand side, labor markets are affected by a variety of interrelated forces: globalization and freer trade; technological change, the computer revolution, and the shift to a knowledge-based economy; industrial restructuring, especially from manufacturing to services; and deregulation and privatization. These pressures in turn give rise to a variety of manifestations, many of which increase the demand for social policy initiatives. Wage inequality has increased (Cline 1997; Rodrik 1997) as the lower end of the wage distribution has been adversely affected by various factors including import competition from low-wage countries, skill-biased technological change, outsourcing, and the supply influx from displaced workers who have lost their former blue-collar, male-dominated, often unionized jobs in manufacturing. Nonstandard, or "contingent," employment has increased in various forms (part-time, limited-term contracts, temporary-help agencies, self-employment, home work, and telecommuting). Many of these jobs have effectively shifted risk from employers to employees and created groups of vulnerable workers often without pensions or health care.

Numerous factors on the supply side are also increasing the demand for social policy initiatives. The population and labor force are aging and living longer, with the large baby-boom cohort entering the ages of retirement where disability and health care costs increase dramatically. The aging "gray panthers" are creating a voting constituency for social policies related to pensions, social security, and age discrimination policies that often have to be financed by a smaller cohort of taxpayers in younger generations. Many are facing issues of elder care for their own ailing and longer-lived parents. The rise of the two-earner family means an increased demand for social policies in areas of institutional elder care and childcare as well as for "family friendly" policies in areas related to working time and parental leaves. The rise of single-parent families has increased the demand for state support as a surrogate parent. The growing diversity of the workforce is creating demands for policies in the areas of human rights, antidiscrimination, and reasonable accommodation for disabled persons.

At the same time as these demand- and supply-side forces are increasing the demand for social policy initiatives, various institutional changes are also working in the same direction. The decline of unionization is creating a vacuum in areas where unions once provided protection and a safety net for unionized workers. The declining real value of the minimum wage has left many lower-wage workers increasingly vulnerable (DiNardo, Fortin, and Lemieux 1996). The decline of employer-sponsored occupational pension plans has exposed workers to more insecurity with respect to their retirement income, and the shift from defined-benefit to defined-contribution pension plans has exposed them to more investment risk.

While these various forces have often increased the demand for social policy initiatives, in other ways they have also reduced that demand. The two-earner family with women increasingly participating in the labor force obviously provides greater income potential and insurance against the risk of income loss associated with one member being unemployed or underemployed or disabled. Nonstandard employment can provide the flexibility for families to provide childcare or eldercare. The ability of older workers to continue working (in part due to legislative bans on mandatory retirement) can provide the potential for retirement income. The application of human rights and antidiscrimination policies as well as employment standards can facilitate individuals' earning income and thereby reduce their reliance on social policies provided by governments.

Forces Inhibiting Governments from Supplying Social Policies Many of the same forces that are increasing the demand for social policies are also reducing the ability of governments to finance social policies. Specifically, under globalization, freer trade, and falling transportation and communication costs, companies are more able to relocate their plants and investment to low-cost jurisdictions and export their goods and services back into higher-cost jurisdictions. Regulatory costs, including those arising from social policies, can be an element of those cost considerations. Such costs can arise from various regulations: labor standards (e.g., such areas as minimum

wages, hours of work and overtime, vacations, holidays and leave, terminations, severance pay, and unjust dismissal protection); collective bargaining regulations; antidiscrimination; reasonable accommodation requirements; workers' compensation; and health and safety regulations.

Because of the threat of the loss of business investment and the jobs associated with that investment, governments are under increasing pressure to compete in part by reducing their regulatory costs, including those arising from social policies. In essence, they are under more pressure to be "open for business." This is the case for governments across different countries as well as for local governments within countries.

Phrases used to describe this phenomenon generally have negative connotations: *social dumping, the rule of the market over the rule of law, harmonization to the lowest common denominator, regulatory meltdown, race to the bottom*, and *ruinous competition.*

Forces for Downward Harmonization to Occur
For such harmonization to occur and for it be to the lowest common denominator (i.e., to the jurisdiction with the least costly regulations and social policies) a number of conditions have to prevail (Gunderson 1998). First, the regulations and policies have to be enforced; otherwise there is no effective cost on employers. In many cases, initiatives that appear extremely costly "on the books" are simply not extensively enforced in practice. In this case, the intended benefit is also not realized.

Second, for the initiatives to be costly, the benefits to employers must be less than the costs. In many cases, employers themselves benefit from the initiatives, and this can offset at least part of the costs. Workers' compensation, for example, imposes a payroll tax on employers, but it also frees them from the threat of being sued by injured workers since workers gave up that right as the quid pro quo for essentially receiving "no-fault" coverage in the event of a workplace injury. Policies that require employers to give advance notice in the case of massive layoffs or plant closings can be costly, but they can also facilitate job searches that can benefit other employers.

Third, employers may shift much of the cost of work-related policies forward to customers or backward to workers. Shifting costs forward to customers is increasingly difficult in a world of global competition since customers can purchase from lower-cost sources that do not have such extensive regulatory costs. Shifting costs backward to labor, however, is possible since labor tends to be the immobile factor of production and hence cannot easily "escape" the cost shifting by moving to employers that do not shift their regulatory costs. Such cost shifting can occur in the form of lower compensating wages paid in return for the benefit workers receive from the policy. In other words, workers who receive those benefits effectively pay for them through receiving lower wages in return for the benefits. Evidence suggests, for example, that the majority of payroll taxes initially levied on employers for policies such as workers' compensation, pensions, and unemployment insurance are ultimately shifted back to workers in return for the expected benefits they receive (Kesselman 1996). In that vein, some of the populist views of imposing regulatory costs on large wealthy corporations are somewhat misguided in that the vast majority of those costs are shifted backward to workers in return for the benefits they receive from the regulations. There is no such thing as a "free lunch" in this area.

Fourth, for the harmonization to be downward, employers must respond to the cost increases by threatening to move their plants and investments to other, lower-cost jurisdictions. Although such a threat is now more credible, given the global conditions outlined previously, business investment and plant location decisions respond to a myriad of factors other than the cost of social programs. Furthermore, social programs can provide benefits to employers in forms such as infrastructure and political and social stability (Rodrik 1997).

Fifth, for downward harmonization to occur, governments must respond to the threat of capital mobility by reducing their costly social policy initiatives. Although there will be pressure in this direction, some governments (reflecting the prefer-

ences of their constituencies) may simply be willing to "pay the price" of their regulation. They may opt to be a "kinder and gentler society" and sustain their social safety net even if it costs them business investment and the associated jobs. They may hope to retain and attract what they regard as socially responsible business.

While these links must all be present for interjurisdictional competition for investment and the associated jobs to lead to downward harmonization to the lowest common denominator, the fact remains that the pressures are in the direction of such harmonization. That is, to a large degree each of the links is present: most policy initiatives are enforced; they impose net costs on employers; employers are not able to fully shift the costs; they have a credible threat to move to other jurisdictions that do not impose such costs; and governments do respond to the need to attract investment and jobs. As such, the pressures are in the *direction* of downward harmonization. The question is: How much? And are there countervailing pressures, often associated with openness and globalization, working against downward harmonization?

Forces for Upward Harmonization Although various forces foster downward harmonization, other forces, often associated with globalization and open economies, foster upward policy harmonization.

Consumer groups and nongovernmental organizations, often internationally organized and coordinated through the Internet, can put pressure on brand-name multinationals through various mechanisms including consumer boycotts, "Internet outings," and requiring a "social label" indicating the conditions under which the product was produced.

Multinationals themselves can foster upward harmonization by "exporting" the more advanced practices they follow in their home country and applying a more uniform set of their company practices across their different operations. Multinationals associated with brand names are especially sensitive to their public image and want to appear as good corporate citizens in the countries in which they operate. They often operate under voluntary corporate codes

of conduct and follow International Labor Organization/Organisation for Economic Co-operation and Development guidelines.

Open economies can also foster upward harmonization of social policies through the use of social clauses and side accords in trade agreements, such as the labor and environmental side accords under the North American Free Trade Agreement and the Social Charter of the European Union (EU). In such circumstances, countries that may not have enforced their labor standards are required to do so or even to raise them to the higher standards of trading partners, perhaps with the aid of funds such as the EU's Social Funds.

Social policies may also be harmonized upward through the emulation of best practices in the policy arena. To the extent that openness and globalization foster income convergence, the more rapid growth of the poorer countries may also enable them to afford more extensive social policies, again fostering upward harmonization. Empirical evidence supports the proposition that as income increases, the demand for social policies also increases (e.g., Fields 1995). Rodrik (1997) also emphasizes how social policies that assist those who are adversely affected by market-oriented policies such as free trade can foster efficiency by reducing public resistance to such market-oriented policies; equity and efficiency need not always conflict.

Forces for Sustained Divergence Various forces are also at work to sustain a divergence in social policies. Lower-income countries, for example, may be caught in a "low equilibrium" trap rather than converging upward. A divergence of social policies may therefore be sustained for an extended period of time, just as divergent growth rates may be sustained.

The conditions under which social policies are first established may exert a persistent influence on future policies. This is especially the case when bureaucracies and interest groups have a vested self-interest in sustaining the policies, and they become embedded in social structures and cultural norms within borders. Seymour Martin Lipset, for example, argued that the United States was initially influenced

by the American Revolution, which fostered a path of individualism and distrust of government. Canada, in contrast, started off on a path of loyalty to Britain and less distrust of collective action through the state. Such different initial conditions and subsequent path dependence may help explain the more extensive social policies that prevail in Canada compared with the United States.

Sustained divergence can also be fostered by the heterogeneous demands of various groups with differences in their preferences or needs for social policies as well as in their willingness and ability to pay for such policies. In such circumstances, a Tiebout-type equilibrium may prevail where individuals and firms sort themselves into jurisdictions that offer the social expenditure tax combination that meets their preferences. Just as openness and globalization can foster diversity in consumer options, they can foster diversity in choices of social policies.

Evidence: Harmonization or Sustained Divergence Clearly, theoretical reasoning suggests that globalization and openness along with other forces can foster harmonization in any direction: downward to the lowest common denominator, upward to a higher standard, or sustained divergence. As is commonly the case, theory covers all bases; hence the need for an appeal to the evidence.

The evidence, however, is not clear-cut. Gomez and Gunderson (2005) review the international evidence and particularly that of the United States and Canada. They conclude that increased openness has fostered a *tendency* toward harmonization of social policies and that harmonization has been *toward* the lower common denominator. Between the United States and Canada, for example, there has been recent downward harmonization toward the lower U.S. level in areas such as collective bargaining laws, minimum wages, unemployment insurance, equal pay laws, pension funding, and welfare and family benefits for working families. There has been sustained divergence in workers' compensation and health and safety, however, and some upward harmonization to the higher U.S. standards with respect to age discrimination. They also cite a wide range of studies, especially by political scientists (e.g., Garnett

1998), who tend to find more sustained divergence and emphasize that governments still maintain considerable degrees of freedom in setting their social policies in spite of greater openness and competitive pressures.

As indicated, Fields (1995 and other studies cited therein) have examined poor countries and indicated that as their incomes grow their demand for social policies also increases; that is, social policies are "normal goods" that are collectively desired and that can be afforded as income grows. In essence, the upward convergence of the income of poor countries toward that of wealthier countries also fosters an upward convergence in their social policies. It follows that prematurely imposing costly regulations on developing countries for example, as a condition of a free trade agreement can dampen the very growth process that would foster a natural upward convergence of social policies.

Countries of the EU did not experience a downward harmonization in their social policies as a result of the greater trade and capital and labor mobility after the formation of the union. This reflects the fact, however, that the EU Social Charter required the poorer countries such as Greece and Portugal to harmonize upward as a condition of entry into the EU. The EU also provided Social Funds to the poorer countries to facilitate their upward harmonization (Gomez and Gunderson 2005).

Even if there is a tendency toward downward harmonization, this should not automatically be regarded negatively. With greater openness, governments are simply under more pressure to pay attention to the cost consequences of their social policies; they face a "harder" rather than "softer" budget constraint. In such circumstances, social policies that are inefficient and involve mainly rent seeking (e.g., possibly procurement policies) are under the most pressure to dissipate since they do not foster the competitiveness that enables countries to ultimately afford their social policies. The competitive position of employers can be jeopardized by such policies, and their costs cannot be shifted back to workers since they do not have associated benefits for workers. In contrast, social policies that have positive feedback

effects on efficiency and support a public infrastructure should survive indeed thrive under greater openness and competitive pressures since they foster competitiveness. The area of greatest concern, however, is whether governments can sustain pure equity-oriented social policies that do not have positive feedback effects on efficiency but protect the most vulnerable and disadvantaged groups in society. This is the main challenge to social policy under increased openness and competitiveness.

■ **South-South trade**

South-South trade (SST) refers to trade between developing countries, which represent a limited share of the world economy in terms of supply capacity and markets. Trade between developing countries has been steadily limited despite the supposed gains associated with better matching of supply and demand characteristics and easier access due to less stringent standards, which should promote regional integration. Contrary to the common perception, however, in recent years SST has been a major contributor to the growth of world trade. Trade between developing countries accounted for 18 percent of world trade in 2005, an increase of 5 percentage points within five years. In contrast, the share of North-North shipments in world trade has been reduced by 5 percentage points over the same period.

China is the most prominent country in this regard. On the import side, China has become in 2005 the second largest market for exports from the South behind the United States, but ahead of Japan or

Germany. Moreover the pace of growth is impressive, with a 232 percent increase of Chinese imports from other developing countries within five years, excluding oil. Besides China, a series of developing countries contribute to SST by offering buoyant markets: essentially Asia (Hong Kong, Singapore, Korea, Taiwan, Malaysia, Thailand, India, etc.) and Mexico.

Still, a large number of developing countries have been missing this general trend, in particular the least-developed countries, and a key pattern of the recent increase is that it has been very unevenly distributed among countries in the South. The sectoral pattern of exports very much reproduces the general pattern of specialization of the developing countries. It does not come as a surprise, therefore, to see China importing natural resources from other developing countries.

Explanations of a deficit of South-South trade (SST) range from geography, institutions, and trade costs to the difficulty of pursuing regional integration in the South. The asymmetric nature of trade liberalization may have played a role too: preferences have been conceded by the North on a nonreciprocal basis, without requesting access to markets in the South. This approach has made it more appealing for the South to trade with the North than with the South (Bouët, Fontagné, and Jean 2006).

Vertical Division of Labor and Extensive Margin of Trade Two main determinants of the recent dynamism of SST must be stressed. First, the vertical specialization of countries (Hummels, Ishii, and Yi 2001) and the associated increasing fragmentation of the production processes translate into large flows of parts and components among developing economies. Vertical specialization accounts for roughly one-third of world trade growth. Such processing trade is well documented in the case of Asia. China, especially, is often used as an export platform, importing and assembling intermediate goods produced by affiliates of foreign firms located elsewhere in Asia.

Second, the diversification of numerous developing economies has led them to compete on a wide spectrum of products with industrialized countries. According to the distinction introduced by Melitz

(2003), the recent dynamism has been based on the extensive margin of developing countries' exports (that is, increasing the number of exported products or destination markets), rather than on the intensive one (exporting increasing values of the same products to the same markets).

Using detailed U.S. import data, Hummels and Klenow (2005) construct measures such that a country's share in world exports decomposes in an extensive export margin (the fraction of world exports occurring in the product-market categories where a country exports), times an intensive export margin (a country's share of world markets in the market-categories in which it exports). Though not specifically addressing SST, such a decomposition is very informative. The underlying question is: As a country develops and accumulates resources, how are these resources used? To increase the quantities exported of the existing set of goods? To improve the quality of these goods? Or to expand the set of goods or destination markets? The bottom line is that two-thirds of the growth pertains to the extensive margin, essentially due to a larger number of exported products: A simple count points to a 62 percent increase in their number when the economic size of the exporter doubles.

In 2005 China overtook France and the United States in terms of diversity of exports. Other highly diversified exporters include Korea, Taiwan, India, Turkey, Thailand, Brazil, Mexico, Malaysia, Singapore, Hong Kong, Indonesia, South Africa, United Arab Emirates, Argentina, and the Philippines. In contrast, Ethiopia has simply kept its number of products constant over the period 2000 2005, while Jamaica, Myanmar, El Salvador, Mali, and Côte d'Ivoire have recorded declines in the number of their exported products. Still, the question remains whether recorded SST flows remain too low, given the characteristics of these countries.

The Gravity Puzzle Using gravity equations to assess deviations between actual and predicted trade has been the most common approach to study SST. The augmented gravity equation explains the value of bilateral trade by the gross domestic products (GDPs) of exporter and importer, the distance be-

tween them, and a vector of control variables accounting for the level of trade resistance between them, such as the level of tariffs, whether they share a common language or a common border, and the existence of a free trade agreement (FTA). In the case of SST, the appealing feature of this approach is that the data involved are readily available.

This approach may be flawed, however, due to omitted variables and endogeneity problems, as examined in Baier and Bergstrand (2006). The latter type of problem is particularly penalizing, since it sheds doubt on the extensive literature addressing the trade impact of integration among developing economies. In a nutshell, are FTAs randomly formed, or are they formed among countries that share characteristics that make them good candidates for integration? If the latter, FTAs' impact on trade might well be overestimated.

Examining intra-WAEMU (West-Africa Economic and Monetary Union) trade, Coulibaly and Fontagné (2006) stress the combined role of economics and geography in the persistence of untapped trade potentials. Being poor and landlocked profoundly reduces trade: beyond distance, the worse combination for SST is accordingly to export from a landlocked country, through a transit country, with a limited share of paved roads.

Poor infrastructure is, however, only a partial explanation for the low level of SST, since it also affects domestic trade. Low levels of SST also result from tariffs, nontariff barriers (NTBs), preferences, and more generally all aspects that make it more difficult to trade with another country than with another region within the same country. Capturing such effects imposes a methodological shift: the right benchmark is domestic trade (the difference between domestic production and exports). A growing literature is using the trade and production database of the United Nations Industrial Development Organization and the World Bank to analyze sectoral trade and production data for a series of countries in the North and in the South. This makes it possible to use the so-called border effect methodology to assess whether something specific is hampering SST.

Controlling for supply capacity, demand, distance, tariffs, NTBs, and common colonial power, SST is much more deflected by the existence of borders than North-North trade or North-South trade are. Mayer and Zignago (2005) estimate that the impact on SST of the barriers (custom formalities and delays, differences in preferences or regulations, etc.) associated with the existence of a border is the equivalent of a 100 percent tax on imports, and this effect is in addition to that of any existing tariffs and NTBs.

In this context, do free trade areas offer a viable solution? Fontagné and Zignago (2007) address this issue in a study designed to control for systematic differences in trade across countries and productive sectors. The six most prominent preferential trade agreements (PTAs) according to their trade impact are the Central American Common Market, the Andean Community, the North American Free Trade Agreement, the European Union, Mercosur (the regional trade agreement among Brazil, Argentina, Paraguay, and Uruguay), and the Association of Southeast Asian Nations; other PTAs have a smaller impact on trade.

Another route to trade liberalization among developing countries proceeds from their active participation in the multilateral arena. Simulations conducted with computable general equilibrium models conclude that this is key to the "development part" of the ongoing multilateral round of negotiations (Francois, van Meijl, and van Tongeren 2005).

Recent literature reexamines the common view that trade promotes peace and finds that the impact of bilateral and multilateral trade is not the same. Considering military conflicts in the period between 1950 and 2000, the probability of a conflict is lower among countries trading more bilaterally, because of the larger trade losses incurred in case of conflict (Martin, Mayer, and Thoenig 2007). Hence regional agreements in the South, as opposed to the multilateral trade liberalization agreements, reinforce the bilateral dependence among developing countries and reduce the probability of occurrence of a conflict.

■ sovereign risk

Sovereign risk refers to circumstances in which governments default on loan contracts with foreigners, seize foreign assets located within their borders, or otherwise prevent domestic holders of foreign capital from meeting obligations. Because there is no supranational authority that can enforce contracts across borders, when sovereigns choose not to honor contracts with foreign investors, those investors have little recourse to recoup their losses. Consequently relationships between foreign investors and sovereigns are dictated primarily by the sovereign's willingness to pay rather than its ability to pay.

Foreign governments could become better credit risks by waiving sovereign immunity. The legal doctrine of sovereign immunity can be interpreted as exempting the property of foreign governments

from the jurisdiction of domestic courts. Historically, this doctrine has sometimes constrained the ability of creditors to sanction foreign governments that have defaulted. The doctrine has evolved over time to grant creditors some recourse against defaulting sovereigns, however.

History is replete with instances of sovereign default. During the 19th and 20th centuries, in many instances the repayments of loans to sovereigns were far from what was called for in contractual obligations. In the 1820s, for example, Latin America experienced a wave of defaults among its newly independent countries. Many Latin American countries defaulted again in the 1870s, as did Egypt and Turkey. In the 1930s, most sovereign debtors suspended interest payments in the wake of the global depression.

Sanctions and Reputation The risk that a sovereign will not honor its obligations with foreign investors is mitigated by two factors: the threat of sanction and the loss of reputation. Direct sanctions may involve significant costs for defaulting countries. For example, sanctions could take the form of intercepting payments that the sovereign might make to exporters or payments it might receive from importers. Potential exporters to the country might then be less willing to supply the debtor country, knowing that their compensation might be intercepted. Generally, however, the net gain to creditors from sanctions will be less than the cost to the debtor. In theoretical models of sovereign borrowing with sanctions, the optimal amount of borrowing is constrained by the sanction cost: the parties to the debt contract write an incentive-compatible contract that never calls on the sovereign to make a payment to foreign creditors in excess of the sanction cost. This incentive-compatibility constraint leads to less lending than would be the case in a world where no country ever defaulted. An implication of this line of theorizing is that stronger, credible sanctions would allow sovereigns to increase the amount of their borrowing.

Reputation considerations provide another motive for sovereigns to honor obligations with foreign investors. A sovereign might choose to repay in order to maintain continued access to international capital markets on favorable terms. This idea was articulated in work that showed formally the conditions under which countries repay debts in order to preserve a reputation for repayment (Eaton and Gersovitz 1981). Subsequent work questioned whether reputational considerations alone were enough to sustain international lending in the absence of effective sanctions (Bulow and Rogoff 1989). If defaulting countries are able to earn a market return on their savings abroad they could, in theory, borrow, invest the funds abroad, default on the loan, and use the proceeds of their investments abroad to finance domestic investment opportunities in perpetuity.

Reputation models of international lending were revived by Cole and Kehoe (1997), who countered that reputation alone may support international lending if reputational spillovers are important enough. They argue that sovereigns participate in many different relationships. If they renege in one of those relationships, the damage may have adverse consequences for other relationships. If the spillovers are large enough and last long enough, then reputation considerations alone cannot support international borrowing and lending, without resort to the threat of direct sanctions. In general, though, if countries with poor credit histories are able to borrow abroad without fear of their assets being confiscated, the threat of reputation loss becomes less of a factor in deterring default.

Causes and Consequences of Default Risk Several factors have been found to influence the likelihood of sovereign default. Historical data suggest that the risk premium on foreign debt (over the return on U.S. Treasury bonds or British consols) increases with the size of a country's trade deficit and budget deficit. In addition, internal political considerations play a role: those countries that respond to a crisis by raising taxes or cutting spending are less likely to default. Severe external shocks have been found to precipitate default (Diaz-Alejandro 1983). In addition, the debt-to-export ratio and deteriorating terms of trade appear to influence the likelihood of sovereign default. In general, a country's internal

and external circumstances play a role in sovereign risk.

The tangible consequences of sovereign default have proven difficult to uncover. The economists Lindert and Morton (1989) examined data on the 10 leading debtor countries from 1850 to 1970 and found that, on average, foreign lending earned a higher return than domestic lending in the United States and the United Kingdom. Eichengreen and Portes (1989) examined data on bond issues in the 1920s and found that for bonds issued in London, foreign lending earned a higher return than on contemporaneous British consols. For loans originating in the United States, overseas lending earned a return only slightly lower than that on U.S. Treasury securities. Actual yields on foreign lending compensated British and U.S. investors for suspension of payments and write-downs of principal.

When countries default, have they been denied access to international capital markets? Here the evidence is somewhat mixed. Countries that did not default in the 1930s appear not have gained wider access to international capital in the 1930s, or following World War I. Indeed, default of some countries led to a shrinking of global capital flows to all, as the international capital market virtually shut down. A review of historical evidence suggests that there is little, if any, evidence to suggest that the volume of foreign funds a sovereign could borrow was adversely affected by a record of prior default (Eichengreen 1991).

Why do lenders keep lending to countries that have a history of default? Lenders are often uncertain about the characteristics of borrowers. Consequently, new information about borrowers can have a large impact on lending. In the case of countries, a credible change in policy regime may negate the influence of a history of default. If a country changes its regime to focus on economic stability and sound monetary and fiscal policies, history suggests that lenders will be willing to extend further credit.

■ sovereign wealth funds

Many capital-exporting developing countries look for systematic ways of raising returns on their international currency reserves on a long-term basis by creating sovereign wealth funds (SWFs), which are designated pools of assets owned and managed by governments and predominantly deployed worldwide to attain higher returns.

Countries usually have their international reserves managed by their central banks and held in liquid assets in reserve currencies. Since the primary functions of international reserves are to finance payment imbalances and limit exchange rate volatility, the reserves must have a high degree of liquidity. Since assets typically have lower rates of return the more liquid they are, however, it can make sense for governments to invest in longer term, less liquid assets such as bonds and equities. Similarly there may be gains from diversification by investing in a broader range of countries than only those with major reserve currencies.

Perhaps the clearest rationale for the establishment of an SWF is to accumulate reserves in countries that are major exporters of nonrenewable resources such as oil and gas. Concern for future generations dictates that all current revenues from the sale of such commodities not be spent on current consumption. Nor, typically, could all of the remainder be spent productively on domestic investment. Usually a substantial proportion of these revenues accrue to governments from tax receipts or direct ownership. Thus governments accumulate reserves.

Oil-producing countries make up more than half of all SWF funds (i.e., commodity-based funds) in terms of assets under management. Kuwait's International Authority, funded by oil, was established in 1953 and is the oldest SWF. Another prime example is Norway's Global Pension Fund, funded by a portion of North Sea oil and gas. The United Arab Emirates' Abu Dhabi Investment Authority Fund, which was established in 1976, is the world's largest SWF currently, with U.S. $625 billion under management. Other oil exporters, Oman and Brunei, also created investment agencies to recycle their reserve holdings in the 1970s and 1980s, and Russia followed suit more recently, creating a Stabilization Fund in 2003 (Lyons 2007).

Among the better-known non-commodity-based SWFs in Asia are Singapore's Government Investment Corporation (GIC) and Temasek Holdings. Since some of the funding sources for the agencies also include pension contributions from Singapore residents, however, these entities are strictly speaking a combination of SWFs and sovereign provident funds. GIC, established in 1981, has around U.S. $215 billion under management and tends predominantly to make financial and real estate investments. Temasek, established in 1974, has around U.S. $100 billion under management and is a more active investor in international companies regionally and globally.

Although SWFs have been around since the 1950s, they have only recently attracted much public attention. SWFs have taken on increased prominence with their phenomenal growth in recent times (both in numbers as well as funds under management), especially with the creation of the China Investment Corporation (CIC) in 2007. The CIC, which is said to be modeled on Singapore's GIC in both concept and design, began operations when the Chinese government transferred U.S. $200 billion of its U.S. $1.3 trillion in reserves to the agency, making it the world's fifth largest SWF. The new fund's first major investment was a $3 billion investment in the U.S.-based Blackstone private equity group. SWFs took center stage at the October 2007 World Bank and the International Monetary Fund (IMF) annual meetings, and the G7 industrial countries have begun to pay greater attention to these entities.

Since many of the SWFs practice considerable secrecy, the total value of their assets is not known, but estimates put the figure at between $2 and $3 trillion, substantially larger than the global aggregate of all hedge funds. Estimates also project a rapid rate of growth, with figures of $10 trillion and more expected to be reached by early in the 2010s.

Another rationale for SWFs is to minimize the destabilizing effects of fluctuations in exports due to periods of more and less rapid growth in the world

economy. Medium-term fluctuations are common for a wide range of agricultural as well as both renewable and nonrenewable raw materials, so economists have long recommended that governments should accumulate international reserves in good times and draw them down in bad. This has proven difficult to do in many developing countries because of political pressures to spend all increases in reserves. These tendencies can be partially countered through the establishment of SWFs. An example is Chile's Economic and Social Fund, established in 2006.

A third rationale for the creation of SWFs is to eliminate a continual surplus. When continuing disequilibrium in a country's balance of payments has led it to accumulate far more international reserves than it needs based on traditional criteria, and the country expects to continue to accumulate reserves (or at least, not have huge reductions), then it makes no sense to hold all of its reserves in low-yield liquid assets. The country could put its excess reserves into a new facility to earn higher returns, but if reserves are clearly excessive then it would most likely take actions to eliminate its continual balance of payments surplus. Only if the rate of return on domestic investment was quite low would it make sense for the government to continue to accumulate international financial assets, even if these were invested in less liquid, higher return securities. In a market-oriented economy without capital controls, private investment would tend to flow from lower- to higher-yield areas. Thus, if domestic investments were indeed lower yield, capital would flow out and eliminate the balance of payments surplus.

A prime example of such clearly excessive reserve accumulation is China since around 2000. China does have extensive capital controls that block this equilibrating flow of capital. The primary reason that the Chinese government has not taken sufficient adjustment actions to slow or reverse China's balance of payments surplus and accompanying reserves accumulation is that in the short run the needed adjustments would hurt some sectors of the economy, and the government is greatly concerned about the short-run political and social instability that such disruptions might generate. Thus, although adjust-

ment is in China's longer-run economic interest, in the government's calculation, this is outweighed by the likely short-run political costs. Numerous policy announcements have made clear that the government would be happier if the surplus were reduced, but its limited actions reveal the high priority given to avoiding short-run adjustment costs.

The limited adjustments taken by the Chinese government have also contributed to global economic imbalances and the risk they pose to global financial stability. Of course, China alone is not responsible for such global imbalances. From a global perspective, however, the creation of the SWF reduces the national economic cost of these continual reserve accumulations and hence reduces somewhat the pressures on China to do its part toward the needed mutual adjustments.

The greatest concerns about SWFs focus on a different type of issue, however: the fear of foreign government influence over the operation of key segments of domestic economies. As long as SWFs limit themselves to passive portfolio investments they do not pose major problems on this score. The problems come when they make direct investments of substantial stakes in sensitive industries. Such fears have been highlighted by the recent efforts of government-controlled enterprises in China and Dubai to purchase a U.S. oil company and port operator, respectively. Although in neither of these cases was an SWF involved (the bidders were state-owned companies), they have led to considerable speculation about what could occur. Concerns have also been raised that the large amounts of money controlled by some SWFs could generate disruptions in financial markets. These concerns and questions have been fuelled further by the purchase of fairly large stakes in major U.S. financial institutions by various SWFs. Although creating such disruptions would seldom, if ever, be in the interest of SWFs, this may not be sufficient to calm all fears. The likely greater danger is that this range of fear would stimulate protectionist backlashes that could hurt both the SWFs and potential investment recipient countries.

Certainly, some SWFs follow policies that are unlikely to generate conflicts. Norway, for example,

provides considerable transparency and spreads its investments over a wide range of equities, taking only small stakes in any one. Many funds are currently quite opaque, however. Such considerations suggest that the development of an international code of conduct for SWFs could be in the mutual interests of both capital-exporting and capital-importing countries. The possibility of developing such codes has become a major topic of attention in many countries and international forums such as the G7 and the IMF (for instance, see Truman 2007).

◼ special and differential treatment

Special and differential treatment (SDT) refers to provisions in World Trade Organization (WTO) agreements under which developing countries or groups thereof receive more favorable treatment or undertake less onerous commitments than other members. Developing countries have long argued that their development status requires that they be subject to different and more favorable trade rules than other members. This principle was accepted in the General Agreement on Tariffs and Trade (GATT, Part IV) and later in the WTO agreements, which contain numerous provisions for SDT for developing countries, as well as additional provisions containing even more favorable treatment for the least-developed countries (LDCs), a group of 50 countries that meet certain development criteria defined by the United Nations.

The main conceptual premise that underlies SDT is that developing countries are intrinsically disadvantaged in their participation in international trade and multilateral agreements involving them, and developed countries must account for this weakness in specifying their rights and responsibilities. A related premise is that trade policies that maximize sustainable development in developing countries differ from those that do so in developed economies, and hence policy disciplines applying to developed economies should not apply to developing countries. The final premise is that it is in the interest of developed countries to assist developing countries in their fuller integration and participation in the international trading system.

The provisions introduced in the WTO agreements fall into two broad categories: positive actions by developed country members or international institutions and exceptions to the overall rules contained in the agreements. Developed countries have also agreed to take three kinds of actions to support developing countries' participation in international trade:

- Provide preferential access to their markets, such as through the Generalized System of Preferences (GSP), under which many developing country manufacturing exports enjoy duty-free entry into developed country markets.
- Provide technical and other assistance to permit them to meet their WTO obligations and otherwise enhance the benefits developing countries derive from international trade.
- Implement the overall agreements in ways that are beneficial or least damaging to the interests of developing countries and LDCs.

Developing countries and LDCs have accepted differential obligations under the WTO agreements, in that they are permitted to undertake policies that limit access to their markets or support domestic producers or exporters in ways not allowed to other members. Examples include GATT Article XVIII on government assistance and the general exemption from reciprocity in trade negotiations with developed countries to reduce or remove tariffs and other barriers to trade. Similar provisions for nonreciprocity are included in the General Agreement on Trade in Services (GATS, Article XIX:2), which states, "There shall be appropriate flexibility for individual developing countries members for opening fewer sectors, liberalizing fewer types of transactions, progressively extending market access in line with their development situation." Second, developing countries and LDCs get more time to meet obligations or commitments under the agreements (for example in Trade-Related Intellectual Property Rights TRIPS).

Both the premises and the practice of SDT have proved controversial. Some have argued that the freedom provided to developing countries to protect their economies has harmed rather than promoted development and, similarly, that the lack of reciprocity in the mutual reduction of tariff barriers has contributed to the relatively high tariff barriers now facing developing countries in developed country markets. It is also argued that the GSP has provided significant benefits to only a few countries and has done little for the poorest and the LDCs.

Others have noted that most of the WTO commitments for SDT made by the developed countries have been vague and legally unenforceable. Many poorer developing countries have been pushed to participate in agreements such as TRIPS, sanitary and phytosanitary measures, technical barriers to trade, and customs valuation without taking into account their lack of capacity to implement their commitments and without ensuring the provision of adequate assistance. Moreover the transition periods envisaged under the WTO were unrealistic. The time limits for extensions had passed, and as of early 2008 there was little evidence that countries had made

sufficient progress in institution building to permit them to implement their obligations. Finally, there is the question of which countries should be receiving SDT. Many low-income and vulnerable economies face the same kind of developmental constraints as the LDCs, yet only the latter receive special consideration, probably because their total participation in world trade is so small as not to constitute a competitive threat to developed country producers. On the other hand, because the principle of self-selection is used in determining who is a developing country, large countries that are well integrated in the international trade such Brazil, China, or Singapore are in principle eligible for the same kind of SDT as small vulnerable economies such as Ghana or St. Lucia.

The Doha WTO Ministerial Declaration underlying the Doha Round of multilateral trade negotiations was replete with pronouncements about SDT. It stated that "provisions for special and differential treatment are an integral part of the WTO agreements," and it called for a review of SDT provisions with the objective of "strengthening them and making them more precise, effective and operational" (para. 44). As of early 2008, little progress had been made on these issues with the exception of a decision related to TRIPS and pharmaceuticals and a number of decisions related to LDCs. It was agreed that LDCs would not have to make any tariff reduction commitments as part of the multilateral negotiations. This was controversial as it raises the risk that LDCs will continue to maintain significant protective barriers that would undermine their development.

In TRIPS, developing countries can use compulsory licensing to reduce the cost of drugs for HIV/AIDS whose patents were held by developed country pharmaceutical companies. But this provision is of no use to countries that have no capacity to produce these drugs domestically. Under heavy public opinion pressure, the WTO agreed to an amendment permitting developing countries that do not have capacity to produce drugs needed to combat epidemics to import them from low-cost suppliers at low prices under carefully circumscribed circumstances. In a related action, negotiators also agreed to

extend the transition period for the implementation of the TRIPS agreement for LDCs until 2013 and for pharmaceuticals until 2016. But the decision does not cover other low-income countries that face similar developmental constraints.

In parallel with the Doha Round negotiations, an effort was made to strengthen the international community's efforts to provide trade-related technical and other assistance. Agreement was reached for an enhanced Integrated Framework for Trade-Related Assistance to LDCs with a new independent secretariat housed in the WTO and the expectation of substantially increased aid resources. On the other hand, a WTO Task Force on Aid for Trade, which was supposed to address assistance needs of all developing countries, could only come up with general and vague recommendations.

Recent experience with SDT suggests an emerging consensus that SDT should be extended to many developing countries that do not have the institutional capacity to implement a number of WTO agreements — or for whom implementation of such agreements is not a development priority — and that many of these countries, especially the LDCs, are deserving of increased trade-related international assistance. Also, a number of proposals to strengthen monitoring of SDT needs and implementation, possibly in the context of WTO trade policy reviews, have received widespread support, though no specific agreement has been reached.

Controversies are likely to continue on specific developing country SDT proposals, however, especially those that affect basic WTO disciplines such as binding of all tariffs, commitments not to use nontariff barriers to trade, or participation in the multilateral trade negotiations, as well as on which countries should receive SDT. Overall, the role of SDT in the world economy is going to continue to be small but important to a considerable number of poor developing countries, especially the LDCs.

■ special drawing rights

Special drawing rights (SDRs) are an internationally recognized unit of account and reserve assets issued by the International Monetary Fund (IMF) and allocated to IMF member countries in proportion to their quotas at the IMF. According to the IMF (2006a), the SDR is "a potential claim on the freely usable currencies of IMF members." SDRs can be exchanged for other currencies in two ways: first, through voluntary exchanges between members; and second, by an IMF directive, designating members with strong external positions to purchase these SDRs.

SDRs were initially created in 1969 to increase the availability of easily convertible reserve assets. Before 1969, reserve assets — those assets held by central banks to clear international transactions — were held mostly in U.S. dollars and gold. The economists Peter Clark and Jacques Polak (2004) note that, at the time, issuing SDRs was seen as a way of preventing

official dollar holdings from undermining the stability of the system. Reserve accumulation was perceived as destabilizing since many central banks converted their dollar reserves into gold, thereby drawing down the limited U.S. gold stocks.

SDRs are also used as units of account by the IMF in all of its transactions. The IMF conditional loans are denominated in SDRs, while the interest rate on these loans is calculated on the basis of the SDR interest rate (in addition to an interest surcharge that varies with the different lending facilities).

Amended every five years, the value of an SDR unit is the sum of the values of the following as of January 2006: 0.632 U.S. dollars, 0.410 euros, 18.4 Japanese yen, and 0.0903 British pounds. As of February 1, 2007, 1.496137 U.S. dollars were worth one SDR unit. The SDR interest rate is calculated as the weighted average of interest rates on short-term instruments in the financial markets of the four currencies included in the SDR valuation basket; it is posted on the IMF Web site once a week. On the week of February 1, 2007, for example, the SDR interest rate was 4.20 the weighted average of the interest rates of a three-month U.S. Treasury bill, a three-month Europe rate, the Japanese government's 13-week financing bill, and a three-month UK Treasury bill.

Role of SDRs From their onset, SDRs could be held only by governments, central banks, and official bodies such as the IMF. The original SDR allocation of 9.3 billion SDRs was disbursed among the IMF members according to predetermined quotas over a two-year period (1970 72). An additional amount of 12.1 billion SDRs was allocated and distributed between 1979 and 1981. SDRs have not been allocated since. As a result of the reluctance among the IMF stakeholders to allocate new SDR issues, SDRs now amount to only about 1 percent of the international reserves held worldwide. SDRs clearly did not end up as the primary reserve asset in the global monetary system as envisioned in the IMF Article of Agreements (XXII). In addition, Clark and Polak (2004) suggest that the concerns of international liquidity (i.e., the worldwide lack of sufficient gold reserves) that led to the establishment of the SDR no longer apply.

Although the original rationale for the creation of SDRs is no longer relevant to the post Bretton Woods system of flexible exchange rates, other reasons for their existence as reserve assets remain. Since capital accounts are now much more open than ever before (with the possible exception of 1880 1914), reserves are seen as a means to prevent fluctuations in the trade balance and domestic consumption that would be required in the face of fluctuations in capital flows. SDRs enable countries to diversify their reserve holdings, and more important for developing countries, the SDR can be held at a much lower cost than major currencies such as the U.S. dollar, the Japanese yen, the euro, or the British pound. This is especially true for the lowest-income countries, which are virtually cut off from the international financial markets and for whom the only means of obtaining reserves is running trade surpluses through reductions in imports.

Another possible future use for the SDR is as an alternative reserve asset that can be issued broadly in case of a dramatic U.S. dollar crash (Lissakers 2006). A dollar crash, a plausible event in light of the persistent U.S. balance of payment deficits, and the central role of the dollar as a reserve currency (roughly 70 percent of all foreign reserves are held in U.S. dollar denominated assets), might create the conditions for a general flight from the dollar; this means that the question of constraints on international liquidity might reemerge.

■ specific-factors model

Most undergraduates in their first year in economics have been exposed to an important ingredient in the specific-factors model, a model in which each in dustry employs some factor used only in that par ticular industry. What happens to total output when more of a variable factor is added in a production process to a fixed quantity of this specific factor? The answer exemplifies the Law of Diminishing Returns, and this ingredient is basic in the general equilibrium context in which the specific-factors model is set. David Ricardo used this concept when referring to the differential rents that various qual ities of land would receive, and Viner (1931) made use of it in his famous article in which he argued with Wong, his draftsman. Haberler (1936) in his classic text on international trade presents verbally some of the logic of what Samuelson (1971) later referred to as the Ricardo-Viner model. The formal exposition of the model in general equilibrium terms was carried out by Samuelson and by Jones (1971), both of whom emphasized the usefulness of the model in the theory of international trade, although the model itself is also applicable to closed economies.

The nature of the model is most easily discussed in the context in which only a pair of commodities is produced in competitive conditions, with each commodity making use of a factor employed only in that sector (i.e., a *specific* factor) as well as a factor of production (typically taken to be labor) that is used in both sectors (the *mobile* factor). In a competitive equilibrium, factor prices and input-output coeffi cients adjust to maintain full employment of all factors, and with constant returns to scale charac terizing production processes, costs of production adjust to equal commodity prices if both commod ities are produced. The process of solving the model formally for changes in factor prices and commodity outputs when commodity prices or factor endow ments are altered is more simple than that found in the Heckscher-Ohlin model (the standard model used in trade theory since the Stolper-Samuelson article appeared in 1941) in that it is not necessary to solve more than one equation at a time. The key equation is the one that asserts full employment of the mobile factor. With techniques in each sector depending only on the wage rate relative to the commodity price in that sector (the important technological parameter being the elasticity of the

demand curve for labor, exhibiting diminishing returns to labor as more is added to a given amount of the specific factor) and each output restricted by the given amount of the specific factor and the intensity of its use (which depends on the wage/price ratio), the change in the wage rate is seen to depend on commodity price changes and changes in factor endowments. These relationships are often portrayed in a "back-to-back" diagram, such as figure 1. A pair of (value of) marginal product schedules face each other, each assuming given values for the quantity of the specific factor available in that sector as well as that sector's commodity price. The intersection point, A, reveals both the equilibrium value of the wage rate and the quantity of labor assigned to each sector.

Details of the solution are found in many places, for example, in the supplement to chapter 5 of the Caves, Frankel, and Jones text (2007). The important results are (1) if either commodity price increases, the wage rate also increases, but by less than in proportion; (2) any increase in the labor endowment at constant commodity prices drives down the wage rate (to the benefit of both specific factors); and (3) any increase in the endowment of either specific factor lowers that factor's return, pushing up the nominal wage rate, and thus driving down the return to the other specific factor as well. The asymmetry found in factor returns when the price of a single commodity increases reflects the asymmetry found in the mobility of the two factors: an increase in the price of the first commodity must lead to a matching increase in average cost. The return to labor is constrained by its use as well in the other sector, one that has not benefited by a price increase, while the return to the specific factor used only in the first sector is not constrained in this fashion. The consequence is that the wage rate cannot increase relatively as much as p_1, thus pushing up the return to the specific factor employed there by a magnified relative amount so that unit costs increase as much as price. With the nominal wage rate rising, the return to the specific factor in the second sector falls.

An important result in the field of political economy is immediately apparent, even in the two-commodity setting. Suppose the primary issue facing voters before an election is whether or not to impose a tariff on imports. The specific factor in the import-competing sector will be strongly in support of the tariff, while the other specific factor would be strongly opposed. This is not surprising. But what of the attitude of voters whose income is in the form of wages? Protection raises the nominal wage rate but also increases the cost of living. This may leave many voters with the desire to stay at home on election day (especially if the weather is inclement) since their real incomes do not depend that heavily on the outcome. (Ruffin and Jones 1977 argue that on balance labor will be mildly against protection in the specific-factors model.) This would help to explain relatively low voter turnout at election times in countries such as the United States. If, instead, the important issue before the voters concerns immigration, both specific factors stand to gain or lose together, and this may result in their joining forces in a political alliance.

The setting of the specific-factors model has two basic interpretations. On the one hand, the two specific factors may fundamentally be different say, land and capital (e.g., in Jones 1971). On the other hand, they may represent, say, two kinds of capital that are specific in the short run but can become interchangeable with the passage of time (e.g., in Neary 1978). As Magee (1980) has argued, a
Figure 1
Wage rate determination

sector-specific type of capital might change its attitude toward protection in the long run. The Neary interpretation has become popular in explanations of how the specific-factors model may be linked to the standard Heckscher-Ohlin model, where both factors are intersectorally mobile. Such a link was given a different rationale in the model of Sanyal and Jones (1982), in which a country produces final commodities by using labor and *middle products,* that is, goods in process, raw materials, or intermediate goods that can be obtained on world markets. The country may export some of its own production of middle products in exchange for imports that are better suited to its own needs in producing final consumption goods. Thus middle products produced at home with labor and the country's own specific factors can be traded for middle products requiring, say, specific factors not available at home. In other words, final consumer goods are produced with two mobile factors: labor and traded middle products. (As the Canadian economist Doug Purvis once remarked, in this setting Heckscher-Ohlin does not explain trade, trade explains Heckscher-Ohlin.)

How does the specific-factors model match up with the Heckscher-Ohlin model? In the setting in which only two commodities are produced, differences between the specific-factors model and the Heckscher-Ohlin model are often emphasized in the theory of international trade, especially as regards the effects of free trade on a nation's factor returns. As Samuelson (1948) demonstrated, if endowment differences are relatively small between two countries sharing the same technology and facing the same traded goods prices, factor prices tend to be equalized by trade despite the fact that each factor has a purely national market. The specific-factors model does not share this property. With the number of factors (3) exceeding the number of produced commodities (2), any tendency for factor returns to become equalized with trade disappears. A related comparison concerns the effects of factors becoming mobile between countries. In the two-factor, two-commodity Heckscher-Ohlin model with countries sharing the same technology and endowments not too dissimi-

lar, a movement of factor(s) from one country to another can be absorbed by a change in the composition of outputs without requiring any change in factor prices. Not so in the specific-factors model with three factors and two commodities, because at given commodity prices changes in factor endowments exercise a direct effect on factor returns. This latter model is often more appreciated by labor economists, who may expect labor immigration to have a depressing effect on national wage rates.

The difference between these two models tends to be less apparent when a specific-factor model with n commodities (and $n+1$ factors, only one of which is mobile) is compared with the so-called *strong* form of the n-factor, n-commodity Heckscher-Ohlin model in which the increase of any commodity price serves to raise the return to the factor used relatively intensively in that sector and to lower the returns to all other factors (e.g., see Kemp and Wegge 1969). Such a *magnification effect* of commodity prices on factor returns is shared by the specific-factors model   the return to one specific factor is raised, and to all others is lowered. Only the return to mobile labor is not so magnified. Indeed, suppose the mobile factor is not labor, but rather some intermediate good that is produced by all of the "specific" factors. This *produced mobile factor* model (Jones and Marjit 1991) becomes a Heckscher-Ohlin model that satisfies the strong conditions   one real winner and all others losers when a price changes   cited earlier.

The case can be made that the specific-factors model   with each sector having a unique specific factor but sharing mobile labor with all other sectors   is especially useful as a general equilibrium model of production because it does generalize so readily to higher dimensions and has highly appealing qualities: (1) If a single commodity price increases, the output of that commodity also rises, drawing resources (mobile labor) from *all* other sectors; (2) if the endowment of a specific factor increases (and commodity prices remain constant) not only is its return lowered, but the consequent increase in the wage rate pushes down the returns to *all* other specific factors. This latter result may yield a surprising consequence   the returns to some other

specific factors may fall by a greater relative extent than does that of the factor whose endowment has increased.

Although the Heckscher-Ohlin model may not be especially useful in the many-factor case because extremely detailed structure must be imposed before explicit solutions can be obtained, it does have a distinct advantage in that the two-factor scenario is consistent with a world in which trade takes place in many commodities. There is no two-factor, many-commodity version of the specific-factor model. The theory of international trade emphasizes that trade encourages each country to specialize in a few activities in which it has the greatest comparative advantage, and the two-factor Heckscher-Ohlin model can well illustrate that *which* commodities a country produces depends both on world commodity prices and local factor endowments. This production choice becomes endogenous   it can vary as, say, the country grows and the capital/labor endowment ratio expands. Suppose, however, that a commodity that had been produced in the past now cannot earn as high a return on its capital as some new commodity on the trading scene. If this capital had become specific, that industry may nonetheless stay in business if its capital can earn anything exceeding scrap value. That is, the specific-factor model may prove useful in modeling why it is that some industries still produce even if they would not be viable if new capital had to be raised for production (Jones 2007).

Some disenchantment with general equilibrium models seems to be based on the widespread difficulty of obtaining comparative static results when an original equilibrium is disturbed by some change in prices or endowments. Detailed structure must be imposed on the model. Sufficient structure is a characteristic of specific-factor models, and further higher-dimensional results can be obtained by employing the following kind of *variation* on such models. Consider first the way in which a "bubble" diagram can be used to illustrate a three-factor, two-commodity specific factors model in figure 2(a). Each of the two X_i outputs is produced with specific factor K_i and mobile labor, L. Figure 2(b) adds another two sectors, with notations suggesting two

countries, with Y-type capitals, K_Y^* and K_Y, specific both to country and occupation. L^* and L are, respectively, foreign and home labor forces, each specific to the country but mobile between sectors, and K_X, assumed specifically used in the X industry, is now internationally mobile. This is a five-factor, four-commodity model, whose structure has specific factors used only for the "end" products and three types of mobile factors   labor in each country mobile between sectors but not internationally and X-type capital, mobile between countries but sector-specific. It is not difficult to analyze (see Jones 2000, chapter 3) because it can be treated in two stages. In the first, suppose that the allocation of X-type capital between home and foreign industries is kept the same so that figure 2(b) resembles two countries, each of the figure 2(a) type. In world markets suppose the prices of X-type goods increase by the same relative amount and that of Y-type goods stay the same. In each country separately standard specific-factor results are obtained: the return to X-type capital increases relatively more than does the price of X goods, the wage rate rises but by less than X's commodity price, and the return to Y-type capital falls. In the second stage, let X-type capital become mobile internationally. In which direction does it flow? Toward the home country if, and only if, in stage 1, the return to X-type capital at home increases by more than it does abroad.

Such a comparison depends largely, and indirectly, on how much the wage rate is stimulated in each country, and this comparison, in turn, is revealed by the solution for wage changes in the
Figure 2

Bubble diagram of three factor, two commodity specific factors model and five factor, four commodity specific factors model

specific-factors model. The formal solution was not derived earlier, but it can be shown (e.g., in Caves, Frankel, and Jones 2007; Jones 2000, chapter 3) to depend on the product of three terms: s_X, i_X, and θ_X. s_X is the relationship between the elasticity of demand for labor (i.e., of the marginal product curve) in the X sector compared to the economy average. If X is "typical," this has value unity; i_X is equal to labor's distributive share in the X sector relative to its share in the economy and would be greater than unity if and only if X is relatively labor intensive. Finally, θ_X is the fraction of the country's income devoted to the production of X. If the X sector is fairly typical in terms of labor demand elasticity and labor intensity, everything depends on the relative size of the X industry. Suppose this is larger at home than abroad. If so, the wage rate will tend to increase more at home than abroad, and since both countries experience the same price rise for X, the return to capital will increase in both countries but tend to increase relatively more abroad. With a greater increase in the wage rate at home, fewer rents are available to attract capital to the home country.

This two-stage process illustrates how the variation in the specific-factors model that is exemplified for the four-commodity case in figure 2(b) leads to a modeling strategy that makes use of the specific-factor logic at the first stage and then completes the analysis by asking how rates of return to a mobile factor compare in two countries. Jones and Marjit (2003) explore a different interpretation of figure 2(b) in which the two labor forces shown there correspond to a single country's supply of skilled and unskilled labor. An interesting question might concern the consequences for the wage premium and wage levels of a training program that converts some unskilled labor into skilled labor.

The specific-factors model is a simple form of general equilibrium model in which an extreme asymmetry in factor mobility is assumed—one factor is mobile and the others are not. A model in which all factors have partial mobility would of course be more complex, even if attractive for modeling dynamic movements. The Heckscher-Ohlin model also has extreme assumptions—namely, that the two factors

(in the two-factor case) have the same degree of mobility instantaneously. As all theorists acknowledge, simplicity in model building is a strong virtue unless it rules out features of the setting that are of most concern. As illustrated earlier, departures from the specific-factors setting can often be better understood by making use of embedded features that do correspond to the specific-factor model even if other features are also involved. And, as Samuelson and others have often remarked, it is the general equilibrium model that captures much of the basic reasoning about diminishing returns in partial equilibrium settings.

■ speculation

The economist John Maynard Keynes (1936) de fined speculation as the purchase of securities at a price above their fundamental value with a view to sell them at yet a higher price in the subsequent trading periods. Ever since the economist Milton Friedman (1953) argued that such destabilizing speculation would be unprofitable and thus unsus tainable in the long run, economists generally have discounted the possibility that speculation could cause asset prices to deviate from fundamental values, that is, prices warranted by the *true* earning potential of firms. The intuition behind Friedman's argument rested on a simple view of arbitrage. In a market that includes both smart traders who know the true values and those who make whimsical and misinformed trades, generally referred to as noise traders, the latter create riskless arbitrage opportunities from which smart traders could profit.

The rise of behavioral finance theory has made economists more receptive to studying the limita tions of arbitrage in real-world markets. Informed traders with a "short" trading horizon who sell overvalued assets short can find that by the time they are supposed to close their position, the true value has increased, or the assets in question have become even more overpriced. Because the smart traders who have sold securities short could make losses in either sit-

uation, they limit the initial positions they take in an over- or undervalued asset, preventing the current price from smoothly adjusting to its true value as Friedman had envisioned. It might even be the case that it pays for smart traders to act like noise traders themselves in the short run, bidding prices further away from true values rather than helping to close the gap between the two (De Long et al. 1990; Griffin, Harris, and Topaloglu 2003). Thus an increasing number of economists now hold that *riskless* arbitrage is not always effective (Shleifer 2000).

This view is reminiscent of Keynes's (1936, chapter 12) famous beauty contest analogy, where speculators base their expectations of future asset prices not only on what they think the true value is, but, more important, on what they think the average opinion about the average opinion is. In other words, *noise* is at least as important as information about true values in causing asset price changes, rendering the resale price uncertain (Black 1986). This, in turn, implies that traders must not only form higher-order expectations (i.e., on what others think others think) but also decide how much weight to assign them relative to what they themselves think the true value is (Hirota and Sunder 2003).

If a trader observes that the price of an asset (or an asset group) which she thinks is already overvalued is still rising in price, she is led to surmise that either her opinion about the true value is wrong or that the price is rising on account of market sentiment (Abreu and Brunnermeier 2003). In either case, the information and opinion of others, as revealed in current price changes, are likely to gain in importance in how the trader forms his/her expectation about the future price. Such information becomes either a proxy for the higher-order expectations or a corrective on opinions about the true value, or some combination of both. Under these conditions whether speculation is stabilizing or not crucially depends on the relative weight traders assign to their higher-order expectations (i.e., what they think others think others think) relative to their own assessment of what the true value is. Though it appears to be long forgotten, this basic idea in its simplest form goes back to Kaldor (1939), where whether speculation is stabilizing or not de-

pends on the elasticity of future price expectations with respect to current price changes. In this early formulation, stability requires a less than unitary elasticity of expectations, where traders revise their expected future price proportionally less than the change in the current price.

In the modern literature, much more elaborate analyses of cases where agents make trades relying on information revealed by the past decisions of other traders rather than their own abound and are generally discussed under the heading of *herding* behavior. These generally model "momentum-investor" or "positive-feedback" strategies, where traders tend to buy assets whose price has been on the rise and sell those that have been falling in price. Short trading horizons, the sequential nature of trades, and information costs are the real-world market attributes that are emphasized in this body of work.

In contrast to standard models of asset pricing that implicitly assume long-term horizons, short-term trading horizons play an important role in persistent deviations of asset prices from true values (Dow and Gorton 1994). In these models, it is argued that the incentive structure that defines money managers' employment gives rise to agency problems (Allen and Gorton 1993), making it rational for speculators to have short trading horizons. In a world characterized by market imperfections and uncertainty, speculators who tie their resources to long-term investments would fail to exploit profitable investment opportunities that would unexpectedly arise (Shleifer and Vishny 1997).

Second, in real-world markets trading is sequential, which implies that traders observe and can learn from one another. Early action can enable traders to rationally exploit information revealed by the actions of other agents. Profit-maximizing traders can thus successfully focus on what other traders also know rather than trying to learn information others do not have. A narrow set of information can then become the primary focus of attention even when it has little bearing on fundamentals (Scharfstein and Stein 1990).

Finally, especially in international markets, gathering information requires large fixed costs which

generate economies of scale for large investors. Thus the greater the cost of acquiring information, the higher is the incentive for uninformed small traders to imitate large investors (Calvo and Mendoza 2000). This also causes small investors to be much more aggressive, especially in their selling in markets where large investors have a significant presence (Corsetti et al. 2001), giving rise to increased volatility and likelihood of abrupt shifts in capital flows, leading to currency and financial crises.

■ **spillovers**

In international finance, spillovers are phenomena in which a change in asset price (or asset price volatility) in one country leads to a change in asset price (or asset price volatility) in another country. Interest in this topic resulted from the simultaneous declines in global equity markets during the 1987 stock market crash and the high comovement of asset returns in many countries during the financial crises in the late 1990s. This topic is crucial for our understanding of how information, often proxied by changes in asset price or volatility, in one market transmits to another market. In addition, the effect of foreign asset prices on domestic asset prices has implications for how we should value domestic assets and how we should allocate wealth across different countries.

Empirical Studies Most studies generally examine the spillover effect from three financial centers the United States, the United Kingdom, and Japan to other international financial markets, and, because of data availability, they focus mainly on equity markets. Existing studies use different sample periods, data frequencies, and econometric methods. The standard methods used to measure the spillover effect can be divided into two groups. The first group measures the spillover effect on changes in asset price (asset return). The second group measures the spillover effect on asset return volatility. This method examines the influence of foreign asset return volatility on domestic asset return volatility. Because the direction of the effect of foreign return on domestic return can vary over time, it is easier to measure the volatility spillover effect as changes in asset price

(independent of direction), which are always reflected in increases in asset return volatility; thus, the effect is always positive. The volatility spillover effect can give us only an indirect measure of asset price linkages, however.

These studies' general findings are: (1) return and volatility spillovers are present among major markets; (2) the majority of the spillover effect appears to originate from the United States to other foreign financial markets; (3) when volatility is high, the spillover effect in returns tends to be higher returns are more correlated; and (4) the spillover effect on volatility is asymmetric, with the spillover effect from bad news (negative unexpected return) having larger effects than that from good news (positive unexpected return) (see Gagnon and Karolyi 2006).

Sources of Spillovers Spillovers have several possible sources. First, economic linkages between countries may lead to spillovers. A common shock to global economic fundamentals may lead to an observed spillover effect. For example, a surprise change in U.S. monetary policy stance may affect foreign asset prices simultaneously, which may generate the impression of a spillover effect. Alternatively, a change in an asset price in one country may affect another country's economic fundamentals. For example, a devaluation of one country's exchange rate may affect other countries' international trade, either directly or indirectly, which may in turn affect their asset prices. By and large, the empirical evidence supporting observable macroeconomic linkages as a primary source of spillovers is very weak.

Second, information asymmetry may lead to transmission of country-specific shocks from one country to another. This explanation was popularized following the stock market crash in 1987. This event not only caught market participants by surprise, but it was also hard to attribute the movements to economic fundamental linkages. The economists King and Wadhwani (1990) propose an information-based model in which price changes in one market depend on price changes in other markets and a domestic investor who observes a price change in a foreign market cannot distinguish between changes driven by economic fundamentals

and those driven by foreign country specific shocks (which should not have any influence on domestic asset prices). The implication of the model is that a price change attributable to foreign-specific shocks can lead to price changes in other countries, which in turn will increase volatility in foreign countries and increase the correlation between the two markets. The term for this channel of spillover with no economic fundamental link is *market contagion*.

Third, trading behavior may generate spillover effects. Following the high correlation among global financial markets during the financial crises in the late 1990s and the increase in global cross-border financial investments, global institutional investors have garnered attention as another source of spillover effects. Similar to the second source of spillovers, this source does not rely on economic fundamental linkages among countries. The spillover effect that occurs during financial crises is often referred to as *contagion*. Spillovers can occur because investors need to liquidate some of their assets when they lose money (Kyle and Xiong 2001) or face liquidity constraints (Yuan 2005), and they choose to sell assets in different countries simultaneously. Alternatively, spillovers may be the outcome of cross-market rebalancing (Kodres and Pritsker 2002). *Cross-market rebalancing* refers to investor behavior in which investors respond to changes in asset price in one country by optimally adjusting their asset holdings in other countries.

Although studies agree on the general empirical features of spillovers, their source is still a challenging research topic. Most studies find little evidence to support the role of economic linkages in explaining spillovers, and only a few studies find evidence to support the role of information asymmetry and trading behaviors in explaining spillovers. The lack of consensus on explanations for spillovers reflects the difficulty of measuring their source (e.g., information asymmetry or investors' trading behaviors). Future researchers will want to use new data and new econometric techniques to reexamine current explanations of spillovers before exploring new hypotheses.

■ steel

Steel, one the most basic industrial commodities, has been the subject of numerous international trade disputes and policy interventions throughout the 20th and early 21st centuries. Because steel is a crucial part of many other manufactured products and of construction activity, policymakers often consider it

to be a key sector for a nation's industrial development. Public support for steel industries has also responded to the recognition that jobs at steel plants usually offer higher-than-average wages, or what economists call "labor rents" (Scott and Blecker 1997). However, many economists consider the efforts of governments to protect or subsidize their national steel industries to be examples of inefficient, socially costly interventions that benefit small groups of workers and firms at the expense of consumers (see de Melo and Tarr 1993).

Technology, Costs, and the Location of Production Steel is a metal alloy of iron, carbon, and other minerals that has tremendous strength and ductility and is thus useful for a wide range of purposes from bridges and skyscrapers to motor vehicles and oil pipelines. Steel production developed during the industrial revolution of the 19th century in response to the discovery that pure iron was too brittle to be reliable for railroad tracks, steam engines, and other applications subject to stresses of heat and pressure. Steel is not a single product; the term encompasses a variety of specific types (for example, rust-resistant galvanized products and stainless steel for decorative uses).

Traditionally, basic steel production takes place in a two-step or "integrated" process. In the first step, iron ore is reduced to molten ("pig") iron in a blast furnace, using coke made from coal as fuel; in the second step, the molten iron is transformed into "crude" or "raw" steel in a steel-making furnace. After crude steel is produced, it is then subject to further casting, rolling, coating, and shaping operations to transform it into useful forms, such as sheets, girders, pipes, plates, tin-coated cans, and wire rods.

The progression from the Bessemer and Thomas steel furnaces of the 19th century to the open-hearth furnace and later the basic oxygen furnace in the 20th century is considered one of the classical examples of process-oriented technological change. In the second half of the 20th century, another important innovation was the electric arc furnace, which produces crude steel from "scrap" (recycled steel) in a one-step process with little or no iron ore and lower capital costs. By 2006, electric furnaces accounted for 57

percent of U.S. production and 32 percent of global production.

Originally, steel mills had to be located near sources of their principal raw materials, iron ore and coking coal, due to high transportation costs. However, advances in ocean shipping in the 20th century revolutionized the location of integrated steel production, allowing resource-poor countries such as Japan to produce steel efficiently using imported raw materials, provided that their steel mills were located near seaports. In addition, "minimills" that use the electric furnace technology can be located farther from resource deposits or seaports and closer to downstream users. These technological developments have led to greater geographical dispersion of steel production both internationally and regionally within nations.

It is often popular in the United States to blame losses of steel jobs on import competition. Although imports have adversely affected steel employment in some short-run situations, by far the main causes of decreased U.S. steel employment in the long run have been the dramatic increase in labor productivity in the industry and the slow growth of domestic steel demand (Grossman 1986). In 1955, the U.S. steel industry employed 707,000 people to make 77 million metric tons of shipments, while 50 years later in 2005 the industry needed only 122,000 employees to produce 95 million metric tons. Using a more refined measure that controls for product composition, the U.S. Bureau of Labor Statistics index of labor productivity in steel production shows a four-fold increase between 1950 and 2000.

Historically, steel industries generated large amounts of employment and were bastions of strong labor unions that won high wages and benefits for their members. The enormous shrinkage in U.S. steel employment in the late 20th century led to the problem of high "legacy costs" of pensions and benefits for retired steelworkers at some large U.S. steel corporations in the 1990s; the U.S. government addressed this problem by having the Pension Benefit Guarantee Corporation take over some of those obligations. However, labor costs of currently employed workers are now a relatively small portion of

variable costs in the most modern steel mills where production is so automated that a small number of skilled workers can operate the equipment using computerized controls and many minimill firms are nonunion.

Steel production was originally concentrated in the technologically leading nations, led by Britain and followed by the United States, Germany, and other European nations, in the late 19th and early 20th centuries. As the technology matured during the 20th century, steel production spread to Japan, the Soviet Union, China, and the major developing nations (especially India, Brazil, South Korea, Turkey, Taiwan, and Mexico). As of 1965, the United States and Soviet Union were the two largest producers of crude steel, with 26 percent and 20 percent of total world output, respectively. By 2006, China had become the world's largest producer, accounting for 34 percent of global production; Japan and the United States ranked second and third at 9 percent and 8 percent, respectively.

The Role of Trade Policies Trade and industrial policies have long been key determinants of the location of steel production. In the late 19th and early 20th centuries, the United States, Germany, and other Western countries used tariffs to protect their "infant" steel industries, a policy that was followed later in the 20th century by Japan, India, Brazil, South Korea, and many others. Communist countries such as the former Soviet Union and the pre-reform People's Republic of China created steel industries based on state-owned enterprises managed through central planning. Steel was one of the most favored industries under "import substitution" policies in many developing nations between (roughly) the 1940s and 1970s and subsequently has been a frequent target of export-promotion efforts in many of these same nations.

Curiously, out of the five largest exporters of steel as of 2005, two countries had some of the most advanced steelmaking facilities in the world (Japan and Germany), while two others had some of the most technologically backward facilities (Russia and Ukraine, which were still using open-hearth furnaces for significant portions of their output); China, the third largest exporter, had a mix of older and newer steelmaking plants. As would be expected, Japan and Germany export relatively more specialty and high value-added steels, while Russia and Ukraine export mostly basic, commodity-grade products, and China is in the process of upgrading its exports.

Given that steelmaking technology is highly mobile and the main inputs (both raw materials and machinery) can be imported, some economists argue that there are no inherent (resource-based) "comparative advantages" in steel today and that competitive industries can be created in a wide range of countries. This view has been used (for example, by Howell et al. 1988) to justify government intervention to protect the U.S. industry against "unfair" competition from other countries that subsidize or protect their industries, or that gain artificial advantages through means such as undervalued currencies. Some East Asian countries have been accused of having "structural impediments" to steel trade because their vertically integrated industrial groups (*keiretsu* in Japan, *chaebol* in Korea) allegedly do not buy steel from outside companies. Other economists counter that steel exports are still explained by comparative advantage, because steel is exported by the countries that can make it relatively cheaper than other products, compared with other countries, regardless of the source of that relative cost advantage. In this latter view, efforts to protect domestic steel industries merely make steel more expensive for domestic consumers and downstream industries.

The nature of steel production has made the industry the subject of many international trade disputes. Steel production, especially in integrated mills, is capital intensive and has large economies of scale, which create a tendency toward the existence of excess capacity (except in times of strong demand). As a result, steel producers often have incentives to export as much as possible in order to bolster capacity utilization, which leads to accusations of "dumping" if the products are sold at lower prices in foreign markets. At the same time, import-competing steel producers also have incentives to maintain high rates of capacity utilization and are therefore likely to seek trade protection if they lose customers to imports.

When one adds in the popular view of steel as a "strategic" product for reasons of both economic development and national security, as well as union support for high-wage jobs, one has an industry in which policy intervention has generally been the norm rather than the exception.

Since World War II, multilateral trade liberalization under the General Agreement on Tariffs and Trade and subsequently the World Trade Organization (WTO) has greatly reduced or, for some products, completely eliminated the ordinary tariffs that formerly were used to protect national steel industries. Nevertheless many steel products continue to receive "administered" or "contingent" protection, mainly through the use of anti-dumping and countervailing duties.

The United States has adopted a variety of "trade remedies" for steel producers since imports achieved significant levels in the 1960s, including voluntary export restraints (VERs) in 1969 74, trigger prices (import price floors) in 1978 79, more VERs in 1982 91, and a safeguard tariff in 2002 3. In addition, many U.S. imports of particular steel products from specific countries have been subject to anti-dumping or countervailing duties, especially since the last VERs expired in 1992. Iron and steel mill products (excluding castings) accounted for 44 percent of all U.S. anti-dumping and countervailing duty orders in effect as of 2006. In spite of these trade barriers, however, the United States remained by far the largest net importer of steel as of 2005.

The United States is far from alone in its use of trade protection for its steel industry. The European Union (EU), Canada, and other industrialized countries have also imposed anti-dumping duties on specific steel imports, especially from newly industrializing countries and transition economies, and the latter groups of countries have begun to impose anti-dumping duties of their own.

An important change in recent decades is the increase in "vertical" trade in steel that is, importing intermediate steel products to manufacture finished or semifinished products. For example, "slabs" of crude steel can be imported for flat-rolling into steel sheet, or steel sheet can be imported for the pro-

duction of pipe and tube products. This change may alter the political economy of steel trade policy, since companies that rely heavily on such imports may not support protection of the intermediate products they import even though they may still seek protection for their own finished goods.

Changing Competitive Conditions In roughly the first six decades of the 20th century (and longer in some developing countries), the combination of large-scale economies, high transportation costs, and significant tariff barriers led to the creation of national steel industries that were relatively closed to international trade and dominated by small numbers of large firms. Steel companies were frequently cited as exemplars of firms that practiced collusion, price leadership, administered pricing, cartels, or other forms of oligopolistic behavior. Large oligopolistic steel firms in some countries were accused of being slow to adopt new technologies such as the oxygen furnace in the 1960s.

Since the 1960s, several of the structural changes referred to earlier have led to a more competitive market structure for most countries' steel industries (Barnett and Schorsch 1983; Blecker 1989). Minimills took advantage of lower unit costs to compete effectively with the older, integrated firms. Trade liberalization and reduced transportation costs, along with the diffusion of steelmaking technology to less-developed countries, led to increased international competition. As a result, basic steel products became "commodities" in the sense that their prices were determined by global supply and demand conditions, with little or no oligopoly power for even the largest national firms in most product lines (except where those firms enjoyed continued protection).

In Europe, the steel industry was at the center of efforts to promote regional integration in the post World War II period. The European Coal and Steel Community (ECSC), founded in 1951, combined six major countries in an effort to rationalize their steel industries and make them more competitive while ameliorating the social costs of adjustment. The ECSC was an important forerunner of the European Economic Community and later the EU. As a result of these integration efforts, European steel

firms began to consolidate on a multinational basis somewhat earlier than steel firms in other regions. However, joint ventures and foreign direct investment also increased in other areas of the world steel industry toward the end of the 20th century.

By the early 2000s, the steel industry was beginning to reconsolidate on a global scale. Through mergers and acquisitions, a number of large multinational corporations were formed with steel operations located across Europe, Asia, and the Americas. As of 2007, the world's largest steel company was ArcelorMittal, which had plants in 27 countries, employed 320,000 workers, and produced nearly 10 percent of total world steel output. Headquartered in London and Luxembourg, ArcelorMittal was formed by the merger of two former companies, both of which had grown through previous mergers and acquisitions, and one of which was founded by an Indian-born entrepreneur (Lakshmi Mittal).

In the late 1990s, the global steel market was afflicted by excess supply conditions, as a number of transition economies (led by China, Russia, and Ukraine) increased the world supply of steel at the same time as international demand conditions weakened due to financial crises in East Asia and elsewhere. This resulted in increased exports, falling prices, lower profits, and increased trade tensions. The U.S. safeguard tariffs of 2002 3 were a lagged response to this crisis, adopted after the recession of 2001 and the appreciation of the U.S. dollar further weakened the U.S. industry, and when a new president (George W. Bush) was more willing to support a safeguard remedy than his predecessor (Bill Clinton) (see Blecker 2008). Ultimately, these tariffs were ruled illegal by the WTO in 2003, partly because they were enacted so long after U.S. steel imports peaked in 1998. Liebman (2006) found that the safeguard tariffs, which covered only about one-third of U.S. steel imports, had little effect on domestic prices.

In a stunning reversal, global demand for steel began to outstrip global supply in 2004, leading to sharp price increases that restored industry profitability worldwide for the next few years. This reversal was due partly to an enormous increase in demand by China, where steel consumption nearly tripled be-

tween 2000 and 2006. However, steel producers around the world responded to the higher prices by building new capacity, and as a result the global industry is likely to experience more boom-bust cycles in the future.

In spite of its reputation as an "old" or "smokestack" industrial product, steel remains an important internationally traded commodity. World steel production grew by about 50 percent from 2000 to 2006, and almost 40 percent of global steel production is exported. Therefore, the global steel industry is likely to remain at the center of trade policy disputes for the foreseeable future.

■ sterilization

Sterilization is the process by which monetary authorities ensure that foreign exchange interventions do not affect the domestic monetary base, which is one component of the overall money supply. Many governments try to influence the value of their currency on the foreign exchange market by selling or purchasing domestic currency in exchange for a foreign currency. If the monetary authority sells domestic currency that was not previously in circulation, the intervention will expand the domestic money base. Likewise, if the monetary authority purchases more of its domestic currency and takes the receipts out of circulation, the intervention will have a contractionary effect on the domestic money base.

Sterilized intervention operations involve domestic asset transactions that restore the monetary base to its original size. For example, a nonsterilized sale of foreign currency on the open market would result in a reduction in the central bank's net foreign assets (NFA) and a contraction of the domestic monetary base (MB). This operation can be sterilized, or neutralized, by an offsetting purchase of domestic currency that increases the central bank's net domestic assets (NDA) and returns the monetary base to its original level.

In theory the process of sterilization is quite straightforward, but in practice it may be difficult for the monetary authority to fully offset the effects of a change in net foreign assets. In countries with less-developed financial markets the ability to sterilize may be constrained by the size and depth of the domestic bond market. Additionally, monetary authorities may not be able to sterilize intervention operations in fixed exchange rate systems with some degree of capital mobility (Obstfeld 1982). For example, sales of domestic-currency assets will attract a capital inflow, forcing the authorities to buy more foreign assets in order to maintain the fixed value of the currency, thereby offsetting any attempt to sterilize the original open-market asset sale.

Costs of Sterilization Sterilization may also come at a fiscal cost. Governments attempting to lower or maintain the value of their domestic currency in the face of market pressure for a domestic currency appreciation will generally be purchasing relatively low-yield foreign assets while selling relatively high-yield domestic assets. The fiscal burden of sterilization will depend on the interest differential between the domestic and foreign assets. Further, the international accumulation that results from these sorts of sterilization operations will expose the government to foreign exchange risk. If the domestic currency eventually appreciates relative to the foreign currency denominations in a country's reserves, the country will experience a capital loss. On the other

hand, governments attempting to prevent a depreciation of their domestic currency will generally be selling foreign assets and purchasing domestic assets. The constraint in this case will be the size of the country's foreign reserves.

The Efficacy of Sterilized Intervention Operations In most monetary and asset-pricing models of exchange rate determination, nonsterilized intervention will affect the exchange rate in proportion to the change in the relative supplies of domestic and foreign money, just as any other form of monetary policy does. The effectiveness of sterilized intervention operations in standard models depends on two additional assumptions: that domestic and foreign bonds are outside assets (i.e., the public considers these bonds as net wealth) and that they are imperfect substitutes (meaning that the currency denomination of the bonds matters to investors). Sterilized intervention can also influence the exchange rate in models where the government is assumed to have more information about relevant economic fundamentals (such as future money and income differentials) than the market and can credibly convey that information using intervention operations.

Governments generally finance their spending by raising taxes or borrowing by issuing bonds. If they issue bonds, the public has more money to spend. Further, if the public ignores the fact that taxes will need to be raised in the future to pay off the bonds, these bonds can be considered "outside assets" and are additions to net wealth. On the other hand, if the public recognizes that they (or future generations) will have to pay higher taxes in the future and therefore save the extra money in order to pay the future tax, bonds are "inside assets" and cannot be considered net wealth. The extra saving by the public would exactly offset the extra spending by the government, so overall demand would remain unchanged. This view of the implications of bond financing is termed Ricardian equivalence. Sterilized intervention operations in such a world are simply swaps in the currency composition of inside assets, and these should have no effect on the foreign exchange market equilibrium.

Even if it is granted that government bonds are outside assets, sterilized intervention will have no effect on the exchange rate if domestic and foreign bonds are perfect substitutes. If investors are completely indifferent between holding domestic and foreign bonds, then changes in their relative supply should have no effect. If bonds are not perfect substitutes, however, even if they are close substitutes, then changes in bond supplies matter, so changes in their relative supply can influence the exchange rate through the portfolio-balance channel.

In portfolio-balance models of exchange rate determination, investors diversify their holdings among domestic and foreign bonds as a function of both expected returns and the variance in returns. By changing their relative supply, sterilized intervention operations alter the risk characteristics of foreign and domestic bonds in the market portfolio, and thus alter the equilibrium exchange rate. For example, a sterilized sale of domestic-currency-denominated bonds may increase their relative riskiness because investors will be more vulnerable to unexpected changes in the value of the domestic currency. Investors will require a higher expected return on domestic bonds to hold willingly the larger outstanding stock, leading to a depreciation of the domestic currency.

Finally, even for those who hold either to the Ricardian equivalence or to the assumption that foreign and domestic bonds are perfect substitutes, sterilized intervention can have an effect on exchange rates if it provides the market relevant information that was previously not known or not fully incorporated in the current exchange rate. The information channel for sterilized intervention is controversial. It relies on the existence of an asymmetry between what is known by the government and what is known by market participants. In order for sterilized intervention operations to influence exchange rates via the information channel, the government must both have inside information and have the incentive to reveal the information truthfully by way of their operations in the foreign exchange market. Indeed, it has been suggested that sterilized intervention may be used by governments to " buy credibil-

ity" for their future policy intentions (Mussa 1981). If market participants believe the signals provided by sterilized intervention, they will influence exchange rates by betting with the operation.

The information channel for sterilized intervention need not exclusively serve to convey future policy intentions. For instance, intervention helps to convey information by the monetary authorities to the market in circumstances when such information might not be made directly available for security or other reasons (Friedman 1953). Intervention signals may also alter the market's expectations, especially when market participants are heterogeneous and there are signs of a bubble developing (Kenen 1987). As long as the information signaled through sterilized intervention policy is relevant and credible, it can potentially influence the exchange rate. If the information revealed involves the monetary authority's own future policy intentions, however, then sterilized intervention should not be considered an additional independent policy tool. The sterilized intervention operation may alter the timing or magnitude of the impact of monetary or fiscal policy on the exchange rate, but its effectiveness is not independent of those policies.

Empirical Evidence Is there empirical evidence that sterilized intervention operations affect exchange rates? In 1982 the Group of Seven (G7) economic summit at Versailles commissioned a comprehensive study of intervention policy in order to answer the question. The G7 working group report, completed in 1983, draws no explicit conclusions but suggests that the effects of sterilized interventions on the exchange rate were small and transitory at most over the period 1973 81 (Jurgensen 1983). Subsequent studies of G3 intervention policy suggest that more recent operations may have been more effective (Dominguez 1990, 2003, 2006; Dominguez and Frankel 1993a, 1993b; Sarno and Taylor 2001).

An indirect test of the efficacy of sterilized intervention involves examining whether the assumptions underlying the portfolio-balance channel are satisfied in the data. In particular, one such test examines whether foreign and domestic bonds are imperfect substitutes in investors' portfolios. If investors are indifferent between holding domestic assets and foreign assets, then once we take into account both the current and expected exchange rate, there should be no return differential (or risk premium) between the two. This hypothesis is commonly referred to in the literature as the uncovered interest parity condition. Most empirical tests of uncovered interest parity find that foreign and domestic bonds are not perfect substitutes.

The failure of uncovered interest parity is a necessary but not a sufficient condition for sterilized intervention to affect the exchange rate through the portfolio-balance channel. There must be a stable relationship between government debt supplies and the return differential between domestic and foreign bonds, and empirical studies have had mixed success relating the two. Studies that include government debt and other outside assets, which usually dwarf foreign exchange intervention in magnitude, in the definition of government debt supplies reject the hypothesis that the two are related. Empirical studies using daily (and intradaily) intervention data, which are able to focus exclusively on short-term changes in asset supplies through foreign exchange intervention, generally find evidence to support the hypothesis that sterilized intervention operations systematically influence return differentials (Dominguez 1990, 2003, 2006; Dominguez and Frankel 1993a, 1993b).

In order for the information channel to be operative, sterilized intervention operations must be observed by market participants. If only for this reason, it is puzzling that more governments do not disclose data on their intervention operations. Comparisons of actual intervention data with newswire reports of intervention suggest that G3 operations are generally reported in the financial media. Empirical tests that distinguish interventions that are reported (and therefore are capable of serving as signals) from those that remain secret generally find that it is mainly reported interventions that significantly influence exchange rates, providing indirect evidence for the signaling channel. The literature, however, has been less successful at finding a systematic link between reported interventions and future fundamentals (the information that is supposedly being conveyed by the

government), making it difficult to find direct evidence for signaling (Sarno and Taylor 2001).

Theory suggests that sterilized intervention operations can potentially provide governments an additional policy tool with which to attain internal and external balance. Practice suggests that governments in both fixed and flexible exchange rate systems have frequently resorted to sterilized intervention policy. Empirical studies of the efficacy of these operations suggest that intervention in developed countries has often been successful, though whether sterilized intervention can serve as a fully independent policy tool remains controversial. The efficacy of sterilized intervention policies in developing countries has been less widely studied, in large part because governments have been reluctant to provide data on their operations. Developing countries are also not always able to fully sterilize their operations due to their illiquid domestic bond markets and the potentially high fiscal costs of foreign reserve accumulation.

■ **structural adjustment**

Since the 1980s, the expression *structural adjustment* (SA) has been used to denote programs of policy reforms in developing countries undertaken with financial support from the World Bank. Structural adjustment programs (SAPs) would normally consist of two components: macroeconomic stabilization and microeconomic, supply-side reforms. The World Bank *Operational Manual* defines structural adjustment lending (SAL) as "non-project lending to support programs of policy and institutional change necessary to modify the structure of an economy so that it can maintain both its growth rate and the viability of its balance of payments in the medium term" (*Operational Manual*, Statement No. 3.58, Annex II, November 1982).

Through SAL the World Bank financed more than 650 reform programs. SAL represented about one-quarter of its total commitments from the mid-1980s to the late 1990s, when it increased to more than 50 percent as a response to the financial crises in East Asia and remained at about one-third thereafter. Sub-Saharan Africa accounts for 34 percent of adjustment operations and 16 percent of commitments. The Latin American and Caribbean region accounts for 24 percent of adjustment operations and, with 34 percent of lending commitments, is the largest recipient of SAL, followed by Europe and Central Asia with 24 percent; East Asia and the Pacific received 15 percent of SAL, South Asia 6 percent, and the Middle East and North Africa 5 per-

cent. SA shaped the strategy of the World Bank for nearly two decades and dominated policymaking in the developing world. During this period, almost all major programs of policy reforms were supported by SALs from the World Bank.

The bank started SAL in 1980 following serious balance of payments difficulties experienced in some of its member countries as a result of the second oil price shock in 1979. Many of these countries also had fiscal deficits and often high inflation, and the root of the external deficits was identified as excessive aggregate demand. In these circumstances, adjustment requires macroeconomic stabilization in order to reduce domestic demand to a level that is consistent with the level of external resources available to the country.

Since restrictive monetary and fiscal policies that cut demand (such as tax increases, spending cuts, and interest rate increases) also cause unemployment, they are normally accompanied by a currency devaluation that, by lowering the relative price of domestic goods with respect to foreign goods, leads to an increase in the foreign demand for domestic goods and an increase in the supply of exportable and import-substitute goods, and minimizes the employment costs of stabilization. Measures to restrain wages complement exchange rate policy to ensure that the competitive effect of nominal devaluation is not offset by wage inflation.

Macroeconomic stabilization alone may not give rise to faster growth in the future. In order to achieve this, a second type of adjustment is required, namely SA, which consists of microeconomic and institutional reforms designed to strengthen the supply response of the economy by letting the market determine the efficient allocation of resources. A central aspect of SA was market liberalization and deregulation along several dimensions, potentially including removal of price controls, deregulation of the domestic goods market, liberalization of the trade regime, deregulation of the domestic financial market, liberalization of the capital market   especially the removal of barriers to foreign direct investment and deregulation of the labor market. A second component involved reform of public sector

management, including fiscal reform, restructuring and privatization of state-owned enterprises, and restructuring of government spending. A final component consisted of reforms to create and strengthen institutions that would support stabilization and SA, such as institutions for banking supervision and the enforcement of property rights, an independent judiciary, and an independent central bank. Many economists believed that these microeconomic reforms would shift the economy to a sustainable path of higher economic growth.

The Rise of Structural Adjustment Lending Several factors contributed to the establishment of SAL. One was the nature of the crisis that was affecting developing countries. Severe balance of payments deficits required faster and larger disbursements than were possible under the standard World Bank approach of project-based lending, in which disbursements are typically slow in the first two years. By contrast, SALs typically disburse within 18 months.

A second factor was the realization within the World Bank that project success was crucially dependent on the state of the broader economic environment. This implied, first, that the World Bank could no longer encourage the pursuit of economic growth without regard for macroeconomic stability, which thus became a priority over growth and was seen as the necessary foundation for sustainable growth. A second implication is that, as the development strategies of many developing countries were now being seen as highly distorted, the World Bank had to turn its attention to removing microeconomic distortions.

SA embodies the drastically new viewpoint that development is hampered not so much by capital shortage as by domestic economic policies that impede the operation of market forces. This new vision was influenced by neoliberal political economy theories that centered on the capture of the state by powerful pressure groups. The state came to be seen as the primary cause of the distortion of incentives, leading to misallocation of resources and economic failure. Free markets work well, and even where there are externalities and market failures, the state does not have the willingness or indeed the capacity to lead

to a better outcome than the market would. This is a complete overturning of the view prevailing until the 1970s, according to which state intervention was necessary in order to correct distortions and facilitate structural transformation in developing countries, where free markets do not work well. In this older view, the state was a benevolent agent for development. By contrast, SA through liberalization, deregulation, and privatization aims to minimize state intervention in the economy and liberalize prices so that they can reach equilibrium levels.

Abandoning structuralist doctrines, which emphasize the existence of special characteristics in developing countries' economic and social structures and were the mainstream in development thinking in the 1960s and 1970s, the World Bank through SA presents a model for all countries to follow, irrespective of their development stage. Indeed SAPs have been characterized by a remarkable degree of uniformity.

With the outbreak of the debt crisis in the 1980s, the main objective of SAL was to prevent an international banking crisis by allowing debt restructuring and the continuation (or the resumption) of interest payments. The objective of poverty reduction one of the bank's priorities since the late 1960s was downgraded. Partly this was also a reflection of the negative assessment within the World Bank of the strategy pursued until then of attacking poverty directly. In addition, this critical assessment led to the view that the best way to reduce poverty is through the promotion of economic growth (the so-called trickle-down doctrine). Thus the policies of SA, which are designed to stimulate higher sustainable growth, may be justified in terms of greater equality and poverty reduction. For example, minimizing state intervention leads to higher growth and, through the trickle-down effect, to lower poverty. Moreover since poverty is particularly acute in rural areas, reducing state intervention which typically favored industry over agriculture lowers poverty and improves income distribution.

Empirical Assessment of the Effects of SAPs The empirical literature in this area is extensive and

its findings are diverse, due to the variety of approaches used in the analyses and the methodological difficulties inherent in the evaluation of SAPs. Any short summary of the evaluation results is therefore inevitably partial. Generalizing and hence partly ignoring the diversity of individual countries' experiences, SAPs appear to have had their stronger positive effects on countries' external accounts (with increases in the rates of growth of exports and improvements in the balance of payments, though such positive results have also been found to be often temporary) rather than on the domestic economic performance (as typically investment fell and economic growth contracted or stagnated).

Indeed, growth in countries that have followed SA policies   especially in Latin America and Africa   was frequently lower than in the 1960s and 1970s, when these countries were following the highly distortionary policies that SA was meant to correct. Both in Latin America and Africa there have been instances when SA seemed to lead to economic success, but such cases were both isolated and short lived. Moreover the 1990s saw the countries that liberalized the domestic financial system and opened the capital account being hit by severe financial crises. The financial fragility of liberalized markets also seemed to make it possible for financial crises to propagate by contagion. In contrast to the experience of the countries that followed SA reforms, the countries that have managed to achieve sustained high growth are those that have significantly deviated from SA, for example by maintaining selective protection of infant industries, by maintaining controls on capital flows, or by liberalizing trade and capital movements at a slow pace.

SAPs also appear to have had negative effects on income equality and the general standards of living, as measured by health, education, and nutrition indicators. Cross-country analyses on poverty and income distribution do not provide a unified picture of worldwide trends (the different results are due to problems with the reliability and comparability of data, different country and time period samples used in the analyses, and different methodological approaches). There is evidence, however, of increases

since the 1980s both in cross-country and within-country inequality as well as in poverty (once China is excluded from the sample). Such trends are attributed to many different factors but some of these factors are related to the adoption of SA policies, such as overly rapid trade and financial liberalizations, rapid and poorly designed privatization programs, and the erosion of labor institutions and of the state's redistributive role. A significant amount of empirical evidence also calls into question the effectiveness of the trickle-down mechanism: increases in average income do not appear to raise the income of the poor for prolonged periods.

What policy implications can be drawn from such empirical findings is a highly controversial matter for two related reasons: first, these findings may be the results of flawed evaluation methodologies, and second, the empirical results may be interpreted and explained in many different ways. Let us consider, for example, the findings concerning the effects of SAPs on economic growth. The expectation is that SAPs would result first in an economic contraction in the short run (as a result of the macroeconomic stabilization), which would then be followed by a recovery (led by the supply-side reforms) that shifts the economy onto a path of sustainable growth. It is clear therefore that SAPs cannot be criticized for causing a contraction, since this is inevitable if the cause of the crisis is an excess of demand over supply. Thus the relevant question to investigate is not whether SAPs caused a contraction but whether the contraction was deeper and/or lasted longer than necessary. Actual program effects should then be compared with what the economy could have done without an SAP (such a hypothetical outcome is called a counterfactual in the literature). Methodologically, the difficulty is that the counterfactual is not observable and can only be estimated.

The different evaluation methodologies can be seen as different approaches for the estimation of the counterfactual. Intuitively, such estimation is based on the economic situation in program countries during the period preceding the start of the SAP or on the economic situation in countries that did not enter a SAP. More sophisticated methodologies would

account for the fact that program and nonprogram countries may be systematically different. For example, program countries are more likely to have been hit by a negative shock in the preprogram period and, consequently, there may be systematic differences in the policies pursued by the two groups of countries during the adjustment period. Alternately, program and nonprogram countries may differ in the extent of their relative policymakers' commitment to good policies. None of these different approaches is fully satisfactory as they all have important shortcomings. Moreover since in any selected sample period not all of the observed growth rates may be sustainable in the long run, ascertaining the true influence of policies on economic growth becomes very difficult. By implication, whatever empirical evidence is found cannot be clear-cut, because it is not possible to know whether it represents the true program effects or is the result of a wrong estimation of the counterfactual.

Inevitably, however, the effects of SAPs have raised concerns about poor economic performance, growing inequality, and increasing social problems, as a result of which the development agenda has been significantly broadened, with greater attention being given to the role of institutions and institutional reforms (particularly with respect to the quality of governance) and with poverty reduction becoming a top priority in World Bank operations. In short, in accordance with much of the empirical evidence, there is consensus   both within the World Bank and among its critics   that SAPs have produced disappointing results. This empirical fact has received different explanations. World Bank critics would argue that SA policies are fundamentally flawed and inappropriate to developing countries' circumstances. Others, including the World Bank, would instead point to the lack of government commitment to policy reform and the ineffectiveness of conditionality (i.e., the set of policy reforms that are required for loan disbursement) as policy leverage. The implication of this view is that policy reform programs can be made more effective by allocating financial resources more selectively to countries with good policies and good institutions.

The End of Structural Adjustment As a response to the perceived shortcomings of SAL, the World Bank formally announced its replacement with Development Policy Lending in August 2004. The latter sees reform ownership   which could be defined as the commitment by a recipient country to undertake reforms independently of the incentives provided by lenders   as essential for the success of reform programs. By implication, the promotion of ownership breaks with the idea, typical of the SA era, that there are universal policy prescriptions. Another major difference from SA concerns the characteristics of conditionality: under Development Policy Lending conditionality must be streamlined, so that the conditions focus only on the reforms that are regarded as essential for program success. In addition, conditionality is ex ante in that loan disbursement is made conditional on a country implementing key reforms, rather than promising to do so in the future, as was the case under SA. This new approach clearly implies much greater selectivity in the allocation of World Bank's financial resources. Criticisms center on the feasibility of the principle of selectivity (particularly its lack of credibility, since withholding finance from a country with weak policies and institutions would deteriorate that country's economic and social situation further) and the conflict between ownership and selectivity (since ownership must be more than the freedom to accept the bank's preferred policies).

■ **subsidies and financial incentives to foreign direct investment**

When considering the efforts of governments to attract foreign direct investment (FDI) through the use of subsidies and financial incentives, the game is not new, just the arena in which the game is played. In general, governments influence particular activities and pursue various objectives using instruments including taxes, public spending, regulations, subsidized credit, contingent liabilities, and others. In past decades, when the countries' economies were relatively closed and there was limited trade and scarce capital movements, the policy instruments were used mainly to influence the domestic allocation of resources. Especially in the 1950s and 1960s, governments, particularly those of developing countries, provided generous incentives to domestic enterprises to increase investment in the hope of stimulating higher economic growth.

In countries with federal structures of government, such as the United States, Brazil, Argentina, Canada, and some others, the subnational governments (states, provinces, regions) have often used their own policy instruments to attract economic activities to their area from the rest of the country. In some of these countries there has been intense competition among the states, often pursued through the use of tax incentives and other instruments to attract companies and investments to particular states. This competition has led to distortions in the allocation of resources and has generated a large literature on competition among the states (see, among others, Tanzi 1995, chapter 3; Kenyon and Kincaid 1991).

In today's globalizing world, countries have become more open to international trade flows and capital movements, and capital has become very mobile and highly sensitive to differences in rates of return earned from investing in different locations. Countries have recognized the possibility of attracting capital from the rest of the world through their policies. World capital has become a kind of common

pool from which countries can extract a larger share of investment by pursuing particular policies. Given that most countries are a small part of the world economy, well-designed subsidies and financial incentives to FDI can, at least in theory, attract large amounts of resources relative to country size. These productive activities could create jobs for unemployed workers, or better jobs for underemployed ones, as well as faster growth for countries successful in attracting capital from the global pool. Malaysia, other countries from Southeast Asia, Ireland, and several transition economies from Eastern Europe have been particularly successful in attracting large amounts of FDI in part through the use of incentives directed to FDI. Other countries, including Latin American, African, and especially Caribbean countries have been much less successful in these attempts.

When a country that provides these incentives has many unemployed workers or many workers in unproductive activities that could find employment in more productive activities, the potential benefits for the country from the provision of incentives to FDI can be potentially high. Foreign capital could then be combined with domestic, previously unemployed or underemployed workers to generate new output. Furthermore FDI is often accompanied by new technologies and new managerial techniques that can be copied by domestic firms thus creating beneficial externalities and further growth. This inflow of new knowledge and technologies can, thus, create a theoretical justification for the provision of incentives (see Harrison and Aitken 1999). Even if the foreign enterprises did not pay taxes to the host country on their profits, the country might benefit because the workers would pay taxes on their wages and on their purchases and the domestic firms would become more productive. For these reasons, developing countries are understandably tempted to provide subsidies and financial incentives to FDI.

Types of Incentives There are several kinds of incentives that governments can give foreign investors to induce them to invest in their countries. First, they can provide incentives in kind, especially at the initial stage, to make a particular location more attractive than others to the investors. For example,

land or other real property can be made available free or at low cost and zoning restrictions can be relaxed to allow the foreign investors to build and operate industrial plants in particular areas. Alternatively countries can offer to build needed infrastructures, including roads, railroads, harbors, and so on. These incentives can be particularly valuable in attracting large industrial investments especially to areas that are still underdeveloped. The investments in infrastructures, although costly to the countries, can stimulate other domestic activities and thus create multiplier effects accompanying the foreign investments. In some cases the countries simply accelerate the building of infrastructures that would have been done at some later time.

Second, the foreign enterprises can be exempted from existing regulations, including labor regulations or environmental restrictions. Third, the countries could provide credit at subsidized rates, or facilitate borrowing from domestic sources. This approach would reduce the net capital inflow and the benefit from the foreign investment, however. Finally, the countries could provide incentives vis-à-vis the payment of taxes. These tax incentives are common and are the ones that attract most attention.

The tax incentives may be of various types. Their value to the foreign investors depends on several considerations but the most important is, probably, the level of effective tax rates to which they would be subjected in the absence of the tax incentives. This would depend on the way the taxes paid to the host country (the country where the investment is made) would be treated by the home country (the country of residence of the investor). If the tax incentive results in a reduction in tax payment to the host country but in a higher payment to the home country, the value of the incentive to the investor would be reduced or even eliminated.

The tax incentives can be divided into those against direct taxes and those against indirect taxes (see Zee, Stotsky, and Ley 2002). Among the incentives against direct taxes, the most important are (1) tax holidays against corporate income taxes (CIT); (2) reductions in CIT rates; (3) investment allowances; (4) investment tax credits; (5) accelerated de-

preciation; and (6) investment subsidies. Among the incentives against indirect taxes, the most important are tariff and value-added tax exemptions and incentives connected with export processing zones.

Tax holidays are especially common in developing countries, but much less so in advanced countries. They generally exempt foreign enterprises from the payment of CITs for a given number of years after the investment is made. Thus they are more attractive for those enterprises that expect quick and large profits. Tax holidays have some good and some less good features. Among the good features (for the enterprises) is the fact that during the period of the tax holiday the enterprises not only do not have to pay taxes but they do not need, generally, to comply with all the complexities of tax laws and regulations that can be quite burdensome and costly, especially when dealing with them for the first time in a foreign country. Thus the investors save in terms of both tax liability and tax compliance. Another good feature, from the point of view of the country, is that tax holidays tend to be neutral vis-à-vis the use of capital and labor. They do not distort the allocation of resources in this sense.

There are, however, some less good features of tax holidays. While tax holidays do not distort the choice between labor and capital, they do distort the choice between projects with short maturities and those with long maturities, favoring the former so that the profits earned by the enterprises can occur during the period when the tax holiday is in effect. Second, in practice, the tax holiday can often be extended (at times almost indefinitely) by making additional and often minor investments that allow the enterprise to claim an extension of the tax holiday. For example, in Jamaica and most Caribbean countries, enterprises that invest in hotels and that benefit from tax holidays can renew the tax holiday period by periodically adding a few hotel rooms. Another worrisome feature is that because the enterprises do not need to maintain accounting for tax purposes, there may not be any estimates of the revenue that the country loses due to the tax holidays. Thus it becomes difficult to make a cost-benefit evaluation of the incentives. Finally, in many cases, the enterprises would have

made the investment even without the tax incentives, so that the country forgoes revenue needlessly.

While tax holidays exempt profits completely, *preferential CIT rates* tax their profits at lower rates than for ordinary enterprises. Thus they imply less revenue loss to the governments than tax holidays. They also require that the enterprises keep accounts so that the revenue forgone by the government due to the incentives can be estimated. The difference in tax rates between the enterprises that do not benefit from the incentives and those that do gives a measure of the revenue cost of the incentive under the assumption that the investment would have taken place even without the incentive.

Investment allowances allow the enterprise the immediate expensing of parts of the initial investment costs in addition to the normal allowable depreciation. *Investment tax credits* allow the deduction of parts of the investment costs from the CIT payment. In particular circumstances these two incentives tend to be the same. They are important for enterprises already in operation and that already have profits. *Investment subsidies* involve direct cash payments by the government to an enterprise for parts of an authorized investment. Thus they are a claim on the budgetary revenue of often cash-strapped governments. Finally, economists generally favor incentives given in the form of *accelerated depreciation*. These incentives have fewer disadvantages and lower budgetary costs than other incentives (see Tanzi and Zee 2000).

Indirect tax incentives can be costly to a country in terms of forgone revenue, because indirect taxes are often a large share of the country's gross domestic product (GDP). These incentives imply exonerations from import duties and from other indirect taxes, such as value-added taxes, excises, and other. These incentives lend themselves to abuses because the goods imported, or acquired duty free for the direct use of the enterprises, often find their way to other uses in the domestic market (for a discussion of the potential abuses of these tax incentives, see Zee et al. 2002).

Unfortunately, information on the use of incentives is limited, country specific, and often contained

in confidential reports. Thus it is difficult, if not impossible, to assemble statistical information on the incentives just mentioned for groups of countries. As a consequence, the discussion that follows will not have the desirable backing of statistical information.

Before moving to the next section, it may be useful to mention a worrisome aspect of tax incentives. At times their features are specified precisely and in detail in the laws of the countries, so they have the backing of rule of law. At other times, they are given largely at the discretion of particular offices or officers. The latter may grant them to "essential" activities or "necessary" investments without a clear specification of what these terms mean. Often, the offices that make the decisions are not in the ministry of finance but in spending ministries (tourism, agriculture, industry, etc.) that are not responsible for the outcome of the public finances of the countries but represent sectoral interests. As a consequence, they tend to be generous at times, too generous with the public money.

Furthermore the discretion given to some bureaucrats in making decisions worth a lot of money to particular enterprises makes this an area particularly exposed to corruption. Foreign investors at times find poorly paid, easy to bribe civil servants to get decisions that to them are worth millions of dollars but that may not be particularly beneficial to the countries or decisions that the investors would have made in any case. For this reason, and apart from the intrinsic value of the incentives to a country, the rules that guide the granting of the incentives should be specified precisely in the legislation and should leave as little discretion as possible to civil servants and elected officials. Furthermore, they should be controlled at the highest level by the ministry of finance and possibly by some accountability office.

The Impact of Incentives on FDI Views about the merit of incentives and their impact on FDI diverge widely between those held by most economists who have studied the issues and those held by policymakers. Generally economists have concluded that incentives are often worthless or at least that they do not justify their costs. However, incentives remain popular with policymakers and, of course, with those who benefit from them, namely, the foreign investors. The latter often exert pressure to get the most generous incentives that the host country could provide.

Surveys of foreign investors that ask them the reasons why they have invested in a given country almost never list incentives at the top or near the top of the motivations for the choice of location. The responses mention reasons such as (1) the existence of domestic demand for the product or service produced; (2) the vicinity or the access to other markets; (3) the existence of valuable natural resources in the country; (4) the availability of cheap and skilled labor; (5) political stability, and so on. Incentives are generally mentioned way down the list. At the same time, attempts at removing the incentives often meet sharp reactions on the part of the investors and threats to move the activity to countries that offer incentives.

In a world of relatively homogeneous countries, the incentives provided by (only) one country would probably attract a lot of foreign investment to that country, especially in an open world in which companies can produce in one country and export what they produce to the rest of the world where import duties are lower than in the past. However, the world is far from homogeneous. There are great differences among countries in factors such as (1) inflation rates, (2) macroeconomic performance, (3) incidence of corruption, (4) stability and certainty of rule of law, (5) regulatory environments, (6) political stability, and (7) security. Often some of these factors overwhelm the advantages that incentives could provide to foreign investors in investing in specific countries. For this reason economists emphasize that the best incentives that countries can provide to investors are (1) a stable and good macroeconomic environment, (2) stable and clear regulations and rule of law, (3) tax rates that are competitive and tax systems that are not too complex, and (4) an environment that is relatively free of corruption.

An important element that often plays a major role in the willingness of countries' authorities to grant incentives for FDI is competition from other countries for FDI. This competition has been stim-

ulated by what is at times called "incentive shopping" on the part of foreign investors. Consider a country, say Costa Rica, that is approached by an American company, say Intel, and is told that the company is considering a large investment in Central America but that the specific location has not yet been chosen. Suppose the investment would create many good jobs and would contribute significantly to the country's economy. The foreign company demands substantial incentives from Costa Rica with the implicit threat that a refusal will cause the company to invest in a neighboring country so that Costa Rica would lose the investment. This is the situation that often confronts policymakers; they face offers that they find difficult to refuse.

This shopping for the best incentive package at times places smaller and poorer countries at a disadvantage and forces them to make concessions that can significantly reduce or even eliminate the benefits that a country can derive from foreign investment. A solution to this problem of incentive shopping by foreign investors could only come in the form of agreements, on the part of all the countries from a particular region, not to give in to such pressures and to establish jointly agreed on rules that restrict what the countries grant in terms of incentives to foreign investors. However, no such agreements exist and the desire to attract foreign direct investment continues to be a strong motivation for providing often too generous terms. The fact that some countries have developed at fast rates with the help of FDI remains a strong reason for policymakers to continue to provide generous incentives.

The foregoing analysis points to two basic questions. The first is whether subsidies and financial incentives can succeed in attracting FDI (or more FDI) to a specific country. The second is whether total FDI to countries can change due to incentives. Different strands of economic literature have dealt with these two questions.

The answer to the first question is probably yes, provided that the pull exercised by the existence of the incentives is not neutralized by other factors. Ample evidence from many countries suggests that they have succeeded in attracting large FDIs through the use of generous and well-targeted incentives (see Tanzi and Shome 1992). Other conditions being equal, incentives can attract FDI to a specific country. However, the situation implicit in such a ceteris paribus assumption rarely holds in the real world so that the value of incentives to foreign investors can easily be wiped out by some of the other factors mentioned earlier. A country such as Haiti will not become as successful as Ireland or Malaysia in attracting FDI strictly by offering incentives to foreign investors. Also, for every "winner" of a competition for FDI, there may be many "losers" that tried to attract FDI using subsidies (or other incentives) but were beaten by the better offer.

The answer to the second question is more difficult and on this issue the literature is more ambiguous. Already in 1962 Kaldor (1965) was raising the question and was giving an agnostic answer. There is no literature that has addressed specifically and directly this question. However, there is a lot of literature that has dealt with the closely related, even though technically different, question of whether taxes have affected the location of firms and investment (see for example Devereux and Griffith, 2002). This literature has generally concluded that "taxation matters," and it is easy to predict that it will matter more with the passing of time. However, the various studies have focused exclusively on taxation and have ignored the effects of other policies that may have biased the elasticity of investment decisions with respect to changes in tax rates. Furthermore it is still not clear how large an effect taxes have on FDI. It should be added that this literature normally discusses the location of FDI within OECD countries rather than the flow of FDI to developing countries that was the main focus of Kaldor's paper. Thus we are unable to state with any certainty whether developing countries, as a group, have received more FDI due to the incentives that they have been providing.

The Costs of Incentives What are the costs of the incentives to the countries that give them, especially to developing countries? Against the potential benefits in terms of employment, transfer of technology, improved productivity, and higher exports, there are costs, some obvious and some less so.

A first cost is the erosion of the tax bases. Incentives can sharply reduce the bases for the corporate income tax, the value-added tax, and the import taxes. At the same time the inflow of FDI may require additional public spending for infrastructures and other costs. If the FDI leads to a significant increase in the country's rate of growth, other taxes may go up and may compensate for the incentives given. But this is not always the case.

A second cost, and one much related to the first, is that the erosion of the tax bases caused by the incentives often forces the countries to raise the statutory tax rates on the sectors and enterprises that do not benefit from the incentives, thus reducing the growth potential of those sectors.

A third cost is that incentives inevitably create distortions in the allocation of resources. These distortions may be desirable if the incentives compensate the enterprises that receive them for positive externalities that they bring to the countries. This is for example the case when FDI brings new technologies that can be used by domestic firms. But this is not always the case, so the distortions created by favoring some firms over others can be economically costly.

A fourth cost is the one mentioned earlier connected with corruption. Incentives often become a fertile field for corrupt acts. Many studies have shown that corruption is costly to countries in the impact that it has on economic growth and also on equity.

Finally, there are potential costs associated with the competition in the granting of incentives. When countries compete for limited FDI and do so by progressively increasing the attractiveness of the incentives that they are willing to give, there is inevitably a race to the bottom that may be costly to all. There is also the possibility of a "winner's curse" where a country overestimates the value of an investment, pays too much, and winds up worse off despite succeeding in attracting the FDI.

In conclusion, in particular circumstances, well-thought-out and limited subsidies and financial incentives to FDI may be beneficial to countries that give them. However, more often than not, the results are not as good as hoped.

■ Swan diagram

The Swan diagram is an analytical tool that facilitates streamlined analysis of macroeconomic policy for a small open economy. Developed in the 1950s by Trevor Swan (see Swan 1960; Salter 1959) for Australia, the Swan diagram was used to model how to achieve the two objectives of internal and external balance with two kinds of policy instruments, one affecting aggregate demand, the other a relative price. More recently, however, the Swan diagram has been generalized to other times, countries, and different sets of instrument variables. It facilitates policy analysis and policymaking by showing the kind of disequilibrium in the macroeconomy and therefore the required policy response. Shocks can also be analyzed according to the kind of disequilibrium they create.

A country attains *internal balance* when the aggregate demand for domestic output equals the aggregate supply of domestic output at full employment of resources and prices are stable. *External balance* requires equilibrium in the balance of payments. The current account surplus or the net balance of trade is exports minus imports. It must be financed by sustainable capital flows. If imports exceed exports, capital inflows are required; otherwise capital can be exported. Adjustment normally requires a change in relative prices combined with changes in demand or expenditure.

A key conceptual distinction for a small country is that it must take international prices as given. If markets are competitive, exportable and importable traded goods can be combined into a single category because a perfectly elastic world demand for exports and a perfectly elastic world supply of imports make their prices independent of domestic variables. But this means that the terms of trade, or the ratio of export to import prices, cannot change to help the adjustment to full equilibrium or balance.

Analytics Because the terms of trade are independent of domestic actions, the key relative price becomes the real exchange rate, Z, defined as the ratio of traded to *nontraded goods* prices (E P^*_T/P_N). Traded goods prices, P^*_T, are determined in world markets. Nontraded goods do not enter world trade; internal costs and demand determine their prices (P_N). Z is, therefore, the ratio of external prices to domestic costs. The nominal exchange rate (E) is measured in units of domestic currency per unit of foreign currency so that a rise is a devaluation or depreciation of the currency.

Domestic aggregate demand, or *absorption*, is total real expenditure on home produced goods and on imports and is the sum of personal and government consumption and investment (A = C + I + G). It must equal domestic output plus exports minus imports or the current account surplus. Therefore output minus absorption gives the current account surplus.

Consider a simple framework where Z and A are the two variables influenced by two policy instruments exchange rate policy, which changes E, and fiscal policy, which changes government expenditure, G. Fiscal policy directly affects absorption through government spending. If perfect capital mobility makes the domestic interest rate equal the international, and the nominal exchange rate is fixed, monetary policy has no freedom to change interest rates and affect domestic demand. If the nominal exchange rate, E, is fixed and world prices, P^*_T, are exogenous, the real exchange rate can change only with the nontradable goods price. E can, of course, be changed

through a periodic devaluation; if the exchange rate is managed more continuous changes are possible, and monetary policy can also affect aggregate demand.

The Swan diagram (figure 1) has the real exchange rate on the vertical axis and real absorption on the horizontal axis. The schedule IB_f gives internal balance or the combinations of Z and A at which output demand equals full employment output. The schedule is downward sloping because a rise in demand raises output and so does a rise in foreign prices, relative to domestic prices. As domestic absorption rises, Z must appreciate to reduce foreign demand for exports, and therefore total demand, to the full employment output level. Values above the schedule generate inflation as a more depreciated exchange rate and higher absorption raise demand; those below the schedule generate unemployment/ recession.

Schedule EB_0 gives external balance or the combinations of the two variables that yield an acceptable current account deficit. The EB schedule is upward sloping because the current account deficit worsens with A as imports rise, but a rise in Z improves it as exports rise and imports fall. As A rises Z must

depreciate to raise exports sufficiently to keep the current account deficit unchanged. The balance of payments is in surplus above the schedule since exports are higher and imports lower; it is in deficit below. The current account deficit is lower than capital inflows can safely finance above, and higher below, the EB schedule.

The point of full internal and external balance is F, where the two schedules intersect. These schedules divide the space into four zones of differing types of disequilibria. A combination of expenditure-changing and expenditure-switching policies is required to reach full balance F. The first changes the level of total demand in the economy. The second changes the direction of demand, shifting it between domestic output and imports and shifting domestic resources between traded and nontraded sectors. The latter is a necessary part of the adjustment process for a small open economy, where the real exchange rate can change only if the relative price of traded to nontraded goods changes. Switching effects are responsible for the slopes of the two schedules; otherwise they would be vertical. The shifting of resources on the production side occurs over a longer run com-
Figure 1
The Swan diagram

pared with the more immediate change in the direction of demand.

Domestic Costs and Wages If, as a simplification, labor is the only domestic resource, nontraded goods prices equal *unit labor costs,* or the nominal wage. Output supply depends on absorption and real wages and therefore on the real exchange rate. A rise in Z will make the production of export goods more profitable and labor will shift to this sector. In addition domestic demand will shift away from tradables, or the demand for imports will fall. But real wages themselves depend on the aggregate price level, which is a weighted average of the prices of traded and nontraded goods. Along EB, as Z rises, real wages must fall. If the price of the domestic good is closely linked to unit wage costs but wage earners spend on a weighted average of imported and nontraded goods, real wages must fall as imported goods become costlier than nontraded goods. Output is demand determined below the IB_f schedule and limited by available labor supply above it. Wage-price rigidities contribute to preventing labor market clearing.

Adjustment to Shocks Even if an economy is in full equilibrium a shock can place it in any one of the four quadrants where internal or external balance or both are missing. In analyzing adjustment to equilibrium it is useful to make a distinction between automatic forces of adjustment and policy responses. Prices of nontraded goods will rise with excess demand. This will reduce demand, but it will also appreciate Z, switch demand to tradables, and deteriorate the balance of payment. Over time labor will also shift to the production of nontradables, reducing the supply of exports and further deteriorating the balance of payments. Thus adjustment will be in the proper direction only in the top quadrant; in the quadrant to the right, the balance of payment will move further into deficit. Policy intervention, reducing government consumption of nontradables and depreciating the nominal exchange rate, would be required. A similar argument shows that deflation of prices and wages in the lower quadrants would be equilibrating for the balance of payment only in the bottom quadrant. In the quadrant to the left the surplus would tend to rise further, requiring policy

intervention that revalues the nominal exchange rate or raises government expenditure.

Depending on the slopes and speeds of adjustment, it can be optimal to assign one policy instrument to achieving internal balance and the other to achieving external balance. This is called the *assignment problem.* Moreover, two instruments are required to reach two objectives. For example, consider the economy to be at E_2, with the nominal exchange rate and real wages fixed so that the only policy instrument is government spending. If the government increases spending to reach internal balance at E_1, it moves further away from external balance. If it decreases spending, it can reach external balance at E_0 as imports fall, but recession deepens as it moves further away from internal balance. Even if there is no conflict and one instrument is pushing toward satisfying both objectives, changing the second may be necessary to reach the equilibrium point.

When deflation is required for automatic market-based adjustment, policy intervention is all the more necessary because deflation can be a very slow and painful process. In most economies it is easier to raise prices and wages than to reduce them. A rise in nominal exchange rates achieves the required adjustment in relative prices with less pain. But this only works if there is nominal but not real wage rigidity. Real wages have to be flexible for real exchange rates or the terms of trade to change. Nominal devaluation can be an effective policy instrument only if there is some flexibility in real wages. Nominal rigidity and real flexibility is the normal assumption in Keynesian models.

Swan originally analyzed what he called the "dependent economy." In the modern literature this has transmuted to "the small open economy," which also takes world prices as given. In this form it lives on with the *microfoundations* of forward-looking consumers who maximize welfare over their lifetime (Gali and Monacelli 2005). Wages and prices that take time to adjust to changed circumstances play a vital role in these models; these delays allow demand to have persistent effects. Prices continue to be closely linked to unit labor costs through markups, validating Swan's other fundamental contribution of the

importance of labor markets and domestic costs. The basic Swan diagram continues to be a useful simple approximation for policy analysis.

tariff-cutting formulas

A tariff-cutting formula is an approach to trade liberalization in which countries bargaining over mutual tariff reductions seek agreement on a general formula for cuts in one another's tariffs, rather than on particular cuts in individual tariffs. Tariff-cutting formulas have been an inherent part of multilateral trade negotiations.

Economists are generally agreed that tariffs and other trade barriers reduce global income, and reducing these barriers will raise world income and the incomes of most countries. For small countries, economic theory provides an even stronger result, that unilateral liberalization will raise national income in all but the most exceptional cases. Despite these important and well-known conclusions, trade barriers remain extremely prevalent. Reconciliation of this apparent paradox needs to take into account the problem of special interests. Within a country, there is scope for these interest groups to collude with policymakers in order to promote their joint interests at the expense of overall welfare   perhaps by the interest groups making campaign contributions to politicians (Grossman and Helpman 1994). However, this outcome is suboptimal, even for politicians, for two reasons. One is the fact that the same decisions taken in partner countries reduce the demand for exports and shrink the supply of imports, causing the country's terms of trade to deteriorate (Bagwell and Staiger 1999). Another is that policymakers alone are unable to commit to rejecting future appeals for protection, allowing interest groups to apply intense pressure for protection   perhaps by threatening plant closures   that create costs rather than benefits for politicians (Maggi and Rodríguez-Clare 2007).

International trade negotiations provide potential solutions to these problems. Negotiations with trading partners can potentially deal with these problems by reducing foreign barriers in line with domestic barriers and providing a mechanism for policymakers to commit to not raising protection in the future. The GATT (General Agreement on Tariffs and Trade) achieves the second of these outcomes by international agreements limiting tariffs on individual products to no more than an agreed, bound tariff rate. Regional trade arrangements typically involve similar international commitments.

Such negotiations typically need to involve a significant share of a country's total trade if there is to be sufficient balance of gains to tackle the more politically sensitive trade barriers. One approach is for countries simply to negotiate bilaterally and sequentially, but this proved unsatisfactory during the 19th century, since a seemingly generous offer to one partner can be undercut by a slightly better offer to the next negotiating partner. The GATT attempted to improve on this through a request-and-offer procedure, under which the best offer given to any negotiating partner was extended to all GATT members under the so-called most-favored-nation

principle. By the 1960s, however, it was clear that this approach was yielding very little progress in terms of liberalization. The problem was that few bilateral trading relationships are intense enough that the gains in improved market access from an offer will offset the political costs involved in extending the offer to all GATT members when the number of participants becomes as large as the 74 participants involved in the GATT negotiations of the 1960s.

One solution, first adopted in the Kennedy Round (1963 67), was to negotiate a formula for cutting tariffs. In this situation, policymakers could potentially evaluate both the political costs of reducing their own tariffs and the political benefits from reducing tariffs in all of their trading partners. By agreeing on a proportional-cut formula during the Kennedy Round, participants in the GATT negotiations were able to achieve substantial cuts in protection 35 percent of initial tariffs as against an average of 2.5 percent in each of the previous four negotiations (Francois and Martin 2003). The next round, the Tokyo Round (1974 79), used a more sophisticated formula, the so-called Swiss formula, and achieved a 30 percent reduction in average tariffs. The Uruguay Round (1986 94) set broad tariff-reduction goals such as a 30 percent average-cut in agricultural tariffs, leaving the distribution of the cut across goods up to negotiations between trading partners, with a minimum cut of 15 percent for agricultural products. The Doha negotiations (2001), the first GATT round conducted under the World Trade Organization (WTO), have been focused on what are known as "Swiss formulas" for nonagricultural tariffs and tiered formulas, under which tariffs are grouped into four bands, with higher cuts on higher tariffs, for agricultural products.

The two classic tariff-cutting formulas the proportional cut and the Swiss formula are both extremely simple, and the contrast between them shown in figure 1 is illuminating. Under the proportional cut, the new tariff, t_1, equals $(1 - \alpha)$ times the original rate, t_0, where α is the fraction by which tariffs are to be cut. The Swiss formula is:

$$t_1 = \frac{a \cdot t_0}{a + t_0} \tag{1}$$

where a is a coefficient, or ceiling parameter, that no tariff will exceed after application of the formula. Figure 1 contrasts a proportional cut of 50 percent with a Swiss formula using a coefficient of 20 percent. Note that the proportional tariff-cutting rule results in a linear relationship between the original and final tariffs, while the Swiss formula is nonlinear. Note also that, for tariffs below the Swiss-formula coefficient of 20 in this case, the Swiss formula involves smaller cuts than the proportional cut of 50 percent. For tariffs above 20 percent, however, the Swiss formula involves larger cuts. These cuts become larger and larger as the initial tariff rises, in order that no postcut tariff will ever exceed the Swiss formula coefficient. This is evident from examination of equation (1), since $t_0/(a + t_0)$ comes closer and closer to 1 as the initial tariff rises toward infinity.

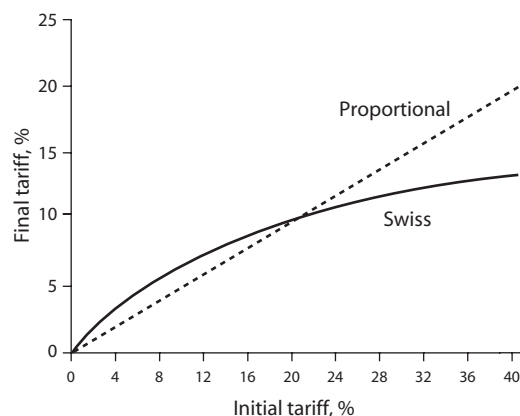
Progressivity A key difference between the approaches that have been used is the extent to which they are progressive in the sense of making the largest cuts in the highest tariffs. As is obvious from figure 1, the Swiss formula is sharply progressive. The proportional-cut approach cuts all tariffs by the same proportion, although this means larger absolute cuts in higher tariffs. The tiered-formula approach is somewhere in between, with higher cuts in higher tariffs. It is unlikely, however, that a tiered formula would be used to achieve such large cuts in very high tariffs as are implicit in the Swiss formula.


Figure 1

Proportional versus Swiss tariff cutting formulas

The average-cut approach, by contrast, tends to focus the largest cuts on the lowest tariffs. It rewards equally a 50 percent cut in a 1 percent tariff and a 50 percent cut in a 1,000 percent tariff   potentially allowing a 50 percent average cut in this case to be achieved by a 100 percent cut in the 1 percent tariff and certainly encouraging policymakers to focus their largest cuts on the lowest tariffs. This approach can result in a seemingly impressive tariff cut, with an agreed average cut of, say, 50 percent, that yields completely insignificant tariff reductions when economies have large numbers of low tariffs. A simple move from focusing on the average cut in tariffs to the cut in the average tariff could avoid this presumably unintended outcome.

Although there are few general rules about which approaches to tariff cutting will bring about the greatest improvements in economic efficiency, there is a general presumption that lowering higher tariffs by the most will be desirable. This follows from the simple rule that the economic cost of protection rises with the square of the tariff, implying that cuts in high tariffs are worth generally much more than comparable percentage cuts in low tariffs. The best approach depends on the goal of the negotiation, however. As Anderson and Neary (2007) have pointed out, when expanding market access is the goal, it may be more useful to focus tariff reductions on goods that already have low tariffs, since these goods tend to have the largest initial trade volumes. They show that, for a given mean tariff, reducing the variability of tariffs around their mean raises economic welfare but actually reduces the market access gains resulting from application of a formula.

The actual choice between different formulas appears, in practice, to depend a great deal on the structure of countries' tariffs. In the Kennedy Round, for instance, the United States resisted application of a progressive tariff formula since it had more high tariffs than the European Community. In the Doha negotiations, the Swiss formula appears to be the most broadly accepted option for nonagricultural tariffs. From the viewpoint of developing countries, this is partly because the industrial countries have only a small number of high tariffs, but many of these

are on products such as textiles, clothing, and footwear that are of great interest to developing country exporters. Since developing countries themselves have tariffs that are much less widely dispersed than those of the industrial countries, they are likely to have to make smaller cuts in their own tariffs than would be the case with a proportional cut that brought about the same reduction in global tariffs. From the viewpoint of the industrial countries, the ceiling feature of the Swiss formula would put limits on the extent to which tariffs could rise in the future in either developed or developing countries.

Flexibility A key difference between the different approaches used is the extent to which they impose disciplines on each tariff line. Line-by-line formulas such as the proportional cut or Swiss formula specify exactly what must be done with each tariff line. More flexible approaches, such as the average cut or an agreed cut in average tariffs, allow countries to choose what they do with individual tariffs subject to some overall constraint. Typically, when a line-by-line approach such as the Swiss formula is used, some flexibility is provided to allow for more lenient treatment for particular tariff lines. In the Kennedy and Tokyo Rounds, this was done by seeking as close as possible to full coverage, but ultimately allowing a substantial number of tariffs to be exempted from the formula treatment. In the Doha negotiations, constraints were being negotiated on the number of tariffs to be exempted from the full formula cut and the extent to which the cuts on these tariffs are allowed to deviate from the formula.

The ideal with such flexibilities is to provide the modest degree of flexibility needed to reach an otherwise unattainable agreement   a small hole in disciplines akin to that provided by the pressure valve on a boiler. The problem is that it is exceptionally difficult to know what represents such a modest degree of flexibility. What looks like a small hole, allowing dangerous pressures to escape, may turn out to be more like the small hole made in a balloon with a pin. Jean, Laborde, and Martin (2006) investigated the effect of allowing just between 1 and 5 percent of agricultural tariffs to be subjected to small tariff cuts instead of the full formula approach. They found that

allowing smaller cuts in just 2 percent of tariff lines was enough to reduce the cut in the average tariff resulting from the formula by more than two-thirds. Providing a balance between allowing the flexibility needed to get an agreement and the disciplines needed to make it worthwhile seems to require discipline on both the number of tariff lines and the degree to which the products subject to flexibilities are cut.

Generalization and Simplicity Trade negotiations tend to be very complex, even if they begin with very simple formulas such as the proportional cut formula. The proportional cut and Swiss formulas are extremely simple, involving only one parameter value to choose in each case. Both of these can be slightly generalized. The proportional cut can, for instance, be converted into a linear formula by adding an intercept term, b (see Panagariya 2002):

$$t_1 = b + (1 - \alpha) \cdot t_0 \tag{2}$$

This allows the marginal rate at which tariffs are cut to be higher than the average rate, perhaps to make the formula more progressive. One potential problem with this formula is that some initially low tariffs might actually be increased by a straightforward application of the formula.

The Swiss formula can be slightly generalized to allow for slightly smaller reductions in the highest tariffs balanced by slightly larger reductions in lower tariffs. Francois and Martin (2003) show that adding an additional flexibility parameter allows the shape of the formula to change in ways that could be useful in securing agreement. The resulting generalized Swiss formula is:

$$t_1 = \frac{a \cdot t_0}{a \cdot b + t_0} \tag{3}$$

A much more common approach to generalization has been to seek to identify different parameters that can accommodate the needs of different negotiating parties. The tiered formula under consideration in the Doha negotiations on agriculture has done this by including four tariff bands each for developed and for developing countries, with different cuts in tariffs within each band. This has resulted in an unfortunate level of complexity, with a total of 14 different parameters to be chosen—a level of specificity that leaves many unsure of the impacts of different choices, particularly the impact on their export market opportunities.

One area in which even the simplest nonproportional formulas, such as the Swiss formula, are much more complex in practice than a proportional cut is in the presence of tariffs that are expressed in non-ad-valorem terms. Such tariffs, which include specific elements such as a tariff of $1 per kilo, are very common in industrial-country agricultural tariffs. These present no particular problem when using a proportional cut formula. Fifty percent of a tariff of $1 per kilo is clearly 50 cents per kilo. But all the nonproportional formulas require that tariffs be converted into ad valorem terms before they can be applied. Such conversions are, in practice, potentially quite complex and subject to manipulation since it is not always clear what import price should be used to make the conversion. In the Doha negotiations on agriculture, months of intense negotiations were required before a compromise was reached on the approach to be used to make this conversion.

Tariff formulas can provide a very useful approach for negotiating reciprocal tariff reductions, particularly when the number of participants in the negotiations is large. They can potentially allow negotiators to secure agreements that would not be attainable by bargaining over individual tariff reductions. Popular, simple formula approaches such as the proportional cut and the Swiss formula were central to the success of the GATT in reducing industrial-country protection between the 1960s and the 1990s. The formula approach is not a panacea, however. In practice, the apparent need for flexibility to deal with particularly sensitive industries and products can result in complex and difficult negotiations about flexibilities and exceptions, which require careful management if negotiations are not either to collapse or to yield agreements that achieve very little.

■ tariff escalation

Tariff escalation refers to a situation in which tariffs are low or nonexistent for raw materials but increase, or escalate, with the degree of processing. If the tariff on cocoa beans is zero, for example, the tariff on cocoa butter is 10 percent and the tariff on chocolate and chocolate products is 20 percent. In the late 1950s and early 1960s, policymakers in developed countries considered escalating tariff structures modern and rational. Some economists, however, found that escalation in importing countries could discourage exports of processed products and thereby limit the scope for processing in exporting countries (see Johnson 1965). Developing countries became increasingly concerned with this problem and made the reduction or elimination of escalation one of their main demands in multilateral trade negotiations.

Tariff escalation has been part of the tariff struc tures of advanced industrial countries, as well as of those of many developing countries, at least since the 1960s. The reduction and elimination of high tariffs, tariff peaks, and escalation figure prominently in multilateral negotiations such as the World Trade Organization's Doha Round (still ongoing as of late 2007).

Measuring Tariff Escalation Tariff escalation can be measured as the difference among the nominal tariffs of products at different stages of the processing chain. Tariff escalation exists if the nominal tariff on the output exceeds that on the input; tariff deesca lation is present when the nominal tariff on the input

exceeds that on the output. The practical difficulty when using this approach is to describe processing chains and/or to identify products at different levels of processing.

Two main methodologies are typically used. The first uses a categorization of all products (tariff items) in a given nomenclature according to their degree of processing: typically raw materials, semifinished products, and finished products. The second requires the identification of processing chains for specific commodities, such as cocoa, cotton, or tobacco (OECD 1999). These two simple methodologies have limitations. They do not measure the intensity of protection afforded the final product, and they cannot be used when the final product incorporates a variety of inputs.

The concept of effective rate of protection (ERP) was devised in the early days of the theory of tariff structure to measure the effects of tariff structures on the allocation of resources. The ERP is defined as the percentage increase in value added per unit in an economic activity attributable to the tariff structure relative to the free-trade situation. It quantifies the intensity of protection afforded to the final product and can be used where multiple inputs are involved.

Consider the following simple example of a producer of bicycle frames that requires only steel as an intermediate input. Suppose that the production of a frame worth 150 in free trade requires the use of steel worth 100 in free trade. Value added at free trade prices is thus 50. Now assume that the country where the producer operates provides nominal protection at a rate of 20 percent on frames and 10 percent on steel. Under this structure of protection the domestic price of frames becomes 180 while the cost of the steel required to produce the frame becomes 110. Value added in this case is 70, which is 40 percent higher than value added in free trade. This increase in value added permitted by the protection structure is known as the *effective rate of protection*.

As shown in this simple example, in the presence of tariff escalation, the ERP (40 percent) is larger than the nominal tariff on the output (20 percent). Its main advantage is to capture certain general equilibrium mechanisms while avoiding the infor-

mational requirements of full general equilibrium computations. In the early 1970s, the utility of the concept of effective protection was challenged by a number of authors. Eventually, economists recognized the descriptive value of the ERP concept in empirical studies of protection as well as its analytical value subject to some caveats.

Effects of Tariff Escalation In principle, tariff escalation would be expected to distort resource allocation in both the importing and the exporting countries. In the importing country, output should be skewed toward processed products while in the exporting country it should be skewed toward raw materials. Yeats (1984), however, argues that the tendency for tariffs to increase over stages of a processing chain is neither a necessary nor a sufficient condition to establish a bias against processed goods. There are two problems: first, the nature of tariff-induced trade biases has never been defined precisely; second, the changes in demand conditions over stages of a processing chain have never been considered. Yeats shows that because import demand elasticities consistently increase with the degree of processing, neutral tariffs (i.e., tariffs that do not change the shares of primary and processed goods in exports relative to free trade while maintaining the aggregate level of imports) would often be deescalating. In other words, a trade bias against processed goods may exist even when actual tariffs deescalate over a processing chain.

In the 1990s, concerns were raised that tariff escalation may be a source of environmental damage to exporting countries. The argument was that by shifting economic activity toward primary production and away from processing, escalation induced excessive extraction of natural resources with consequent degradation of the resource base. A literature review by Hecht (1997), however, suggested that tariff escalation was not a significant source of distortion in the economic system or of damage to the environment. First, tariff escalation decreased with the Uruguay Round of international trade negotiations (1986 94) and was further reduced by preferences. Second, there was evidence that processing activities would tend to cause more environmental

harm in developing countries than in developed countries. Finally, the elimination of escalation would not boost income sufficiently in developing countries to significantly promote environmental protection.

Magnitude of Current Tariff Escalation In the last decade, a number of studies have assessed the incidence of tariff escalation in agricultural markets. These studies differ significantly in terms of methodology, country, and commodity coverage, as well as in the type of tariffs they consider. The studies generally point out the persistence of tariff escalation in the post Uruguay Round tariff landscape, and they provide a number of more specific results.

The Uruguay Round reduced escalation of developed country bound agricultural tariff rates. Even after full implementation of Uruguay Round tariff cuts, however, escalation persisted in developed countries in about half the agricultural product chains considered (Lindland 1997; UNCTAD 2003). USDA (2001) extends these results to developing countries. OECD (1999), which covers both agricultural and nonagricultural products as well as developed and developing countries, found that most processing chains in both members of the Organisation for Economic Co-operation and Development (OECD) and nonmembers are affected by escalation.

Applied tariffs also exhibit escalation. Elamin and Khaira (2004) show that for major developed importers, escalation prevails in 12 out of 16 of the agricultural product chains they consider. In developed countries, tariff escalation seems to be lower in the case of applied most-favored-nation tariffs than in the case of bound tariffs, while the opposite prevails in developing countries. When the nonreciprocal preferences that developed countries extend to developing countries are taken into account, escalation is clearly lower. In fact, the least-developed countries do not face any tariff escalation in markets where they are granted duty and quota-free access. It may be worth underlining, however, that nontariff barriers may also be escalating.

Since its effects on exporting countries were identified in the 1960s, escalation has been a concern for developing countries. Successive rounds of tariff negotiations have not gotten rid of it. How much the Doha Round of international trade negotiations will reduce escalation will largely depend on the degree of flexibility available to governments to protect specific products from formula cuts. In any case, for a reduction of escalation to have a substantial effect on the export structure of those countries that have not been able to diversify away from natural resources, most of which are least-developed countries, a number of other constraints on improved export performance will need to be released. Least-developed countries' poor export performance may be due in no small part to binding export supply response capacity constraints, which prevent fuller utilization of available market access opportunities.

MARC BACCHETTA

■ tariff rate quotas

A tariff rate quota (TRQ) is unlike an ordinary quota because it does not set an absolute maximum level of imports. Instead, it sets a specified quantity of imports that can enter at a lower tariff (called an "in-quota tariff") than imports in excess of that limit. If the higher "over-quota tariff" is set so high that no imports occur above the limit, then the TRQ functions like an import quota. Historically the purpose of TRQs is to harmonize the common external tariff in a customs union or free trade area, implement tariff preferences for developing coun-tries, or provide a special safeguard against import surges (Rom 1979). More than 1,425 TRQs were established in the Uruguay Round Agreement on Agriculture to facilitate the conversion of import bans and quotas into tariffs (WTO 2006). In some cases, these agricultural TRQs increased trade be-cause countries were to provide "minimum access" (at least 5 percent of domestic consumption by 2001) and not restrict "current access" (quotas at historically established import levels). TRQs for agriculture are very important in members of the Organisation for Economic Co-operation and De-velopment, protecting upward of 50 percent of the total value of domestic production (de Gorter and Kliauga 2006).

Article XIII of the General Agreement on Tariffs and Trade (GATT) 1994 governs the administration of quantitative restrictions including TRQs and can be interpreted as inherently contradictory because it advocates nondiscrimination yet allows "supplier tariff quotas" as opposed to global quotas open to all exporting countries (Skully 2001). The GATT ad-vocates two criteria for proper administration: quota fill (where imports are to be determined by market conditions) and distribution of trade (trade patterns are to approach that without the restrictions). But importing countries have a GATT-consistent means of discrimination, because if agreement among all interested parties is "not reasonably practical," then quotas can be apportioned to exporting countries on a historical basis.

Disputes have resulted over the method by which country-specific export quotas are allocated. A classic example is the "Banana Dispute" (WTO 1997) where the method used by the European Union (EU) was deemed discriminatory because it did not reflect recent trade patterns. The WTO Appellate Body also ruled that the EU practiced discrimination in not requiring export licenses for all countries. The Ba-nana Dispute also highlighted problems in allocating import licenses because the EU was found to be in-consistent across countries in terms of the period of validity of the license, the size of license, eligibility requirements for a license, reallocation of unused licenses, and the requirements for the use of the li-cense. Some firms from Latin American countries faced complicated licensing procedures and had unnecessary burdens imposed on them. They were deemed to have been treated in a discriminatory and trade-distorting manner, so that the EU had to re-form its banana quota licensing system.

Ideally quotas should be auctioned, but mostly other forms of administration along with additional regulations have been imposed. The issue of TRQ administration is one of two major issues; the other is how best to liberalize trade with TRQs.

Trade Liberalization Effects of Reducing Tar-iffs versus Expanding Quotas Three basic "re-gimes" can determine imports and domestic prices, corresponding to each of the three policy instruments comprising a TRQ: the in-quota tariff (t_1), the over-quota tariff (t_2), and the quota level itself. The in-quota tariff regime can result for two reasons: market conditions are such that underfill occurs (the quota is not binding) or the quota (and over-quota tariff) is

disregarded, in which case either quota underfill or overfill can result. "Overfill" occurs when the government allows imports at the in-quota tariff to exceed the level of the quota. Imports paying the over-quota tariff (described later) are called "over-quota" and are not counted toward overfill.

Figure 1 shows the case of a small-country importer facing an import supply ES and an import demand curve ED such that the quota is not binding and underfill occurs. This shows that a quota fill rate of less than 100 percent does not necessarily imply inefficiency. But it could also be the case that the government allows the market to determine the equilibrium regardless of the quota level and so quota overfill could occur (not shown in figure 1), depending on market conditions and the levels of the quota and in-quota tariff. In either case, there are no quota rents. The domestic price Pd is equal to the world price inclusive of the in-quota tariff. Because the MFN over-quota tariff is the one under negotiation in the WTO, the difference between the over-quota and in-quota tariff represents "water" in the tariff, defined as that range over which a reduction in the over-quota tariff will have no impact on trade. An increase in the quota will have no impact initially with underfill due to market conditions and no impact at all if by government decree the quota is not a constraint.

The over-quota tariff determines the equilibrium in figure 2. One would normally expect the quota to be exactly filled, and imports beyond the quota to pay the over-quota tariff. But this particular case in figure

2 has quota underfill, which necessarily implies inefficiency in the administration of the quota licenses because some suppliers are forgoing quota rents in paying the higher tariff. Underfill in this case could be due to import quota licenses being allocated to higher-cost suppliers. Empirical research finds the situation depicted in figure 2 to be very common, but cases of exact fill and overfill also exist. Overfill can occur by government decree, when imports paying the lower tariff are extended beyond the quota while over-quota imports occur at the same time. In all cases, quota rents are positive, as are tariff revenues from both in-quota and over-quota imports. A reduction in over-quota tariffs will have an immediate trade liberalizing effect, while a quota expansion will have no initial impact because of over-quota imports and either quota underfill or overfill. Note that when a quota expansion does have an impact, there is a regime switch to the quota binding case (described next) but continued quota expansion will result in a switch to the in-quota tariff binding regime, in which case any further increases in the quota will have no trade liberalizing effects.

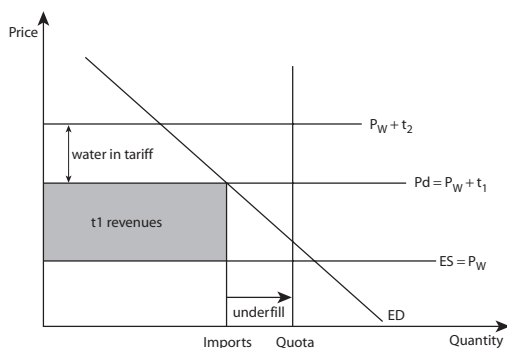
The case where the quota is binding initially is given in figure 3. The particular case shown has quota underfill, necessarily due to inefficient quota administration, but the cases of exact fill or quota overfill can occur as well. In all cases, there are positive quota rents and in-quota tariff revenues. A reduction in over-quota tariffs will have no immediate impact on trade because of water in the tariff due to


Figure 1

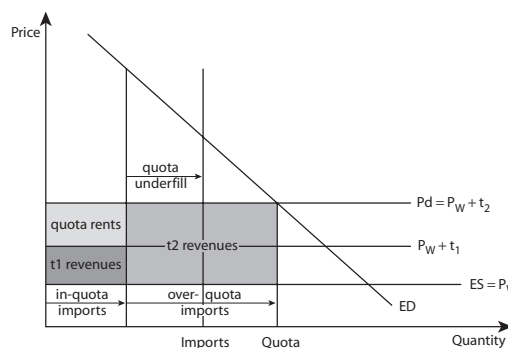
In quota tariff with quota underfill


Figure 2

Over quota tariff with over quota imports and quota underfill
Figure 3
Quota binding with underfill

the binding quota. Expanding the quota will have an immediate impact only if there is exact quota fill initially; otherwise there will be no initial trade expansion with overfill and perhaps a less than one-to-one increase in trade with underfill, depending on the reason for the underfill.

The discussion shows that the efficacy of a tariff cut versus a quota expansion depends on a complex set of factors. The impact of tariff reductions depends on the level of water in the tariff, whereas that of quota expansion depends on the levels of over-quota imports, overfill or underfill, whether the in-quota tariff is initially binding, or how soon the in-quota tariff regime becomes binding with continued quota expansion.

TRQ Administration How the rights to quotas are distributed can affect the volume and distribution of trade, as well as the distribution of rents. With country-specific allocations, the exporting country may obtain the quota rents, depending on how the import licenses are awarded and the bargaining power between exporting and importing firms. The WTO (2006) identifies six principal methods of TRQ administration: applied tariffs; licenses on demand; first come, first served; historical imports; state trading enterprises (including producer groups); and auctions.

Applied tariffs refer to cases when the in-quota tariff determines imports and are usually used for less politically sensitive products. No licenses are allocated to importers   imports are not limited. There is

no inefficiency as a result except that due to the in-quota tariff itself.

With the *licenses-on-demand* method, firms request licenses and if the total licenses requested exceed the quota, then requests are reduced pro rata. Inefficiency is incurred because high-cost firms are allowed to operate closer to their optimal levels while low-cost firms are further from their desired levels. The ability to overbid exacerbates this inefficiency (Hranaiova, de Gorter, and Falk 2006).

Licenses allocated on the basis of *historical imports* also generate inefficiency if cost structures or demand change over time. Furthermore, firms may rent seek by importing at a loss at the over-quota tariff to increase their share of the licenses in the future.

The *first-come, first-served* basis hurries up imports and so causes inefficient allocation of imports over time. Because many agricultural products are perishable, rents are not dissipated with waiting in line. Instead domestic prices fall to world levels as exporters compete for the rent, which falls and so is appropriated by consumers. Domestic producers face the world price until the quota is filled, when the domestic price then spikes. The ability for firms to rent seek by storing the commodity or changing the seasonality of production will generate inefficiencies and reduce rent appropriation by consumers.

State trading enterprises (STEs) have direct control over imports; inefficiencies can result, depending on the STE's objectives and degree of control over imports and the domestic market. Some STEs in Asia tender licenses to the lowest-price bidder, resulting in low-quality imports (sometimes for animal feed) and so minimize the damage to producers for a given import quantity (Agricultural and Resource Economics Review 2000).

Because tariff quota administration is a rationing problem, economists favor a market-based system *auctioning* licenses to the highest bidder. Auctions account for the lowest level of agricultural trade under TRQs, however (de Gorter and Kliauga 2006).

Many additional regulations on import licenses can accompany each of these administration methods. The more onerous ones include domestic purchase requirements, time limits, limits per firm, and

seasonal licenses. A restrictive *domestic purchase requirement* can cause underfill, whereas *time limits* and *limits per firm* can impose increased costs of importation. *Seasonal licenses* increase inefficiency, especially in agriculture, where different harvest seasons cannot be taken fully advantage of between countries in the northern and southern hemispheres.

The role of TRQs in the modern world economy is mostly limited to agriculture, where they are facilitating the transition from nontariff barriers to tariffs as the principal means of protection. As of 2007, several outstanding issues in the WTO trade negotiations remain unresolved, including how best to liberalize TRQs. Reducing over-quota tariffs is generally agreed to be the more trade-liberalizing approach, but many countries instead expand quotas. This would reduce the amount of preference erosion for developing countries who often receive the quota rents. But it also leaves open the possibility of continued inefficiency due to the many ways quotas are administered, often with restrictive additional regulations.

■ tariffs

Tariffs are taxes levied on imported or, less often, exported goods when they cross the border between one customs territory and another. The use of customs duties, a synonym for import tariffs, can be traced back to the Babylonian civilization (18th to 6th centuries BCE). In the 20th century, tariffs fluctuated considerably. Since the end of World War II, however, thanks to eight rounds of tariff negotiations under the General Agreement on Tariffs and Trade (GATT) and to a number of preferential tariff agreements, developed country tariffs have been on a downward trend from an average of 20 30 percent to

between 3 and 7 percent. Developing country tariffs have also been substantially reduced, but only since the 1980s. Despite a substantial increase in the number of tariff lines, international comparability and overall transparency in the tariff area increased significantly with the adoption by all countries of a common nomenclature, the so-called Harmonized System (see Hoda 2001).

Because they are relatively easy to collect and seem to be paid by foreigners, tariffs have long been an instrument of choice for governments to collect revenue. In the late 20th and early 21st centuries, however, this role lost its importance among developed and most developing countries as governments became more interested in the effect of tariffs on the economy. Tariffs raise the price of imported products on the domestic market and reduce imported quantities. They yield revenue for governments and afford protection to domestic producers of the goods that compete with imports. A tariff imposed on some imported products will have two effects on the importing country: it will introduce welfare-reducing distortions of both production and consumption, and if the country that imposes it is large enough to affect foreign export prices, it will improve its terms of trade.

Types of Tariffs Tariffs are generally ad valorem, which means that they are expressed as a percentage of the value of imports, but they can also be *specific*, expressed as a number of monetary units per quantity unit (e.g., $5 per Kg). Other less common tariffs include *compound* tariffs, which have two components, one ad valorem and the other specific ($5 per Kg + 3 percent); *mixed* tariffs, which take the form either of a specific rate or of an ad valorem rate, whichever is the highest ($5 per Kg or 3 percent, w. i. t. h.); or *technical* tariffs, the level of which depends on the product's content of one or more specific input(s), such as sugar or alcohol. Non ad valorem tariffs are most frequent in agriculture but they are also used by a small number of countries for certain nonagricultural products.

An important distinction that relates to tariff negotiations and trade agreements is between most-favored-nation and preferential tariff rates. A basic

principle of the GATT and the World Trade Organization (WTO) is that governments should not set different tariff rates for different trading partners. This nondiscrimination principle takes the form of the most-favored-nation (MFN) clause, which dictates that a country must immediately extend any advantage, favor, privilege, or immunity granted to any product originating from or destined to any other country to the like product originating or destined to all other member countries. MFN tariffs apply to all trading partners with the exception of those that benefit from preferences. Multilateral rules allow exceptions to the MFN principle for regional trade agreements (GATT Article XXIV) and for non-reciprocal preferences granted to developing countries (1979 Enabling Clause). There are thus two different types of preferential tariffs: the nonreciprocal preferences granted by developed countries to developing countries, and the reciprocal preferences granted by participants in regional trade agreements to other participants.

From a legal perspective, a distinction is sometimes made between tariffs that are stipulated by laws, called statutory tariffs, and tariffs that are stipulated by conventions. The first category comprises, among others, the general rate that remains unchanged unless the situation substantially changes, temporary rates, preferential rates applicable to developing countries, and so on. Two types of duty rates are stipulated by conventions: conventional rates established in the WTO and preferential rates negotiated in regional trade agreements.

A second distinction that relates more specifically to the GATT/WTO is between bound and applied tariffs. When governments negotiate tariff reductions in the GATT/WTO, their commitments take the form of tariff bindings. MFN bound tariff levels, which are listed in a country's tariff schedule, indicate the upper limit at which the government is committed to set its MFN applied tariff. For a given tariff line, the MFN bound tariff must thus be higher than or equal to the MFN applied tariff, which is higher than the preferential tariff.

The concept of effective tariff or effective rate of protection serves to measure the encouragement

provided to domestic production by tariffs on both inputs and outputs. Nominal tariffs do not measure this encouragement appropriately. If they are imposed on imports that compete with a country's outputs, tariffs provide a positive stimulus to domestic producers. If, however, tariffs are imposed on a country's imported inputs, domestic producers are worse off. To capture the net protective effect of a tariff structure, effective tariffs measure the stimulus to value added, in the production of a particular product provided by nominal tariffs. The effective rate of protection is defined as the difference expressed in percentage terms between a sector's value added at world market prices and its value added with tariffs imposed. If the nominal tariff on inputs and output is the same, the effective tariff is equal to the nominal tariff. If the nominal tariff on the output exceeds the nominal tariff on the input, the effective tariff is higher than the nominal tariff.

Economic Effects of Tariffs Starting from a situation of free trade, consider the effect of a specific tariff t introduced by country A on product X. In the absence of any tariff or other distortion, the domestic price of product X is equal to the world price. When tariff t is introduced, however, exporters renounce shipping product X to country A if the price in A does not exceed the world price by t. The price in A starts rising while, if A's market is large enough, world price starts decreasing until the wedge is equal to t. The rise in price in A encourages domestic supply and discourages domestic demand. The volume of trade decreases. If A's market is large enough, the price increase in A is less than the amount of the tariff t. The decrease in A's demand lowers the world price so that only part of the tariff is passed on to consumers in A. If A is small enough, however, the world price remains constant and the tariff is fully passed on to consumers.

Consumers in A lose from the tariff while producers gain and the government collects tariff revenue. If A is large enough and the world price decreases, foreign producers lose and foreign consumers gain. A simple cost-benefit analysis using the notions of producer and consumer surplus reveals that for a country without market power the best

policy is free trade. The cost of the tariff to consumers is only partly compensated by the gain to producers and the increase in government revenue. The tariff induces a net welfare loss (deadweight loss) that can be linked back to both a consumption distortion (consumers do not consume enough X) and a production distortion (producers produce too much X). For a country that is large enough for changes in its demand to affect world prices, however, free trade is not necessarily optimal. In the large market case, the loss resulting from the two distortions must be compared with a "terms-of-trade" gain resulting from the lower price paid by consumers for the imported product. Note that this gain corresponds to a loss in the exporting country, which adds up to a deadweight loss resulting from the distortions of both consumption and production.

Arguments in Favor of Tariffs The cost-benefit analysis of tariffs has shown that for small countries without influence on their terms of trade, free trade is optimal. For countries that are large enough to influence the price of their imports, however, a nonzero tariff can be preferable to free trade on efficiency grounds. As first demonstrated by Bickerdike (1906), an "optimum tariff" can be calculated that maximizes national welfare. This optimum tariff level is the one at which the marginal benefit from improved terms of trade is equal to the marginal cost from production and consumption distortions. The so-called terms-of-trade argument for a tariff raises a number of empirical and practical problems, however. First, the practical relevance of the terms-of-trade argument is a matter of controversy among international economists. Second, as explained in the previous section, the terms-of-trade gain comes at the expense of the exporting country. If a large country uses its market power to extract gains from its partners, it will most likely induce retaliation and trigger a trade war (Johnson 1954).

Another argument that may justify the use of tariffs is the presence of market failures. If, for instance, capital or labor markets do not function properly and slow down or prevent resource reallocation, if activities of potential interest for production and export diversification generate learning

by doing spillovers, or if unemployment or under-employment is significant, the basic theoretical case for free trade does not hold. In the presence of market failures, the consumer and producer surplus concepts do not measure the costs and benefits of tariffs adequately. Consider the case where the production of some good or service generates productivity gains for the sector or even the whole economy and firms that produce the good cannot appropriate these benefits and thus do not take it into account in their production decisions. In such a case, firms will not produce the good despite the fact that it would be socially optimal to produce it. The spillovers could then be used as a justification for a temporary tariff that would stimulate production and thereby generate social benefits.

The market failure argument for protection has been criticized on two grounds. First, tariffs are not the first best response to most domestic market failures. In the spillover case, a production subsidy would also stimulate production, but unlike the tariff it would not distort consumption and would therefore be preferable. Second, the market failure argument in favor of tariffs has been criticized for practical and political reasons. For some economists, government failures cause more problems than market failures. Market failures are difficult to identify and appropriate policy responses difficult to design. Moreover special interests are likely to have more influence where governments pursue a more flexible trade policy.

Recent History By the end of World War I, high tariff levels, quantitative restrictions, and prohibitions combined with exchange controls dominated the trade policy scene. Countries that had become creditors to other nations, such as the United States, Argentina, Australia, Canada, and India, increased or kept tariffs very high by international standards. In the early 1920s, while various nontariff barriers introduced during the war were progressively lifted, tariffs were raised in compensation. In the late 1920s, a sharp fall in agricultural prices jeopardized attempts to negotiate tariff reductions. Germany, France, and Italy raised their agricultural tariffs and the U.S. Congress passed the protectionist Smoot-Hawley Tariff Act, which even before its implementation provoked widespread retaliation, contributing to a general increase in tariffs. The new trade restrictions aggravated the economic crisis and openly discriminatory trade relations evolved. In 1931, after almost one hundred years of a very liberal trade policy with minimal protection, the United Kingdom, still the largest importer, retreated via the Ottawa Agreement into a preferential trading system.

World War II severely affected the world trading system. A low level of trade went together with major trade imbalances. Trade policies were characterized by relatively high tariffs, the use of preferences by some countries, the extensive use of nontariff trade barriers by the European countries, and widespread government control of international transactions in order to manage scarce foreign exchange reserves of U.S. dollars. In 1947 the average tariff rate was between 20 and 30 percent (WTO 2007). The average U.S. tariff in 1947 was still considered to be among the highest in the major industrial countries despite a shift away from the extreme protectionist trade policies of the early 1930s. The average applied tariff rate among European countries ranged somewhere between 10 and 20 percent. A low-tariff country group (comprising Denmark, Norway, Sweden, and the Benelux countries Belgium, the Netherlands, and Luxembourg) had tariffs somewhat below 10 percent while a high-tariff group (comprising France, Italy, Portugal, and the United Kingdom) had tariffs averaging close to 20 percent (Woytinski and Woytinski 1955). The situation in other regions of the world was relatively diverse, but available evidence suggests that independent countries had relatively high tariffs. Brazil, for instance, had shifted toward a strict form of industrial protectionism in the late 19th century to become one of the most highly protectionist countries in the world.

Since 1947, eight rounds of multilateral tariff negotiations under the GATT and the WTO contributed to a substantial reduction of industrial tariffs in developed countries. Tariffs on agricultural and textiles and clothing products, which did not follow the downward trend, stick out above the average. Until the 1980s, a majority of developing countries pursued import-substitution policies with relatively

high tariffs. Starting in the 1980s, however, many if not most of them switched to more outward-oriented development strategies and started reducing their tariffs unilaterally, often in the context of structural adjustment programs.

At the same time, tariffs were also reduced on a discriminatory basis. In various regions of the world regional trade agreements were signed that resulted in the reciprocal elimination of tariffs on trade between a limited number of trading partners. Most developed countries also introduced nonreciprocal preferential tariff schemes aimed at encouraging imports from developing countries.

Priorities Because they have been brought down in most countries, tariffs are sometimes seen as history. In reality, however, they are still alive, and the evolution of the Doha Round of multilateral trade negotiations (ongoing as of late 2007) reflects how difficult it is for governments to agree to further cuts and bindings. There are a number of reasons for this. Tariff reductions tend to follow the path of least resistance, so the remaining duties can be expected to offer more resistance to liberalization efforts. It is not clear whether discriminatory tariff reductions facilitate or impede MFN reductions. More than anything else, however, skepticism regarding the benefits from tariff reductions in the public and in a number of governments has been growing. This may mean that the case for cutting and binding tariffs needs to be reassessed or simply that it needs to be made more convincingly.

■ technical barriers to trade
Standards and technical regulations exist to ensure consumer safety, environmental protection, national security, interoperability of electronic products, and many other goals. There is a wide variety of standards and technical regulations. These include guidelines for product certification, performance mandates,

testing procedures, conformity assessment rules, and labeling requirements, for example. The simple distinction between standards and mandatory technical regulations is that the latter refers to rules imposed by government, while standards are voluntary guidelines. Standards development may be encouraged by nongovernmental organizations, or required of a supplier to a manufacturer of a final good, for example.

From a producer's perspective, standards and technical regulations can overcome problems of fragmented markets and result in economies of scale. It is potentially more costly to produce for a market with many different incompatible products. This can deter firms from exporting to multiple markets with one product. Moreover, standards and regulations that promote compatibility or interoperability between products allow firms to supply goods at lower prices. From a consumer's perspective, efficient standards and regulations can make it easier to compare products to meet individual preferences and help to ensure that goods are safe or operate efficiently. Standards and mandatory regulations may also, however, act to restrict competition and act as a technical barrier to trade (Maskus, Otsuki, and Wilson 2005). This is particularly true when standards are nontransparent, imposed on a discriminatory basis, or not harmonized to international norms.

The majority of mandatory product regulations are set by national governments. Technical regulations may vary across countries given different views regarding optimal levels of safety, risk, levels of environmental protection, or national security, among other factors. Technical regulations that deviate from principles of reliance on international science, private sector led development, or international norms can raise costs for producers seeking to enter export markets and act as a technical barrier to trade. Technical regulations may discriminate against foreign suppliers, both in their design and implementation, and may be used to provide strategic trade advantages for domestic firms over foreign competitors. Technical regulations can also force firms to duplicate product testing and certification procedures required to test conformity to

standards and therefore raise design and production costs. Regulations can also be crafted to exclude foreign entrants into a particular market in order to support domestic monopolies.

Firms in developing countries may be especially affected by these factors, given less efficient production facilities, or lack of access to testing and certification procedures or information on international standards. The overall findings from the World Bank Technical Barriers to Trade (TBT) survey conducted in 17 developing countries indicate that 70 percent of firms that export must comply with mandatory technical regulations. The majority of firms responding to the survey perceive technical regulations to be important for entering export markets (Otsuki and Wilson 2004).

There are general commitments under the World Trade Organization (WTO) Technical Barriers to Trade Agreement that address the use of technical regulations to block trade (WTO 2007). These provisions encourage use of international standards to meet regulatory goals, promote mutual recognition of tests and certification where possible among members, and codify the principles of nondiscrimination and national treatment in regard to technical regulations. The TBT Agreement also mandates that governments notify the WTO of any new draft technical regulation prior to final implementation.

There is an increasing number of empirical studies that examine standards and technical regulations and their impact on trade flows. Among others, Chen, Otsuki, and Wilson (2006) examine how meeting foreign standards affects firms' export performance, reflected in export propensity and market diversification. The study uses firm-level data from the World Bank Technical Barriers to Trade Survey. The results indicate that firms subject to mandatory testing procedures have an export share nearly nine percentage points lower than other firms. The existence of information inquiry difficulties in major export destinations is estimated to decrease exports by 18 percent of their total sales. Furthermore, long inspection times for products significantly reduce firms' export incentives.

The study also explores how standards and technical regulations vary across different types of firms and how market diversification might be affected. Results suggest that the export propensity of domestically owned firms is affected more by testing procedures relative to other firms and that the negative relationship between informational inquiry difficulty and export propensity is strongest for manufacturing firms. In terms of market diversification, the results imply that standards reduce the likelihood for exporters to enter multiple markets.

Questions of the utility of harmonization of national standards and technical regulations to international norms are also increasingly important in regard to the role of standards as technical barriers to trade. Czubala, Shepherd, and Wilson (2007) examine the impact of European Union (EU) standards on African textiles and clothing exports, a sector of particular development interest. Evidence suggests that EU standards not harmonized to de facto international standards reduce African exports of these products. EU standards that are harmonized to ISO standards are less trade restricting. Results suggest that efforts to promote African exports of manufactures may need to be complemented by measures to reduce the cost impact of product standards, including international harmonization. In addition, efforts to harmonize national standards with international norms, including through the World Trade Organization Technical Barriers to Trade Agreement, promise concrete benefits through trade expansion.

Technical barriers to trade represent one of the more important potential obstacles to the expansion of world trade. Nontariff barriers have fallen over the past decades, and traditional nontariff barriers such as quotas and other policy tools of protection have been reduced. Efforts to deregulate, basing technical regulations on international scientific risk profiles, and reliance on suppliers' declaration of conformity reinforced by postmarket surveillance systems, among other steps, can help reduce the scope for governments to protect domestic firms behind technical barriers. Strengthening the WTO disciplines in the TBT Agreement, including stronger provisions on

notifications of new regulations by members and further encouragement of harmonization of standards to international norms, can also help.

■ technological progress in open economies

Long-run economic growth is driven by technological progress, which in general takes two forms: product innovations and process innovations. The former refers to introduction of new or better quality products and the latter refers to implementation of resource-saving technologies. Diffusion of new products/technologies via imitation and direct technology transfer also promotes economic growth. This is especially valid for developing countries that are further away from the world technology frontier. The question of whether openness stimulates technological progress is important since openness is to a large extent determined by policy choices. Openness of an economy is measured by the degree of barriers to international trade, investment, and labor flows as well as by the volumes of these indicators.

Theory Openness can affect technological progress through a variety of channels. First, open economies can more easily acquire the state-of-the-art technologies available abroad via imports, foreign direct investment (FDI), and immigration. Second, exposure to international trade promotes competition among domestic firms. On the one hand, this can accelerate the pace of technological progress by motivating firms to escape competition via innovation. On the other hand, more intense competition can hurt profits, reduce the returns to research and thereby discourage innovation. Third, entrepreneurs in open economies have access to larger markets and thus enjoy larger returns on successful innovation. This raises the profitability of innovation and boosts growth. Fourth, open economies can avoid duplicating research conducted abroad and thus allocate their innovation resources more effectively. Fifth, under certain initial conditions, lowering trade barriers may reduce the relative price of skilled labor

and render research and development — which is a skilled-labor-intensive activity — less costly and thus stimulate growth. Finally, economies open to labor flows can experience higher growth by attracting human capital from abroad, which is known as brain gain. The opposite, brain drain, holds when human capital leaves the country. It should be noted that all of these mechanisms exert a short-run influence on economic growth but not necessarily a permanent influence on growth rates.

Case Studies Economists first investigated the linkages between growth and openness using case study techniques. These studies were conducted in the 1970s under the auspices of the World Bank, the Organisation for Economic Co-operation and Development, and the National Bureau of Economic Research (NBER). The basic methodology involved comparing the outcomes of import substitution (IS) strategies, as practiced in Argentina, Chile, Ghana, Mexico, Turkey, and other countries, with those of export promotion (EP) strategies, as implemented by Korea, Taiwan, Hong Kong, and Singapore. The premise of the IS policy was that developing countries need to protect their infant manufacturing industries by quotas and import tariffs in order to foster capital and technology accumulation. Proponents also suggested that by pursuing IS strategies developing countries would be able to avoid the adverse terms-of-trade effects associated with exporting raw materials. The premise of the EP policy was to provide market discipline to domestic firms by encouraging them to compete with foreign firms while keeping tariffs on imports at low levels. The case studies documented that pursuing EP strategies was a much more effective policy tool in fostering growth compared with IS strategies. These studies also underscored the need to complement trade liberalization with other fiscal, monetary, and structural changes such as stable government debt, market-determined exchange rates, and an improved education system.

Cross-Country Openness Growth Regressions Since the advent of broad international data sets in the early 1990s, economists have used cross-country growth regressions to investigate the openness-

growth link. The basic statistical methodology involves running regressions to identify the impact of openness on economic growth while controlling for other factors that are known to affect growth such as initial income per capita, investment in physical and human capital, political stability indicators, and so on. These studies can be classified into two categories based on their choices of openness indicators.

Trade volumes regressions. The first group of these studies has used total trade share, import share, and export share in gross domestic product as openness measures. In general, these cross-country growth regressions have established a positive and statistically significant link between growth and trade volumes. They have been criticized on two accounts, however. First, statistically significant correlations do not necessarily imply a causality from trade to growth. Second, trade is an endogenously determined variable that responds to income per capita. To tackle these issues, economists have used geographic indicators that is, variables that affect trade but are not influenced by policy and income as instruments and have obtained predicted values for total trade flows. They then regressed income per capita on these predicted values in the presence of control variables. The instrumental variable (IV) estimates have shown that the empirical findings from the standard cross-country growth regressions continue to hold to a large extent. The robustness of these IV estimates, however, have also been challenged by economists who incorporated institutional quality and geographic indicators in the regressions.

Trade restrictions regressions. The second group of econometric studies has used tariffs and nontariff barriers as openness indicators. These studies offer mixed results on the relationship between openness and growth and are plagued with measurement problems and data availability issues. These problems led economists to construct trade restrictiveness indexes that combine tariff and nontariff barriers with other indicators that are known to adversely affect international trade and investment. The most popular among these is the Sachs and Warner (SW)

index, which combines information on tariff rates, quotas, political control of exports, exchange rate distortions, and market structure. Although many studies have found this index to have a positive correlation with economic growth, the index is too broad to interpret as a measure of trade or investment policy. Further, it was shown that when one uses specific trade-related subcomponents of the SW index in particular tariff rates and nontariff barriers the relationship between openness and economic growth becomes statistically insignificant.

As an alternative to cross-country studies, recent work has focused on within-country effects of trade liberalization. The methodology involved comparing the pre and post trade liberalization growth rates using econometric techniques. One study that determined the timing of trade liberalization based on the SW index calculates that on average countries that switch from being closed to being open experienced a large and statistically significant increase in their growth rates. Obviously, not all of the gain in growth can be attributed to opening up the economy, because in most cases trade liberalization is accompanied by other policy changes that may foster growth such as financial reform, privatization, and investment in infrastructure.

International Technology Diffusion via Imports and FDI Empirical studies have also examined the magnitude of technology diffusion via imports by accounting for the stock of knowledge embodied in imported products. These studies show that knowledge-intensive imported goods in particular differentiated capital goods and high-technology imports exert a large and significant influence on domestic productivity. This is consistent with endogenous growth theory, which predicts that openness increases access to new technologies and specialized high-quality intermediate inputs and thereby stimulates productivity growth.

Technology spillovers can also take place through FDI and multinational firm (MNF) activity. MNFs can bring new technologies that can be diffused to the local economy via labor training, labor turnover, and provision of high-quality intermediate products. Interactions between MNFs and domestic firms in

the form of vertical production relationships can further contribute to technology diffusion. A number of industry- and plant-level studies have found that the presence of foreign-owned firms leads to technology spillovers, but the nature and magnitude of these spillovers may differ across countries. For instance, a study focusing on Venezuela finds that the intensity of foreign ownership adversely affects the productivity of domestic firms. Another study focusing on the United States reports that 11 percent of U.S. manufacturing productivity growth is accounted for by inward FDI to the United States. The number of industry- and plant-level studies has been quite limited so far, but recently there has been a call for such studies and more work appears to be on the horizon. In the meanwhile, cross-country growth regressions have found that the growth-promoting effects of FDI materialize only for countries that attain a threshold level of human capital and financial development.

Implications for Policy Even though substantial empirical evidence supports the view that trade promotes growth, most economists caution that it is not necessarily and exclusively policy-induced trade that serves as the magic bullet. Changes in national trade and investment policies bring forth a reallocation of resources within an economy. Growth-promoting effects of trade liberalization can be reaped fully only when complemented with appropriate fiscal, monetary, and structural policies that facilitate the allocation of resources to their most productive use. These include but are not limited to stable government budget positions, low inflation, market-determined exchange rates, an improved education system, a well-functioning legal system, and reduced corruption.

M. FUAT SENER

▪ technology licensing

Technology licensing occurs when an economic agent with a particular technology sells that technology to another economic agent without it. Depending on the characteristics of the licensed technology, technology licensing may either reduce the licensees' cost of production or increase the quality of the licensees' products.

The literature on technology licensing can be separated into two categories based on whether the licenser and the licensees compete in the product market. Whether the licenser and the licensees are

from different countries may have also important implications.

Kamien (1992) surveys the work on patent licensing in cases where the licenser and the licensees are not competitors in the product market. This entry, in contrast, will concentrate mainly on cases where the licenser and the licensees compete in the product market.

Since licensing improves the licensees' technology, it affects the intensity of product market competition and the profits of the licenser and the licensees, thus changing the firms' product market strategies (such as output or pricing decisions), which may have important welfare implications.

Optimal Licensing Contract and Quality of the Technology Considering licensing between two final goods producers, Rockett (1990) derives optimal two-part tariff licensing contracts, which consist of an up-front fixed fee and a per-unit output royalty. Royalty-only licensing is the optimal contract if there is no threat of imitation from the licensee and the licensee's output is verifiable. If imitation is costless to the licensee, however, the optimal licensing contract involves only an up-front fixed fee. Combining a fixed fee and a royalty is optimal if the threat of imitation is credible and the cost of imitation is positive.

With regard to the quality of the licensed technology, where a lower marginal cost of production represents relatively better technology, the optimal decision of the licenser is not to license its best possible technology if the threat of imitation is credible and the cost of imitation is moderate.

Since output royalty softens competition in the product market, a licenser who competes in the product market with the licensee may find it optimal to charge a positive royalty rate even if the royalty rate distorts the licensee's output. If the products of the licenser and the licensee are horizontally differentiated (e.g., by different brand names or after-sales services of the firms), however, the incentive for fixed-fee licensing increases since product differentiation itself softens competition between the firms. Whether product differentiation increases the threat of imitation and the incentive for licensing a rela-

tively better technology is ambiguous. Product differentiation increases the incentive for imitation for a given royalty rate by increasing the gain from imitation, but product differentiation also reduces the royalty rate, thus reducing the incentive for imitation.

If the products are homogeneous, the optimal licensing contract may involve only an up-front fixed fee if the high cost of either technology licensing or technology adoption makes it possible to license the technology to only some competitors. Stealing market share from the nonlicensees makes fixed-fee licensing optimal.

The royalty rate does not have a competition-softening effect if the licenser and the licensee do not compete in the product market. As shown in Gallini and Wright (1990), however, there still may be a rationale for charging a positive royalty rate if the quality of the technology is proprietary information of the licenser, as the royalty rate helps to signal the quality of the technology. If there is licensing between competitors from different countries, the presence of trade costs provides a rationale for a combination of a fixed fee and a royalty.

In Rockett (1990), licensing intensifies competition in the product market and may induce the licenser not to license its best technology. Kabiraj and Marjit (1993) argue that even if the licenser and the licensee do not compete in the product market in the absence of licensing, a licenser may have an incentive not to license its best technology if the licenser and the licensee are from different countries. Government policy may prevent competition in the licensee's market; the licenser's having better technology than the licensee may prevent competition in the licenser's own market. If licensing the best technology would create competition in the licenser's market, the licenser may find it optimal not to license its best technology.

Licensing and Other Product Market Strategies While technology licensing allows a firm to increase its profit, other business strategies such as mergers, joint ventures, and capacity commitments also help firms to increase their profits.

Consider the impacts of product market competition on a bilateral licensing contract and a bilateral

merger. If there are multiple technologically superior and technologically inferior firms, a licensing contract always dominates a merger in a Cournot oligopoly. If there are multiple technologically inferior firms and only one technologically superior firm, however, merger dominates licensing for a sufficiently large technological difference. Under merger, the merged firms lower their total outputs compared with no merger, which, in a Cournot oligopoly, induces the nonmerged firms to increase their outputs. Hence merger creates a positive externality on the nonmerged firms and reduces the benefit of merger. On the other hand, licensing increases output of the licensee by reducing its marginal cost of production. Hence in a Cournot oligopoly, licensing reduces output of the licenser and also steals market shares from the nonlicensed firms. Therefore, along with the benefit of cost efficiency of the licensee, stealing of market shares from the nonlicensed firms provides the incentive for licensing. The trade-off between the positive externality of merger on the nonmerged firms and stealing of market shares from the nonlicensed firms is responsible for these results. Roy et al. (1999) extend this line of research in open economies and show the relative profitability of licensing, joint venture, and cross-border merger.

In the case of international technology transfer, proprietary information about the quality of the foreign technology and imitation by the licensee are two common problems. Though strategic choice of the fixed fee and output royalty may help to resolve these problems, a joint venture between the licenser and the licensee may induce relatively better technology to be transferred compared with licensing.

If imitation under international technology transfer creates the threat of competition in the licenser's other product markets, a technologically superior firm may choose foreign direct investment (FDI) over licensing. Though FDI requires significant investment in the host country, it may help to protect the licenser's other markets by reducing imitation by host-country firms. Hence the patent policy of the host country may influence a foreign firm's incentive for licensing versus FDI, with FDI more likely to be observed under weak patent protection.

Instead of a cooperative strategy such as merger, a noncooperative strategy such as investment in capacity or incentive delegation to managers may also help to raise the profits of the firms. Using licensing with an up-front fixed fee, Mukherjee (2001) shows that capacity commitment and incentive delegation have significantly different effects on licensing. Whether both the licenser and the licensee or one of them has the opportunity to adopt these precommitment strategies also plays an important role.

Licensing and Innovation Differences in technologies, which create reasons for licensing, stem from innovation. The interaction between innovation and licensing is an important topic.

In a duopoly market structure, where the firms innovate and compete in the product market, Gallini and Winter (1985) consider licensing ex ante and ex post innovation. The trade-off between the replacement of inefficient production technology and the elimination of inefficient research expenditure shows that licensing encourages innovation if the firms' initial technologies are close in costs, but it reduces innovation if the costs are asymmetric.

Katz and Shapiro (1985) consider separately an innovator and producers who can be engaged in licensing and show that licensing between the producers reduces innovation if the licensee appropriates most of the gains from licensing. If the licensee appropriates a significant amount of gains from licensing, the incentive for getting property rights to the innovation is reduced, thus reducing the innovator's earnings and the incentive to innovate.

These two papers have important implications for innovation policies, but they are unable to show the effects of licensing on R&D organization. It is often found, however, that firms do cooperative R&D to reduce the cost of innovation, avoid duplication of research efforts, or both. Whether licensing increases the incentive for cooperative R&D depends on the motive for cooperative R&D and the nature of the product market competition.

Even if licensing does not affect innovation, it may affect the decision on technology adoption,

which occurs after innovation. Given that a technology has a finite life span, Mukherjee and Pennings (2004) show that licensing (compared with no licensing) induces technology adoption earlier by eliminating imitation.

Glass and Saggi (2002) show the effects of licensing and FDI on innovation and growth in an open economy. There is a cost disadvantage under FDI, whereas licensing may require the firms to share the gains from licensing. If the mode of operation (i.e., licensing or FDI) of the foreign firm is fixed, a rise in the licensee's share of rents is detrimental for innovation and economic growth. A mode switch from licensing to FDI increases innovation and economic growth on average, however.

Welfare-Reducing Licensing The reason for encouraging technology licensing is its positive effect on welfare, since it replaces relatively inefficient technologies, thus eliminating production inefficiencies. Recent research shows, however, that one must be cautious in encouraging licensing. Since licensing makes the licenser and the licensee more symmetric, it helps to sustain collusion between the firms. This argument was first put forward by Eswaran (1994), who showed that cross-licensing of products between firms can be a collusive device.

Licensing of a superior process technology also helps to sustain tacit collusion between the licenser and the licensee by making them symmetric in terms of costs.

Faulí-Oller and Sandonis (2002) show that licensing may be welfare-reducing even in the absence of collusion. They show that if the firms compete on prices, licensing may reduce welfare by contracting output and thus raising product prices. If the firms compete on quantity and the licenser can commit its output before the licensee, the provision of output royalty in the licensing contract helps to reduce industry output and to raise the product price, and thus may reduce social welfare.

Another strand of literature shows that licensing may reduce welfare by affecting either an innovator's incentive to innovate or the firms' incentives for doing cooperative R&D.

In the presence of multiple licensees, if the technologically superior firm can choose a licensing contract contingent on the number of firms taking licenses, the licenser can earn the profit of a monopolist with the licenser's technology. Hence if the licenser can use a more complete contract in the sense that it does not need to follow a per-unit output royalty and can charge nonlinear royalties, it may reduce welfare by increasing market concentration.

Licensing to Create Competition A surprisingly common feature of most research on licensing is the assumption that input markets are perfectly competitive. Hence it is assumed that technology licensing, while affecting the licensees' marginal cost by making superior technology available to them, does not affect the licenser's marginal cost. It is often the case, however, that input markets are imperfectly competitive.

One such possibility arises when there are labor unions bargaining over wage rates. In this case, a monopolist final goods producer may license its technology to a potential competitor to create competition in the product market. While licensing increases competition in the product market, it may help to reduce the wage rate charged by the labor unions. Since a suitably designed royalty rate softens competition between the firms, the benefit of lowering the wage rate induces the monopolist final goods producer to create competition through licensing.

Even if there are no labor unions but a monopolist final goods producer is selling to a foreign country and is exposed to the host-country tariff policy, the monopolist may be better off creating competition through licensing. Whether the monopolist licenses the technology to another foreign firm (which also faces the tariff rate of the host country) or to a host-country firm may be a decision variable of the foreign monopolist.

Farrell and Gallini (1988) and Shepard (1987) show the rationale for licensing by a monopolist input supplier, which is a well-known phenomenon in the Ethernet market and the semiconductor industry. Licensing by the monopolist input supplier to a potential competitor creates competition in the

input market and helps to reduce the input price, which in turn, increases profitability of the final goods producers. Hence higher competition in the input market due to licensing encourages entry in the final goods market, thus increasing the demand for inputs, and makes the monopolist input supplier better off compared with no licensing. Even if licensing in the input market does not affect the entry decision in the final goods market, it may increase the demand for inputs by raising the (expected) input quality, thus making the monopolist input supplier better off under licensing than no licensing. Higher competition in the input market due to licensing helps to commit to a lower input price or to a higher input quality, thus increasing the profit of the monopolist input supplier.

Future Research Significant effort has been devoted to several issues related to technology licensing; at least two areas deserve more attention, however. First, the literature has mainly focused on licensing of cost-reducing innovations, but firms often innovate to improve the quality of the product and/or to invent new products. Second, the licensing literature ignores licensing by several technologically superior firms. The presence of multiple licensers will affect market outcomes such as the terms of the licensing contracts, the quality of the licensed technology, and social welfare. Work by Saggi and Vettas (2002) that considers the equilibrium contracts when two upstream firms contract with multiple downstream firms may be reinterpreted as technology licensing by multiple technology producers to multiple final goods producers. However, this area requires further research.

ARIJIT MUKHERJEE

■ technology spillovers

Technology spillovers are the beneficial effects of new technological knowledge on the productivity and innovative ability of other firms and countries. Technology is "nonrival": one's use of a technology does not limit its use by others, and the cost for an additional agent to use an existing technology is negligible compared with the cost of inventing it. Hence not all the benefits of technological knowledge are appropriated by the inventor; technological investments typically generate social returns that far outweigh private returns. Technology, once invented, can be used and diffused internationally with small added cost but substantial added benefit.

Technological research and innovation is mostly undertaken by firms and governments in the leading world economies that are also the world technological leaders. Then technology diffuses to the rest of the world through the main channels of trade, migration, foreign direct investment (FDI), and technological licensing (patents and copyrights).

International technology spillovers have received much attention in recent economic research from both theoretical and empirical perspectives. Theory identifies them as a key mechanism for the sustained growth of productivity and its diffusion across countries. From an empirical point of view, economists have studied how to measure technology spillovers and what channels are conducive to them. From a policy point of view, countries desiring greater technology spillovers use policies to promote trade and FDI and to promote better conditions for taking advantage of spillovers by absorbing them into domestic productivity gains.

Theory of Technology Spillovers Recent theories of economic growth and income differences across countries (see Eaton and Kortum 2002; and Klenow and Rodriguez-Clare 2005 for reviews) identify available technological and scientific knowledge as the most important determinants of productivity in a country. Scientific and technological innovation are the main engines of productivity growth in the rich countries (Europe, Japan, and North America). Their diffusion to industrializing countries, accompanied by investments in physical and human capital, is the main reason for the growth in productivity and income per capita of those economies. Yet some countries seem stuck far behind the technology frontier. The process of technological diffusion has a central position in the recent literature on development and growth. A better understanding of the nature of technology spillovers should help shed light on why some countries grow faster than others.

Due to its nonrival nature, technological knowledge can be used by producers other than the inventor to increase their productivity. Hence it generates two types of benefits called "spillovers."

1. First, new technological knowledge can be used in any country to produce more

efficiently or higher quality goods. This spillover increases the labor productivity of the country that adopts it.

2. Second, technological knowledge can be used in any country to produce new ideas or new applications in research and development (R&D). This increases R&D effectiveness in receiving countries.

Inventors usually appropriate at least part of the benefits from the first type of spillovers, either by producing goods with the new technology and exporting them to foreign markets (trade) or by setting up production that uses the new technology in other countries (FDI) or by licensing out the new technology and receiving royalty payments for it. International trade, FDI, and international patents and copyrights are therefore common channels for diffusing the benefits of technological innovations to consumers in other countries. At the same time those flows carry the knowledge related to the new technology embodied in goods, in machines, or in instructions. This new knowledge enables receiving countries to benefit from the second type of technological spillovers: other firms and producers may learn and improve their productivity as a consequence of exposure to better technology. The first type of technology spillovers are usually mediated by market mechanisms (trade, investments, and intellectual property rights) and are sometimes called technology diffusion. The second type of technology spillovers involve diffusion of knowledge to other firms of the receiving country via mobility of workers, learning, imitation, and subcontracting and are considered technology externalities.

In the light of these beneficial effects on productivity and growth, international technological spillovers (even more than international trade of goods and international movements of capital per se) have been identified as potentially the most beneficial aspect of globalization. The empirical research has consequently focused on measuring the intensity, quantifying the effects, and identifying the most relevant channels of these spillovers. At the same time researchers and policymakers have analyzed what are the characteristics that make a receiving country best

positioned to receive the benefits from those spillovers.

Empirical Analysis of International Technology Spillovers Technology spillovers are not recorded in the data. The channels of their transmission (trade, FDI, patents) and their consequences (productivity benefits) can be recorded and measured, however. The recent empirical analysis has used a plurality of data and approaches to qualify and quantify the intensity and productive impact of those spillovers across countries.

Measuring Technology Spillovers Technological and scientific knowledge is an intangible asset not measurable directly. Economists have used measures of R&D resources (input) or measures of innovations such as patents or productivity (output) to approximate it. Aggregate studies have used country-level data, while microlevel studies have used firm-level data. Two general methods are used to identify spillovers. The first method considers the effects of R&D done in some countries (or firms) on the productivity of other countries (or firms) that are linked to the former via trade, FDI, or technological/geographical proximity. The basic features of this approach were first developed in a very influential paper by Coe and Helpman (1995) and will be described in the next section. The second approach considers directly the association between the presence/intensity of trade and FDI (channels of technology spillovers) and the productivity of the importing/receiving country or firms there. Both methods infer the existence of spillovers indirectly from the effects on productivity in firms of the receiving economy.

A third approach aimed at identifying more directly the linkages that reveal technology spillovers analyzes citations from a patent to previous patents, considering them as tangible signs of a knowledge spillover (Jaffe and Trajtenberg 2002). An existing idea recorded in a patent contributes to the development of a new idea (new patent), and the citation link reveals this spillover. This method isolates only spillovers of the second type described above (from R&D to R&D) and tends to emphasize the geographic localization of those technology

spillovers. This method complements (but cannot substitute for) the other type of studies, as it only identifies the intensity and characteristics of technological spillovers but cannot quantify their impact on productivity.

Trade and Technology Spillovers A popular approach for analyzing the presence and the intensity of technology spillovers has been to analyze the association (correlation) between productivity in country j (or industry or firm) and the R&D activity in countries (industries or firms) other than j that are linked to j by potential channels of spillovers. The basic empirical procedure, presented in Coe and Helpman (1995), and expanded and updated since then, is to estimate some version of the following regression: Productivity$_j$ = Function($\mathbf{X}_j$, R&D$_j$, R&D$_{spillovers}$). The variable Productivity$_j$ represents some measure of the productivity (usually total factor productivity or labor productivity) of country (industry, firm) j. The vector $\mathbf{X}_j$ is an array of country (industry, firm) characteristics relevant for its productivity. R&D$_j$ is a measure of research and development activity performed in the country (industry, firm) j, and R&D$_{spillovers}$ = $\sum_{i \neq j} m_i(\text{R\&D})_i$ is a weighted sum of R&D activity in other countries. This term captures technology spillovers because the weights m_i are constructed to reflect the intensity of potential spillover channels between country (industry, firm) j, the receiver, and country (sector, firm) i, the sender. In the original work of Coe and Helpman (1995) m_i was measured as the share of imports from country j among trade partner of country i assuming that imports are the most relevant channel of technology spillovers. Subsequent research has experimented with different weights to capture other potential spillover channels. Some alternative measures of m_i have been the share of FDI from country j in total capital formation of country i, the share of imports of capital goods (rather than all goods), and the share of direct and indirect trade (i.e., trade through third-country mediation). More recently Keller (2002) has constructed the weights m_i based on geographical proximity between country j and i. This approach is based on the assumption that a whole array of potential spillover channels

(trade, FDI, migration, technological licensing, business travel, and others) are strongly enhanced by geographical proximity. A popular variation of the approach described above, mostly used on individual firm data, is to measure the effect of technological spillovers on production costs rather than productivity.

The limit of this type of approach is that the identification of externalities is based on correlations, and it is not easy to establish a real causation link. To address the limits of the reduced form approach, recent research by Eaton and Kortum (2002) has studied the relationship between R&D technology diffusion and domestic productivity in the context of general equilibrium models. In those models one can analyze and simulate the impact of increased research and trade liberalization on technology spillovers and productivity.

Overall the findings of this literature point to two rather robustly estimated regularities. First, the effect of R&D spillovers on productivity is consistently larger than zero and significantly positive for the average analyzed country (usually the data cover economies that are members of the Organisation for Economic Co-operation and Development, OECD). Second, while for the leading economies (G7 countries), the impact of domestic R&D on productivity is consistently larger than the spillover effects from other countries, for smaller and less advanced economies (other OECD countries) the impact of spillovers is larger than the impact of domestic R&D on productivity. These findings confirm that technological leaders tend to perform most of the R&D and innovation in the world and that spillovers from those technologies are a major source of productivity growth in other countries.

FDI and Technology Spillovers A second approach to identifying and quantifying international technology spillovers is based on the idea that FDI is an explicit activity set up to transfer technology across national borders (e.g., Markusen 2002). Hence FDI is a direct carrier of technology flows. The question is how much these flows benefit the productivity of the receiving economy and what are the features or policies of the receiving economy that enhance the

positive effects of technology spillovers. Several theoretical models argue that multinational enterprises should generate technology spillovers to local firms through several channels, and many of them have been studied in detail using firm-level data. Imitation, learning, and acquisition of human capital through worker turnover are considered as the most important channels of spillovers. Competition, subcontracting, and supply of high-quality intermediate inputs are market-mediated mechanisms that make better inputs available to the local firms, stimulate more efficient technologies, and may also have positive productivity effects.

The typical empirical approach for identifying technological spillovers through FDI estimates the following model: Productivity$_{jk}$ = Function($\mathbf{X}_j$, FDI$_k$). The term (Productivity$_{jk}$) measures the productivity of firm j in sector k and the right-hand side of the expression implies that it is a function of a vector of firm characteristics $\mathbf{X}_j$ and of some measure (usually the share of employment or of sales) of the presence of multinational enterprises in sector k, (FDI$_k$). Usually these studies analyze firm-level data for one country at a time (hence no country subscript) and often they consider geographical proximity as a requisite for (or enhancer of) the technology spillovers: multinationals have larger productivity effects if they are located in the same region or area as the potential spillover-receiving firm j. Another relevant dimension of the spillovers is whether they benefit domestic firms "horizontally" (namely, those in the same industry) or "vertically" (those that supply inputs to or buy inputs from the multinational enterprise).

Using cross-section and panel data from several different industrialized and industrializing countries, many researchers have estimated technology spillovers through FDI using the method described above. Interestingly, the evidence in favor of positive effects of technology spillovers on productivity of domestic firms is scant, especially when considering developing countries. Blomström and Kokko (1998) and more recently Görg and Greenway (2004) review dozens of such studies and conclude robust evidence of positive effects of FDI spillovers is found

mainly for industrialized countries. For developing countries results are much less clear. A typical example of those studies is the influential article by Aitken and Harrison (1999), which, in analyzing evidence from FDI in Venezuela, does not find any positive effect on productivity of local firms. In fact, the study finds some negative effects on domestic firms and attributes them to increased competition from FDI and crowding out of domestic firms.

Absorptive Capacity These findings have prompted research on the role of the receiving firm or country in determining the impact of technology spillovers. While the potential for technology spillovers is intrinsic to FDI activity, the actual impact on productivity of domestic firms depends on the absorptive capacity of those firms. Human capital and investment in R&D by the receiving country (firm) are important prerequisites to generating positive effects of technology spillovers on productivity. Insufficient human capital in local firms could be the explanation for the lack of spillovers from FDI in developing countries. Using firm-level data, several articles (e.g., Glass and Saggi 1998) confirm that firms using low-skilled workers and backward technology are unable to benefit from FDI technology spillovers.

Policy Considerations FDI is seen by governments of several industrializing countries as highly beneficial to the domestic economy. Technology spillovers are only one of its effects, as FDI also increases employment opportunities, consumption, and government income. Nonetheless technological spillovers generate probably the most important and lasting effects in the long run as they channel technological transfer and induce productivity growth. In the light of the empirical findings, policies promoting higher education and skill-formation of workers and R&D investment of domestic firms are needed complements to policies that attract FDI, if a country is to maximize the absorption of technological spillovers. At the same time some policies such as R&D requirements, technology transfer requirements, and local hiring targets for multinational enterprises can increase the intensity of technological activity and the benefits for the local economy.

Probably, however, a general framework of openness to international flows and free competition in trade, FDI, and technological licensing is the most important component for a country to attract technology spillovers and benefit from improved technologies as they become available to the global economy.

GIOVANNI PERI

■ **temporary movement of natural persons**

The phrase *temporary movement of natural persons* (TMNP) refers to one of several ways by which, according to the General Agreement on Trade in Services (GATS), international trade in services takes place when workers from one country travel abroad temporarily to supply particular services there.

The exact World Trade Organization (WTO) definition of TMNP can be found in Article I 2 (d) of the GATS, which refers to "the supply of a service, . . . by a service supplier of one Member, through the presence of natural persons of a Member in the territory of any other Member." This

definition is further qualified in the GATS Annex on the Movement of Natural Persons Supplying Services under the Agreement, which states that GATS rules, negotiations, and commitments do not apply to persons seeking permanent citizenship, residence, or employment. TMNP in the strict WTO sense applies only to temporary migration of workers in service occupations and not to foreign workers employed temporarily in the manufacturing, mining, or agricultural sectors of another country. National immigration policy in most countries, however, covers temporary workers in different sectors of the economy. For example, U.S. visa rules on temporary foreign workers include an H2 visa category for temporary farm workers.

TMNP thus implies at least two things: first, the overseas travel by the worker has to be *temporary* in nature; second, it must have been undertaken in order to perform a *specific job or supply of a service*. Examples include senior managers posted abroad to manage operations of a multinational firm operating in the services sector of a foreign country; IT technicians traveling overseas to provide backup technical support for computer hardware or software; academic faculty traveling to foreign universities on short-term teaching assignments; nurses or teachers employed in foreign hospitals or educational institutions for a fixed tenure; seafarers working on contract in a foreign shipping line; household workers hired for a specific period as au pairs by families abroad; an accomplished doctor traveling to a foreign country to perform complicated surgery; cultural troupes performing overseas; and unskilled and semiskilled workers from one country employed on contract on construction sites in other countries.

Examples of TMNP that do not strictly fall within the GATS definition, but are perhaps as numerous and of equal economic significance include farm labor employed annually on agricultural lands and plantations overseas during peak seasons; foreign workers in major mining projects; and workers employed in labor-intensive manufacturing activities during, for example, an export boom in a foreign country. Several bilateral and some regional agreements cover such TMNP that takes place outside the services sector.

Temporary overseas travel that is *not* considered TMNP includes travel undertaken for tourism or for obtaining medical assistance or education. Such journeys, though recognized as contributing to international trade in services, are classified under a different category, namely "consumption abroad," in the GATS. The movement of refugees seeking temporary asylum in other countries is also excluded, as travel is not undertaken for a specified period or to perform a specific task.

Origins Temporary migration has been under discussion for a long time in various forums such as the International Organization for Migration and the International Labor Organization but only as a subset of migration in general. The WTO was the first international organization to focus exclusively on the temporary migration of workers. Furthermore, while other organizations use the conventional word *workers*, the WTO introduced the phrase *natural persons* instead, in order to distinguish people from juridical persons such as companies or organizations. This merely reflects a preference for legalistic terminology by the drafters of the GATS text, however; in practice, the terms are interchangeable.

The origins of the concept can be traced to the Uruguay Round trade negotiations (1986 94) of the General Agreement on Tariffs and Trade. During discussions to develop a framework for an agreement on international trade in services, it was recognized that one way in which services are delivered overseas is through the travel of workers. Although overseas travel to supply particular services was not a new phenomenon traders, religious missionaries, and diplomats had been doing so for centuries there had been a sharp rise in such travel during the preceding decades. Lower transportation costs, widening income differentials between countries, and global distribution of production chains facilitated by technological improvements in communications were some factors responsible for this trend. Aging workforces and income growth have also led to worker shortages in some countries, creating a de-

mand for foreign workers. The emergence of significant numbers of temporary migrant workers worldwide by the 1980s appears to have contributed to the inclusion of TMNP as a negotiable trading activity during the Uruguay Round.

Leading TMNP Countries Reliable data on TMNP flows are not readily available. This is mainly because many countries do not keep records of persons going abroad for work. In host countries the statistics are complicated by the fact that many workers admitted temporarily get themselves converted into permanent workers.

Traditionally Mexico and the Philippines have been regarded as the world's leading source countries for TMNP. Because of the previously mentioned data limitations, some experts prefer to use workers' remittance figures as an indirect measure of TMNP, given that temporary workers tend to remit a significant part of their earnings to their home countries relative to permanent migrants. Measured in terms of the magnitude of remittances received in 2005, the top 10 countries sending temporary workers abroad were India, China, Mexico, the Philippines, France, Spain, Belgium, United Kingdom, Germany, and Egypt, in that order.

A similar indirect measure can be used for estimating the leading host countries for temporary migrant workers. This makes use of the data on wages and salaries earned by nonresident workers who have lived in the host country for less than a year. According to these data, in 2005 the United States was by far the leading host country for temporary foreign workers, followed by Saudi Arabia, Switzerland, Germany, Spain, the Russian Federation, Italy, Malaysia, the Netherlands, and France, in that order.

Significance for the World Economy The economic significance of TMNP for the world economy stems from the fact that the majority of temporary workers move from areas of low productivity to areas of higher productivity, thus bringing about global efficiency gains. Projections such as those made by Winters et al. (2003) also predict large economic gains for the world economy if TMNP is liberalized. Such studies also usually predict that the gains will be shared equally between sending and receiving countries. Despite this, both developed and developing countries have adopted a conservative policy approach with regard to the entry of foreign workers compared with other areas of international trade. WTO commitments on TMNP attached to the Third Protocol to the GATS are mostly confined to highly skilled labor and typically qualified by restrictions and exemptions. Part of the reason is the recognition that the labor market consequences of trade liberalization unravel differently for different sectors. For instance, the impact on the labor market of lower tariffs on industrial products occurs indirectly, and domestic workers lose jobs after a time lag. Liberalizing the entry of foreign workers, on the other hand, creates immediate and direct competition for domestic workers and is therefore much more challenging politically.

Experts have compiled lists of benefits and drawbacks of permanent migration for both source and host countries. The economic consequences of TMNP generally are the same as those of permanent migration, with a few important exceptions:

- There is no permanent brain drain caused by TMNP, although there is temporary loss of the migrant's contribution to home country output. It is argued that a returning migrant can bring back new ideas, technologies, and networks that would contribute to improved efficiency and productivity and partially compensate for the loss to national welfare caused by temporary absence.
- With TMNP, the option to post and rotate senior corporate personnel of choice abroad improves efficiency and control in the international operations of source country firms. This is especially helpful if qualified local personnel are not available in sufficient numbers in the host country.
- Unlike permanent migrants, temporary workers are less likely to put pressure on host-country public goods or infrastructure or undermine a foreign country's culture, customs, and values on account of the transitory nature of stay abroad.

- Remittances are likely to be higher from temporary migrants, so host countries are likely to experience a higher outflow of earnings under TMNP compared with permanent migration.

■ terms of trade

The current world economic situation is the legacy of the days of industrial revolution in the North and colonization of the major countries of the South. This divided the world economy into two regions: the industrially developed North and less-developed South. In the context of the North-South divide of the world economy, the long-term behavior of the terms of trade between the two regions has been a much discussed and much debated topic.

By terms of trade we usually mean commodity terms of trade, the term popularized by Jacob Viner. The commodity terms of trade of the South in rela-tion to the North can be defined as the price (unit value index) of exports of the South to the North divided by the price (unit value index) of exports of the North to the South.

The commodity terms of trade is also known as net barter terms of trade, thanks to Frank William Taussig. He introduced another concept, the gross barter terms of trade. It is the ratio of the volume index of imports to the volume index of exports. It is not widely known or used in the literature.

G. S. Dorrence introduced the concept of the income terms of trade. It is an index of the value (= volume x unit value) of exports divided by the unit value of imports and it corresponds to the com-modity terms of trade (= unit value of exports/unit value of imports) multiplied by the volume of ex-ports. It measures the purchasing power of exports the amount of imports that can be financed by total exports of a country or region.

If, instead of volume of exports, the commodity terms-of-trade index is multiplied by some index of factor productivity in the export sector, we get the single factorial terms of trade. To construct the double factorial terms of trade, the single factorial terms of trade is deflated by the index of factor pro-ductivity in the export sector of its trading partner. So, the double factorial terms of trade is the com-modity terms of trade multiplied by the ratio of the indices of factor productivity in the export sec-tors of the trading partners. Usually labor produc-tivity is considered for factorial terms-of-trade index calculation.

The single factorial terms-of-trade index has a simple intuitive implication: it indicates the amount of wheat (say) that can be imported by a country (say, Ghana) by employing one hour of labor in production of its export item, say, cocoa. An improvement in the index implies a rise in the country's labor productivity in the export sector valued in terms of its import goods. Among other possibilities, it may be due to a rise in the labor productivity in its export sector not fully counterbalanced by a (resulting) fall in its export prices relative to its import prices (that is to say, a fall in its commodity terms of trade)   trade has not wiped out the whole fruit of technical progress in its export sector. In the process, its trading partner can experience a rise in its single factorial terms of trade through an improvement in its commodity terms of trade.

There are many other cases where the single factorial terms of trade of two trading countries can rise or fall together, but a rise (fall) in the double factorial terms of trade of one country must imply a fall (rise) in the double factorial terms of trade of its trading partner. That is why the economists interested in relative gains from trade or unequal exchange focused on this concept of terms of trade.

Suppose the North and the South experience the same rate of technical progress and labor productivity improvement in their respective export sectors. One region (say South) experiences lower export prices in response to technical progress and cost reduction   wages do not rise in proportion to the rise in productivity because of (say) surplus labor and the consequent weak labor union. Suppose the other region (North) experiences rising wages and profit because of strong labor union and monopoly power of the producers and no fall in their export prices. Then double factorial terms of trade would move in favor of the North and against the South. This is what was highlighted by Prebisch (1950) and Singer (1950) in the context of trade between the industrially developed North and the less-developed South and gave birth to the well-known Prebisch-Singer hypothesis. They provided some evidence of a long-term decline in the commodity terms of trade of primary products and the primary-product exporting South since the last quarter of the 19th century and indicated a long-term decline in the double factorial terms of trade of the South vis-à-vis the North on the basis of the well-accepted fact that the industrial sector of the North experienced a higher rate of technical progress in those days.

This Prebisch-Singer hypothesis generated much controversy in the academic world both on empirical and theoretical grounds, and it was virtually discarded in mainstream economics. But there is now an increasing volume of literature in its support (see Sarkar 1986, 2001).

In the "mainstream" neoclassical, perfect competitive framework, each factor (including labor) is paid according to its productivity. So the single factorial terms of trade is the real wages measured in terms of import goods and the double factorial terms of trade is the wage ratio (measured in a common currency). In a simple classical political economy framework of the (North-South) world economy with free mobility of capital and labor, the North-South commodity terms of trade would be equal to the ratio of labor embodied in the production of export goods in the two regions (in accordance with the classical labor theory of value) and the double factorial terms of trade would be equal to one. This is the ideal situation   "equal exchange"   the Marxist economist Emmanuel (1969) had in mind. But in a world of nearly perfect mobility of capital and imperfect labor mobility, the commodity terms of trade is not in accordance with the labor theory of value. The double factorial terms of trade are equal to the wage ratio as in the neoclassical framework. Granted that Northern workers get higher wages (even after adjusting for their higher skill and productivity), the double factorial terms of trade of the South are less than one. That implies that one hour of Southern labor is exchanged for less than one unit of (comparable) Northern labor. This is a case of (static) "unequal exchange" at a point of time. If over time this North-South wage gap rises, the double factorial terms of trade would decline indicating increasing "unequal exchange." Thus there is a convergence between the Prebisch-Singer hypothesis and Emmanuel's dynamic "unequal exchange" idea.

Last there is another concept, employment-corrected double factorial terms of trade, introduced by Spraos (1983). It is based on the idea that if a country or region such as South has a large pool of unemployed labor force, a decline in its double factorial terms of trade is welcome if that is more than compensated by a rise in employment through the growth of trade and production. This index is calculated by multiplying the double factorial terms of trade of a country or region by the total employment in its traded sector (if both the countries or regions face this unemployment problem the multiplicative factor would be the employment ratio and the index would be turned into a ratio of export values!). On the assumption of near full employment in the North and a large-scale unemployment problem in the South, he calculated such indexes and found some evidence of decline in the terms of trade of the South from 1960 to 1977.

The concepts of terms of trade and a study of their behavior are useful in understanding whether the evolution of the world economy led to some kind of uneven development through the terms-of-trade movements against the interest of the less developed South, thereby hampering the process of catching up.

■ **textiles and clothing**

The textiles and clothing supply chain consists of production of raw materials; spinning, weaving, or knitting; finishing; design; sewing; distribution; and marketing. The production of textiles was the first economic activity to be industrialized, starting in the United Kingdom around 1765 with the invention of the spinning jenny, a machine for spinning wool or cotton.

The clothing industry is unskilled and labor intensive. The technology is cheap and simple and did not change much over the 20th century. The fabric is first cut and then grouped, tied into bundles (pre-assembly), and sewn together. A worker receives a bundle of unfinished garments, performs her single task, and places the bundle in a buffer. It takes about 40 operations to complete a pair of pants, and about 100 operations for men's blazers. Improvements in technology have taken place in two areas: specialized machines for each task and better coordination of the tasks.

The textile and clothing sector also includes market segments where innovation, technology, and design are important for competitiveness. Examples are sophisticated textile materials for industrial and

medical use, athletic sportswear and equipment, and up-market fashion clothing. In the United States about two-thirds of textiles production is for industrial use and household goods. Italy and, to a lesser extent, France are important producers and exporters of up-market fashion products, and the two combined accounted for about 10 percent of world clothing exports in 2005. In Italy, textiles and clothing as a share of total manufacturing value added declined from 12 percent of total manufacturing value added in 1980 to 10 percent in 2003.

Economies of scale in distribution favor large supplier countries that cover the entire supply chain, such as China, India, Mexico, and Turkey. Smaller producers tend to find niches where they establish a significant market position. Sri Lanka, for instance, is among the world's leading exporters of lingerie.

Although production technology has not fundamentally changed, distribution technology and the division of labor between manufacturers and retailers have changed substantially since the late 1970s. The shift of key functions from manufacturers to retailers started with the establishment of large discount retailers such as Wal-Mart in the United States. Using modern information technology to improve supply chain management and transforming the relationship between retailers and manufacturers, Wal-Mart pioneered a practice that has been coined "lean retailing."

Lean retailers insisted that suppliers take up information technologies in order to facilitate more efficient supply chain management. They typically require manufacturers to adopt their standards and make apparel shelf-ready, which includes price tags and other required labeling. This ensures quick replenishment of apparel, which in turn allows the retailer to offer a broad variety of clothing without holding much inventory. The attractiveness of such contracts for suppliers is first and foremost the scale of operation of the lean retailers, which provides a stable marketing outlet and often also low-cost fabric and other material inputs purchased in bulk by the retailer.

With the introduction of private labels or store brands, design has shifted from the manufacturer to

retailers. Specialized clothing retailers such as H&M and The Gap led this development. Most retailers of cheap, mass-market apparel source private label/store brand items from manufacturers in low-cost countries. However, a much studied Spanish retailer (Zara, which is part of the Inditex Group) has combined lean retailing with vertical integration of design, manufacturing, and distribution. Zara is among the world's largest retailers with retail outlets in 68 countries in 2007. Its innovation is production in small batches, introducing new designs as frequently as twice a week. New designs are based on information from the retail outlets. According to the company's Web page, Zara largely manufactures in Spain, arguing that the benefits of being close to the market outweigh the higher cost of production in Spain compared with low-cost countries. The numerous studies of this retailer suggest that its business model may multiply.

As a labor-intensive industry, textiles and clothing have always been an important source of employment for unskilled workers, particularly women. Furthermore the sector typically clusters geographically, for instance in the Carolinas and Georgia in the United States and in the Emilia-Romagna district in Italy. Because the industry tends to cluster in regions where it constitutes an important source of employment, job losses, for example, due to trade liberalization, can have serious local labor market consequences. Trade in textiles and clothing has therefore always been politically sensitive, and the sector was governed by an international trade regime of import quotas from the early 1960s until 2005.

International Trade Regime The textiles and clothing sector has a long history of import protection. As new countries emerged as important exporters of textiles and clothing, demand for protection arose in the United States and other developed countries. Thus in the 1950s the United States entered into agreements on voluntary export constraints on cotton textiles and clothing with Japan, Hong Kong, India, and Pakistan. In 1962, a Long-Term Agreement Regarding International Trade in Cotton Textiles (LTA) was negotiated under the auspices of the General Agreement on Tariffs and

Trade (GATT). The LTA was extended to materials other than cotton in 1974 and became known as the Multifiber Agreement (MFA).

The MFA governed a trade regime in which the major importing countries negotiated import quotas bilaterally with exporting countries. It became part of the multilateral trading system in spite of breaking fundamental principles of the GATT, including the most-favored-nation (MFN) principle and the idea that trade restrictions should be in the form of tariffs, as tariffs are less trade distorting than quotas. The MFA was renegotiated four times, the last time in 1991, and it finally expired in 1994. At that point the European Union (EU), the United States, Canada, Norway, Austria, and Finland (Austria and Finland joined EU in 1995) applied quotas, almost exclusively on imports from developing countries.

While the most competitive textiles and clothing exporters such as China, India, Pakistan, Hong Kong, Taiwan, and South Korea faced binding quotas, several poorer developing countries had unfilled quotas and therefore attracted foreign investment from the quota-restricted countries. In addition, former colonies and other low-income countries obtained preferential access to the EU and the United States, including tariff and quota-free access in textiles and clothing. This further encouraged the establishment of export-oriented clothing production, often in export processing zones. Preferential access was typically conditioned on a minimum local content (intermediate input) requirement or complicated rules of origin.

Many low-income countries have a narrow industrial base and cannot easily source materials used in the manufacturing of apparel locally and fulfill the local content requirements. In such cases imports of material inputs from other low-income regional trading partners or preference-receiving countries were sometimes allowed. Finally, the United States and the EU had production-sharing programs in which the partner countries could import textiles or cut fabric and other inputs from the United States or EU and export ready-to-wear clothing back to them duty free or paying tariffs only on the value added in the exporting country. The relevant program in the

United States was the 807/9802 production-sharing program (referring to chapter 9802 in the Harmonized Tariff Schedule of the United States relating to articles assembled abroad with components produced in the United States), while the EU had outward processing agreements with several countries, both as part of regional free trade agreements and as stand-alone agreements with a number of Asian countries.

The managed trade system   including the MFA, preferential access to major markets for small, low-income countries, and outward processing agreements   resulted in a highly distorted trade and production pattern. It has been estimated that the MFA regime cost the average U.S. household $105 per year, and the average EU household €270 per year around the year 2000. During the Uruguay Round of the GATT it was agreed to gradually phase out the MFA and subject the textiles and clothing sectors to the normal multilateral trade rules in the GATT. The MFA was replaced by a transitory regime known as the Agreement on Textiles and Clothing (ATC) in 1995. ATC envisaged the gradual phasing out of quotas over 10 years, ending January 1, 2005. Quotas were to be eliminated in four steps in 1995, 1998, 2002, and 2005, while the quotas remaining at each point in time were to be increased every year. In 2004 about 20 percent of U.S. imports came in under a binding quota.

While the ATC was followed to the letter, liberalization was largely back-loaded until 2005, as the nonbinding quotas were lifted first. When China became a member of the WTO in 2001, its considerable textiles and clothing sector became part of the liberalized multilateral trading system. Due to the size and competitiveness of China's manufacturing sector, many studies predicted that China and to a lesser extent India would dominate the post-quota world markets, to the detriment of preference-receiving developing countries and producers in the EU and the United States. Therefore safeguards were incorporated in China's Accession Agreement with the WTO.

When the remaining quotas were lifted on January 1, 2005, there was indeed a surge in imports to the

United States from China. Imports increased by more than 50 percent in value terms from 2004 to 2005, and China's market share increased from 20 to 28 percent in textiles and clothing. This surge triggered requests for safeguards, and the United States signed a Memorandum of Understanding with China in November 2005. The two countries agreed to set annual quantitative levels of imports in 22 categories of textiles and clothing for 2006, 2007, and 2008, in which import expansion volumes of 173 640 percent were allowed between 2004 and 2006 and thereafter by increases of 12.5 16 percent in 2007 and 15 17 percent in 2008.

Imports from China into the EU surged by almost 100 percent in value terms in the liberalized categories during the first three quarters of 2005 and the increase was even sharper in volume terms, as unit prices fell sharply. Imports from China largely replaced exports from other developing countries, while the total import value did not change much. This triggered a Memorandum of Understanding with China, and safeguards on 10 sensitive products were imposed, allowing imports to grow by between 10 and 12.5 percent for the years 2005, 2006, and 2007 in these products. It should also be noted that China has become one of the fastest-growing markets for EU textiles exports.

Both tariffs and quotas impose a wedge between world market prices and the domestic price in the importing country, allowing local high-cost producers to sell in the local market. Quotas have the additional effect that exporters shift to higher-value-added, higher-quality products within the quota in order to maximize income from the allocated quota. A sharp fall in unit prices both in the EU and the United States on imports from China in liberalized product categories during 2005 suggests that this effect may have been important, although elimination of quota rents and more competitive markets have also contributed to lower unit prices.

In spite of import protection, employment in the textiles and clothing sector has declined steadily over time in the United States and the EU. Furthermore the declining trend has continued, but apparently not accelerated, during the phaseout of import quotas under the ATC. In the United States, employment in the textiles sector fell from 701,000 in 1990 to 539,000 in 2001 and further to 390,000 in 2005. The clothing sector experienced an even sharper fall in employment, from 929,000 in 1990 to 426,000 in 2001 and further to 260,000 in 2005. The EU experienced a similarly falling long-term employment trend, from 2.6 million workers in 1995 to 2.2 million in 2001.

Even in the countries with an expanding textiles and clothing sector, employment has increased much less than output as increased international competition has led to the adoption of modern technology and sharp increases in labor productivity. The textile and clothing sectors employed 4.8 and 2.6 million people, respectively, in China in 2002, together about 16.5 percent of China's total manufacturing employment.

World Trade in Textiles and Clothing Textiles and clothing's share of world merchandise exports in value terms has fluctuated between 5 and 8 percent since the early 1960s and stood at 4.7 percent in 2005. The direction of trade has shifted substantially over the decades as textiles and clothing production tends to migrate to countries with relatively low labor costs. The first wave of migration came in the 1950s and 1960s from Europe and the United States to Japan. The second wave came in the 1970s and early 1980s from Japan to the rapidly industrializing countries in Asia: the Republic of Korea, Taiwan, and Hong Kong, which together accounted for about a third of world clothing exports at their peak. Finally there is an ongoing migration of production and trade from these middle-income Asian countries to China, India, Bangladesh, Vietnam, and other South Asian countries.

China has increased its world market share in clothing from 6 percent in the early 1980s to 26 percent in 2005, while India's world market share has fluctuated between 2 and 3 percent since the early 1980s. India's exports have been hampered by quotas and by domestic labor and product market regulation, but are likely to increase sharply in a quota-free trading regime, provided that domestic reforms take hold.
Figure 1

Exports of clothing by income group, shares of total. Source: Comtrade database (UNCTAD/World Bank).

The migration of clothing from high-income countries to developing countries is illustrated by figure 1, which depicts the shares of total WTO member countries' exports for high-income countries, least-developed (poor) countries, and other developing (middle-income) countries during the period 1962 2004. The countries that are currently classified as middle-income countries have increased their world market share from about 3 percent in 1962 to almost 70 percent in 2004. The countries currently classified as least-developed countries had a negligible world market share until the mid-1980s, but have since established themselves in the export markets. In 2005 the 10 largest exporters of clothing were China, the EU (extra-EU trade only), Turkey, India, Mexico, Bangladesh, Indonesia, the United States, Vietnam, and Romania. China alone accounted for 27 percent of total world exports, up from 4 percent in 1980 and 18 percent in 2000, while Hong Kong added another 10 percentage points in 2005 (with domestic exports plus reexports). The 10 largest exporters in textiles in 2005 were the EU (extra-EU trade only), China, the United States, South Korea, Taiwan, India, Pakistan, Turkey, Japan, and Indonesia.

The export success of some least-developed countries is largely based on preferential access to the quota-restricting countries. Some of these countries are not competitive under the normal market conditions that are emerging following the phasing out of quotas. Thus exports of textiles and clothing from ACP countries (African, Caribbean, and Pacific countries with preferential access to the EU market) to the EU fell by 17 percent in 2005.

With the increasing importance of design and rapid response to shifting consumer preferences and fashion trends, there has been a trend toward regionalization of the textiles and clothing trade. This development has been masked by the lifting of quotas where China and India were the most restricted countries. Mexico is the second largest exporter (after China) of clothing to the United States, however, while Turkey is the second (after China) and Romania the fourth (after India) largest exporter of textiles and clothing to the EU.

■ time inconsistency problem

Suppose a government is responsible for setting a policy for several periods into the future. If the government chooses to change its policies from those promised at an earlier date, the policies are said to be *time inconsistent*. The modern interpretation of this issue relates to the time inconsistency of optimal policy rules (Kydland and Prescott 1977). Policymakers may announce in advance the policies they will follow to influence the expectations of private households. Once private decision-makers have acted on the basis of their expectations, however, a policymaker may be tempted to renege on an announcement, leading to suboptimal outcomes.

For example, consider the example of a central bank that is concerned about the inflation rate and the unemployment rate in an economy. The Phillips curve, which postulates an inverse relationship between inflation and unemployment, predicts that the trade-off between inflation and unemployment depends on expected inflation (Mankiw 2007). If policy setting in the central bank is guided by the Phillips curve, to reduce expected inflation the central bank might announce that low inflation is the main goal of its monetary policy. This is because a favorable trade-off between unemployment and inflation depends on the expected inflation rate being low. The announcement of a policy of low inflation is not credible, however. The central bank has an incentive to renege on its announcement and implement an expansionary monetary policy to further reduce the unemployment rate once firms and households have formed their expectations of inflation for the future, and set wages and prices accordingly. Private decision-makers understand the central bank's inherent incentive to shirk its announced policy and do not believe the central bank's announcement in the first place. The implication is that the economy ends up with a higher inflation rate without any lowering of the unemployment rate. Time inconsistency therefore leads to suboptimal outcomes.

Insights from the time inconsistency problem underlie the widely accepted contemporary view among economists that the best policies are the most

predictable policies, or those that follow simple rules. This basic insight also relates to an earlier debate on rules versus discretion in macroeconomic policy (Friedman 1959). A rule specifies in advance the actions that policymakers will take or commit to. Commitment refers to the ability of a government to make binding choices. Economists have long recognized that unless a government can commit to a policy rule, it will in the future want to modify policies that are optimal from the standpoint of today. Further, without such binding policy commitments (i.e., policies aimed at tying the hands of the government), the private sector will fear that today's governments will make promises that its successors will refuse to honor.

Monetary Policies to Overcome Time Inconsistency Time inconsistency provides a rich explanation for a wide variety of issues, such as why capital accumulation in countries is low, or why countries choose to fix their exchange rate. In line with the earlier example, however, one of the most important applications of time inconsistent policies is the "inflation bias" inherent in monetary policy (Barro and Gordon 1983a, 1983b). *Inflation bias* refers to prolonged episodes of high inflation above what is socially desirable. An example is the "great inflation" of the 1970s in the United States. Time inconsistency hampers a government's efforts to keep inflation stable and leads to high and persistent inflation despite repeated promises to fight it. This affects the volatility of inflation, output, and interest rates, leading to a misallocation of resources.

Given the implications of time inconsistency, a large body of research has evolved since the 1980s on ways to overcome the time inconsistency problem in macroeconomic policy. For example, in the case of monetary policy, economists have suggested various types of monetary policy rules. Other solutions involve the delegation of monetary policy to an independent authority with well-defined objectives. This in turn has led to greater central bank independence. Central bank independence can help in situations where credible policy rules are not enforceable. In contrast to rules,

discretion implies the absence of commitment to a particular rule, leaving policymakers more flexible with their future actions.

Another solution to the time inconsistency problem involves reputation building. By acting consistently over a long period, a policymaker builds up a reputation that causes the private sector to believe its announcements. Once a reputation has been built, expectations of inflation become consistent with the announced low inflation policy. In some cases reputation can be imported. For instance, the monetary authority can peg its currency and import the monetary policy of another country with more credible institutions. This is often the primary motivation behind the adoption of hard pegs such as currency boards, dollarization, and common currencies.

Political Macroeconomics Since the early 1990s a line of research called political macroeconomics has evolved to explore the political determinants of macroeconomic policy (Drazen 2000; Persson and Tabellini 1994). This line of research recognizes that a policymaker's incentives and constraints originate in the political process. For example, within the context of fiscal policy, elected officials may be motivated by electoral reasons to enact time inconsistent expansionary policies that have long-term inflationary consequences. Alternatively, fiscal stabilizations attempts to reduce a large fiscal deficit of a country are likely to fail if the adjustments are achieved by higher taxes, as in Ireland's fiscal stabilization of 1982. The time inconsistency of this policy is that governments are unlikely to deliver on the promise of higher taxes, given the nature of the political business cycle. With respect to monetary policy, the economist Rogoff (1985) argues for the appointment of a conservative central banker who has greater inflation aversion than society as a whole to eliminate the inflation bias inherent in monetary policy. Welfare improves because the central bank trades some flexibility for some gain in credibility. Indeed, different views about rules and discretion with the associated themes of commitment, credibility, and time inconsistency are

among the most pressing issues concerning the conduct of macroeconomic policy in a strategic setting.

■ Tobin tax

Nobel Laureate economist James Tobin (1974, 1978) advanced a now well-known case for what has come to be known as the Tobin tax, namely, the imposition of a modest ad valorem tax (i.e., a percentage of value) on all spot transactions in foreign exchange. (Spot transactions are those that entail actual exchanges of currency at the existing market rates.) Tobin wrote that "the tax would apply to all purchases of financial instruments denominated in another currency. It would have to apply . . . to all payments in one currency for goods, services, and real assets sold by a resident of another currency area" (1978, 159). Tobin advanced the case for this tax on currency trading following the collapse of the Bretton Woods system of pegged exchange rates and attendant concerns about speculation, volatility, and misalignment in currency markets. Tobin also suggested that the tax could restore "some fraction of short-run [policy] autonomy"; however, he was careful to explain that "it will not, should not, permit governments to make domestic policies without reference to external consequences" (1978, 158).

The Tobin tax built on John Maynard Keynes's case for a securities transactions tax. Keynes (1936) proposed a substantial transfer tax on all transactions as a means to dampen the general tendency for speculation to dominate enterprise in liquid, competitive financial markets. Keynes (1980, chap. 36) also proposed taxation of foreign lending to contain speculative capital movements.

Several factors stimulated interest in the Tobin tax in the 1990s. These factors included the increase in currency speculation and volatility; the frequency of currency crises in developing countries; and the debate over the adequacy of the international financial architecture and the volume of international capital flows available to developing countries. This attention stood in sharp contrast to the silence that greeted Tobin's original presentation in the 1970s. The recent interest in the Tobin tax is located in a number of quarters namely, academic economists identified with the Keynesian tradition, various United Nations agencies, governments in some countries that express support for the Tobin tax (namely, Canada, Belgium, and France), and nongovernmental organizations concerned with development finance and financial architecture. Tobin distanced himself from many of the nongovernmental organizations that advocated for the tax in the 1990s, however.

There is broad consensus that the tax must be levied at a low rate (Nissanke 2004 suggests 0.01 to 0.02 percent) in order to minimize the incentive to undertake tax evasion strategies (e.g., geographical or asset substitution) and to avoid other distortions of the foreign exchange market. Research has also focused on the issue of tax collection. In Tobin's original formulation, governments would levy and collect the tax nationally. But in view of the potential problems of tax competition among nations and the diversion of trading activity to "Tobin tax havens," many proponents focus on the need for a global tax agreement and the creation of a supranational authority to administer and collect the tax (Griffith-Jones 1996) and to allocate its revenues to projects that promote development (Kaul and Langmore 1996). Others, however, suggest that a Tobin tax could achieve some of its objectives absent global implementation (Baker 2001; Nissanke 2004).

Modifications to the Original Tobin Tax Concept In 1996 Tobin amended his original proposal to take account of the importance of new instruments of foreign exchange trading. In the amended version, Tobin (1996) argued that forward and swap transactions would be subject to taxation as well. (A for-

ward transaction is a contract in which parties agree to exchange currencies in the future at a price agreed on today. A swap combines spot and forward transactions.) Indeed, it is likely that if the tax is limited to spot transactions it would lead to a tax-saving reallocation of financial transactions from traditional spot transactions to derivative instruments. As such, in order to prevent tax avoidance via asset substitution or a changed product mix, it ought to be applied on all derivative products such as forwards, futures, options, and swaps.

Some proponents of the Tobin tax argue for modified versions of the proposal aimed at enhancing its ability to reduce currency market volatility. For instance, Crotty and Epstein (1996) argue for joint implementation of Tobin and securities transaction taxes. They argue that a securities transaction tax might reinforce the market-stabilizing function of a Tobin tax by increasing the cost of investor flight (since the sale of assets or borrowing must precede the flight of large sums of money from a country).

Spahn (1996) advances a case for a two-tiered Tobin tax. In this formulation, low transactions taxes on currency trading would be maintained during tranquil (or "normal") times. But a higher transaction tax would be activated whenever levels of market activity accelerated dramatically. Spahn argues that with knowledge of this variable tax structure, investors might be less likely ex ante to engage in activities that aggravate various types of financial risks. Moreover activation of a prohibitively high transaction tax (as a type of speed bump) might discourage some investors from liquidating their portfolios at precisely the time of greatest financial volatility.

The Debate over the Tobin Tax Most proponents of the Tobin tax argue that it has the potential to shift the balance of factors influencing the exchange rate away from short-term expectations toward long-term factors and to decrease exchange rate volatility caused by speculation in this market. Advocates maintain that speculation in currency markets would be dampened because the annualized cost of even a low tax could change trading behavior. Many proponents argue that the Tobin tax consti-

tutes a progressive form of taxation, given its likely incidence (Baker 2001; Palley 2001). Following the East Asian financial crisis of 1997 98, a few advocates suggested that had a Tobin tax been in place it might have reduced the buildup risks that culminated in the crisis (Wade 1998).

Advocates of the Tobin tax are sanguine on the matter of revenue creation. For instance, Nissanke (2004) forecasts that a Tobin tax (even if not implemented by all countries at once) has the potential to raise between U.S. $17 billion and $35 billion in one year (using data for 2001). The taxes harvested would be allocated to various projects of developmental or global importance.

Critics of the Tobin tax, such as Dodd (2003), advance a number of arguments. Dodd argues that the tax is not politically feasible; that it is not feasible administratively or technically without imposing unreasonably high costs; that the issue of leakages through shifts to nontaxed assets and/or to Tobin tax havens is not considered seriously; that the tax would have perverse consequences insofar as it would reduce financial market stability and increase volatility in prices and capital flows; and that the proposed rate for the Tobin tax is actually quite large when one compares it with the transaction costs of trading in foreign exchange markets and most liquid securities and derivatives.

Critics have also taken issue with the claim that the Tobin tax could play any role in reducing the tendency toward financial crises in developing countries (Grabel 2003). This is because the Tobin tax is not designed to dampen speculation in all of the sectors of the economy that are prone to bubbles (e.g., real estate and construction). Even in those sectors that do fall under the authority of the tax, the presence of a tax is unlikely to undermine the attractiveness of activities and financing strategies that aggravate fragile financial environments. Implicit in this critique of the Tobin tax is the view that other strategies ranging from prudential financial regulation, exchange controls, capital controls, capital management techniques, and taxation of other "global public ills" (such as pollution) represent far better means than does the Tobin tax for reducing

financial volatility and currency misalignments, enhancing macroeconomic policy autonomy, and raising revenues for projects of global social importance.

■ trade and economic development, international

Since the study of economic development covers a wide array of topics, this entry looks at how international trade affects only certain very important aspects of development, particularly per capita real incomes and their growth rates, and the distribution of income. In studying the impact of trade on distribution-related aspects, the focus is first on poverty, then on the welfare of workers.

The Impact of Trade on Income Levels Theoretically trade is expected to have a positive impact on per capita real incomes through efficiency gains from specialization and exchange, as well as through the availability of larger varieties of goods. Trade has a further beneficial effect on resource allocation through the destruction of the monopoly power of inefficient domestic firms. Recent calculations using standard trade models for a small country show that the gains from moving from no trade to frictionless trade can result in substantial increases in real gross domestic product (GDP). Positive effects of trade on welfare (real incomes), however, may not be obtained in the presence of market distortions, externalities, or imperfections in institutions. Nevertheless, when direct policies to attack these distortions are in place, the positive effects of trade on welfare are restored (Bhagwati 1971).

At the macro level, Frankel and Romer (1999) find a positive effect of trade openness on income levels across countries. They address the issue of reverse causation through an instrumental-variables approach. Rodrik, Subramanian, and Trebbi (2004) use a simultaneous, structural-equations approach to study the effects of institutions, geography, and trade on per capita income levels. They find that "the quality of institutions trumps everything else." Trade and institutions have positive effects on each other, however, so trade affects incomes through institutions.

It is important to mention a few microlevel studies that look at a couple of channels mentioned above. Levinsohn (1993), Harrison (1994), and Krishna and Mitra (1998), using plant/firm-level data have found that the price-to-marginal-cost markup fell as a result of trade reforms in Turkey, Ivory Coast, and India, respectively. Thus the monopoly power of domestic firms (and therefore the deadweight losses associated with this monopoly power) went down. There is also some evidence on the variety channel. Using 8 10-digit level data, Broda and Weinstein (2006) show that the gains from trade for the United States from greater varieties of goods through trade amounts to about 3 percent of GDP. These authors, in their more recent research, extend this empirical analysis and approach to investigating the growth effects of trade through an increase in varieties and find the gains to be even larger. The growth effects of trade will be discussed in detail in the next section.

In summary, the clear theoretical predictions of the positive effect of trade openness on real income or welfare have been supported by macro, cross-country studies. The microlevel studies have identified the main channels to be the market disciplining function of trade and its role in providing greater varieties of goods.

The Impact of Trade on Economic Growth The dynamic effects of trade are not straightforward to analyze and are sensitive to changes in assumptions. As a result, unlike the level effects of trade, there is disagreement on its growth effects.

In the beginning of the second half of the 20th century, the newly independent countries were concerned about possible adverse effects of trade on their growth, as their comparative advantage was in agricultural products. Furthermore they were concerned about adverse changes in the world relative prices of primary products. The early literature on trade and growth is motivated by such concerns.

According to Findlay (1984), the first implicit dynamic model of trade and growth is in David Ricardo's (1815) *Essay on the Influence of a Low Price of Corn upon the Profits of Stock*. This is explicitly and elegantly modeled by Findlay (1984) himself in a two-sector setup. While the profits in manufacturing are invested in increasing production and employment in the next period, land rents in agriculture are spent on consumption by "profligate landlords." Thus a country with a comparative advantage in manufacturing (agriculture) will experience an increase (decrease) in its growth rate on opening to trade.

Similar models of trade and growth were written to study how the North-South terms of trade move over time (Findlay 1984). Feeding stylized facts about relative productivity growth rates in the production of food, coffee, and steel into such models, the implication derived was that terms of trade for the South will deteriorate over time. Working with such models also showed that high growth in the presence of trade could result in a terms-of-trade loss, that is, the good that this rapidly growing country sells (exports) to the rest of the world becomes relatively cheaper while the good that this country buys (imports) from the rest of the world becomes relatively more expensive. When this terms-of-trade loss is large enough, there would be the possibility of a country's own growth reducing its real income. This possibility is called "immiserizing growth," analyzed in detail in Bhagwati (1958).

Another issue studied in the trade and growth literature was the impact of trade on growth through capital accumulation. In neoclassical models of trade and growth, there is either exogenous or no technological progress. Findlay (1984) presents such two-sector Solow- and Ramsey-type growth models to study the effects of trade. A country with a high

savings rate has a high steady-state capital stock in autarky. Such a country will have a comparative advantage in the more capital-intensive of its two sectors. Opening to trade will result in (incomplete) specialization in the capital-intensive sector and will in turn lead to an increase in the rate of return on capital. Incentives to capital accumulation will therefore increase, and we will see an increase in the steady-state capital stock as a result of trade. Opening to trade also leads to transitional growth in this country. A country with a low savings rate has exactly the opposite experience. Importantly, in such multisectoral growth models, unlike a closed economy a small open (but diversified) economy does not experience diminishing returns to capital. With an increase in capital stock, production in a small open economy moves to more capital-intensive goods at a fixed world-price vector.

The issue of capital accumulation in an open economy has also been addressed by the "two-gap" models that emphasize the role of savings and foreign exchange in facilitating growth (Findlay 1984). Investment results in growth but it has to be financed by savings. Since this investment also requires the purchase of foreign capital goods, adequate foreign exchange should be available. That is why these models emphasize the need for aid and promotion of exports in generating growth.

In addition to these types of models, the early trade and growth literature also consisted of North-South models and the dual-economy models. While the former type focuses on the unequal relationship between the developed and the developing world, the latter looks at the asymmetry between regions within the same country. In North-South models, the developing world (the South) is structurally quite different from the developed world (the North) not just in the model parameters but also with respect to the nature of factor markets and institutions. In dual-economy models, there is a modern urban sector and a primitive rural sector. In addition, there could be an unorganized subsector within the urban sector (see Findlay 1984).

While neoclassical growth theory assumed exogenous technological progress, in the endogenous growth theory, pioneered by Romer (1986), the rate of technological progress was determined within the model. Endogenous growth was a major breakthrough in growth research and attempted to explain the growth miracles of East Asia.

Grossman and Helpman (1991) developed a series of models using this new approach, where they clearly show that the growth effects of trade are very sensitive to the model structure assumed. While trade can increase productivity growth by avoiding duplication of effort in research and development (R&D), through the international exchange and transmission of technical knowledge and by allowing the pooling of knowledge across borders, it can reduce or increase productivity growth depending on whether a country is scarce or abundant in skilled labor (Grossman and Helpman 1991).

At the firm level, Rodrik (1992) shows that the market size of a domestic, import-competing firm may shrink as a result of reducing import protection (i.e., allowing more imports) and so will reduce the returns from and investment in R&D and in turn will reduce productivity growth. This is called the "market-size effect"; there is also what Devarajan and Rodrik (1991) call the "procompetitive effect" of trade liberalization, which results in the flattening of the demand for an import-competing good. The greater foreign competition increases the return to R&D and thus also R&D and growth.

At the macro level, the effects of trade barriers on growth and income have been studied empirically since the early 1990s. A variety of openness measures have been used to show positive effects of trade on growth. These studies have come in for heavy criticism by Rodriguez and Rodrik (2001), however, for problems with their openness measures and econometric analysis, as well as for the difficulty in establishing the direction of causality. One of the openness measures criticized by Rodriguez and Rodrik (2001) is the one used by Sachs and Warner (1995), which captures many aspects of the macroeconomic environment in addition to trade policy. However, the Sachs-Warner approach has recently been defended on the grounds that the other policy reforms captured in the measure accompany most major trade

reforms and that we would like to know the value of the entire package of trade and accompanying reforms.

We next turn to the microlevel evidence. Harrison (1994) and Krishna and Mitra (1998) estimate a modified version of the traditional growth accounting equation to incorporate imperfect competition and nonconstant returns to scale. Using plant/firm-level data, they find evidence for an increase in productivity growth after trade reforms in the Ivory Coast and India, respectively. Pavcnik (2002), using a more sophisticated method to correct for simultaneity and selection problems, also finds evidence in support of productivity improvements in Chile after their trade reforms.

In summary, the trade and growth literature began by addressing interactions between trade and the asymmetries across developed and developing countries as well as those within developing countries. Subsequently the focus shifted to the interaction between capital accumulation and trade, in many cases analyzed in the presence of exogenous technical progress. This was followed by the trade and endogenous growth literature, motivated by the East Asian growth miracle. Across these three stages of the literature, the trade and growth models do not agree with each other on the predictions they make, as the results are highly sensitive to changes in assumptions. While most of the empirical literature has shown that trade has a positive effect on growth, the macro cross-country studies have come in for considerable criticism.

The Impact of Trade on Poverty While the literature on trade, incomes, and growth has implications for the trade-poverty linkage, there is also a small literature on the direct determinants of poverty rates (see comprehensive surveys by Goldberg and Pavcnik 2007; and Winters, McCulloch, and McKay 2004).

Dollar and Kraay (2002), using cross-country data, find that the growth rates of average incomes of people in the bottom quintile are roughly equal to the growth rates of overall per capita incomes, and the two are strongly correlated. Also policies known to be growth promoting, such as trade openness, macro-

economic stability, moderate government size, financial development, strong property rights, the rule of law, and the like, promote growth in the incomes of the poor as well. In subsequent work, the same authors infer from the data on the post-1980 "globalizing developing economies" that per capita income growth arising from expansion in trade in those countries has led to a sharp decrease in absolute poverty in the past 20 years.

Ravallion (2001) finds in his cross-country study that an increase in per capita income by 1 percent can reduce the proportion of people below the $1-a-day poverty line by about 2.5 percent on average. This varies across countries, depending on initial inequality.

Finally, a paper by Hasan, Quibria, and Kim (2003) argues, using cross-country evidence, that "policies and institutions that support economic freedom are critical for poverty reduction." Economic freedom indicators used by these authors include, among many components of freedom, the freedom to trade with foreigners.

Moving away from cross-country studies to within-country analysis, Topalova (2005) has examined the impact of trade liberalization on district-level poverty in India. She finds that "rural districts where industries more exposed to trade liberalization were concentrated experienced a slower progress in poverty reduction." She finds this effect not to be statistically significant in urban India. A recent study by Hasan, Mitra, and Ural (2007) uses data at the state and region levels for India and in no case do the authors find reductions in trade protection to have worsened poverty. Instead they find that states whose workers are on average more exposed to foreign competition tend to have lower rural, urban, and overall poverty rates (and poverty gaps), and this beneficial effect of greater trade openness is more pronounced in states that have more flexible labor market institutions. They also find that trade liberalization has led to poverty reduction to a greater degree in states more exposed to foreign competition by virtue of their sectoral composition.

Recent work by Guido Porto at the World Bank looks at the trade-poverty link in a more structural

(model-based) way in a series of papers (e.g., 2006). Using this method, he decomposes the effects of trade into the consumption and income effects. Consumption effects take place through changes in goods prices, while income effects take place through changes in factor incomes. This methodology, developed by Porto, helps us understand how households in different income classes are affected by trade policies. Using this approach, Porto finds a beneficial impact of the South American regional trade agreement Mercosur on average and poor households in Argentina but not on rich households.

The literature on trade and poverty has evolved from cross-country studies to microlevel household studies. The state-of-the-art approach is fairly structural and can identify the various channels through which trade affects poverty. The literature, mainly but not entirely, provides evidence in support of the poverty-reducing effects of trade.

The Impact of Trade on Labor in Developing Countries There is, by now, a fairly rich microempirical literature on how labor is affected by trade policy in developing countries. Recent research draws attention to two opposing effects of trade for which there is some evidence: (1) an increase in wages (the Stolper-Samuelson effect in a labor-abundant country), everything else being equal, which reduces the amount of labor demanded, and (2) a reduction in the price-cost markup (due to more competition), which causes producers to increase their demand for labor. Also, there is evidence that imports can destroy or reduce monopoly rents that can be shared by employers and employees and thus lead to a reduction in the firm-specific wage rate and employment. Currie and Harrison (1997) argue that the employment reducing effects of trade reforms in import-competing firms may be partially or fully offset by positive effects brought about by attempts to reduce profit margins and to invest more resources into productivity enhancement to counter new competition. The mutually opposing forces end up offsetting each other as seen in their firm-level evidence from Morocco. It is important here to point out that many of the studies in the literature, including some of the studies described above, find little change in

the structure of employment across industries as a result of trade reforms, but there is evidence that sectors with larger tariff cuts experience larger declines in relative wages (see Goldberg and Pavcnik 2007).

Another important issue related to the trade-labor link is that of trade and wage inequality. Feenstra and Hanson (2003) summarize their research on this issue, published in a series of papers. Their analysis is based on a new type of trade, namely outsourcing through capital mobility. They assume that there is a final good that is produced using different types of intermediate goods, each of which in turn is produced using skilled and unskilled labor and physical capital. Different inputs have different skill intensities. Under free trade and no capital mobility, the Northern country produces inputs that are more skill intensive than those produced in the Southern country. Under a configuration in which the return to capital is lower in the Northern country than in the Southern country, allowing capital mobility leads to a flow of capital from the North to the South. There is a consequent shift in the production of the North's least skill-intensive intermediate inputs to the South (which still are more skill intensive than all the other inputs being produced in the South). Thus the relative demand for skills and consequently wage inequality go up in both countries. Feenstra and Hanson have found support for their theory using U.S. and Mexican data.

Let us next look at the pressure exerted by trade on labor markets through a new channel that has an impact on employment and wage risk and on the bargaining power of workers. This new linkage is the one between openness and the elasticity of labor demand emphasized by Rodrik (1997) and Slaughter (2001). The elasticity of labor demand here refers to the responsiveness of the quantity of labor demanded to its wage rate. Product-market elasticities (the responsiveness of quantity of final output demanded to the price of output) are likely to rise with trade liberalization. This is due to the availability of a greater variety of (imported) substitutes after opening up to trade, which makes it easier to move away from a good (or reduce its use) on a price increase. According

to Hicks's well-known "fundamental law of factor demand," output-demand elasticities and factor-demand elasticities move in the same direction (see Slaughter 2001 for a more detailed discussion). Thus greater trade openness should lead to an increase in labor-demand elasticities. As Rodrik (1997) notes and as explained in Slaughter (2001) and Krishna, Mitra, and Chinoy (2001), bigger labor-demand elasticities shift the incidence of nonwage labor costs toward workers, lead to wider fluctuations in wages and employment due to fluctuations in labor demand, and reduce the bargaining power of workers. Slaughter (2001) was the first to perform an empirical investigation of this positive relationship between openness and labor-demand elasticities, but only for a developed country, namely the United States. He found mixed empirical support for this relationship using U.S. four-digit industry-level data. The first developing-country study in which this link has been investigated is Krishna, Mitra, and Chinoy (2001). Using a partial equilibrium, imperfectly competitive setup and plant-level data from the Turkish manufacturing sector, they find no linkage between greater trade openness and labor-demand elasticities. However, a recent paper by Hasan, Mitra, and Ramaswamy (2007), using state-level, industry-level data from a large developing country, namely India, finds a statistically significant effect in the predicted direction, the result being stronger in states with more flexible labor markets.

The literature on the link between trade and labor provides evidence that trade affects wages but does not affect industry-level employment due to the presence of various mutually offsetting channels. Trade has also been shown to have increased wage inequality. In addition, a new literature, with mixed evidence on the effects of trade on labor-demand elasticities has emerged.

Finally, there is some recent work on trade openness and child labor, which has not been covered in this entry (see Edmonds and Pavcnik, 2005).

The purpose of this entry is to examine the impact of trade on a few important aspects of development. Growth in incomes is an important component of development. However, if this growth takes place

without any reduction in poverty, an important purpose of development is defeated. Therefore the impact of trade on incomes, growth, and poverty reduction has been discussed in this entry. Additionally, the trade-labor nexus has also been studied, as a large majority in developing countries does not possess any productive assets other than raw labor power.

trade and the environment

Trade, the exchange of goods and services across countries, is often viewed as an engine of economic growth. Benefits of liberalized trade include access to a larger variety of goods and services to consumers, easier access to foreign technologies, access to larger markets for producers, and increased efficiency in resource allocation. The impact of trade on the environment, however, is a contentious issue; air and water pollution, the degradation of natural habitats, loss of species, and global pollutants, particularly carbon dioxide emissions, are major concerns.

Recent Trends In the late 20th and early 21st centuries international trade has rapidly increased worldwide, while average tariffs and quantitative restrictions to trade (import and export quotas) have fallen steadily. Export growth has outpaced growth in gross domestic product (GDP) (World Bank 2006). With respect to the environment, there are persistent and widespread improvements in most *local* urban pollutants, mainly airborne pollutants (e.g., sulfur dioxide, nitrogen dioxide, carbon monoxide, air particles, and lead). An important exception is local ozone, a highly dangerous local pollutant that has increased over time in most cities, in part as a consequence of measures taken to reduce some other air pollutants. There are also less clear but perceptible trends to improve some indicators of water quality (United Nations 2006). In contrast, there is a clear worsening of the *global* pollutants (e.g., carbon dioxide) as well as of the rural or "green" environment (i.e., the natural forests and other important natural habitats). The latter phenomenon is causing a precipitous loss of species and has contributed to increased global warming through the emissions of carbon dioxide due to massive forest burning.

Thus while trade has rapidly expanded, the environmental trends show a sharp dichotomy: the local urban environment improves but the green or rural environments continuously deteriorate. One reason for this may be that local urban pollution is directly felt by large concentrations of population able to exert strong pressures on politicians to control it, while the rural environment affects directly a smaller fraction of the population which, due to its

geographical dispersion, is less able to pressure governments. Rural environmental degradation and global pollution are less visible to the majority of the population than local urban pollution, which might explain the generally more lax response by governments to rural than urban environmental problems and to global rather than local pollutants.

Effects of Trade on the Environment The central issue is whether opening up to trade has magnified the trends described above or has instead mitigated some of them. The effects of trade on the environment can be broken down into scale, technique, composition, and growth effects (Antweiler, Copeland, and Taylor 2001; López, Galinato, and Islam 2007).

Scale effect. Most forms of pollution are a by-product of a production process. Increased trade openness often implies an increase in economic activity. The scale effect, holding constant production techniques and the mix of goods produced, is likely to cause an increase in the level of local and global pollution and also faster degradation of natural resources. For example, expanding agricultural exports may increase agricultural activities, which may result in water pollution from extensive fertilizer use and deforestation from increased demand for agriculture. The scale effect may also include trade-related direct increases in pollution emissions through increase in air and road transportation. Empirical studies usually employ gross domestic product (GDP) per square kilometer as a proxy for the scale effect. López (1997), for example, found that in Ghana trade liberalization induced a faster rate of deforestation. Given the more lenient attitude of governments toward rural environmental degradation and global pollutants than to urban local pollution, the negative impact of the scale effect is likely to be worse for the green-global environment than for the urban environment.

Technique (wealth) effect. The technique effect refers to reductions in emission intensity per unit of output. If trade raises income, emission intensity may fall if environmental quality is a normal good. A normal good is one for which, as incomes rise, individuals would prefer more of it. Higher income may lead to stricter environmental regulation, under

the assumption that country governments are responsive to the citizens' demands. A trade-induced rise in incomes would thus make higher environmental quality desirable. Empirical studies often use per capita GDP as a proxy for income. A more accurate measure is per capita household consumption expenditure, which is more directly related to permanent income or wealth than per capita GDP (López, Galinato, and Islam 2007). The technique effect of trade has been found to reduce certain pollutants, particularly air pollutants, but the effects on other environmental factors is less significant. The strength of the technique effect is weaker for the green and global environment than for the local urban environment because the citizens' demands for environmental quality are likely to be feebler in the rural areas and for global pollutants than for the control of local urban pollutants.

Composition effect. Trade may also alter the composition of the economy's output. If the economy's comparative advantages favor clean industries, increasing trade openness may switch from pollution-intensive "dirty" goods to less polluting, or "clean," goods and services. The general assumption is that production of dirty goods is more intensive in physical capital and natural resources while clean goods production is more intensive in human capital. Holding the scale of production and other factors constant, an economy that shifts its production toward physical capital intensive goods will pollute more, and conversely, an economy that shifts its production away from physical capital intensive goods will pollute less. Countries that have large endowments of natural resources are likely to relatively specialize in resource-intensive industries and thus increase the extraction of natural resources when they open to trade. In countries where property rights on resources are poorly defined or where environmental regulations are not properly enforced, increased trade is likely to result in more resource degradation and deforestation.

Even more seriously, lack of property rights on resources may lead countries to specialize in natural resource intensive activities and hence to further environmental degradation even if they are not richly

endowed in resources. That is, the institutional and regulatory failures may lead to false comparative advantages, in which case trade may reduce rather than raise income as is normally assumed (this is behind the *pollution haven hypothesis* as discussed later). In this perverse case the technique effect discussed earlier (which assumed that income increases with trade) would be reversed. Also, once again, the weight of the composition effect may be felt on the green-global environment because environmental control institutions and regulatory policies are less developed for the rural-global resources than for urban pollutants.

Growth rate effect. Trade openness may cause a number of dynamic forces that promote not only a once-and-for-all effect on the income level but also a faster pace of economic growth over time. For example, trade openness may cause an economy to adopt new technologies at a faster rate due to the fact that many new technologies are generated abroad. A faster pace of economic growth may cause lower environmental quality than a country growing at a slower rate (López, Galinato, and Islam 2007). The issue here is that environmental institutions and policies need time to be adapted. An economy growing at a fast rate will find it much more difficult to timely adapt their policies and institutions to properly respond to increasing pollution than an economy growing at a more moderate pace. This trade-induced growth rate effect may result in a decline in environmental quality.

The net effect. Empirical studies seem to corroborate the hypothesis that the positive-technique effect dominates the other effects for certain local urban pollutants resulting in trade being good for the urban environment (Copeland and Taylor 2003). However, the few empirical studies of the impact of trade on the rural environment, particularly the impact on wetlands and natural forests, suggest that the net effect of trade is negative (López 1997). This is consistent with the earlier conceptual discussion regarding the relative strength of the various partial effects on the urban and rural environments. The net effect of trade is also likely to be negative for global pollutants because the technique effect may be weak

for such pollutants as people care less for pollutants that do not affect them directly.

Pollution Haven Hypothesis According to this hypothesis the direction of trade between two countries may be dominated by differences in environmental regulatory strengths. Developed economies tend to have better environmental institutions and more efficient regulation than poorer countries. The pollution haven hypothesis states that rich countries may export their dirty industries to poorer countries due to the differences in regulation. Freer trade thus results in declining environmental quality in poorer economies and improving environmental quality in richer ones (Chichilnisky 1994). There are two main assumptions behind the pollution haven hypothesis: first, that pollution regulation differences are a key determinant of industry location, and second, that environment is a normal good and thus differences in regulation are due to income differences. A further implication of this hypothesis is that global environmental quality may deteriorate and the income of the poorer economies may fall. As polluting industries migrate to regions with less stringent pollution policy, overall global pollution will increase. The available empirical evidence generally rejects the pollution haven hypothesis, but this does not mean that environmental regulation plays no role in affecting trade (Copeland and Gulati 2006). The evidence simply says that environmental regulatory differences do not necessarily dominate the direction of trade as the pollution haven hypothesis suggests.

Factor Endowment Hypothesis The factor endowment hypothesis deviates from the pollution haven hypothesis by postulating that factor endowments, and not just differences in environmental regulations, are the main motivation for trade patterns. Economies engaging in trade will specialize in production where comparative advantage is exhibited. If the most developed countries are relatively abundant in factors (usually capital) used in pollution-intensive industries, then they may have a comparative advantage in dirty industries and thus will specialize in them. Consequently, dirty goods production may shift from developing to developed economies. Developed economies have better

environmental regulation and institutions, and thus the consequence of trade would be an overall decline in pollution. Proponents of this hypothesis point to the fact that Europe and the United States have the most stringent pollution policies yet export manufactured goods that are highly pollution intensive. If developing countries have an abundance of the factor needed by pollution-intensive production, the predictions of the factor endowment hypothesis would be consistent with the pollution haven hypothesis. Furthermore, developed countries will lose their comparative advantage in dirty industries if stringency in pollution policy is increased. Thus there are two forces at play, pollution policy differences and factor endowments.

Trade Openness and the Environmental Kuznets Curve Part of the empirical environmental literature has been on the relationship between income and pollution, otherwise known as the Environmental Kuznets Curve (EKC) (Shafik and Bandyopadhyay 1992; Grossman and Krueger 1995). The EKC is an inverted U-shaped relationship: as income increases, pollution first increases until it reaches a turning point and then declines. The first empirical estimation of the EKC for air and water pollutants was carried out by Grossman and Krueger (1995). Estimation of the EKC has also been carried out for natural resources such as forests (López and Galinato 2005). There is much debate with regards to the empirical estimates, data accuracy, robustness, and theoretical underpinnings of the EKC (Harbaugh, Levinson, and Wilson 2000; Deacon and Norman 2007).

Trade plays an important role in some of the conceptual explanations of the EKC. The income effect theory identifies environmental policy response as the main reason for the EKC. As an economy grows, at first the benefits of increasing output are so large that they dominate the increased demands for environmental quality caused by a higher income and thus the scale effect dominates (the curve is upward sloping in this segment). Beyond a certain level of income, the marginal preference for more consumption declines and the preference for clean environment increases until the turning point occurs. Pollution declines as income

increases beyond this point. What trade does is to enhance the process of economic growth and thus has an indirect effect on the EKC.

Another story focuses on the composition effect. In the early stages, countries grow through physical capital accumulation and expansion of industries intensive in physical capital, which are generally dirty; in the latter stages, a country grows through human capital and knowledge accumulation and thus cleaner industries emerge, yielding an EKC relationship. Trade liberalization may assist in the switch from dirty to clean industries by allowing the growing economy to increasingly specialize in clean industries. Without trade the assumptions required for an EKC process are much more stringent than with trade.

The Resource Curse Countries with larger endowments of natural resources apparently tend to grow less than resource-poor countries (Sachs and Warner 1999). There are several explanations for such a phenomenon (Barbier 2005). One of the most credible explanations is directly linked with trade, the so-called Dutch disease effect. As a natural resource dependent economy booms, resources are allocated from other sectors to the natural resource sector. Furthermore, the currency of the economy appreciates, which renders other sectors in the economy uncompetitive in international markets. This results in further dependency on the natural resource sector. Hence the economy is more vulnerable to the price fluctuations inherent to primary commodities. Examples of the resource curse can be seen in oil-producing countries that are resource rich but are growing slowly.

The Role of Government Environmental quality is a public good; thus by definition the market will underprovide it. Although much emphasis has been placed on government efficiency and the provision of public goods such as environmental quality, there has been less emphasis placed on the efficiency of government subsidies. Governments that provide trade and other subsidies do so at the expense of underproviding public goods, given a fixed budget constraint. Public good investments by the government can complement private investments and alleviate

market failures, thus resulting in economic growth (López and Miller 2007; López and Galinato 2007). Furthermore, government subsidies, including trade subsidies, would promote activities that would be more demanding for the environment as opposed to public good expenditures, which may compensate for credit market failures and promote human capital accumulation. A study by López, Galinato, and Islam (2007) finds that increasing the share of public goods in total government expenditures reduces SO_2, NO_2, and lead pollution.

Empirical and conceptual analyses suggest that trade has contributed to economic growth and has accelerated trends to ameliorate local air pollutants. This is particularly true of most local air pollutants affecting cities. Trade does not seem to mitigate the ever-increasing emission of global pollutants, particularly carbon dioxide. The few studies focused on the links between trade and the green environment suggest that increased trade appears to exacerbate the losses of natural forests and other natural habitats, thus aggravating the trends toward global climate change and loss of biodiversity.

■ trade and wages

Beginning with Adam Smith and David Ricardo, economists have demonstrated the benefits of free trade in numerous ways, yet free trade has hardly become a universally accepted strategy. Even in cases where free trade maximizes a country's welfare (or generates a higher welfare than trade restriction), it is not necessarily a superior policy. Free trade creates both winners and losers in a trading nation. It is only through a compensation principle (by which the winners are forced to compensate the losers) that everyone can be made better off under free trade. In practice, however, such a compensation principle is seldom applied; more relevant, then, is how trade affects factor incomes or wages and thus the income distribution within a country. The study of trade and wages is important for two other reasons. First, as most of the poor belong to the working class, study of the effects of trade on wages helps us understand how trade alleviates poverty in the short term. Second, if free trade widens income inequality, it fuels interclass conflict. This makes it difficult for a democratic government to pursue free trade as a long-term de-velopment policy.

Theory The best-known result regarding the static effect of trade liberalization on wages is the Stolper-Samuelson (SS) theorem, or its more general version known as the price magnification effect (Jones 1965): In a two-commodity two-factor (2x2) world, a decline in the (domestic) price of imports relative to that of the exports consequent on, say, trade liberalization leads to a more than propor-tionate fall in the rate of return to the factor used intensively in the import-competing sectors and a more than proportionate increase in the rate of return to the other factor used intensively in the export sectors. Thus one factor of production is unambig-uously better off and the other unambiguously worse off in terms of their *real* returns.

Factor-intensity ranking of goods does not mat-ter, however, in a two-commodity three-factor setup of the specific-factor model, or in a 2x2 Heckscher-Ohlin (HO) model with sectorally immobile capital. The factor specific in the export sector gains unam-biguously whereas the factor specific in the import-

competing sector loses unambiguously in both absolute and real terms when trade is liberalized. The mobile factor, on the other hand, gains only when it spends a greater proportion of its income on the import-competing good than on the export good.

The impact of trade liberalization on income distribution is less clear in a many-good many-factor scenario. If goods are ranked and indexed according to the descending order of magnitude of their price changes, the price magnification effect at most tells us that there exists one factor h that is unambiguously better off and one factor k that is unambiguously worse off (Samuelson 1953). But not much can be said about changes in the rate of return to other factors of production in particular, whether they are rising or falling with trade liberalization. The natural enemy and natural friend propositions of Jones and Scheinkman (1977), however, provide us some direction in this regard. Commodity j is said to be a natural enemy (friend) of factor h if an increase in its price, all else being equal, lowers (raises more than proportionately) the rate of return to factor h. But whereas each factor has at least one natural enemy, there may not be any natural friend. The strongest resemblance of the 2x2 SS theorem can be found in Jones and Marjit (1985), which identifies for each factor a good as a natural friend and all others as natural enemies. It provides a natural sufficiency condition for the theorem in higher dimensions.

All these variants of the SS, or price magnification, effects, however, predict that opening up or multilateral liberalization of trade among nations leads to asymmetric wage movements. The wage-rental ratio should rise in the country exporting relatively labor-intensive commodities and should decline in its trading partner that exports relatively capital-intensive commodities. In a reinterpretation of capital as human capital, trade liberalization, therefore, should widen the wage gap between skilled and unskilled workers in one country and reduce it in the other. These asymmetric wage movements are due to the fact that starting from autarky the domestic prices move asymmetrically in trading nations to converge toward an intermediate equilibrium once trade opens up.

There are, however, two special cases where wages move in the same direction. First is the case of factor-intensity reversal with large difference in the factor-endowment ratios of the trading nations. Thus, for example, though the price of good X relative to that of good Y rises in one country and falls in another, since given the endowment patterns the same good X has different intensity ranking in the two countries, by the price magnification effect the wage-rental ratio (or the wage gap in a human capital reinterpretation) should move in the same direction in both the countries.

Second is the case of Metzler's paradox where deterioration of the terms of trade is so large after a tariff reduction by a home country as to raise, rather than lower, the tariff-inclusive domestic price, which can occur when the price elasticity of foreign import demand is smaller than home consumers' marginal propensity to consume the export good. With the foreign country keeping its (nonprohibitive) tariff rate unchanged, the domestic prices rise in both the countries and thereby produce symmetric wage movements.

Recent developments in theory, however, have provided us with three more *general* cases in which trade and investment liberalization can produce *symmetric* wage movements across the trading nations. In particular, as a response to the observed fact that relative wages of the unskilled have worsened all across the globe, such models bring in the trade pattern and structural characteristics of the developing world.

The first is the case of the generalized HO model with three goods but only two factors of production discussed in Marjit and Acharyya (2003) and Davis (1996). With different cones of diversification for North and South due to asymmetric endowment patterns, the middle good Y is ranked differently in two countries. Therefore, one can get symmetric movement in wages as effectively factor intensities differ. A large capital inflow from the capital-rich country to another (the host) country has the same effect, because such flows induce the host to specialize completely in the most capital-intensive good and relocate the global production of good Y entirely in the host country, thereby raising the demand for

capital (relative to labor) everywhere. In a human capital reinterpretation, therefore, the skilled-unskilled wage gap should increase in both countries in such a generalized HO setting. At the same time the framework can be used to explain asymmetric wage movements following trade liberalization among the Southern countries (Davis 1996). Whereas symmetric changes in wage inequality in both North and South follow from the *local factor intensity ranking*, the asymmetric effect across the Southern countries follows from *local factor abundance*.

The other two cases arise in the context of trade in intermediate products. Using a model with a continuum of stages of production, Feenstra and Hanson (1996) provide an interesting case in the context of the North American Free Trade Agreement and foreign investment. An inflow of U.S. capital into Mexico transfers some production activities from the United States to Mexico that are more skilled-labor-intensive in Mexico but less skilled-labor-intensive in the United States. Therefore relative demand for skilled labor increases in both countries, resulting in growing wage inequality across the border. Marjit and Acharyya (2006), on the other hand, present a more traditional production structure, with one homogeneous intermediate good being produced by skilled labor, which is then combined with skilled labor to produce the manufacturing good. This possibly captures the case of the computer industry. Some of the Southern countries such as India have emerged as phenomenal exporters of software-related products. But software sectors depend on hardware capabilities. If computers are imported from the North, a decline in the import tariff in the South must help the skilled labor in the software-processing industries in the South. But a lower tariff on hardware implies that items that are skilled-labor-intensive will be more profitable to produce in the North. This tends to increase wages for skilled labor across the globe. Marjit, Beladi, and Chakrabarti (2003), Jones and Marjit (2003), and Marjit and Kar (2005) present cases explaining how declining information costs, capital inflow, and unskilled labor outflow can lead to a rise in the relative wage of skilled labor in a developing economy.

Evidence: Developed Countries Since the late 1970s there has been a dramatic increase in the inequality of earnings based on education, experience, and occupation in the United States. The ratio of the average wage of a college graduate to that of a high school graduate rose by 15 percent. Leamer (2000) also observed a steady and persistent widening, since 1971, of the earnings gap in the manufacturing sector between college graduates and high-school dropouts. The 1994 share of salary of high-school dropouts compared with college graduates was only 15 percent of its 1971 level. For high-school graduates the situation improved during the first half of the 1970s, but after that deteriorated steadily. Similar increases in wage inequality during the 1980s and 1990s have been observed for Australia, Canada, Japan, and Europe. Between 1978 and 1988, the ratio of manual-labor to nonmanual-labor wages fell by 8.1 percent in Germany and by 3 percent in Italy whereas it actually increased in Belgium and Denmark. In the United Kingdom there was a substantial increase in the ratio of earnings of the highest to lowest percentiles.

Such a dramatic change in relative wages has triggered heated discussions and debates on the causes of these changes (Krugman 2000; Jones and Engerman 1996; Leamer 2000). Essentially, two sets of issues have become dominant in this debate: trade-related and technology-related. Though this debate is yet to be settled once and for all, to many researchers global competition has bifurcated American workers into two groups: the high-earning "symbolic analysts," whose talents are rewarded by globalization, and the mass of ordinary production workers, whose earnings are depressed by it. Similarly in the case of Europe, downward competitive pressures on working-condition standards as a result of freer trade with Eastern Europe and Asia have been conceived as the major cause of low wages. Moreover the accession of low-wage countries such as Spain, Portugal, and Greece into the European Union has worsened the scenario through relocation of firms to these countries. The relocation of the Hoover Corporation from France to Scotland in the year 1988, attracted by both lower wage costs and lower working-condition standards, is a glaring example. More recently, com-

paring merchandise trade with merchandise value added, Feenstra and Hanson (1996) have observed that, except for Australia, Japan, and the United Kingdom, all other industrial countries experienced substantial growth in trade in 1990 than in 1913.

Developing Country Experience There are quite a few systematic studies on the impact of liberal trade policies on internal distribution of wage and income in the developing world. Robbins (1995) demonstrated that while wage inequality decreased a bit in the East Asian nations, Latin America in general experienced a widening wage gap between the skilled and the unskilled after trade liberalization. Wood (1997) argued why such evidence was untenable in terms of traditional trade theoretic arguments. We have mentioned how subsequent theoretical research has used variants of standard trade models to justify double-sided wage gap outcome. A more detailed survey of the related empirical literature is available in Marjit and Acharyya (2003). Whether it is trade or technology that lies at the root of rising income inequality in the developing world is still very much an open question.

Trade and Skill Formation Globalization has meant a remarkable degree of economic integration, thanks to declining tariff walls and revolutionizing changes in information technology. There is a general tendency for the process to reward skills that tend to flourish through international trade and investment. Hence skill formation becomes the most fundamental driving force determining local as well as global patterns of income distribution. An enduring line of research will be whether trade promotes or inhibits acquisition of skills that are adaptable to changes in the global environment. Early attempts to model these are made in Marjit and Acharyya (2003) and Acemoglu (2003).

AND RAJAT ACHARYYA

■ trade costs and foreign direct investment

Foreign direct investment (FDI) takes place when a firm from one country sets up a plant or acquires a plant in another country. This entry explores the relationship between trade costs and various types of FDI, such as horizontal FDI, export-platform FDI, mergers and acquisitions, and vertical FDI. Trade costs refer to all costs incurred in getting a good from its production location to the final destination. They include transportation costs (both freight costs and time costs), policy barriers (tariffs and nontariff barriers), information costs, contract enforcement costs, costs associated with the use of different cur rencies, legal and regulatory costs, and local distri bution costs (wholesale and retail). Mirroring the literature, this entry focuses on tariffs and transpor tation costs but also discusses the impact on FDI of information costs, contract enforcement costs, and costs associated with the use of different currencies.

Horizontal FDI Horizontal FDI refers to the case where a multinational firm produces and sells its product in a foreign market. The standard frame work to study horizontal FDI is the ownership-location-internalization (OLI) framework of Dun ning (1973). It suggests that a multinational firm wanting to sell goods in a foreign market faces a choice between exporting and FDI. The key trade-off involved in this choice is between the economies of scale in production and the trading costs of shipping goods to a foreign market, known as the proximity-concentration trade-off. While economies of scale in production favor exporting to the foreign market from the home production facility, a high trading

cost of exporting to the foreign market favors FDI. The implication is that, for a given level of economies of scale, the higher the trading cost the greater the likelihood of FDI occurring. FDI in this framework acts as a substitute for trade, that is, increased FDI involves decreased exports. Brainard (1997) provides empirical support for this finding using data on U.S. multinationals: local production by the affiliates of U.S. multinationals relative to exports from the U.S. parent increases the higher the transport costs and trade barriers and the lower the plant level economies of scale.

Licensing versus Horizontal FDI While the proximity-concentration trade-off framework focuses on the choice between exports and FDI, in the OLI framework, once a multinational firm decides to produce the good locally rather than export it from its home production facility, it faces a choice between licensing the technology to a local firm and undertaking FDI. Since licensing involves arm's length transaction between two independent parties, contracting issues become important. The licensor and the licensee have different sets of information, which gives rise to the standard asymmetric information problem. For example, the licensee has a better idea about the local market conditions, while the licensor knows more about the technology. Neither party has an incentive to reveal its private information to the other party, and the acquisition of more information is costly for each party. In addition, the writing of a contract and its enforcement are costly as well. Therefore, the choice between licensing and FDI depends on these contracting costs. If these costs are high then there are internalization advantages, that is, a firm prefers to keep production internal by undertaking FDI rather than licensing its technology to a local firm. Therefore, while trade costs in the form of tariffs and transportation costs affect the location choice of production, costs arising due to informational asymmetry and contract enforcement determine the choice between production within the firm boundary (FDI) and licensing. All other things being equal, a reduction in the costs of information and contract enforcement would lead to more licensing and less FDI.

The proximity-concentration trade-off framework implies that a decrease in tariffs and transportation cost would reduce FDI, but this prediction is not borne out by the recent experience of European Union (EU) countries, where trade liberalization has been accompanied by increased FDI. One must consider other types of horizontal FDI (and other types of FDI) that could increase with trade liberalization.

Export-Platform FDI If two countries A and B preferentially liberalize trade with each other while keeping the trade barriers on the rest of the world intact, then the firms in a third country C will have an incentive to set up a plant in either country A or B and sell in both those markets from its single production facility. In this case, FDI by firms from country C into country A or B is not just meant for local sales but also serves as its export platform for sales to the other country. Ranjan (2006) shows that preferential trading agreements can create new investment as well as divert investment from nonmembers to members, thereby increasing FDI in the member countries. Ekholm, Forslid, and Markusen (2007) show that a free trade agreement between a high-cost and a low-cost country generates an incentive to an outside high-cost country to set up a plant in the low-cost country within the free trade area. Therefore, mutual trade liberalization within a group of countries can attract FDI into the group from outside countries.

Mergers and Acquisitions A multinational firm building a new plant in a foreign country is called a greenfield FDI, while if instead it acquires an existing plant, then it is classified under mergers and acquisitions (M&A). There is evidence from UNCTAD (2000) that a large amount of FDI is in the form of M&A rather than greenfield. M&As take place for both efficiency and strategic reasons. Efficiency gains come from the fact that a multinational firm may be able to produce at a lower cost by acquiring an existing firm rather than setting up a new plant. Strategic gains from acquiring an existing firm stem from the possibility that profits may increase due to a reduction in the number of firms in the market.

Focusing solely on strategic issues, Neary (2007) shows that a decrease in trade costs may increase the

incentive for M&A. To see the intuition behind this result, suppose there are two countries, Home and Foreign, with oligopolistic market structures. In the case of free trade, only low-cost firms in each country survive. In the presence of high trade costs, relatively higher-cost domestic firms also survive because foreign firms have to bear the trade cost in addition to their production cost. A move from autarky to free trade would make many high-cost domestic firms in each country unviable, leading to M&A.

This result can be shown to hold for incremental trade liberalization as follows. Suppose a Foreign firm is contemplating acquiring a Home firm. Trade liberalization increases the Home firm's profits on its initial exports, which makes it a more expensive takeover target, thereby making cross-border M&As less likely. However, trade liberalization also increases the Foreign firm's profits from exporting and reduces both firms' profits in their home markets, both of which make cross-border M&As more likely. In the neighborhood of autarky, the first effect does not arise. Therefore starting from a high level of trade barriers, a small amount of trade liberalization raises the possibility of cross-border M&As.

Thus both export-platform FDI and M&A type FDI could potentially explain increased FDI in the EU countries concomitant with trade liberalization. However, there is another possible explanation: this result could also arise if FDI is of the vertical type.

Vertical FDI Vertical FDI refers to the case when a multinational firm breaks its production process into parts and carries out different parts in different countries. A standard modeling approach is to divide the production process into two stages: headquarters stage and production stage where the former is carried in the home country while the latter is carried in a foreign country. The motivation for fragmentation of production comes from differential factor intensity of different stages of production and differences in factor prices. In the presence of differences in factor prices, minimizing cost requires each stage of production be undertaken in the country where the cost of doing so is the lowest. With vertical FDI, the goods produced in a foreign country have to be sent back to the parent country and hence are subject to

the trading cost. Therefore there is a trade-off between a lower cost of production in a foreign country and a trading cost of shipping these goods back to the parent country. In this framework, higher trading costs in the form of tariffs and transportation cost would discourage FDI. Therefore while horizontal FDI is encouraged by high tariffs and transportation cost, vertical FDI is discouraged by it. Consequently EU trade liberalization could generate increased FDI of the vertical type.

Outsourcing versus Vertical FDI Even if it is cheaper to conduct a part of the production process in a foreign country because of lower costs of production, the question remains as to whether this activity should be done within the firm boundary (FDI) or at arm's length (outsourcing). Analogous to the choice between licensing and FDI for a horizontal multinational, a recent literature has emerged that focuses on the choice between outsourcing and FDI for a vertical multinational. The key determinant of this choice again is the cost due to informational asymmetry and contract enforcement. In general, a high contracting cost makes FDI more attractive compared with outsourcing (see Helpman 2006 for a recent survey of this literature). Therefore, while a reduction in tariffs and transportation cost increases vertical FDI, a decrease in contracting cost favors outsourcing over FDI.

Other Trade Costs and FDI In addition to the types of trade costs discussed earlier, there are several other trading costs that affect both horizontal and vertical FDI. A legal system protecting the property rights of foreign investors reduces the risk of expropriation and hence encourages foreign investment. A strong intellectual property rights regime on the other hand may reduce FDI and increase licensing or outsourcing by reducing opportunistic behavior in arm's length transaction.

Another type of trade cost that could affect FDI is the cost associated with exchange rate volatility. Since multinational firms repatriate their profits from their activities in the host countries to their home countries, exchange rate fluctuations affect their profits in their home currency. Theoretical work on the relationship between exchange rate volatility and FDI

identifies offsetting effects. On the one hand, volatility increases the value of having production facilities in both the home country and the host country, allowing a multinational firm to shift production between the two plants depending on input costs. On the other hand, since FDI involves sunk costs to be incurred in the currency of the host country, greater volatility in exchange rate increases the option value of waiting for a multinational firm leading to reduced FDI. There is empirical evidence showing that exchange rate volatility reduces entry by multinational firms contemplating investment in the United States.

Policy Implications To the extent that FDI raises welfare in the host country, there would be scope for intervention to attract FDI. However, as discussed above, the relationship between trade costs and FDI is not straightforward. It depends on the type of trade cost and the type of FDI. While high tariffs and transportation cost may promote horizontal FDI of some types, they may discourage export-platform FDI and FDI through M&As. There is evidence of tariff-jumping FDI by Japanese firms in the automobile sector in the United States in the 1980s in response to a threat of higher tariffs. However, threatening a higher tariff to attract FDI is questionable strategy.

Tariffs and transportation cost usually reduce vertical FDI. If the good is assembled in the host country by a multinational subsidiary and sent back to the parent, then a higher tariff in the parent country will discourage this type of FDI. In this case, a higher tariff in the host country will also discourage FDI because usually some inputs are shipped from the parent country to the host country for assembly or further processing. If these inputs incur tariffs, then FDI would be discouraged. Therefore in the case of vertical FDI the policy implication would be for the host country to reduce tariffs to encourage FDI.

High contracting costs promote FDI at the expense of licensing in the horizontal case and at the expense of outsourcing in the vertical case. Therefore a reduction in the contracting cost is likely to reduce FDI and increase licensing and outsourcing. However, one should not jump to any policy conclusions here, because it is not clear whether FDI leads to greater welfare gains compared with licensing or outsourcing.

More important, the welfare implications of a policy of increasing trading cost to attract FDI is ambiguous even if FDI is welfare improving because an increase in trading cost has a direct negative effect on welfare that must be offset by the indirect positive effect arising from increased FDI.

In sum, the relationship between trade costs and FDI depends on the nature of FDI. Any view that trade costs always promote FDI is simplistic as it does not hold true for vertical FDI or even all types of horizontal FDI.

■ trade facilitation

The expansion of world trade in the late 20th and early 21st centuries has been driven, in large part, by the changing nature of production and increased competition in international commerce. Another important factor has been the periodic rounds of successful multilateral trade negotiations. Talks at the World Trade Organization (WTO) have led to a considerable reduction in tariffs on goods crossing national borders. As the role of traditional trade barriers gradually vanishes, the focus of trade policy has shifted to lowering the remaining nontariff barriers to trade, including trade facilitation.

Trade facilitation involves a wide range of activities centered on lowering trade transaction costs for firms in global commerce. These costs include the price of moving freight from the factory to final destinations. Firms must manage border clearance procedures and pay trade services fees, among many other steps after goods and services are produced. As such, trade facilitation involves much more than trucking goods across national borders or shipping a package by sea transport.

Since trade facilitation can encompass a wide variety of measures, there is no single definition of the term. One might distinguish, however, between trade facilitation in a narrow or broad context.

Multilateral trade rules reflected in the three GATT articles V (freedom of transit), VIII (fees and formalities), and X (publication and administration of trade regulation) constitute a relatively narrow definition of trade facilitation. These articles call on WTO members to harmonize and simplify procedures related to the international exchange of goods and services.

Modern commerce involves a much broader scope of activities affecting trade facilitation not directly covered by WTO rules. This includes domestic policies, such as sanitary and phytosanitary standards, regulation of services, and use of information technology to lower trade costs. This wider definition takes into consideration the fact that "inside-the-border" issues such as the transparency of domestic regulations, institutional policies on foreign ownership of companies, and legal frameworks all affect a country's investment climate and transaction costs. In addition, the potential for efficiency savings due to electronic transmission of trade documentation and automation of customs operations suggest that global information technology infrastructure also drives trade facilitation.

The policy focus on these issues reflects the fact that trade can be a powerful engine for accelerating economic growth, job creation, and poverty reduction. Success in export markets for developed and developing country firms, therefore, is increasingly affected by the ability of countries to support an environment that promotes efficient and low-cost trade services and logistics.

Cross-Country Comparisons and Performance There is an increasing body of empirical evidence about the impact of trade facilitation on export competitiveness and growth. Studies reviewed by the Organisation for Economic Co-operation and Development (OECD 2002) indicate that trade transactions costs can amount to as much as 15 percent of the value of traded goods globally. A subsequent OECD study (2003) found trade transactions costs to be higher on agricultural and food products, fish, and forest and wood products (since these products are subject to additional border procedures due to sanitary and phytosanitary requirements). These are

products for which many developing countries have an advantage. The same study also reported that small and medium-size enterprises suffer most from poor trade-related practices and poorer developing countries have a larger share of such enterprises. A number of other studies have illustrated the specifics of why trade facilitation matters and specific sources of trade costs. One study, for example, found that barriers to export performance in Africa are closely related to firm characteristics and policies that raise trade costs. This includes nontransparent customs laws and administration. Much less evidence, in comparison, was found that transportation infrastructure had a significant impact on export performance (Clarke 2005).

The World Bank's *Doing Business* report (2007) documents the wide range of reform needed in developing countries to lower trade costs. The report outlines procedural requirements for importing and exporting a standardized cargo of goods in 155 countries. While the total cost to import (in U.S. dollars per container) was $842 on average in high-income countries, it was $1,960 in low-income countries. Typical regulations in low-income countries required 13 documents from domestic regulatory agencies, as compared with 6 signatures in high-income, 9 in upper-middle-income, and 10 in lower-middle-income countries. On average it still costs almost two and a half times in expenses and requires more than twice as many documents and four times as many signatures to trade in a poor country as it does in rich countries.

The *Doing Business* report also provides concrete examples of efficiency savings made possible through trade facilitation reforms. Much of these relate to addressing regulatory reform and other steps that in contrast to hard infrastructure constitute the major part of why engaging in trade takes longer in developing countries. Progress in reducing costs, however, has been made. For example, Guatemala with the support of the Inter-American Development Bank changed to an electronic system for export authorization in 2000. Within four years the time for authorization of export documents dropped from one day to around three minutes. Tunisia has also introduced an automated system that provides a one-stop trade documentation-processing platform. Due to this innovation the processing time for trade documentation was reduced from 18 to 7 days, which probably has led to substantial productivity gains according to the United Nations Economic Commission for Africa.

The Gains to Trade from Cutting Costs and Red Tape What about the gains to trade with an ambitious reform agenda? There are important gains to lowering trade costs and facilitating trade with some variation across countries and sectors (Francois et al. 2005; OECD 2003). Several studies have focused on the impact of trade facilitation on the microlevel (e.g., Nomura Research Institute 2004; Keen 2003; OECD 2005). They observe that in some developing countries inefficient trade regulations, documents, and procedures are hindering firms' participation in export markets. The studies find large potential benefits from streamlining trade regulations and hence cutting the costs of exporting.

Analysis by the World Bank suggests that raising global capacity in trade facilitation (port efficiency, customs, regulatory transparency, and information technology used in trade transactions) halfway to the global average would increase world trade by $377 billion (Wilson et al. 2005). This is an increase of about 9.7 percent in global trade with the majority of the gains due to domestic reform and capacity building. About $107 billion of the total gain comes from the improvement in port efficiency and about $33 billion results from the improvement in customs environment. The gain from the improvement in regulatory environment is $83 billion. The largest gain ($154 billion) comes from an improvement in information technology infrastructure, which is increasingly applied all across the trade value and logistics chain. The important work ahead to lower trade costs, however, is outside the scope of trade policy and squarely centered within domestic reform agendas, including transportation, telecommunications, and other services that affect trade transactions costs. There is also a key role to be played by private sector led policy reform.

Moving Ahead: Cutting Trade Costs Talks on revisions to the WTO rules on trade facilitation continued on the agenda in the Doha Development Agenda negotiations at the end of 2007. The outlines of a possible agreement included, among other provisions: (1) new obligations to promote electronic distribution and transmission of government trade regulations on imports and exports, (2) standardization of certain basic fees for imports, and (3) stronger rules to help ensure freedom of transit for goods crossing national borders. The WTO Secretariat tabulation of proposals from August 11, 2006, includes consideration of more ambitious changes to current obligations, such as establishment of a single window for exporters and importers at customs or accepting copies of documents for import and export in lieu of originals. Since 2002 there have also been talks about explicit ties between a package of technical assistance and development aid as part of any final agreement. Developing countries participated very actively in these negotiations and before the suspension of the Doha Round in late 2006 considerable progress had been achieved (World Bank 2006; Neufeld 2007).

Changes to the multilateral trade rules noted above can help in advancing transparent and predictable trading procedures for exporters. These rules have not been revised in more than 50 years, and crafting an achievable and focused next step in the Doha Agenda will be helpful to traders. This is especially true for small and medium-sized firms that lack resources and networks to overcome some of the more complex border rules now in place. Meeting trade facilitation goals in a broader and deeper context, however, will require action well outside and beyond the WTO framework. More effective delivery of development aid and technical assistance especially in projects to advance regulatory reform and support public agencies that promulgate and administer trade regulations is needed. A better understanding is required of conditions under which developing countries are ready to receive such assistance so that aid is effectively delivered.

The Agenda Ahead At the most basic level, better data, analysis, and indicators of performance are needed to inform discussions moving forward on how trade costs and facilitation measures affect global commerce. Progress in reaching development goals in trade can be made only with accurate data and analysis to drive policy choice and action. Taking advantage of the energy behind reaching the Millennium Development Goals (MDGs) and building on the data sets in the Global Monitoring Reports, which track progress in reaching poverty reduction goals, among other reports, makes significant sense. In sum, the data gathered to date illustrate the fact that the nontariff agenda in trade is increasingly important to economic development.

JOHN S. WILSON

■ trade in services

Since the conventional definition of trade where a product crosses the frontier would miss out on a whole range of international services transactions, it is now customary to take a broad view of ser vices trade to include all modes of conducting in ternational transactions. Services trade, according to this wide definition, is an increasingly important part of global commerce. Advances in information and telecommunication technologies have expanded the scope of services that can be traded across borders, from accounting to education. Many countries now allow foreign investment in newly privatized and competitive markets for services, such as tele communications, transportation, and finance. More and more people are traveling abroad to con sume tourism, education, and medical services, and to supply services ranging from construction to software development.

The Emerging Pattern of Trade Rigorous anal ysis of patterns of trade in services has been inhibited by the paucity of data. The only services trade sta tistics available on a global basis are the International Monetary Fund's balance of payments (BOP) sta tistics, which register transactions between residents and nonresidents. These statistics suggest that ser vices have been among the fastest growing compo nents of world trade, growing by more than 15 per cent per year since 1980. The value of global services exports is now close to $3 trillion, representing more than one-fifth of aggregate world trade in goods and services. This value is certainly understated, because it does not include sales through an established presence, that is, via FDI and by individuals who stay longer than a year, both of which are treated as resi dents by the BOP statistics. Today more than half of annual world FDI flows are in services, and the value

of sales abroad by foreign affiliates of U.S. service firms is estimated to be 3.5 times greater than their cross-border exports.

The United States and the European Union lead the world in a broad spectrum of services trade telecommunications, transportation, finance, retail trade, and a range of business services. Together they account for more than 60 percent of world services exports. China and India jointly account for only 3 percent. But several developing countries are emerging as the most dynamic services exporters. Over the last decade, while the exports of the United States have grown at around 10 percent per year, the exports of countries such as India, China, and Brazil have grown at rates well above 15 percent per year. Some developing countries are even beginning to invest abroad to provide services for example, Malaysia in environmental services, South Africa in telecommunications and retail, and India in software but many more are supplying services via cross-border sales (e.g., data processing), tourism services for visiting foreign consumers, and the movement abroad of individual services providers (e.g., professional services or construction workers).

What Determines the Pattern of Services Trade? The two major explanations for trade between countries, comparative advantage and gains from specialization arising from increasing returns to scale or agglomeration effects, are equally relevant to services trade. Moreover both explanations apply not only to cross-border trade but also to other modes of trade, including commercial presence and the movement of people. Examples of trade based on comparative advantage include call centers in India that provide customer contact services for U.S. firms; nannies from the Philippines who move to Canada temporarily to provide child care services; and Europeans who travel to Peru for a week in the jungle as part of an ecotourism package. The trade in both child care and call center services is driven by differences in labor costs across countries; and the Amazon has unique attributes that are not available at home to the European tourists.

Although differences between countries are one of the major explanations for services trade, particularly between countries with very different income levels, they cannot account for all trade. Much of the world's trade occurs between high-income countries, and much of the trade between similar countries is in similar services. For example, European banks operate in the United States and U.S. banks in Europe. Canadian engineers work on projects in the United States, and U.S. engineers work on projects in Canada. A labor market example helps explain how services trade can emerge between similar countries. Two students starting university are equally bright and talented. At this point their productive capacities may seem indistinguishable. However, suppose one chooses to study medicine and the other chooses to study engineering. If we revisit these same students 10 years later, they will have very different skills and they can trade with each other via the labor market, with the doctor selling medical services and the engineer selling engineering services. This example illustrates the genesis of a large part of trade today in services ranging from finance and communications to transport and education all services where there are large economies of scale and consumers desire variety.

What Restricts Services Trade? In spite of recent liberalization, services trade still tends to be quite restricted. First, many types of services were publicly provided and a significant number continue to be produced by state-owned or regulated monopolies. The traditional rationale was the existence of natural monopoly in services such as telecommunications and transportation, and a social concern for equitable access in services such as health care and education. Second, entry and operation in a range of services, from financial to professional, are regulated on the grounds that it is particularly difficult for consumers to judge the quality of these "invisible" services before they are consumed.

In contrast to goods, relatively few services are subject to simple discriminatory taxes on trade. Instead barriers to trade in services arise from domestic regulations that often serve the dual purpose of responding to market failures (such as ensuring quality standards for medical practitioners) and protecting

local suppliers from foreign competition. This means that identifying and measuring trade barriers in the service sector is very complex. It also means that simple rules for trade liberalization that have worked for goods trade (such as reducing all tariffs by 30 percent) are not available as an option for service trade liberalization. Instead service trade liberalization is organized around the notion of nondiscrimination and is often linked with domestic regulatory reform.

Even though tariffs are rare, quotas are pervasive. On cross-border trade, they are most evident in the transportation sectors. Foreign providers are either completely shut out of certain segments, such as cabotage (i.e., transport between locations within a country), or only provided limited access, as in international transportation. On commercial presence, quotas are imposed on the number of foreign suppliers who are allowed to enter sectors such as telecommunications and banking, or on the extent of foreign ownership in individual enterprises. Quotas are most stringent in the case of movement of service-providing personnel and affect trade not only in professional services but also in a variety of labor-intensive services.

What Are the Consequences of Liberalization?
Economic theory suggests that a country gains from the import of services, irrespective of the mode of transaction, if the terms at which international transactions take place are more favorable than those available on the domestic market. The limited empirical evidence suggests that liberalization of trade in services, accompanied by the reform of complementary policies, can produce substantial gains.

Removing barriers to trade in services in a particular sector is likely to lead to lower prices, improved quality, and greater variety. As in the case of trade in goods, restrictions on trade in services reduce welfare because they create a wedge between domestic and foreign prices, leading to a loss to consumers that is greater than the increase in producer surplus and government revenue. Furthermore, since many services are inputs into production, the inefficient supply of such services prevents the realization

of significant gains in productivity for downstream firms. As countries reduce tariffs and other barriers to trade in goods, effective rates of protection for manufacturing industries may become negative if they continue to be confronted with input prices that are higher than they would be if services markets were competitive.

Several empirical studies provide evidence of gains (reviewed in Deardorff and Stern 2007). Estimates of benefits vary for individual countries depending on the initial levels of protection and the assumed reduction in barriers. Developed countries tend to gain more in absolute terms — which is not surprising given the relative size of their economies — but developing countries also see significant increases in their gross domestic product (GDP). One model predicts gains of between 1.6 percent of GDP (for India) to 4.2 percent of GDP (for Thailand) if tariff equivalents of protection were cut by one-third in all countries. The gains from liberalizing services are usually estimated to be substantially greater than those from liberalizing trade in goods, because current levels of protection are higher and because liberalization would also create spillover benefits from the required movement of capital and labor. Finally there is also some evidence — relatively strong for the financial sector and less strong but nevertheless statistically significant for the telecommunications sector — that openness in services significantly influences long-run growth performance.

These results are particularly striking because they are derived from models that do not fully allow for the temporary movement of individual service suppliers — potentially a major source of gain. Such movement offers arguably the neatest solution to the dilemma of how international migration is best managed, enabling the realization of gains from trade while averting social and political costs in host countries and brain drain from poor countries. Recent research finds that if members of the Organisation for Economic Co-operation and Development (OECD) were to allow temporary access to foreign services providers equal to just 3 percent of their labor force, the global gains would be more than $150 billion — more than the gains

from the complete liberalization of all trade in goods (Winters et al. 2003). Both developed and developing countries would share in these gains, and they would be largest if both high-skilled mobility and low-skilled mobility were permitted.

How Is Liberalization Best Implemented? It would be wrong to infer that these gains can be realized by a mechanical opening up of services markets. A flawed reform program can undermine the benefits of liberalization.

For example, if privatization of state monopolies is conducted without concern to creating conditions of competition, the result may be merely transfers of monopoly rents to private owners (possibly foreigners). Similarly, if increased entry into financial sectors is not accompanied by adequate prudential supervision and full competition, the result may be insider lending and poor investment decisions. Also, if policies to ensure universal service are not put in place, liberalization need not improve access to essential services for the poor. Managing reforms of services markets therefore requires integrating trade opening with a careful combination of competition and regulation.

Sustaining openness may also require action to alleviate adjustment costs, even though the available evidence suggests that openness to services trade has not hurt overall employment. For example, in the United States, which in recent years has seen a significant growth in services outsourcing, private employment in services has actually expanded (in contrast to manufacturing) by more than a million jobs. The structure of employment has changed but more because of new technology than trade. Between 1999 and 2003, it is estimated that in the United States more than 70,000 computer programmers lost their jobs, whereas more than 115,000 higher-paid computer software engineers obtained jobs (Kirkegaard 2004). As in the case of goods trade, assisting dislocated workers is imperative if the gains from new trade opportunities and technological progress are to be widely shared. But this assistance is best provided through improved income support, retraining, and health insurance, rather than through restrictions on technology and trade.

To conclude, services trade continues to grow rapidly thanks to technological change and policy reform. Industrial countries dominate international transactions, but several developing countries are among the most dynamic participants. Trade has already produced significant benefits but the potential gains are even larger. There is a strong economic case for eliminating remaining barriers to trade, in particular the restrictions on foreign investment and temporary migration. But successful liberalization needs complementary policy action to improve the regulatory environment, to alleviate adjustment costs, and to ensure that the benefits of openness are widely shared.

■ Trade Policy Review Mechanism

The Trade Policy Review Mechanism (TPRM) involves periodic reviews of the trade and trade-related policies, practices, and measures of each member of the World Trade Organization (WTO). The reviews take place in the WTO's Trade Policy Review Body (TPRB), a senior body composed of representatives of all WTO members. The WTO's four largest trading entities (the United States, the European Community, China, and Japan) are reviewed every two years; the next sixteen are reviewed every four years; and other members are reviewed every six years, although a longer period may be allowed for least-developed countries. Each review is based on a report prepared by the member(s) under review and on a report drawn up by the WTO Secretariat, in its Trade Policies Review Division (TPRD), on its own responsibility. Both reports are published.

The TPRM's objective is to achieve greater transparency in, and understanding of, members' trade policies, practices, and measures. It permits the evaluation of trade and related policies and measures, including those that do not necessarily contravene, or indeed are not subject to, WTO obligations.

Transparency entails four key elements: (1) a description of the nature of policies and measures; (2) their rationale or objectives; (3) their costs (in terms of expenditures or taxes forgone); and (4) an economic evaluation of their effectiveness of policies and measures (relative to alternatives) in achieving their objectives. Accordingly, the TPRM enables the regular collective appreciation and economic evaluation of a full range of individual members' trade policies and practices, their consistency with the broad principles of nondiscrimination and predictability that underlie the WTO, and their impact on the functioning of the multilateral trading system.

By reviewing broad macroeconomic and structural policies, trade policy reviews (TPRs) attempt to place trade and trade-related policies in their broader policy setting, thereby assessing the coherence of these policies in achieving their objectives. In this regard, TPRs are being seen increasingly by many countries as a useful form of technical assistance.

The TPRM is not intended to serve as a basis for the enforcement of obligations under WTO agreements or for dispute-settlement purposes. Nor is it intended to impose new rules on members. Rather, one purpose is to contribute, essentially by moral suasion, to improved adherence by all members to disciplines and commitments agreed to under the WTO and thus to a smoother functioning of the multilateral trading system.

Trends and Lessons from Reviews Reviews conducted since the establishment of the TPRM have brought to light the benefits countries have obtained through their integration into the world trading system, while also highlighting the difficulties encountered by many (often developing) countries in this process. By and large, countries have become integrated in the world economy through unilateral measures and the multilateral trading system rather than through initiatives they have taken in regional agreements. Thus in numerous countries, developed and developing alike, unilateral liberalization of trade and investment policies, as well as deregulation programs, have taken place. Such reforms are often part of comprehensive integrated policy packages that include macroeconomic and other structural reform measures.

More generally, the reviews have shown that in most trade regimes tariffs have largely replaced quantitative restrictions and other nontariff measures as the main form of protection, although the process remains incomplete in some cases. Many tariff structures have been or are being rationalized and average tariffs have been reduced.

Although there have been reversals of trade liberalization in some countries (in the form of tariff increases, new surcharges on imports, or the re-imposition of quantitative restrictions), in most cases these setbacks have been limited, rarely offsetting the earlier liberalization measures. The reviews have also shown that, in general, the experience in trade reform in less-developed countries has lagged behind that of developing countries.

Members that have undergone a review have repeatedly testified to the value of the experience for the development of their own trade policies. Past experience shows that through a review members engage in a process of self-examination in which they reflect both on their own policies and on their participation in the multilateral trading system and their engagement with the WTO. Many countries have started internal reviews of their trade policies on a yearly basis.

Inconsistencies identified in trade regimes have made members more aware of the necessity of having consistent trade policies, formulated and implemented at national levels, with the involvement of all the relevant departments. Thus in the process of reviews, members also increase their awareness of the economic role of customs tariffs, broadening their perception of tariffs as a fiscal policy instrument only. Many countries have also been led, in consequence of their reviews, to take steps to address some of the concerns likely to be expressed by other WTO members; as a result many, particularly less-developed, countries have improved compliance to their WTO commitments in areas such as notification. Throughout the process, members develop confidence in the TPRD professionals involved in their reviews and use them as de facto inquiry/focal points on WTO issues. More generally, the reviews help build knowledge in, and understanding of, the WTO. Also,

members that are in a process of trade policy reform have an opportunity to present the challenges, the process, and its results to a world audience. Discussions take place in the TPRD and with WTO economists that encourage trade policymaking to take directions foreseen in the WTO agreements and contribute to a member's greater integration into the multilateral trading system. In this context countries are provided with a framework for the formulation, implementation, and assessment of their trade policies and with an instrument to facilitate interministerial consultations for these purposes. The TPRM now also increasingly undertakes group reviews, for example of the Southern African Customs Union, the East African Community, and the Organization of East Caribbean States. This can foster regional integration that complements the WTO system.

Reviews also allow future technical-assistance priorities to be identified more clearly. In this respect, each Secretariat report for a review of a less-developed country now includes a section on capacity-building and technical-assistance needs; there is now also close cooperation with the WTO's Institute for Training and Technical Cooperation such that a needs assessment can be established and elaborated in the member's own report. The needs are invariably discussed during the review and have subsequently often been endorsed by the TPRB, thus forming the basis for a well-articulated future program of technical-assistance activities. In this context also, the process of reviewing less-developed countries now responds more systematically to technical-assistance needs. The review process for a less-developed country, and indeed for many developing countries, includes a two- to three-day seminar for its officials on the WTO and, in particular, the trade policy review exercise and the role of trade in economic policy.

Coverage of the TPRM Table 1 provides a list of WTO members reviewed in the period 1989 2007. In all, the TPRM conducted 248 reviews by the end of 2007. Increasing emphasis is given to less-developed countries, both because such members ask for reviews as an important element in their own

Notes:

( ) = Number of reviews completed where this is greater than one.

Reviews conducted at end 2007 = 248.

WTO members reviewed = 133 out of 151 members.

Least developed WTO members reviewed = 27.

Share of world trade of WTO members reviewed (excluding significant double counting and intra EC trade) = around 97%.

[a]First review in 2007.

[b]Least developed member.

[c]Now included in European Communities (EC).

[d]Joint review with Switzerland (counted as two members, but one review for statistical purposes).

[e]Reviewed as member of the Southern African Customs Union (counted as five members, but one review).

[f]Reviewed as a member of the Organization of East Caribbean States (counted as six members, but one review).

[g]Reviewed as a member of the East African Community (counted as three members, but one review).

[h]Joint Review (two members, but one review for statistical purposes).

policymaking process and because the membership sees these reviews as essential to coming to a better understanding of the challenges that these members face and of how to respond to them.

WTO members have twice appraised the operation of the TPRM. In reports to WTO Ministerial Conferences they concluded that the mechanism, as the only multilateral, comprehensive evaluation of trade policies, functioned effectively, demonstrated a valuable public-good aspect, was a vehicle for members to reflect on their policies, served as an input into policy formulation, and highlighted general technical-assistance needs.

■ trade-related capacity building

Trade-related capacity building (TRCB) helps developing and transition economies to benefit from trade liberalization and a growing volume of trade opportunities. The underlying philosophy of this form of foreign aid is based on the conviction that trade positively affects economic development and provides domestic clients access to a greater variety of goods and services at lower prices. The aim of TRCB is to improve information flow, skills, relationships, institutional arrangements, and infrastructure, which affect a developing country's trade performance. This form of development aid enhances organizational and human capital through training, conducting research and consultancy projects, learning-by-doing, networking, and establishment of appropriate facilities. It aims at improving the beneficiary country's export performance (including widening its range of exports and selling in a greater number of markets), attracting foreign investment to create jobs and trade, and ensuring that the country benefits from the institutions of international trade, especially the World Trade Organization (WTO).

Depending on the area covered, two types of TRCB may be distinguished: (1) capacity building addressing trade policy issues and (2) capacity building in the area of trade promotion. The latter aims at improving the international business performance of the beneficiary country's firms and trade support institutions. The former focused on trade policy and trade-related policy issues develops know-how, networks, and institutions with the objective of optimizing the beneficiary country's policies and procedures, as well as implementation and control.

Capacity building aimed at business promotion may be seen as a value chain disaggregated into two types of strategically relevant activities: (1) primary activities, which are essentially marketing related, and (2) support activities, which provide the inputs needed for primary activities to occur. Primary activities relate to export market analysis, quality improvement of export products, transfer of technology and management skills, partner search, institution building in the area of trade and foreign direct in-

vestment support institutions, and improvements in the performance of trade infrastructure. The support activities comprise the maintenance of business data networks; organization of seminars, workshops, and corporate internships; publication of the relevant training material; execution of business consulting projects; organization of buyer-seller meetings, fairs, and expositions; and the like.

The nature and scope of TRCB have been evolving in response to the larger issue coverage of the trading system, increased participation of developing countries in the WTO and regional trade agreements, increased focus on market orientation and governance, and greater complexity of trade rules and procedures. Government administration in developing economies has been particularly affected by these developments. In addition there has been a clear tendency in the developing world toward a proactive involvement in trade negotiations and an increased role of advocacy in domestic and international decision making. In such an environment, it has been widely felt that the relevant institutions are weak and qualified personnel not easily available. Especially in least-developed countries (LDCs), the complex WTO procedures and requirements necessitated institutional capacities and budgetary resources that could not be provided, and TRCB was needed to reduce the transaction costs of integration into the global market. There was also a growing need for TRCB in trade promotion resulting from the desire to intensify the role of markets and the private sector, and a growing international orientation in development strategies. International rules are meaningless if they are not used, and the rules' real users   the business firms   need managerial capacities and support by trade-facilitation agencies, chambers of commerce, and business associations in order to compete in global markets.

Actors in the TRCB process include donors and beneficiaries, providers, policymakers, numerous government departments and specialized development agencies, the business community, nongovernmental organizations (NGOs), and academia. Considerable resources are donated to multilateral, regional, and bilateral TRCB activities. The budget

of the TRCB projects of the U.S. Agency for International Development (USAID) alone   the leading supporter of TRCB   was close to US $700 million in fiscal year 2005, and it is estimated that more than US $2 billion per annum were spent on TRCB in the first years of this millennium. The other major donors include the European Union (EU) and the EU member states, such as the United Kingdom, Germany, and France, the Scandinavian countries, and Japan, Canada, and Australia. (A TRCB database established by the WTO jointly with the Organisation for Economic Co-operation and Development provides detailed information on TRCB projects.)

Most donors channel their support through governmental institutions (multilateral, regional, and national), NGOs, academia, or private firms. Among the beneficiaries are government departments and agencies, educational units, business associations, prioritized business firms, and other members of civil society. Among the leading providers of TRCB at the multilateral level are the World Bank and the International Monetary Fund (IMF), the WTO Secretariat, the United Nations Conference for Trade and Development (UNCTAD), the United Nations Development Program, the International Trade Center (ITC), and the World Intellectual Property Organization (WIPO). The WTO's assistance puts emphasis on trade policy rules, procedures, and rights and obligations of the WTO member states. The TRCB projects implemented by the World Bank, IMF, and UNCTAD emphasize the policy outcome and analysis of trade issues in the larger macroeconomic context. The ITC activities in TRCB are focused on issues of interest to the private sector, and WIPO concentrates on trade-related aspects of intellectual property. Regional governmental organizations conducting TRCB include the Organisation for Economic Co-operation and Development, the Asia Development Bank, the Secretariat of the Asia-Pacific Economic Cooperation (APEC) Forum, and so on.

At the national level many donor countries distinguish between the government departments in charge of formulating international development policies and the government-sponsored

implementing organizations. The former comprise ministries such as the Department for International Development in the United Kingdom, the Federal Ministry for Economic Cooperation and Development (Bundesministerium für Wirtschaftliche Zusammenarbeit und Entwicklung) in Germany, the Ministry of Foreign Affairs in Japan, and the Department for International Cooperation and Development (Coopération internationale et développement) in France. Among the national providers, the leading agencies include USAID (an independent federal government agency that receives overall foreign policy guidance from the Secretary of State), the Canadian International Development Agency, Deutsche Gesellschaft für Technische Zusammenarbeit GmbH, the Japan International Cooperation Agency, Le Groupe de l'Agence française de développement in France, and the Australian Agency for International Development.

The nongovernmental or mixed government/ private providers include a wide range of institutions such as the International Center for Trade and Sustainable Development (ICTSD), the Agency for International Trade Information and Cooperation, the North-South Institute, and the Center for Trade Policy and Law. An example of a nonprofit organization building trade law capacity in southern Africa is the Trade Law Centre for Southern Africa. The World Trade Institute, a joint venture between the University of Bern and the University of Neuchâtel in Switzerland, is a good example of another academic institution involved in TRCB with a special focus on international trade law. The role of such organizations is gaining importance with growing attention being paid to local ownership, efficiency, and diversity of TRCB services.

The lack of cooperation or coordination between the various providers is often quoted as one of the weaknesses of capacity building. Efforts for improvement included the launching of multiagency programs such as the Integrated Framework for Trade-Related Technical Assistance Programs to LDCs and the Joint Integrated Technical Assistance Program to selected LDCs and other African countries jointly conducted by ITC, UNCTAD, and WTO. It is expected that important "aid for trade" provisions of the Doha Development Round (WTO) will further reinforce the TRCB activities.

The TRCB multilateral activities in the beginning of the 21st century were dominated by concerns such as (1) assistance in the WTO accession negotiations, (2) developing country compliance with the WTO rules and institution building to reap the benefits of WTO membership, (3) promotion of developing country service industries through appropriate reforms, (4) trade in agricultural products, (5) trade facilitation, (6) trade-related infrastructure development, (7) trade and environment, (8) modernization of the financial system, (9) improvements in labor standards, (10) competition policy, (11) procedures of trade policymaking and governance, and (12) assistance in dispute settlements or bilateral consultations on trade disputes.

Property Rights (TRIPS)

■ trade-related investment measures (TRIMs)

Governments adopt measures to attract foreign in
vestment and to encourage the use of foreign in
vestment in accordance with national priorities. Such
measures that affect trade are known as *trade-related
investment measures*. TRIMs designed to attract in
vestment include fiscal incentives, tax rebates, and
preferential terms on land and service. Common
TRIMs designed to encourage investment in accor
dance with national priorities include local content
requirements (requiring investors to use local inputs
in production) and export performance require
ments (requiring investors to export a certain pro
portion of their output). TRIMs also include trade-
balancing requirements, foreign exchange balancing
requirements, exchange restrictions, domestic sales
requirements, manufacturing requirements, product
mandating requirements, manufacturing limita-
tions, technology transfer requirements, licensing
requirements, remittance restrictions, local equity
requirements, and employment restrictions.

The primary reason countries adopt TRIMs is to
promote development. For example, some countries
adopt TRIMs to foster domestic industries (through
local content requirements), to expand exports
(through export performance requirements), and to
remedy deteriorating balance of payments (through
foreign exchange balancing requirements). Coun
tries also adopt TRIMs to address restrictive business
practices and anticompetitive behavior of multina-
tionals. One means is through technology transfer
policies. For example, licensing requirements stipu-
late that foreign investors license technologies to host
firms; and technology transfer requirements oblige
foreign investors to transfer technologies on non-
commercial terms or to conduct research and de-
velopment locally.

The evolution of TRIMs as a policy tool coincides
with changes in trade and investment. Since the late
1980s, foreign direct investment (FDI) has grown
worldwide. According to the United Nations Con
ference on Trade and Development (UNCTAD),
FDI increased from $203 billion in 1990 to $735
billion in 2001. Developing countries received $238
billion of this investment in 2001. Accordingly de
veloped countries are the predominant sources and
recipients of FDI. Further, FDI tends to be *horizontal*
in that the output of foreign affiliates is sold in the
foreign country. As FDI has grown, trade within
companies has also grown. This trade (referred to as
intrafirm trade) includes trade between subsidiaries
located in different countries and between a subsid-
iary and its headquarters. According to the World
Trade Organization (WTO), approximately one-
third of the $6.1 trillion total of world trade in 1995
was intrafirm trade. Consequently since the 1980s an
increasingly large share of trade is *related* to investment.

History of Agreements and Treaties Before
1995 few international frameworks provided disci-
plines for foreign investment. During the Uruguay

Round (1986 95) of the General Agreement on Tariffs and Trade (GATT), the United States proposed negotiations on policies that affect FDI. Weak support for these proposals, particularly among developing countries, resulted in negotiations on the narrower concept of trade-related investment measures.

At the conclusion of the Uruguay Round in 1995, members adopted the Agreement on Trade-Related Investment Measures (TRIMs Agreement) as one of four agreements of the WTO treaty. The agreement requires countries to phase out policies identified as inconsistent with GATT rules on national treatment and quantitative restrictions. TRIMs identified as inconsistent with national treatment rules include local content requirements and trade-balancing requirements. TRIMs identified as inconsistent with rules on quantitative restrictions include trade-balancing requirements constituting restrictions on imports, exchange restrictions resulting in restrictions on imports, and domestic sales requirements involving restrictions on exports.

On adoption in 1995, the TRIMs Agreement required member states to notify the WTO of existing TRIMs within 90 days. Members were then given a transition period to phase out the notified TRIMs (two years for developed countries, five years for developing countries, and seven years for least-developed countries). The agreement allows exceptions for developing and least-developed countries and permits the extension of the transition periods. For countries acceding to the WTO since 1995, obligations depend on their accession terms.

In addition to the TRIMs Agreement, other WTO agreements address specific aspects of TRIMs. These include the agreements on Trade-Related Aspects of Intellectual Property Rights, on Subsidies and Government Procurement, and the General Agreement on Trade in Services. However no comprehensive framework on TRIMs exists within the WTO to bridge these agreements.

Given its limited scope, the TRIMs Agreement was to be reviewed within five years to consider additional provisions. The 1996 WTO Ministerial Conference in Singapore initiated this process by calling for discussions in four areas (the "Singapore issues") including trade and investment, and by establishing working groups to facilitate analyses. The 2001 Ministerial Conference in Doha then produced the Doha Development Agenda (DDA), which mandated negotiations on new rules to begin after the 2003 Conference pursuant to a consensus on modes of negotiations. However the 2003 Ministerial Conference in Cancun ended without a consensus on several Singapore issues. In 2004 members dropped trade and investment from the DDA. Other efforts to create a multilateral agreement on investment include the Organisation for Economic Cooperation and Development's Multilateral Agreement on Investment. Negotiations on this agreement began in 1995, but subsequently stalled when participants were unable to reach a compromise.

The greatest challenge to creating a comprehensive framework is the divergent interests of countries. Those in favor of a new agreement on trade and investment (primarily developed countries) argue that the existing regime of bilateral and regional arrangements is confusing. They argue that a multilateral agreement would create a stable nondiscriminatory environment that would increase investment. Those against (primarily developing countries) argue that the existing regime provides adequate protections for multinationals and question whether a multilateral agreement would increase investment. Critics claim that a new multilateral agreement would add obligations while limiting countries' ability to align investment with development objectives.

■ transaction costs

See foreign market entry

■ transfer pricing

Transfer pricing decisions arise when one division of a firm sells goods or services to another autonomous division within the same firm. The firm's best interest is served when it selects a transfer price that maximizes total firm profits, which are generated by the aggregate efforts of the firm's separate divisions. Selecting the ideal transfer price, however, requires the firm to consider many facets and implications of its decision, including costs, incentives, and the details of the policy environment.

Firms often organize themselves as multidivision entities to reap the benefits of decentralized decision making. For example, in addition to the firm's headquarters, which coordinates the firm's activities and sets the rules for its subsidiaries, the firm might create separate divisions for parts production, assembly, research and development, advertising, and distribution. Thus transfer prices must be set when components from the parts division are provided to the assembly division, or when the final goods from the assembly division are supplied to the firm's distribution arm.

Hirshleifer's (1956) pioneering work on transfer pricing demonstrated that when there is no separate market for intermediate inputs, the transfer price should be set to the marginal cost of the producing division. In contrast, if there is a perfectly competitive market for intermediate inputs, the transfer price should be set at the market price for the intermediates. Aside from these simple cases, however, the optimal transfer price depends on a number of economic fundamentals, including the nature of competition in intermediate and final good markets, the structure of firm costs, and whether there is demand or technical dependence between separate divisions of the firm. As a result, firms not only must ask what the optimum transfer price is, but also, as noted by Holmstrom and Tirole (1991), need to determine whether it is best to organize the firm vertically, placing the coordination of all price decisions at the top.

When a firm locates its divisions in different jurisdictions either different countries or different fiscal entities (states, provinces, or prefectures) within a country differences in jurisdictional tax rates may influence transfer prices; firms have an incentive to maximize firm profits by strategically manipulating transfer prices as a means of locating profits in low-tax countries or locations. For example, consider a firm that produces inputs in a low-tax country that are used for assembly in a high-tax country. This firm can reduce its tax payments if it increases the declared value of the parts it sells to its assembly division in the high-tax country, because the price manipulation increases revenue and profits in the low-tax country while it increases costs and reduces profits in the high-tax assembly country. Similarly if the country tax environment is reversed such that the corporate tax rate is higher in the country where parts are produced

and lower in the country where the firm does its assembly, the firm could reduce its tax burden by reducing the transfer price it declares on the parts it exports from the parts affiliate to the assembler in the low-tax country.

A full understanding of the incentives to manipulate transfer prices requires more information yet on the organization of the multinational and the firm's environment. For example, the simple case of transfer price manipulation suggests that a firm will reduce its current tax payment by the change in the declared value of its exports multiplied by the tax differential between the sending and receiving countries. Depending on the form of taxation in the firm's headquarters country, however, remaining taxes not paid in the current period may come due when income from a firm's overseas subsidiaries is repatriated to the firm's headquarters. Further, if the definition of taxable income differs across countries, the firm will have to evaluate the effect of its changed declaration on its worldwide tax payments. Finally, a firm's decision to engage in tax-driven transfer price manipulation may trigger other policy considerations. Along these lines, Horst (1971) describes how multinationals need to consider the effect of ad valorem tariffs, which provide a disincentive to increasing declared export prices and an incentive to underreporting of the export price. Further, when a horizontal multinational sets its transfer price, it may face further constraints on its choice of prices, since arbitrage conditions define the maximum degree of cross-country price differences that are sustainable.

Since tax authorities are aware that multinational firms may have strong financial incentives to manipulate their declared transfer prices to shift income from highly to more lightly taxed countries, most governments provide guidance on the setting of transfer prices for international transactions. For example, U.S. transfer price regulations instruct firms to use transfer prices for their internal transactions that are the same as the prices that would apply if the firm were conducting the sale at arm's length, as is the case when the firm sells the part or service to an unrelated party. Thus the ability of multinational firms to engage in tax-induced transfer price manipulation is limited when firms sell homogeneous goods or services. When firms do not have arm's length transactions to guide them in their choice of transfer prices, they are advised to use cost-plus or comparable profits as alternative methods for setting transfer prices. Although these guidelines prevent firms from declaring any arbitrary price, they nonetheless provide some latitude in price setting; the fact that many accounting firms have large divisions dedicated to transfer pricing attests to the complexity of these decisions, as well as the value associated with these choices.

Although transfer pricing decisions can occur in either a purely domestic or an international context, the nature of international investment makes transfer pricing a particularly salient issue. For example, due to international differences in comparative advantage, it often is attractive for firms to place their assembly facilities in low-wage, labor-abundant countries while they conduct more capital-intensive activities at home or in a capital-abundant country. Alternatively, in the case of horizontal investment, firms may decide to set up overseas production sites as a means of reducing variable transportation and tariff costs. In either case, firms that operate as multinationals are generally more productive than firms that are purely domestic, and it is the possession of intangible assets   designs, blueprints, trademarks, proprietary management systems   that enables firms that go multinational to expand across national borders successfully. As a result, the fact that intangible assets are generally present in and responsible for multinational firm activity implies that multinational firms will have more scope to manipulate transfer prices. At the same time, transfer pricing is not the only avenue for tax minimization, as multinational firms can reduce their worldwide payments through other means, such as their allocation of debt, timing of dividends, or   in the case of compensation for transferred intangible assets   use of royalty payments or licensing fees.

Finally, although there are many avenues for tax minimization by multinational firms, transfer price manipulation appears to be one that is actively pursued. Grubert and Mutti (1991) provide empirical

evidence of this from U.S. multinational firms, showing that variation in the location of reported profits is consistent with income-shifting incentives and that real investment activity and firm exports of multinational firms are influenced by international differences in corporate taxation. Similarly, Swenson (2001) and Clausing (2003) find evidence in U.S. trade data that variation in trade prices is consistent with transfer pricing motives.

DEBORAH L. SWENSON

■ **transfer problem**

International financial transfers take many forms. The classic example is war reparations, such as the payments by France after the 1870 Franco-German War and by Germany after World War I. The same general principles apply to other types of interna tional transfer. These include foreign aid to devel oping countries, capital transfers from the richer to the poorer members of the European Union, and the remittances sent home by emigrants. Other pertinent cases include commodity producers that enjoy a windfall improvement in export prices (think of the impact of an increase in world oil prices on oil pro ducers) and countries with net external liabilities that must make interest payments to foreign creditors.

The transfer problem relates to the impact of an international transfer on the structure of exchange rates and relative prices. To evaluate the full impact on the economies of the countries that pay and re ceive the transfer we need to assess the transfer problem.

There are circumstances under which an inter national transfer has no price impact. In the classic formulation of Keynes (1929a), "If £1 is taken from you and given to me and I choose to increase my consumption of precisely the same goods as those of which you are compelled to diminish yours, there is no Transfer Problem." It is implicit in this formu lation, however, that the wealth transfer has no im pact on supply capacities in either economy. This is open to question, since there is a natural tendency for an increase in wealth to be associated with a reduction in aggregate work effort. Accordingly, we may expect a decline in the level of production of the recipient economy relative to the level of production in the sender economy. To the extent that the two econo mies specialize in different goods, this shift in relative production levels may be expected to raise the prices of the goods produced by the recipient economy relative to the prices of the goods produced by the sending economy, even if consumption patterns are identical in both economies.

Moreover it is unrealistic to assume that house holds in both economies have the same consump tion patterns. First, transportation costs means that

domestically produced goods sell for lower prices to domestic consumers than to foreign consumers, which naturally tilts domestic spending patterns toward home-produced goods. For this reason, a transfer of wealth from the foreign country to the domestic country will be associated with an increase in the demand for home-produced goods and a decline in the demand for foreign-produced goods, leading to an increase in the relative price of home goods in terms of foreign goods. From the perspective of the home country, this implies an improvement in the terms of trade the price obtained for exports improves relative to the price of imports.

Second, all countries produce a wide range of goods and services that are sold exclusively to domestic residents. A transfer of wealth from the foreign country to the home country means that demand for such nontraded goods rises at home and declines overseas. If the supply of such goods is somewhat inelastic, this will translate into an increase in the relative price of nontradables in the home country and a decline in the relative price of nontradables in the foreign country.

Third, there is considerable evidence that firms in some industries are able to set different prices in different markets, through segmentation strategies that make it difficult to arbitrage price gaps. An intuitive pattern is for firms to charge higher prices in wealthier markets. It follows that a transfer that enriches the home country relative to the foreign country may result in an increase in the prices of such goods at home relative to the foreign market. Each of these factors points to an increase in the domestic price level relative to the overseas price level the recipient country experiences real exchange rate appreciation (equivalently, the sender country experiences real exchange rate depreciation).

The scale of the real exchange rate movements can be mitigated by several factors, however. For instance, international capital flows and the intersectoral mobility of labor between the traded and nontraded sectors may eliminate the impact of demand factors on the relative price of nontraded goods: if there is an increase in demand for nontraded goods, workers and entrepreneurs can switch from the export sector to the nontraded sector in order to meet the expansion in demand and capital can flow in from overseas to provide extra capacity. This supply response is more likely to apply over the medium term, with factors unlikely to move across sectors quickly or in response to purely temporary surges in demand. Similarly the supply response will be stronger for transfers that are signaled in advance, rather than unanticipated windfalls. Some factors (such as land) have limited supply elasticity, however, such that it remains likely that the level of demand influences the relative price of nontradables even over the long term.

In addition, an increase in demand for domestic tradables may in part be met by the entry of new firms that produce new varieties of goods this is known as the "extensive" margin of adjustment. In this case, the expansion in demand has a smaller impact on the conventionally measured terms of trade, since the "extensive" margin of trade expands. This is most likely in advanced economies in which an active research and development sector fosters innovation.

Moreover, if countries have the ability to borrow and lend in international financial markets, the recipient may opt to save much of a temporary transfer by accumulating foreign assets. This strategy would allow the recipient to maintain a permanently higher level of consumption even after the expiration of the transfer, since the investment income on the accumulated assets would still be available. For this reason, countries such as Norway and Kuwait have opted to park much of their oil revenues in national investment funds, rather than enjoy a temporary boom in consumption that could not be sustained. A further advantage from this strategy is that it may help a recipient avoid the "Dutch Disease" syndrome whereby the increase in domestic wage costs that is precipitated by a surge in domestic demand leads to a contraction in the domestic export sector, which is costly if that sector has the greatest potential for delivering long-term productivity growth.

Unfortunately many developing countries have experienced problems in managing resource inflows (whether windfalls from surges in commodity prices

or foreign aid receipts), such that there is a domestic demand surge and a sharp initial real appreciation. This is compounded by a propensity to increase external borrowing on the back of an increase in wealth, with the political pressures to increase spending exceeding the scale of the transfer. This "voracity effect" means that such countries experience macroeconomic instability, with the initial boom followed by a period of debt repayment, depressed consumption, and a decline in the real exchange rate (Tornell and Lane 1999).

Finally, we should note that the scale of the transfer problem may be expected to vary across economies of different sizes. In particular, the nontraded sector is relatively bigger in economies with larger populations and those that are more geographically isolated; larger economies may also have greater market power in international markets, such that their terms of trade respond more strongly to shifts in demand. For this reason, the empirical evidence shows that the transfer problem is much less important for small, open economies than for continental-sized economies (Lane and Milesi-Ferretti 2004). Even for small, open economies, however, the transfer problem remains central to the analysis of international resource flows.

■ transition economies

Transition economies are those that are in the process of moving from central planning to markets. A centrally planned economy, sometimes also known as a command economy, is one where the means of production are publicly owned, the division of total product between investment and consumption is a centrally made political decision, and all economic activity is controlled in accordance with a central plan that assigns quantitative production goals and allots raw materials to enterprises. A market economy, on the other hand, is one where the means of production are mostly privately owned, the production and consumption of goods result from decentralized decisions made by individuals in pursuit of their own ends in light of prevailing prices, and prices adjust to equate supply and demand.

These definitions describe idealized types; in practice, most economies incorporate elements drawn from both, with the mixture determining whether they are closer to centrally planned or market economies. That said, an event of seminal significance in the late 20th century was the transition from plan to market in the countries of Eastern Europe and the former Soviet Union. An economic transition has also been underway in China and Vietnam. The former group of countries has, however, mostly seen transition as a broader concept, embodying a political transition from communism to multiparty democracy alongside the economic transition. This entry focuses on the economic transition in Eastern Europe and the Commonwealth of Independent States. Eastern Europe comprises Albania, Bosnia and Herzegovina, Bulgaria, Croatia,

the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Macedonia, Montenegro, Poland, Romania, Serbia, Slovakia, and Slovenia. The Commonwealth of Independent States (CIS) includes Armenia, Azerbaijan, Belarus, Georgia, Kazakhstan, the Kyrgyz Republic, Moldova, Russia, Tajikistan, Turkmenistan, Ukraine, and Uzbekistan.

An Analytical Framework The fall of the Berlin wall in 1989 heralded the demise of communism in Eastern Europe, whereas the exit from communism did not occur until 1991 in the former Soviet Union. A key first element signaling economic transition was the liberalization of most prices, so that households and firms henceforth faced international prices for tradable goods. However, large parts of the planned economy transacted at subsidized prices based on cheap energy and subsidized transport. Price liberalization, together with the disruption of the organizational arrangements governing production and trade under central planning, implied that many enterprises inherited by the transition countries were no longer viable. This found expression in what has come to be known as the "transition recession," during which gross domestic product (GDP) is estimated to have fallen by about 15 percent in Eastern Europe and by 40 percent in the CIS, reflecting in part the more distorted structure of the latter and, in the case of some of the poorer ex-Soviet republics, the cessation of budget transfers from Moscow. These numbers are not uncontroversial because the GDP data for the early years, by focusing on large enterprises where output had been declining and not adequately incorporating new businesses and an emerging informal sector, likely overestimate the severity of the transition recession. But this does not modify the qualitative thrust of the observations made here.

An important second element consisted of policy and institutional measures to elicit a supply response that would allow output to recover. These included (1) limiting state assistance (such as tax exemptions, fiscal and financial subsidies, budget and tax offsets, and directed credits) to enterprises, thereby promoting their restructuring or closure and making possible the transfer of assets and labor to viable enterprises; (2) preventing the theft of state assets, through either (a) privatization and an enforceable set of property rights in a private ownership economy, or (b) administrative methods in the few countries where centralized political structures had remained substantially intact; and (3) creating a business environment that did not discriminate among firms, whether old, restructured, or new, and comprised elements such as business licensing and registration, tax policy and administration, and a legal-cum-judicial system protective of property rights.

While restructuring and reallocation of resources in the enterprise sector constitutes the essence of the transition, implementation of this agenda required attention to two other sets of policies. Price liberalization implied that inflation, hitherto repressed in centrally planned economies through unavailability of consumer goods, and expressed in the form of forced monetary savings, had the potential to erupt into hyperinflation. This called for a third element in the set of policies, macroeconomic stabilization, to bring inflation under control.

Fourth, since restructuring and reallocation of resources involved the loss of workers' livelihood, social safety nets needed to be used   fiscal resources permitting   to finance retraining, early retirement, and cash assistance to bridge the period between job destruction and job creation and thus lower the political costs of the transition. This quartet of measures   (1) price liberalization; (2) creation of conditions for the growth of the private sector, including hard budget constraints on enterprises, a nondiscriminatory investment climate, and institutions to control managerial behavior; (3) macroeconomic stabilization; and (4) creation of social safety nets   made up the core of economic policy on managing the transition in Eastern Europe and the former Soviet Union from central planning to a market economy during the early years.

Initial Conditions or Policy Reforms? GDP in 2006 compared with 1990 was 50 percent higher in Eastern Europe and had nearly caught up with its 1990 level in the CIS. This was an increase of some three-quarters from the nadir of the transition re-

cession in each subgroup of countries. An extensive debate surrounds the identification of the causes of the transition recession and the subsequent recovery from it. Cross-country statistical analysis suggests that initial conditions such as the degree of industrialization, trade dependence on other communist countries, repressed inflation, and black market exchange rates during the communist period were closely associated with lower growth during the early years of the transition. On the other hand, policy reforms, including elimination of central planning and mandated allocations through government orders, macroeconomic stabilization, trade liberalization, and competition, as well as a history of prior experience with market reforms and nationhood, were closely associated with subsequent growth performance, becoming stronger as the transition progressed.

The positive association between reforms and growth may seem surprising when the period of analysis includes recent years because the CIS, which has generally made less progress with reforms, has been growing particularly rapidly, more so than Eastern Europe since the Russian financial crisis of 1998. However, the positive impact of reforms on growth indeed continues to hold once two factors are controlled for: first, that the rapid growth in the CIS reflects in part catch-up from a deep recession, and second, that a surge in the price of oil has benefited the CIS oil exporters and other CIS countries through their trade linkages with those exporters (European Bank for Reconstruction and Development 2004).

Country Patterns of Transition The patterns emerging from cross-country statistical analysis need to be complemented by examining the experience of individual countries or subgroups of countries. The transition countries are highly diverse, with per capita incomes in 1991 ranging from an estimated $96 in Armenia to $6,368 in Slovenia. Although countries pursued different combinations of policies in the early years of transition, some broad generalizations are possible regarding the quartet of measures previously identified as key to managing the transition. Macroeconomic stabilization packages including,

among other things, tight monetary and credit policies, wage control policies, budget deficits financed from noninflationary sources, and suitable choice of exchange rate regimes, had been put in place in virtually all the transition countries by 1995. This helped bring down inflation, which had ranged from 26 percent in Hungary to a hyperinflationary 57,000 percent in Georgia prior to stabilization, to single digits in most countries by 1998 (Fischer and Sahay 2000).

Turning to enterprise sector reform, Estonia, Hungary, and Poland exemplify the imposition of hard budget constraints and the creation of an investment climate conducive to the entry of new firms in the early years of transition. This was less evident in those years in the Czech and Slovak republics and Lithuania, and it was only later that harder budget constraints were introduced, whereupon faster restructuring helped set these economies on the path followed by the earlier set of countries. In contrast, Bulgaria, Moldova, Romania, Russia, and Ukraine liberalized their economies but failed to impose hard budget constraints or contain the theft of assets either through law or administrative control. Russia and Ukraine encouraged new entry early in the transition, but the capture of the state by narrow vested business interests, comprising both old enterprises and well-connected early entrants, created a poor investment climate and discouraged further entry by potential competitors. Countries such as Belarus, Uzbekistan, and Turkmenistan, which retain strong elements of central planning, neither liberalized prices nor hardened budget constraints, but the survival of a highly centralized political structure allowed the apparatus of the command economy to be used to limit the extent of asset stripping by enterprise managers that had proved so damaging to growth elsewhere in the CIS.

Finally, adequate fiscal resources allowed countries in Central Europe to use social safety nets to cushion the impact of transition on displaced workers through retraining or early retirement. This option was not available to countries in the CIS due to a major loss of revenue from those state enterprises that were no longer profitable in a market economy.

The lack of a functioning social safety net implied that the deindustrialization that occurred in transition economies, which were typically overindustrialized compared with market economies at similar income levels, led to a movement of workers away from industry and into subsistence agriculture.

Institution Building The far-reaching nature of changes characteristic of the transition from a centrally planned to a market economy, particularly illustrated by the challenges of reforming the enterprise sector, implied that the countries of Eastern Europe and the former Soviet Union faced a formidable agenda of institutional reform. While this fact was recognized early, progress in creating the institutions of a market economy has lagged those reforms that could be accomplished by stroke-of-the-pen policy changes in all countries. As an example, this distinction is captured for the private and financial sectors by the European Bank for Reconstruction and Development's annual reports on transition. The EBRD defines "initial phase" reforms to include small-scale privatization, price liberalization, and trade and foreign exchange liberalization. "Second phase" reforms are defined to include large-scale privatization, governance and enterprise restructuring, competition policy, financial sector development, and infrastructure, the implementation of which calls for deep institutional reform. Initial phase reforms are virtually complete in the countries of Central Europe and the Baltic states that joined the European Union in 2004 and, to a lesser extent, in Bulgaria and Romania, which became European Union members in 2007. In contrast, second phase reforms lag virtually everywhere and especially in Eastern Europe outside the European Union and the CIS countries. In the context of economic integration, for example, most transition countries have generally liberal trade policy regimes. However, the countries where second phase reforms are lagging have not been able to attract the foreign direct investment that would enable deeper integration into global production and distribution chains and improve their longer-term prospects for economic growth. This is due to insufficient progress in developing institutions capable of implementing competition policy; effective regulatory supervision of services such as banking, telecommunications, and transport; as well as trade facilitation (World Bank 2005b).

Developing the Private Sector The share of the private sector in GDP, which is estimated to range from 25 percent in Belarus to 80 percent in Estonia, the Czech Republic, and Hungary, is often regarded as an important indicator of progress in transition. The private sector reflects both the results of privatization as well as entry and exit of privately owned firms that had never been owned by the state. Together with price liberalization and macroeconomic stabilization, privatization has been an important and widely discussed element in the transition from a command to a market economy. Privatization in the early years of transition was seen as a way of generating incentives for the new owners to use enterprise assets efficiently. This consideration was particularly important in the CIS countries, where weakening governments were unable to prevent asset stripping by enterprise managers, which had begun well before the exit from communism in the former Soviet Union. And, politically, privatization also helped ensure the irreversibility of the transition in its early years by creating a class of owners with a stake in the market economy.

While the privatization of small-scale enterprises was relatively uncontroversial, policymakers were faced with a difficult choice regarding the management of assets in medium- and large-scale enterprises. On the one hand, privatization in the absence of institutions of corporate governance could not guarantee that assets would not be stolen or that the rights of minority shareholders would be protected by the new owners. On the other hand, as noted, neither was the success of continued state ownership in an environment of weak government control assured. The problem of adequate monitoring of managerial behavior by shareholders could be overcome to some extent in cases where enterprises could be sold to concentrated private owners, that is, a few owners with larger stakes rather than many stakeholders with smaller stakes in the enterprise. However, the type of concentrated ownership mattered as

well. Enterprises sold to strategic investors equity capital investors that usually operate in the same or similar field and have a long-term interest in developing the company particularly if they were foreign investors, performed much better than those controlled by holding companies or other financial institutions. The selection of strategic investors mattered too. Enterprises sold through transparent tenders or auctions generally attracted better owners, outperforming enterprises sold directly to politically connected parties, frequently at highly subsidized prices. Without such safeguards, concentrated ownership could not avoid the risk of expropriation of assets and income belonging to minority shareholders.

Many of the dilemmas surrounding medium- and large-scale privatization arose when the preferred method of privatization direct sales through transparent tenders or auctions to strategic investors was unavailable and a minimum of institutional capacity to prevent asset stripping by enterprise managers in the interim period was absent. Indeed the evidence suggests that privatization to concentrated outside owners has benefited restructuring whereas privatization to diffuse owners and to enterprise owners and managers has not (Djankov and Murrell 2002). Reforming laws and institutions to protect investors and monitor managerial behavior in countries with no market experience was rendered even more difficult when opposed by early winners from transition, who did so because such reforms would dissipate the rents accruing to them. In Russia, for example, powerful insiders frequently hampered enforcement efforts by the Securities and Exchange Commission. Hence in an environment of substantial capture of the state by narrow private interests, privatization did not create enough demand for the enforcement of property rights, contrary to early expectations. Indeed, while privatization has been found to be positively associated with a measure of public governance, namely, the state's capacity to provide key public goods in low-state-capture environments, the association turns out to be negative in high-state-capture environments (European Bank for Reconstruction and Development 1999).

The development of the private sector is also shaped by firm turnover entry and exit which has been substantial in the transition economies. The role of hard budget constraints on all enterprises and a business environment that does not discriminate between firms has been of particular importance in this regard. This is because the entry of new firms, which were able to occupy market niches that did not exist under central planning, as well as the exit of obsolete firms that were adapted to the command economy, contributed relatively more to productivity growth in transition economies compared with industrial and other developing countries. Furthermore, hard budget constraints and a nondiscriminatory business environment were mutually reinforcing. This is because hard budget constraints led to job destruction, which would have been politically difficult to withstand in the absence of job creation by new firms, which required, inter alia, a nondiscriminatory business environment. Early reformers such as Estonia and Hungary provide examples of job creation that was able to offset job destruction to a greater extent than in late reformers. Conversely the continued subsidization of unprofitable state-owned firms (soft budget constraints) could result in macroeconomic crises, as was the case in Bulgaria and Romania in the mid-1990s, resulting in a business environment that was not conducive to the development of new firms. Hence it is important that the share of the private sector in GDP as an indicator of progress in transition be complemented by an assessment of the extent to which the business environment provides incentives to privatized and new private firms to add value rather than engage in theft and rent seeking.

The Political Economy of Transition Why were most countries in Central Europe and the Baltic states able to implement more comprehensive reforms than those in the CIS? The answer depends, in part, on whether a government could credibly commit to a comprehensive reform program. This commitment would give potential winners such as owners of entrant firms and workers the confidence that they would eventually realize high enough returns to offset the initial adjustment costs incurred by

them in exiting the state sector and entering the private sector. As reforms progressed, the expanding private sector created gains that were large enough to offset the losses of both (1) workers in a downsizing state sector and (2) early winners from partial reforms who had already established positions of advantage and whose gains would be competed away in the event of more comprehensive reform.

In former Soviet states such as Russia and Ukraine, the collapse of communism was rooted in a contest among competing elites rather than in any broad social movement. Governments, which had been captured by early winners from activities such as asset stripping and arbitrage between different sets of prices during price liberalization, lacked the credibility to build and sustain political support for a comprehensive reform program. This discouraged entry by competing groups that did not believe that the reform process would proceed far enough to deliver them a return net of adjustment costs. In much of Central Europe and the Baltic states, by contrast, political institutions emerged from round-table negotiations among broadly representative popular fronts in the aftermath of revolutions against communist rule. This, together with the pull of potential European accession that has been a powerful driver of political and economic institutional development, contributed to a wider social consensus on the main directions of reform and broad public support for comprehensive reform programs in the early stages of transition. These developments allowed those governments to be seen as credibly committed to such programs. As constituencies with a stake in reforms grew stronger, those groups that had gained an early advantage from liberalization and privatization were unable to convert those gains to erect barriers to competition and entry (World Bank 2002).

■ **Triffin dilemma**

Little more than ten years after the creation of the Bretton Woods system, which was founded on the belief that the gold standard had contributed to the financial instability and widespread unemployment in the 1920s and 1930s, the Yale University econo mist Robert Triffin predicted in two separate articles in 1959 60 that internal contradictions would soon bring to an end the new international architecture constructed at Bretton Woods. Around ten years later his prediction, commonly called the Triffin dilemma, proved to be correct.

The major problem with the gold standard system was the failure of gold supplies to keep pace with the requirements of an expanding international trading system for adequate reserves and liquidity and its asymmetric adjustment mechanism that led to a predominance of restrictive domestic policies and a tendency toward global recession. Since limited gold reserves were used to meet international payments deficits, a country would eventually have to restrict domestic demand for foreign goods by reducing economic activity. On the other hand, there was no necessity for countries with payments surpluses who were receiving gold to contribute to adjustment by increasing their imports. Thus there was always a bias toward restrictive policies.

Despite many proposals to base the new system on an international unit of account or an international currency whose supply could by managed by a su pranational bank to provide symmetric adjustment and support the needs of trade and global economic activity, the new system forged at the United Nations Monetary and Financial Conference held in 1944 at Bretton Woods, New Hampshire, was much less ambitious.

Under the Articles of Agreement of the Interna tional Monetary Fund (IMF), countries were given the choice of setting the par exchange value of their currencies for current account transactions in terms of gold or dollars. Since the United States held virtually all of the world's gold, it was the only country able to fix the par value of its currency in terms of gold. All other countries had no choice but to fix the par values of their currencies in terms of the dollar. This meant that these countries had to hold dollar reserves to ensure that market exchange rates did not diverge by more than 1.25 percent from par. The fixed exchange rate system was thus main tained by means of intervention in foreign ex change markets by all central banks, except the U.S. Federal Reserve, buying or selling dollars. The U.S. dollar was thus the sole intervention currency and effectively replaced gold in the Bretton Woods system.

Thus, the Bretton Woods system differed in one important respect from the gold standard. Instead of

the supply being determined by mining and dishoarding, the supply of dollars to serve as international liquidity was determined by a deficit on the external trade and financial payments balance of the United States. In the immediate postwar period this balance was in substantial surplus, and most experts believed that the main problem with the new system would be dollar scarcity and a lack of international liquidity.

U.S. Dollar Overhang Unilateral transfers by the United States for political and military purposes, however, eventually led to current account deficits and an increasing stock of dollars held outside the United States. Triffin pointed out that while the successful operation of this new international financial system depended on an expansion of the U.S. current account deficit to keep international liquidity growing in step with rapidly expanding world trade, this would eventually create foreign claims on the United States that exceeded the gold supply. Once foreign claims on the United States exceeded the dollar value of the gold supply at the $35-an-ounce parity, the United States could no longer guarantee convertibility of the dollar into gold at the official parity. Fixed exchange rates required that foreign claims on the United States be kept below its holdings of gold reserves, while maintaining the growth in the supply of global liquidity to meet the needs of trade required just the opposite.

The survival of the dollar-based Bretton Woods fixed exchange rate system then depended on the willingness of foreigners to refrain from buying gold with their dollar reserves. Foreign holders of the dollar thus faced a dilemma: if they converted excess dollar balances into gold they risked devaluation and losses on their dollar holdings measured in their domestic currency on their balance sheets, but if they delayed and the dollar was devalued relative to gold they risked even larger losses.

Many countries argued that the United States could resolve the problem of excess dollar balances if it reduced domestic growth to create balance of payments surpluses, but this remedy would simply have reduced the growth of international liquidity

and created the risk of global recession. It was just such a case that John Maynard Keynes had warned against when he pointed out the necessity of avoiding asymmetric balance of payments adjustments. During the 1960s the United States introduced a series of ad hoc measures to manage the convertibility of the dollar into gold and to increase foreign demand for dollars, but the internal contradictions elucidated by Triffin were not eliminated.

There were three ways to resolve the problem:

1. create an international currency issued by a global central bank to replace the dollar at the center of the international system,
2. produce global deflation through an attempt to reduce the supply of dollars to the level of the remaining U.S. gold supply, or
3. allow the U.S. to default on its foreign debts through the elimination of the convertibility of the dollar, devaluation of the dollar, and the introduction of flexible exchange rates.

Triffin's prediction was proven correct when the last remedy was chosen in the early 1970s and fixed exchange rates were abandoned. Abandoning the dollar peg to gold did not completely resolve the problems Triffin raised, however, nor did it eliminate asymmetric adjustment. The current international financial system seems to exhibit a variant of the Triffin dilemma due to divergent policy objectives between developed and developing countries. The former tend to pursue policies to ensure exchange rate and asset price stability and allocative efficiency of financial markets at the cost of domestic growth performance below potential, that is, conditions of excess supply. On the other hand, developing countries are more interested in increasing their income and wealth levels via rapid growth.

Post–Bretton Woods: Flexible Exchange Rates One advantage of the shift to a floating exchange rate system after the collapse of the Bretton Woods system was to make diverse policy objectives compatible. The free global flow of capital in search of the most remuneration should maximize global growth. Developing countries in the post Bretton Woods

world, however, have high potential growth rates relative to developed countries and need to run balance of payments deficits to fill resource gaps by importing necessary goods. To pay for these imports, the developing country must borrow from foreign suppliers, which is financing with foreign capital inflows.

These flows are supported by the assumption that developing countries with high growth potential also have high relative real rates of return on investment and thus are ideal investment targets for developed countries with excess savings and few attractive domestic outlets for investment. Large differentials in relative growth rates as well as large resource gaps require large capital inflows and associated balance of payments deficits. The larger the deficit, the higher the likelihood of an exchange rate adjustment or depreciation, creating higher volatility in returns and greater risks to developed country investors. Thus the more successful the system is in allowing developing countries to achieve their potential growth rates, the less willing developed country investors are to finance these deficits.

Thus the Triffin dilemma of the 21st century implies that the more successful developing countries are in achieving their potential growth rates by borrowing in international capital markets to fill their resource gaps, the larger will be their foreign imbalances and the less likely they will be to retain the capital inflows required to support the growth rate. Just as large U.S. deficits increased the risk of holding dollars, larger developing country deficits increase the risk of holding assets denominated in their currencies.

Under the Bretton Woods system, countries held dollar balances because central banks had to support their Bretton Woods parity, and the dollar retained international value in excess of its gold backing. Since the Bretton Woods system ended, exchange rates in developing countries are held up by the force of capital flows themselves, which prior to crises exceed the funds needed to meet balance of payments shortfalls and produce a continuous upward pressure on the currency. Also, because of their higher po-

tential growth rates, the monetary policies in most developing countries produce interest rates that are higher than those abroad, providing an additional attraction for foreign investors. This produces a condition for foreign investors that is much like the catch-22 faced by central banks under Bretton Woods. As the balance of payments continues to deteriorate, the required risk-adjusted rate of return on investment increases but withdrawing capital will inevitably produce exchange rate instability that erodes or eliminates the nominal excess returns expected to be earned in developing countries. Eventually the balance tips toward increased risk, and an exchange rate crisis requires an adjustment policy that generates a decline in income growth and employment.

Thus the same asymmetric adjustment that made deficit countries adjust their policies to those of surplus countries also forces developing countries to make their policies compatible with the policy objectives of the developed countries. Post Bretton Woods, it is the reversal of international capital flows that produces the adjustment. A country that grows too rapidly and produces a large balance of payments deficit that threatens exchange rate stability, and thus its excess rate of return, finds that foreign capital flows out and a financial crisis forces adjustment.

New Triffin Dilemma After the 1997 Asian crisis, many developing countries shifted their policies toward current account surpluses and the accumulation of dollar reserves to protect themselves against capital outflows and the need to borrow from the IMF. As a result, the United States has accumulated large external account imbalances, so dollar holders face the same Triffin dilemma that occurred at the end of the Bretton Woods system. The Triffin dilemma thus seems to be of more general application than its author might have originally envisaged.

■ twin deficits

The *twin deficits hypothesis* refers to the belief that changes in fiscal policy that increase the budget deficit will also increase the current account deficit. The term gained popularity in the 1980s, when tax cuts that caused the U.S. budget deficit to increase by 3 percent of gross domestic product (GDP) between 1980 and 1985 were followed by trade deficits exceeding 3 percent of GDP in 1985 and 1986. The concept received renewed attention in the first decade of the 21st century, when a deterioration of the U.S. long-term or structural budget balance of 6 percent of GDP between 2000 and 2004 was accompanied by current account deficits of 5 percent of GDP in 2004 and 6.5 percent of GDP in 2005.

Accounting and Theoretical Relations In terms of accounting, the current account deficit and the budget deficit are related through the identity:

$$\text{Saving} + \text{Current Account Deficit}$$
$$= \text{Investment} + \text{Budget Deficit} \qquad (1)$$

The identity implies that an increase in the budget deficit that does not cause a change in private saving or investment will increase the current account deficit. Equation (1) can be rewritten as:

$$\text{Current Account Deficit}$$
$$= \text{Investment} - \text{National Saving} \qquad (2)$$

where national saving equals private saving minus the budget deficit (or private saving plus government saving). Written in this way, the identity highlights the fact that a country with insufficient domestic saving to finance its domestic investment must make up the shortfall by running a current account deficit (i.e., drawing on foreign saving).

To understand the relationship between budget deficits and current account deficits it is necessary to go beyond accounting identities to theoretical models. In the Mundell-Fleming model, a fiscal expansion increases aggregate demand and the domestic interest rate. This in turn generates a capital inflow that causes the currency to appreciate. The stronger currency then reduces net exports, returning aggregate demand and output to their original levels. Similar transmission mechanisms are operative in larger-scale general equilibrium macro models that build on equation (2) and the fact that income and exchange rate changes affect exports and imports (e.g., see Cline 2005).

An alternative theoretical perspective in which budget deficits do not affect current account deficits is the Ricardian equivalence model (Barro 1974). Under this theory, a reduction in taxes that raises the budget deficit will be followed by an increase in taxes in the future. Rational taxpayers will anticipate these future tax liabilities that will fall either on them or on their descendants and will increase savings by the amount of the tax cuts. Thus in equation (1), savings will increase by the same amount as the budget deficit. An increase in the budget deficit will thus have no effect on in-

terest rates, exchange rates, investment, or net exports.

Choosing empirically between the Ricardian equivalence model and models where deficits matter has proven difficult. The simplest test may be to examine whether budget deficits raise interest rates. Since budget deficits vary countercyclically and interest rates vary cyclically, however, these tests are biased against finding a relationship between the variables. After many empirical studies of the Ricardian model, no clear consensus has emerged.

In spite of the difficulty with empirical testing, many have argued that the theoretical requirements for Ricardian equivalence to hold are too stringent (see, e.g., Haliassos and Tobin 1990). The model requires parents, children, grandchildren, great-grandchildren, and so on to be linked in an unbroken chain through the giving of intergenerational gifts. It requires capital markets to be perfect and agents to be able to borrow and lend on the same terms as the government. It requires taxes and transfers to be lump sum. Finally, it requires that tax cuts be followed by tax increases rather than by new debt issues to service the existing debt. Because these theoretical requirements seem too restrictive, many have argued that an increase in the budget deficit will not produce a dollar-for-dollar increase in private saving. In this case, an increase in the budget deficit will partly crowd out either net exports (the twin deficits hypothesis) or private investment.

The Mainstream Perspective on the Twin Deficits Proponents of the twin deficits hypothesis do not argue that budget deficits and current account deficits move in lockstep, but only that fiscal policy changes that increase the budget deficit can also increase the trade deficit. Many factors can attenuate the relationship between the two variables. For instance, a stock market boom can reduce savings, increase investment, and attract funds from abroad. These factors would all lead to a larger current account deficit. Greater tax revenues from the stock market boom, however, would move the budget toward surplus. Similarly a recession would reduce imports and improve the trade balance but reduce tax revenues and worsen the budget deficit.

The fact that the two deficits do not always move together is borne out by the data. The two deficits moved in the same direction in only ten years between 1980 and 2004 (Cline 2005). Formal econometric and calibration studies indicate that a $1 reduction in the budget deficit will reduce the current account deficit by between 20 and 40 cents (see Erceg, Guerrieri, and Gust 2005; Cline 2005; Chinn and Prasad 2003).

A major concern with the twin deficits is whether the borrowing associated with them will prove sustainable. The same framework can be used to think about the growth of government debt and the growth of external debt (Gramlich 2004). In both cases, the long-run value of the stock of debt relative to GDP n^* is given by:

$$n^* = d/(g - r) \qquad (3)$$

where d is the nominal primary budget deficit or current account deficit relative to GDP, g is the nominal growth rate of the economy, and r is the net nominal interest rate on the debt. Many authors have calculated that, given current trends, the stock of U.S. external debt could reach levels exceeding 100 percent of U.S. GDP.

An important question is whether foreign investors will at some point become unwilling to accumulate additional U.S. debt. This could lead to a hard landing for the dollar and the U.S. economy. The reluctance of foreigners to acquire additional U.S. assets could cause the dollar to fall, interest rates to rise, and stock prices to tumble. The adjustment could prove disorderly if the fall of the dollar led to a rush for the exits among investors holding dollar assets.

Arguments That the Twin Deficits Do Not Matter While many are concerned that the twin deficits will cause a hard landing for the U.S. economy, others are more sanguine. Arguments that the twin deficits do not matter point to valuation effects, the size of global capital markets, the impact of a global savings glut, and China's willingness to accumulate dollar assets.

Valuation effects refers to factors that offset the effect of large current account deficits on the value of the U.S. external debt. One such factor can be seen from equation (3). The interest rate r has been per-

sistently negative (i.e., favorable to the United States), driving down the value of n*. The interest rate is negative because, up until now, investment income earned by U.S. residents from abroad has exceeded investment income paid by U.S. residents to the rest of the world. Since net international investment income has remained positive for the United States, some have in fact argued that the United States is a creditor and not a debtor in an economic sense (Cline 2005).

In a similar vein the economists Hausmann and Sturzenegger (2006) have argued that positive net income for the United States in every year from 1980 to 2005 implies that the economic value of U.S.-owned assets abroad exceeds the economic value of foreign-owned assets in the United States. They attribute the difference between the U.S. economic status as a creditor and the official data showing that the United States is a debtor to the presence of "dark matter." *Dark matter* refers to the value of know-how and brand recognition associated with U.S. foreign direct investment (FDI) abroad, the seigniorage gains the United States receives because people throughout the world are willing to hold U.S. dollars, and the "insurance premium" that the United States receives because investors are willing to hold U.S. Treasury securities at a lower rate of return than the United States can earn on foreign currency assets.

Others take issue with the argument that, because of dark matter, the United States is actually a net creditor. The data on net international investment income may be inaccurate because foreign firms underreport profits from U.S. operations to minimize tax liabilities. Further, U.S. assets from abroad are largely in the form of equities (including FDI), while U.S. external liabilities are largely in the form of fixed-income assets (including U.S. Treasury securities). Thus the average return received by U.S. investors exceeds the average return received by foreign investors because the United States is holding riskier and more profitable assets (Frankel 2006).

Some have argued that because global capital markets are large, the United States can continue borrowing massive amounts in the future without the

U.S. economy experiencing a hard landing (Cooper 2005). According to one calculation, the non-U.S. financial wealth equals about 700 percent of U.S. GDP (Cline 2005). Assuming that "home bias" in the rest of the world continues to decline, some have argued that foreign investors in the future may be willing to hold even the very large quantities of U.S. external debt implied by large U.S. current account deficits. Others suggest that country risk is better measured by a country's debt relative to its own exports or GDP rather than relative to the size of foreign portfolios (Frankel 2006). If measured by these criteria, U.S. external debt is on a trajectory in the first decade of the 21st century to reach precarious levels (see Obtsfeld and Rogoff 2005). Many argue that this growth in U.S. debt/GDP and U.S. debt/exports will multiply the risk of a hard landing.

The chairman of the Federal Reserve, Ben Bernanke (2005), has argued that the budget deficits of the George W. Bush administration were not an important cause of large trade deficits but instead that the external imbalances were driven by a global savings glut. Indeed many developing and developed countries have excesses of saving over investment that have flowed to the United States. These surplus funds have in turn reduced U.S. interest rates and pushed up U.S. housing prices. The resulting increase in household wealth has reduced U.S. private saving and led to large trade deficits. According to calculations by Cline (2005), a global savings glut can explain at most 35 percent of the U.S. current account deficit. The rest he attributes to U.S. fiscal policy and other factors.

Another argument against the significance of the twin deficits is that China and other developing countries running surpluses with the United States are willing to accumulate massive quantities of dollar assets. It has been suggested that this arrangement constitutes a new Bretton Woods system (see Dooley, Folkerts-Landau, and Garber 2004). China and East Asia are playing a role analogous to the role played by Europe in the 1960s. China has accumulated $1 trillion of reserves, predominantly in dollars, in order to maintain a competitive exchange rate and thus sustain the export-oriented thrust of its econ-

omy. This strategy will help China to provide jobs for hundreds of millions of underemployed rural workers and also facilitate the development of financial infrastructure and modern systems of corporate governance. If this thesis is accepted, the current system could well be sustained for a long time.

Others claim that this arrangement is not sustainable. For instance, China may either develop a workable system of finance and corporate governance or experience a financial crisis (Frankel 2006). Either way, the excess liquidity flowing from China to the United States will stop. In addition, foreign reserve accumulation can increase the money supply and exacerbate inflation. Sterilization policies to offset this effect may force commercial banks to hold more and more central bank bills, erode bank profitability, and interfere with the allocation of credit through the banking system. Further, continued accumulation of U.S. Treasury securities (external reserves) results in an increasingly inefficient allocation of resources since both private and social rates of return would be much higher for investments in the domestic economy (see Summers 2006). Thus many believe that foreign reserve accumulation by Chinese and other central banks will not prove sustainable.

There is thus a lively debate about the empirical relevance of the twin deficits hypothesis. More research is needed to clarify the relationships among budget deficits, current account deficits, and other variables.

U

■ unions and foreign direct investment

Unionization has been falling over time, especially in the United States. In 2005, the unionization rate in Great Britain was 29 percent; Japan, 18.7 percent; Korea, 11.9 percent; and the United States, 12.5 percent. According to data for other years, the unionization rate in Australia was 24.7 percent (2000 data); Canada, 29.7 percent (2006 data), Germany, 26.6 percent (2002 data); Singapore, 21.5 percent (2004 data); and the Philippines, 26.0 percent (2002 data). Meanwhile foreign direct investment (FDI) has been growing rapidly. The United States, the largest recipient of FDI, has one of the lowest unionization rates. Is there a connection?

Theoretical Frameworks FDI can benefit or hurt labor, depending on factors such as its motivations, the structure of firms, the organization of labor-management negotiations, the preference of labor unions, and the location of workers. Firms can be horizontally or vertically related; labor-management bargaining can be firm specific, industrywide, or even nationally centralized; and unions may prefer wages more than employment, or vice versa.

Often the motivation for undertaking FDI is market access. With the classical *tariff-jumping FDI*, the motivation is to jump over existing import barriers such as tariffs, quotas, anti-dumping duties, and safeguard measures. By producing directly in the destination country, the multinational firm avoids import barriers that a national firm must face when exporting.

Related is the so-called *quid pro quo FDI*. The quid pro quo literature suggests that FDI may be induced by the threat of protection (possible protection in the future), and furthermore, that FDI may be used as an instrument to defuse a future protectionist threat. By investing directly in the host countries, foreign firms are creating jobs in the host country. As a consequence, domestic lobbying pressure against foreign imports decreases.

If FDI is undertaken for the purposes just mentioned, it benefits labor in both countries compared with the case of no FDI at all, because it raises output and employment, which in turn puts upward pressure on wages.

In unionized industries, multinationals may undertake FDI to reduce labor costs, to improve their relative bargaining position with the union, or to avoid employing union workers. Consequently, unions historically tend to view multinationals and FDI negatively, regardless of their sources or destinations.

When the motive is to reduce labor costs, FDI may benefit or hurt labor, depending on whether the multinational enterprise (MNE) is horizontally or vertically structured. A horizontal MNE produces identical goods in several countries, while a vertical MNE produces inputs in some countries and final goods in other countries. The theoretical literature suggests that horizontal MNE can hurt labor, because by moving production facilities across borders, firms shift the demand for labor, which drives down the negotiated union wage (see for instance Zhao 2001 and the references cited). Further, usually labor unions are assumed to maximize an objective function consisting of union employment and a union

wage premium above the nonunion wage. If the labor unions are more interested in higher employment than in the wage premium, then horizontal FDI reduces union employment also. This result remains true regardless of whether labor-management bargaining is firm specific or industrywide. And if labor-management bargaining is firm specific and unionization is industrywide, the previously mentioned effects of FDI are substantially reduced, because union members can find work in other firms if bargaining breaks down. In this case, unions may welcome horizontal FDI also. In addition, under subsidiary bargaining in which the union negotiates with branches (not headquarters) of the MNE, union strikes affect only portions of the MNE earnings, while under headquarter bargaining in which the union negotiates with the MNE headquarters, the MNE's total earnings are affected. Thus the labor union prefers to bargain with the headquarters rather than with the subsidiary, even though the MNE may use transfer pricing to strategically influence the negotiated wages and employment by shifting profits across branches to gain a better position in negotiations.

Leahy and Montagna (2000) investigate the effects of different degrees of centralization in wage setting on the incentive of a MNE to locate in a host country, on the host country's welfare, and on the MNE's preference for centralized or decentralized bargaining. They find that if international product markets are interrelated, then centralized bargaining would help the MNE and hurt the host country. This arises because the more efficient MNE would try to raise the wage in the host country above the level host-country firms can afford (i.e., raising rivals' costs), thereby capturing a larger market share. Skaksen and Sorensen (2001) show that home workers may lose or gain depending on the substitutability of the multinational activities. If there is a high degree of substitutability (complementariness) between the activities in the home country and the host country, it is likely that the workers lose (gain) on FDI. Naylor and Santoni (2003) show that FDI is less likely, other things being equal, the greater the union bargaining power and the more substitutable the firms' products in the potential host country.

On the other hand, a vertical MNE can be good or bad for labor in the source country, depending on host-country wages and how much production is shifted overseas. Zhao and Okamura (2008) show that undertaking FDI in a lower-wage country has two effects: an output-expansion effect and a demand-shifting effect. The output-expansion effect stems from using cheaper labor in the host country, which reduces the MNE's overall average cost and enables higher output and employment. The demand-shifting effect is that FDI reduces labor demand in the source country but increases that in the host country. If the first effect dominates the second, then FDI benefits labor in the source country as well as in the host country. This case arises more often if the wage in the host country is not too much below that in the source country. Otherwise the second effect dominates the first and labor in the source country loses from FDI. One important conclusion is that if the wage in the host country is relatively high (nevertheless lower than in the source country), then FDI benefits the labor union and the MNE in the source country, as well as the host country itself.

Empirical Studies There are very few empirical studies concerning labor unions and FDI, and they use U.S. data and mostly confirm the theoretical predictions. Using U.S. Department of Commerce data published in 1992, Cooke (1997) examines the influence of several key industrial relations variables on U.S. outward FDI across nine industries and 19 members of the Organisation for Economic Co-operation and Development. He finds that FDI is negatively related to high levels of unionization, centralized bargaining structures, and industrial relations environments unfavorable to firms such as governmental restrictions on layoffs, but FDI is positively affected by high levels of worker education and policies requiring works councils. Using 1981–83 data on U.S. inward FDI, however, Coughlin, Terza, and Arromdee (1991) are surprised to find that higher unionization rates were associated with increased FDI.

Slaughter (2007) examines whether globalization has played a role in the falling private-sector unionization rate in the United States, with unions feeling pressured to reduce employment and/or compensation demands. He assembles a panel of U.S. manufacturing industries that matches union-coverage rates with measures of global engagement such as exports, imports, tariffs, transportation costs, and FDI. He finds a statistically and economically significant correlation between falling union coverage and greater numbers of inward FDI transactions. Because U.S. affiliates of foreign multinationals have higher unionization rates than U.S.-based firms do, this correlation may reflect pressure of international capital mobility on U.S.-based companies, consistent with research on how rising capital mobility raises labor-demand elasticities and alters bargaining power.

In sum, while the theories of unions and FDI are many, the empirical tests of these theories are few. More work is needed to establish the effects of FDI on unions, of unions on FDI, and of unions on how FDI affects host and source countries.

■ United Nations Conference on Trade and Development

The United Nations Conference on Trade and Development (UNCTAD) was set up in 1964 as a forum for the negotiation of international trade policy issues that fell outside the scope of the General Agreement on Tariffs and Trade (GATT). In the 1990s, with the establishment of the World Trade Organization (WTO), it lost that function and has since become the UN body responsible for research, advocacy, and technical assistance on international trade issues.

The seeds of UNCTAD lie in the failure to establish an International Trade Organization (ITO) after World War II. Although negotiations for an ITO were concluded successfully in 1947 48, the United States subsequently failed to ratify the agreement and the ITO was stillborn. All that remained

was an interim GATT, which covered the process for negotiating reduced tariffs on industrial goods traded across borders. This was of limited interest to developing countries that were then scarcely industrialized. Their major concern was the regulation of international trade in primary commodities, which had been provided for, to a limited extent, in the failed ITO agreement. During the 1950s, they pressed in the forum of the United Nations for new international machinery to address this and other issues of special interest to them.

Geopolitical circumstances proved favorable to their demands. As part of its Cold War tactics, the Soviet Union supported the developing countries' demand for a new international trade conference. The John F. Kennedy administration decided to abandon the U.S. government's public opposition to that proposal to prevent the issue from recruiting developing countries into the Soviet camp. As a result, the first UN Conference on Trade and Development was convened in Geneva from March to June 1964. The secretary-general was Raúl Prebisch, an Argentine economist who had previously been executive secretary of the UN Economic Commission for Latin America. The developing countries organized themselves into a caucus known as the Group of 77   even though its membership eventually exceeded 100.

Little was achieved initially, and the continued existence of the conference was at first in doubt, but eventually the United States agreed that it should reconvene. Thus UNCTAD is unlike most other international organizations. It is an international conference convened every four years in a different location and is serviced by a section of the UN Secretariat, based mainly in Geneva and numbering about 440 officials. Its governing organ, the Trade and Development Committee, meets regularly in Geneva between sessions of the conference to direct the Secretariat's programs.

Campaign for International Commodity Agreements The first several conferences were the site of negotiations on various trade issues that were not being negotiated in the GATT, but on which the UNCTAD Secretariat had produced a range of in-terventionist proposals. Most important, in 1974 UNCTAD emerged to international prominence as one of the forums for globally negotiating a New International Economic Order (NIEO). These negotiations centered on the Secretariat's proposal to extend the number of International Commodity Agreements (ICAs). The aim was to dampen the volatility of primary commodity prices, using a buffer stock mechanism, to be financed by a Common Fund that would also fund commodity diversification schemes.

This package of policies ultimately proved insufficiently attractive for the commodity-consuming countries, which did not really want a fund that they did not control and were more concerned about the security of oil supplies than security of supply of other primary commodities. The commodity-producing countries were also ultimately   for quite different reasons   ambivalent about it. Since many developing countries were highly dependent on just a few commodities, each was worried that a new Common Fund would weaken the control that they already exercised within existing ICAs over the commodities of special interest to them. In the end, no new ICAs emerged and the Common Fund that came into being was very much smaller than the $6 billion Fund first envisaged by Gamani Corea, UNCTAD's secretary-general from 1974 to 1980.

Post-NIEO Development UNCTAD has taken up a variety of other trade-related issues of special concern to developing countries. The transfer of technology was a concern that in the 1980s led to attempts to negotiate an international code of conduct on the subject. Projects of economic cooperation among developing countries were taken up as a theme in UNCTAD, as well as special issues affecting the least-developed countries. The results of this proliferation of activity following the NIEO failure were varied. It contributed to a loss of coherence and focus in the organization as a whole, as small units engaged on marginal and unrelated work multiplied. This fragmentation was aggravated by the UNCTAD Secretariat's growing practice of taking on technical assistance work as a subcontractor to other international public agencies. On the other side

of the account, in some of these new niche activities, the UNCTAD Secretariat was able to develop special skills and deliver technical assistance that was valuable. By the 1990s, its sternest critics recognized its achievements in several important areas the provision of information on statistics of international trade and of global data on private foreign investment and specialized technical assistance in debt management systems.

UNCTAD has also maintained some high-quality publications that regularly analyze the world economic situation and its impact on trade, finance, and development. The annual *Trade and Development Report* series is preeminent in that respect. The UNCTAD Secretariat publishes several flagship reports, the others being the *World Investment Report* and *Least Developed Countries Report.*

Impact of the World Trade Organization The establishment in 1995 of the World Trade Organization (WTO) radically changed UNCTAD's position among the international trade institutions. In the presence of the WTO, it no longer made sense to have two international bodies for the negotiation of trade issues. The disempowerment of UNCTAD as a North-South negotiating forum started at UNCTAD VIII in Cartagena (1992) and was completed at UNCTAD IX at Midrand, South Africa (1996). After 1996, UNCTAD ceased to be a negotiating forum for world trade issues, and in line with this, it reduced the scale of its intergovernmental machinery and consolidated its divisional structure. It replaced 25 separate work programs and subprograms with 1 program consisting of 5 subprograms; it halved the number of intergovernmental bodies; it cut the number of meetings to one-third of what it had been in 1992; and it reduced the number of divisions in the secretariat from 9 to 5.

From 1996 on, its role has been ancillary to the WTO, providing a place to discuss trade and development issues, advocating for the views of developing countries, and offering advice and technical assistance to developing countries preparing for trade negotiations in the WTO. This reduction in function and size implied greater interagency cooperation

between UNCTAD and the WTO, building on previous GATT/UNCTAD cooperation, such as their joint International Trade Center to help developing countries to promote their exports.

The duration of each full session of UNCTAD has been shortened. The 11th session, held in July 2004 in Rio de Janeiro, lasted only a week and was used as a showcase for the organization and its remaining functions. As UNCTAD secretary-general from 1995 to 2005, Rubens Ricupero, himself a former trade negotiator for Brazil, was successful in adapting UNCTAD to this more modest role, and thereby gaining the goodwill of G8 governments. As of 2008, the current secretary-general is Panitchpakdi Supachai of Thailand, who was director-general of the WTO from 2002 to 2005.

No longer a forum for major global trade negotiations, UNCTAD is confined to carrying out international trade research, advocacy, and technical assistance functions and acting as a junior partner of the WTO.

■ Uruguay Round

The Uruguay Round of multilateral trade negotiations (1986 94) was launched during a period when the world economy was experiencing slow growth. Stagflation a mix of rising prices, weak output growth, and rising unemployment was complemented by a debt crisis that affected a number of major developing countries. The need for developing countries to generate foreign exchange to service debt, the rapid growth of export capacity for labor-intensive manufactures such as textiles and clothing in East Asian economies (the "newly industrializing countries" or "East Asian tigers"), and rising trade imbalances gave rise to strong pressures to restrict imports in major countries of the Organisation for Economic Co-operation and Development (OECD).

Although large-scale protectionism was avoided during the late 1970s and early 1980s, extensive recourse was made to quantitative import restrictions, "voluntary" export restraint agreements (VERs), and anti-dumping actions. Trade restrictions formed part of an inappropriate policy response to structural adjustment pressures. Starting in the early 1980s, a number of contracting parties to the General Agreement on Tariffs and Trade (GATT) suggested that renewed efforts were needed to strengthen the trading system to address both rising protectionist pressures and to subject key areas of trade policy to multilateral disciplines. Of central importance

was agriculture largely exempted from GATT disciplines and the Multifiber Arrangement (MFA), a complex system of bilateral trade restrictions that had been put in place to manage trade in textiles and clothing. In addition the United States argued for expanding the coverage of multilateral rules to new areas such as trade in services, intellectual property rights, and investment.

The Uruguay Round was the eighth round of trade negotiations under GATT auspices. It was very ambitious, spanning many more subjects than any of its predecessors or its successor, the Doha Round. Among the major achievements of the Uruguay Round were the creation of the World Trade Organization, new multilateral disciplines for trade in services and intellectual property, and the reintegration of agriculture into the trade regime. It also led to further liberalization of international trade in merchandise. In addition to an average 40 percent cut in tariff bindings, there was agreement to abolish quantitative restrictions on textiles and clothing trade over a 10-year period and, for the first time, to impose specific limits on agricultural export subsidies and trade-distorting production support. Few observers at the time had expected such an ambitious outcome to be feasible. At numerous points during the eight-year marathon the talks came close to failure. Their successful conclusion marks a high point for multilateral cooperation in the 20th century.

The process that led to the establishment of the negotiating agenda for the Uruguay Round took five years, starting with the preparation for a 1982 ministerial meeting on trade, during which the United States sought but failed to obtain agreement to launch a new round. This failure was not surprising as the previous round, the Tokyo Round, had only recently been concluded. The work program that was agreed at the 1982 ministerial laid the foundation for the Uruguay Round, however. Working groups were established to review, among other topics, the use of quantitative restrictions, agricultural trade policies, and trade in services. In March 1985 a study group established by Arthur Dunkel, Director-General of the GATT, and chaired by Fritz Leutwiler, the president of the Swiss central bank, who had been

actively involved in efforts to address the ongoing debt crisis, issued the Leutwiler report. This provided support for the launch of new negotiations to tackle trade restrictions in agriculture and labor-intensive manufactures.

The 18 months after the publication of the Leutwiler report saw active efforts by proponents and opponents of a new round. The former spanned the OECD countries and many developing countries, especially in East Asia, that confronted trade restrictions in export markets. The latter comprised a number of developing countries, including India. By the time of the 1986 ministerial meeting in Punta del Este, Uruguay, the majority of the GATT contracting parties supported launch of a new round of negotiations. The main opponents a group of ten developing countries (the G10, which included Argentina, Brazil, Cuba, Egypt, India, Nicaragua, Nigeria, Peru, Tanzania, and Yugoslavia) sought to make new negotiations conditional on so-called standstill and rollback of existing trade restrictions imposed by OECD nations. They also rejected launching talks on services, trade-related aspects of intellectual property rights (IPRs), and trade-related investment measures (TRIMs).

The majority prevailed, adopting a compromise draft text proposed by Colombia and Switzerland. The major concession to the G10 was agreement that the services negotiations would proceed on a parallel track to talks on goods and that disagreements on IPRs and TRIMs would not be allowed to affect progress in other areas. Notwithstanding this procedural agreement, it was agreed that the negotiations were to be a "single undertaking."

The Negotiations: 1986–93 The talks spanned 14 areas related to trade in goods, plus services. The 14 subjects were tariffs, nontariff measures, tropical products, natural resource based products, textiles and clothing, agriculture, GATT articles (rules), safeguards, the codes of conduct negotiated during the Tokyo Round, subsidies and countervailing measures, dispute settlement, trade-related aspects of IPRs, TRIMs, and "the functioning of the trading system." It was agreed that the talks were to be concluded by the end of 1990

and that there would be a midterm review meeting in the course of 1988.

The midterm review was held in Montreal in December 1988. Differences on agriculture dominated the meeting, but there was disagreement on other subjects as well, including liberalization of trade in textiles and clothing, how to deal with safeguard actions and VERs, and the scope of ambition regarding protection of intellectual property. Instead of an "early harvest" of agreements in a variety of areas, the meeting failed and the midterm review was suspended. The primary reason was the huge disparity in objectives on agriculture between the United States and the EU, with the former insisting that complete liberalization should be the long-term goal. Given that no compromise seemed possible, the main protagonists suggested that ministers sign off on interim agreements that had been reached in other areas and instruct negotiators to return to Geneva and continue efforts to negotiate on agriculture. This "solution" to the deadlock was rejected by a number of Latin American countries. For the first time in GATT negotiating history, developing countries made it clear to the EU and the United States that their differences would not define the outcome of a meeting. The result was a decision by ministers to suspend the Uruguay Round for four months giving time to negotiators to come up with a substantive compromise on the outstanding issues, and making agreement on all other matters conditional on consensus regarding progress on agriculture. The Montreal meeting made clear that the EU had to make substantive commitments to liberalize trade in agriculture. Not doing so would mean the end of the Uruguay Round. The compromise that was hammered out in the subsequent months largely revolved around ideas proposed by the Cairns Group (see the next section).

During 1989 90 negotiations in all areas continued, the goal being to finalize negotiations at a December 1990 ministerial meeting. This meeting, held in Brussels, also ended in failure reflecting substantive disagreements in a number of areas, but particularly in agriculture. The failure did not come as a surprise. The draft Final Act submitted to

ministers had a huge amount of "square-bracketed" text, indicating alternative options or proposals on a subject, as well as "open questions." The unwillingness of the EU to make policy reform commitments on a commodity and instrument basis a key demand of exporting countries forced the round into overtime. The bottleneck was very similar to what would emerge in the Doha Round strong resistance by the EU to suggestions that border protection be reduced and export subsidies constrained.

Talks continued through 1991, leading to a new draft Final Act in December 1991 encompassing some 30 negotiated agreements, including a proposed framework for market access commitments. Again it was agriculture that precluded agreement, with the EU and several in the Cairns Group rejecting the overall package. Although another two years of negotiations would be needed to conclude the deal, in the end the contours established by the 1991 draft final act the so-called Dunkel text defined what was ultimately agreed. What was missing were the specific market access commitments of the countries participating in the negotiations. This became the focal point for bargaining in 1992 93, which eventually led to a deal under the leadership of a new Director-General, Peter Sutherland, appointed in mid-1993.

In June 1993, the U.S. Congress granted an extension of fast-track authority to the U.S. Administration under which Congress could not propose amendments to the outcome of negotiations setting a December 15 deadline for talks to be concluded. This proved to be an effective focal point the substantive negotiations were concluded on December 13, 1993. In Marrakesh, on April 15, 1994, ministers signed the Final Act establishing the World Trade Organization (WTO) and embodying the results of the Uruguay Round.

Key Issue Areas What follows briefly discusses a number of the main negotiating topics that figured in the final "grand bargain."

Tariffs In contrast to the previous two rounds (Kennedy and Tokyo), in the Uruguay Round negotiators did not use a formula approach to cut tariffs. Instead they reverted to an item-by-item, request-offer approach. This reflected the U.S. view that because average MFN tariffs were low, it made more sense to focus talks on specific sectors and on tariff peaks. Although a large number of countries would have preferred to use a formula approach, the United States prevailed. The result of the negotiations was to lower the average bound tariffs on manufactured products of industrial countries, weighted by the volume of trade in the products concerned, from 6.4 percent to 4.0 percent, a cut of some 40 percent. This compares with a weighted-average duty of about 25 percent before the creation of GATT (1947) and around 15 percent at the time of the Dillon Round (the early 1960s). Developing-country participation as measured by the scope of tariff bindings increased substantially during the Uruguay Round, with the percentage of bound lines increasing from 22 to 72 percent. In addition, all countries agreed to bind 100 percent of their agricultural tariff lines.

Agriculture The Punta del Este declaration broke new ground in making an explicit reference to liberalization, with all policies affecting agricultural trade to be discussed, including domestic and export subsidies. This contrasted with the Kennedy and Tokyo Round ministerial declarations, which emphasized the status of agriculture as a special (unique) sector and were oriented toward the negotiation of commodity-specific agreements. The Uruguay Round talks on agriculture were largely between the United States and a group of 14 other agricultural exporters that sought significant liberalization, and a set of countries that provided heavy protection for their farmers: the EU, other European countries (Switzerland, Norway, and Finland), Japan, and South Korea.

The coalition of 14 exporters was called the Cairns Group, after the Australian city that hosted the meeting at which it was established. Members included Argentina, Australia, Brazil, Canada, Chile, Colombia, Fiji, Hungary, Indonesia, Malaysia, New Zealand, the Philippines, Thailand, and Uruguay. It therefore had both high-income and developing country members, illustrating that on agriculture in contrast to IPRs, safeguards, and textiles and clothing the negotiations did not involve a North-

South split. The objective of the Cairns Group was to gradually attain free trade in agricultural commodities, eliminate production distortions, and ensure that binding undertakings to this effect were negotiated. The United States initially called for the complete liberalization of trade in agriculture, including the abolition of all export subsidies. The EU, in contrast, initially proposed that negotiations adopt the approach used in past GATT talks: focus on "emergency measures" for specific commodities such as cereals and sugar to reduce supply and seek to stabilize world agricultural markets. The differences between the United States and the EU were therefore very great: one proposing free trade, the other "managed trade." The Cairns Group was less extreme in pushing for liberalization than the United States, but took a position much closer to that of the United States than that of the EU and other protectionist countries.

Bridging the gap between the EU and the U.S.-Cairns positions proved extremely difficult, not only because of fundamental, substantive differences, but also because of the negotiating strategies that were pursued. Although it was clearly unacceptable to the EU, for the first two years the United States maintained its demand for the total elimination of trade-distorting support policies within 10 years. As already noted, the resulting standoff led to the breakdown of the Montreal midterm review of the round in December 1988. The April 1989 compromise was that the objective would be "substantial progressive reductions in agricultural support," to be implemented through specific commitments and/or agreement on a maximum "aggregate measure of support" (AMS).

At the December 1990 ministerial meeting in Brussels, the EU refused to accept the compromise text proposed by the chairman of the negotiating group which would have averaged a cut of about 25 percent in protection levels. This had significant implications for EU farm policy, the reform of which was under active discussion at the time. The EU needed to settle its internal debates on agriculture first in particular to placate the French, who opposed any significant move toward meeting U.S.-Cairns Group demands. Latin American members of

the Cairns Group played a major role in opposing any significant weakening of the chairman's proposed text. Argentina and Brazil refused to accept the proposed deal and were ready to scuttle the Uruguay Round over the issue.

An agreement between the EU and the United States was eventually reached after much brinkmanship with the so-called Blair House Accord in November 1992. Under the deal, EU policies to pay farmers to take land out of production would not be included in the definition of the Aggregate Measure of Support, nor would similar U.S. payments. The two players also agreed that the proposed 20 percent reduction in the AMS would be an average cut and not apply on a product-by-product basis and that the volume of exports benefiting from export subsidies would be cut by 21 percent.

Textiles and Clothing Liberalization of trade in textiles and clothing was a key demand of developing-country exporters, in particular those that were most restricted under the MFA. Negotiations were difficult. Major areas of disagreement concerned the modalities of phasing out the MFA, the implementation period, and the need for special safeguards. All these matters were eventually negotiated without the brinkmanship and breakdowns that characterized the agricultural negotiations. The deal stipulated that the MFA would be phased out over a 10-year period (1995 2004) in four stages. In 1995, quantitative restrictions affecting at least 16 percent of product lines were to be removed, in 1998 another 17 percent, in 2002 a further 18 percent, followed by the remaining 49 percent at the end of 2004. This did not imply the removal of all trade barriers: tariffs would continue to be imposed. As a result of the Uruguay Round, average tariffs were reduced to a trade-weighted average of 12.1 percent, down from 15 percent.

Services The move to consider rules for trade in services originated with the United States, which had a large services trade surplus. Early in the negotiations, many developing countries argued for a narrow definition of trade in services, excluding sales of services by foreign affiliates of multinational firms. These countries also emphasized the need for

governments to remain unconstrained in their freedom to discriminate against foreign suppliers of services, including inward foreign direct investment (FDI). A consequence was outright rejection of any suggestion that the principle of national treatment apply to services. The EU disagreed with developing countries on how trade in services should be defined, arguing that all types of transactions required to achieve effective market access should be covered, including FDI. The EU agreed, however, that a multilateral agreement on trade in services should not necessarily involve far-reaching obligations of a generally binding nature. Specifically it proposed that national treatment be a specific commitment, to be negotiated on a sector-by-sector basis. As was the case in agriculture, the United States made the most far-reaching proposal, arguing that the nondiscrimination principle should apply to all countries as a binding, general obligation and that all measures limiting market access should be on the table.

Given the lukewarm interest of many developing countries in services negotiations, the EU position emerged as the compromise. In return for acceptance that trade in services be defined broadly to include FDI, national treatment would be sector specific and not a general commitment. In addition, commitments could be made on a limited number of specific policies deemed to restrict access to markets. Virtually all commitments made in the Uruguay Round were of a lock-in nature, that is, a promise not to become more restrictive than what was implied by actually prevailing policies for specific sectors.

In the closing days of the Uruguay Round it became clear that it would be difficult to come to closure on a number of services sectors, including financial services, basic telecommunications, maritime transportation, and one important mode of supply: movement of natural persons (service providers). (Air transportation was excluded from the negotiations altogether.) Rather than allow a situation to develop in which countries would withdraw previously negotiated commitments in these areas, it was agreed that talks on these services were to continue after the conclusion of the Uruguay Round. In addition, on a number of subjects where no agreement proved possible   subsidies, procurement, and safeguards   specific rules were left for future deliberations.

IPRs The negotiation on IPRs was one of the more difficult of the Uruguay Round, both politically and technically. The subject was new to the GATT. Moreover, in contrast to agriculture, it involved a North-South confrontation. Industrial countries, led by the United States, sought an ambitious and comprehensive agreement on standards of protection for IPRs, enforceable through the dispute settlement mechanism. The G10 and other developing countries sought to differentiate discussions on trade in counterfeit goods from IPRs more broadly defined, indicating a willingness to cooperate on the former but not the latter. A general concern was that greater protection of IPRs would strengthen the monopoly power of multinational companies and detrimentally affect poor populations by raising the price of medicines as well as other products.

The first two years of negotiations were dominated by disagreements over the mandate of the negotiating group. Areas of disagreement included standards of protection, use of unilateral sanctions, and the need for   and length of   transitional periods. One of the most difficult questions was whether it was acceptable for GATT contracting parties to draft substantive standards for IPRs. Some developing countries, led by India, argued that the trading system should not be in the business of setting or enforcing IPRs. This was a task for the World Intellectual Property Organization and national governments.

At the end of the day the outcome of negotiations was a far-reaching and comprehensive set of disciplines on IPRs. One reason why this was accepted by developing countries was that they obtained concessions in other areas that mattered more to them. Also important was that by agreeing to the inclusion of disciplines on IPRs, industrialized nations would no longer be able to impose unilateral sanctions on countries that they deemed to be violating IPRs. The United States in particular was an active user of such sanctions. Given a multilateral agreement on IPRs,

multilateral dispute settlement procedures would apply. Finally, although the negotiations involved a confrontation between developing countries, led by India, and OECD nations, led by the United States, a number of developing countries felt that stricter IPR protection would be in their interest because it would encourage FDI, technology transfer, and innovation.

Safeguards and VERs Contingent protection was a key issue in the Uruguay Round. In the Tokyo Round, no agreement had proven possible on rules pertaining to safeguard actions   the reimposition of import barriers to protect domestic industries from serious injury caused by import competition. As noted previously, due to the global macroeconomic situation in the late 1970s and early 1980s, an increasing number of countries were imposing protectionist instruments, including in particular VERs. A major objective of developing country exporters   especially in East Asia   was to outlaw the use of these measures and to achieve stronger disciplines on the use of quantitative restrictions. In contrast to the Tokyo Round, these objectives were achieved, with not only agreement to abolish the Multifiber Arrangement that constrained trade in textiles and apparel, but also a new agreement on safeguards that banned VERs.

Other Subjects Space constraints preclude a discussion of the many other areas in which negotiations occurred. These resulted in many new disciplines on matters such as import licensing, customs valuation, product standards, nonagricultural subsidies, state-trading enterprises, TRIMs, transparency, and dispute settlement. The last subject was an important one. As a result of the round, significant changes were made to the way disputes are dealt with. Under the new WTO, countries would no longer be permitted to block adoption of dispute settlement findings by arbitration panels, instead being limited to appealing findings before a new Appellate Body whose rulings would be final.

Developing Countries Developing countries participated actively in the Uruguay Round negotiations and had a significant impact on the outcome. It became obvious that it was no longer appropriate to regard developing countries as a bloc (assuming this had ever been the case). Instead, countries pursued their self-interest and teamed up with high-income countries on a number of issues. The Cairns Group was just the most prominent example of a North-South coalition.

In contrast to the Kennedy and Tokyo Rounds, the Uruguay Round was a single undertaking: all agreements were to apply to all members. As a result, developing countries became subject to a large number of new obligations   some newly negotiated in the Uruguay Round, others originally negotiated during earlier rounds among industrialized nations. In recognition of the fact that the implementation burden associated with the round would fall heavily on developing countries, they were generally given longer transition periods.

The WTO The 1986 Punta del Este ministerial declaration made no mention of the possible creation of a new organization. A 1990 Canadian suggestion to establish a multilateral trade organization   supported by the EU   was therefore something of a surprise. The proposal was motivated by a desire to create a single institutional framework to encompass the modified GATT and the new agreements on services (the GATS) and intellectual property (TRIPS), as well as all other agreements and arrangements concluded under the auspices of the Uruguay Round. The United States initially opposed the idea of a new institutional framework, but eventually agreed to the creation of the World Trade Organization.

The Uruguay Round was a watershed event in the history of the trading system. In creating the WTO, it led to the realization of the original vision of those who had sought to create an international trade organization 50 years earlier but failed. It involved very active participation by developing countries and pragmatic cooperation between rich and poor nations on specific issues of mutual interest, and it illustrated that very politically sensitive policies could be subjected to multilateral disciplines. The "grand bargain" that was negotiated was a very complex one. Concerns that it was not sufficiently balanced became prominent in the

years immediately following the conclusion of the round and were a major factor in the launch of the first round under WTO auspices, the Doha Round.

V

▪ vehicle currency

A vehicle currency is a reserve currency that central banks or monetary authorities use for the purpose of exchange intervention and the pricing of goods, services, and assets entering international trade and finance. A vehicle currency allows the nation issuing the currency to pay a somewhat lower price for imports, borrow at marginally lower rates, and earn seigniorage. The U.S. dollar is by far the most important vehicle currency in the world today. The euro (the currency of the European Monetary Union, or EMU) has also been used as an increasingly important vehicle currency since its creation in 1999.

A vehicle currency fulfills in the world economy the same basic functions that the currency performs in the economy of the nation. It serves as a unit of account (i.e., it is the primary invoicing currency for international commodity and asset trade), as a medium of international exchange (in that global foreign exchange transactions are overwhelmingly conducted in that currency), and as a store of value (i.e., it is the currency in which official reserve assets are primarily held by nations' central banks or monetary authorities). A national currency becomes a vehicle or international currency as a result of market forces that allow it to function as money for both private and official transactions in the world economy. The U.S. dollar serves as the vehicle currency par excellence in global foreign markets. More than 60 percent of the U.S. currency is actually held abroad.

During the 19th and early 20th centuries, the British pound sterling was the dominant vehicle currency. Since then, the international use of the U.S. dollar increased in step with the increase in the relative economic and political importance of the United States. After World War II, the dollar became the dominant vehicle currency. The reasons for the decline of the pound sterling and rise of the U.S. dollar as a vehicle currency after World War II were (1) the high rate of inflation in the United Kingdom and sharp fluctuation in the value of the pound compared with the low inflation in the United States and stability of the U.S. dollar during the late 1940s and early 1950s, (2) the existence of exchange controls in England in contrast to the relative openness of the U.S. financial market, and (3) the decline in the sterling area's share of world exports in comparison with the rise in the U.S. share. Today the pound sterling remains a vehicle currency, although to a much smaller extent than the U.S. dollar, because London remains a sophisticated international financial center. One indication of the changed international roles of the dollar and pound after World War II was the decision by the Organization of the Petroleum Exporting Countries (OPEC) in the mid-1970s to price petroleum in dollars instead of pounds.

Table 1 shows the relative importance of the dollar, the euro, and other major currencies in the world economy in 2004. The table shows that 44.1 percent of foreign exchange trading was in dollars, as compared with 18.6 percent in euros, 10.2 percent in Japanese yen, and smaller percentages in other currencies. The table also shows that 50.3 percent of international bank loans and 48.4 percent of

Table 1

international bond offerings were in dollars, and 52 percent of international trade invoicing was denominated in dollars. Also, 65.9 percent of foreign exchange reserves were held in U.S. dollars, as compared with much smaller percentages for the euro and other currencies.

Besides being the most important vehicle currency, the U.S. dollar is also used as the currency in a number of Latin American countries (Ecuador, El Salvador, Guatemala, and Panama), as well as in the Commonwealth of Puerto Rico and the U.S. Virgin Islands in the Caribbean, in a process called dollarization. Many developing countries also peg their currency to the U.S. dollar. Similarly, a number of small states use the euro as their national currency. Besides the 12 countries of the Eurozone, the euro also is the legal tender of Monaco, San Marino, Vatican City, Andorra, Montenegro, and Kosovo, as well as of the Eurozone overseas territories of French Guiana, Guadeloupe, Martinique, Mayotte, Reunion, and Saint Pierre et Miquelon. Slovenia adopted the euro on January 1, 2007. Cyprus, Estonia, Latvia, and Malta were scheduled to adopt the euro in 2008; Bulgaria, Slovakia, and Lithuania in 2009; the Czech Republic and Hungary in 2010; and Poland and Romania in 2011.

In recent years, the United States has faced unsustainably large trade deficits (exceeding 6.5 percent of gross domestic product GDP in 2005). Reducing U.S. trade deficits to sustainable levels (say, to 2 or 3 percent of GDP) may require, among other things, a large depreciation of the dollar. This could lead central banks or monetary authorities (particularly Asian ones, which are by far the largest foreign holders of dollar reserves) to reduce their holding of dollars and induce petroleum-exporting countries to switch to euros in the pricing of petroleum, and thus put at risk the vehicle-currency status of the dollar. Similar risks for the dollar arose at the time of the collapse of the Bretton Woods system in 1971, in the face of large U.S. trade deficits and the U.S. suspension of the dollar convertibility into gold. The dollar survived, however, and even increased its vehicle-currency status during the 1980s and 1990s because no other currency could assume that role. The situation is different today because of the existence of the euro as a possible alternative to the dollar. Although the vehicle-currency status of the dollar seems secure for now, the importance of the euro (and eventually of the Chinese yuan) is likely to grow at the expense of the dollar in the future (especially if Britain also adopts the euro), and these currencies could become as important vehicle currencies as the dollar if U.S. trade deficits remain excessive and the international value of the dollar falls significantly.

■ vertical versus horizontal foreign direct investment

Horizontal foreign direct investment (FDI), in which multiplant firms duplicate roughly the same activities in multiple countries, has been distinguished from vertical FDI, in which firms locate different stages of production in different countries. The bulk of FDI is horizontal rather than vertical. That developed countries are both the source and the host of most FDI suggests that market access is more important than reducing production costs as a motive for FDI.

Brainard (1993) reports that foreign affiliates owned by U.S. multinationals export only 13 percent of their overseas production back to the United States, so most production by U.S. multinationals appears to be motivated by the desire to serve markets abroad. Similarly, the U.S. affiliates of foreign multinationals export only 2 to 8 percent of their U.S. production back to their parents; 64 percent is sold in the U.S. market. The bulk of FDI is attracted to big markets, rather than to cheap labor (or other factors of production). The large volume of two-way FDI flows also seems to fit horizontal FDI models better than vertical ones.

Standard models of horizontal FDI revolve around the trade-off between plant-level fixed costs and trade costs (see Markusen 1984). When the potential host country is small, the potential savings in trade costs (which accrue per unit of exports to the country) are insufficient to offset the fixed costs of setting up a production facility there; hence, exports are chosen over FDI as the method for serving the

market abroad. When a host country is large enough for the fixed costs of the plant to be offset by the trade costs saved, however, FDI is chosen over exports. Bigger market size of the host country, smaller plant-level fixed costs (smaller plant-level scale economies), and larger trade costs are more conducive to horizontal FDI. The *proximity-concentration hypothesis* refers to the common tenet that FDI occurs when the benefits of producing in a foreign market outweigh the loss of scale economies that could be reaped if produced in only one plant (in the firm's home country).

FDI may exist to avoid not only actual trade costs but feared trade costs as well. FDI, such as by Japanese firms into the European Union (EU) in electronics and into the Unites States in autos, may be motivated more by fear of impending trade barriers (anti-dumping duties or voluntary export restraints) than by any barriers in place at the time of the investments.

When the choice between FDI and exports involves a simple trade-off between trade costs and fixed costs, an interesting implication is that no firm should simultaneously engage in both FDI and exports. Even for the exact value of trade costs where the trade costs times the number of units exported equals the plant-level fixed costs, when the firm is exactly indifferent between FDI or exports, the firm will either pay the fixed costs to build the plant and serve the market exclusively through FDI, or not build the plant and serve the market only through exports.

Unlike horizontal FDI, with vertical FDI, firms engage in both FDI and exports. Whereas in horizontal FDI models, the two countries are often envisioned as being of similar size, in vertical FDI models, the home country is usually thought of as being much larger than the host country. Thus the horizontal FDI framework is more representative of a pair of developed countries, whereas the vertical FDI framework is like a developed source country and a developing host country. In horizontal FDI models, the question is how best to serve the host market (abroad), whereas in vertical FDI models, the question is typically how best to serve the domestic market.

Standard models of vertical FDI involve deciding where to locate production to minimize costs. Headquarters services are located in the home country; production of the good can be located with the headquarters in the home country or else separated from headquarters and located abroad. Production costs are assumed to be lower in the host country than at home. Hence the trade-off is between the lower costs of producing abroad and the need to pay trade costs to bring the goods back home. FDI occurs if the cost savings from producing abroad are greater than the trade costs incurred. Lower trade costs should encourage vertical FDI but discourage horizontal FDI. As trade costs fall, vertical FDI occurs for smaller differences in factor prices. In a simple setup where only one unit of labor is required to produce the good in either country, vertical FDI occurs if the wage difference across countries is greater than the trade costs. As vertical FDI is often called international *outsourcing/offshoring*, the production cost savings minus the trade costs can be called the gain from offshoring.

Anyone fearing that, as trade costs fall, all production will shift from rich countries such as the United States to poorer countries such as China or Mexico (where wages are lower) should bear in mind that the United States remains the largest recipient of FDI inflows. Also the comparison is not of wage levels alone, but efficiency wages labor costs per unit of production. If wages elsewhere are one-tenth U.S. wages but workers are less than one-tenth as productive, labor there is not truly less expensive.

The *knowledge-capital model of the multinational enterprise* is an overarching model that includes both horizontal and vertical FDI as special cases. It has been used to test for evidence in support of horizontal versus vertical FDI. Most findings have been more supportive of horizontal FDI, but other research (such as Braconier, Norback, and Urban 2005) has emphasized that vertical FDI does indeed occur and is important to the host countries in which it occurs (sales by affiliates are large relative to GDP). Both

horizontal and vertical FDI can occur in Markusen and Venables (2005)   the split between market-oriented and export platform activity depends mostly on trade costs, and factor endowments influence whether to specialize in components or assembly.

Given that the bulk of FDI is horizontal in nature, and that horizontal FDI is motivated by avoiding trade costs (tariff jumping), the trends in the 1990s were rather perplexing. Dramatic reductions in trade costs due to trade negotiations and technological change occurred together with substantial growth in FDI (outpacing the fast growth in world trade). Neary (2008) has put forth two potential explanations. He shows that cross-border mergers can be encouraged by reductions in trade costs. As mergers and acquisitions are quantitatively more important than greenfield investments (building from scratch), falling trade costs can be consistent with expansions in horizontal FDI. He also argues that horizontal FDI in trading blocks can be encouraged by trade liberalization within the trade block. When trade costs fall within the block, outside firms invest in one country as a means for serving the entire trade block. For example, a U.S. firm may produce in Ireland to serve all of Europe, or a German firm may produce in Canada to serve all of North America. These are examples of export-platform FDI, discussed below. Which explanation is most empirically relevant remains to be determined.

Export-Platform FDI Export-platform FDI is FDI motivated by a desire to export rather than to serve the local market. Vertical FDI is export-platform FDI where the exports are sent back to the home market. However, there is an increasing trend toward export-platform FDI where the exports are sent to third markets. The rise of trade blocks with low internal trade barriers but higher external barriers may contribute to this trend. Multinationals are establishing production subsidiaries within a trade block and using that plant to serve the entire block. To the degree that the host country is small relative to the overall size of the trade block, the vast bulk of production will be exported to other countries in the trade block.

Motta and Norman (1996) find that improved market access within a trade block leads to export-platform FDI in this manner. As an additional benefit, since FDI into the block becomes more attractive to outside firms, due to firms being better able to reach the majority of markets within the block through exports from one plant, the subsidies required to entice firms to locate in the block will be reduced. Instead of considering only the market size of a potential host country, firms now consider the broader, regional market that can be easily reached from the country. As trade blocks are often formed on a regional basis, avoiding artificial trade barriers (such as tariffs) and natural trade barriers (transportation costs) tend to go hand in hand.

Kumar (1998) emphasized the need to distinguish between export-platform FDI oriented toward the home market versus that oriented toward third countries. FDI for export back to the home market occurs to take advantage of cheaper factors of production elsewhere, and only trade costs between the home and host country matter. FDI for export to third countries, in contrast, is critically dependent on the ease of access to the third countries, and the trade costs back to the home market matter little.

Ekholm, Forslid, and Markusen (2007) further distinguish between three types of export-platform FDI. Home country export-platform FDI involves export back to the parent. Third-country export-platform FDI involves export to another large country (not home or host). With global export-platform FDI, the host plant exports to both the home country and the third country. When the home and the host countries form a free trade area, the outcome can be that the inside firm engages in home (or global) export-platform FDI, while the outsider firm opts for the third-country approach. Fitting this scenario, the North American affiliates of U.S. multinationals concentrate on exports back home, whereas affiliates in Europe concentrate on exports to third countries (see also Yeaple 2003). With the North American Free Trade Agreement, Mexico has seen increases in the share of production

by affiliates of multinationals (both U.S. and from elsewhere) sent to the United States.

Using data for U.S. outbound FDI to members of the Organisation for Economic Co-operation and Development from 1980 to 2000, Blonigen et al. (2004) find evidence consistent with export-platform FDI in Europe. When measures of market potential (size of proximate third country markets) are included, they find a clear negative relationship between FDI into proximate countries. This pattern of substitution between industrialized countries in Europe provides strong evidence of export-platform FDI. Ireland is the EU economy most successful in attracting export-platform FDI.

The implications of export-platform FDI need further study. For example, when multinational enterprises (MNEs) use the host country as an export platform, local firms are often not competitors (unless also exporting) and thus the MNEs need not worry about restricting technology spillovers. As there is less risk of damaging local competitors, local governments may view export-platform FDI more favorably than FDI for the purpose of serving the local market. While there are potential employment gains from both, export-platform FDI does not generate the gains in consumer surplus that market-access motivated FDI would.

■ **Washington consensus**

The term *Washington consensus* was coined by John Williamson (1990) to encapsulate the set of policy reforms advocated with a reasonable degree of consensus by international financial institutions, the U.S. government, the Federal Reserve Board, and the leading think tanks based in Washington. Those policies were deemed necessary to achieve growth, low inflation, a viable balance of payments, and equitable income distribution in the developing world at large, and especially in Latin America, which was still recovering from the debt crisis that erupted in 1982. The policies that defined the Washington consensus included (1) fiscal discipline, (2) increased public expenditure on social services and infrastructure, (3) tax reform to broaden tax bases and reduce marginal tax rates, (4) market-determined interest rates, (5) unified and competitive exchange rates, (6) import liberalization, (7) openness to foreign direct investment, (8) privatization, (9) deregulation, and (10) secure property rights.

As the term evolved in the 1990s, it became synonymous with the main policies promoted consensually by the International Monetary Fund (IMF), the World Bank, and the U.S. Treasury, with an emphasis on macroeconomic stability through sound fiscal and monetary policies, and a wider role for markets in relation to governments in the allocation

of resources through privatization, trade and capital account liberalization, and domestic market deregulation. The prescription to stabilize, privatize, and liberalize had gained traction among many policymakers in developing countries since the 1980s as import substitution and interventionist policies had led to bloated bureaucracies, grossly inefficient state-owned enterprises, unsustainable public indebtedness, inflation, and slow or even negative growth. The collapse of the Soviet bloc and the success of countries, such as Chile, that had already experimented with the new policies, contributed to their acceptance in the early 1990s. The limited role of government and the expanded role of markets have led some to refer to Washington consensus policies as "neoliberal" or based on "market fundamentalism," an expression that does not do justice to the scope and richness of the policies, especially those originally listed by Williamson (1990). This entry adopts the more recent and more widely used meaning of Washington consensus policies, in spite of its partial overlap with Williamson's list.

The Set of Policies For convenience, Washington consensus policies can be divided into macroeconomic and microeconomic, or structural, policies. The macroeconomic policies are mostly concerned with achieving price stability (more strictly, low inflation rates) and preventing foreign exchange or public debt crises. The cornerstone of macroeconomic stability is fiscal discipline. This need not imply a balanced budget, but rather a fiscal position that does not lead to a rising debt to gross domestic product (GDP) ratio, loss of international

currency reserves, or (unacceptably high or rising) inflation (caused by monetary financing of the deficit), and therefore is "sustainable" without major policy adjustments.

Monetary discipline, a second key element of macroeconomic stability, is best achieved when monetary policy instruments (the intervention interest rate, open market operations, etc.) are aimed at controlling the supply of money and/or the price level and not at reaching other objectives such as accelerating growth or reducing unemployment. Central bank independence from government and other sources of political interference is additionally seen as facilitating monetary discipline.

Though no consensus exists in regard to the exchange rate regime most conducive to macroeconomic stability, it is well established that fixed or pegged exchange rate systems make monetary policy instruments ineffective in an environment of international capital mobility. Furthermore, fixed exchange rates insufficiently backed by international reserves may induce speculative attacks that often lead to abrupt exchange rate corrections. Nonetheless, fully floating exchange rates are seldom desirable, as central banks cannot allow exchange rates to freely fluctuate when a large portion of government or private sector debts are denominated in foreign currency and therefore exposed to exchange rate risks, as is the case in most Latin American countries (an attitude known as "fear of floating"). Thus international financial institutions often advocate for strong international reserve positions and limited reliance on external finance as precautionary measures to weather potential external shocks.

Given a sound macroeconomic framework, structural policies are primarily intended to stimulate and sustain growth by facilitating the functioning of markets and minimizing government interference in economic agents' decisions regarding investment, saving, consumption, and work. This entails lifting tariff barriers and other restrictions on international trade (*trade liberalization*); eliminating restrictions on foreign direct investment and on the free movement of funds in and out of the country (*capital account liberalization*); privatizing state-owned en-

terprises and opening to private investment industries previously controlled by the public sector, such as telecommunications, electricity, or mining (*privatization*); reducing bank reserve requirements and dismantling interest rate controls, subsidized loan programs, and directed credit systems (*financial liberalization*); simplifying the tax code, lowering tax rates, and widening tax bases (*tax reform*); facilitating labor hiring and firing, eliminating wage controls, simplifying the labor code, and reducing payroll taxes (*labor deregulation*); and lifting price controls and license requirements, and easing the procedures for entry and exit of firms (*goods markets deregulation*).

The Extent of Policy Reform Little reform had taken place in the developing world before 1989, but the launch of the Brady Plan by the U.S. government (an initiative to convert the nonperforming bank debts of the developing countries into long-term bonds to restore access by those countries to international finance) and the fall of the Berlin Wall that year signaled the beginning of ambitious macroeconomic and structural reforms in Latin America, Eastern Europe, and the former Soviet Union.

The extent of macroeconomic reforms in the following decade and their degree of success were remarkable. The incidence of high inflation rates among developing countries declined sharply, and median inflation rates among medium-income countries declined from 16 percent in 1990 to 6 percent a decade later. The overall fiscal deficit of developing countries, which had reached 7 percent of GDP in the early 1980s, has remained approximately 2 3 percent of GDP since 1990. By the end of the 1990s, the median developing country posted a primary surplus (the fiscal balance excluding interest payments). In addition, the volatility of key macroeconomic variables such as economic growth and real exchange rates declined in the 1990s, though partially in response to a more stable external environment.

The extent of microeconomic, or structural, reform since the late 1980s has also been substantial, especially in Latin America and the countries of the former Soviet bloc, although the effects of this reform remain a matter of intense debate. Aside from Chile,

which slashed import tariffs and lifted other restrictions on international trade, liberalized the financial sector, privatized many state-owned enterprises, and streamlined the tax and labor codes under the Pinochet dictatorship (1973 90), no other country in Latin America had fully embraced structural reform until the late 1980s, when the Brady Plan created the opportunity of attracting much-needed external capital by adopting the "right" set of policies in the view of international financial institutions and investors. According to reform indexes computed for Latin America, trade and financial liberalization took off first and advanced furthest in the majority of countries. Privatization and tax reforms were more uneven in depth and timing, while labor reform was timid and erratic. Argentina, Bolivia, and Peru were among the most aggressive reformers, while Costa Rica, Ecuador, Mexico, Uruguay, and Venezuela undertook more cautious but nonetheless substantial reforms. Reform lost momentum in the second half of the 1990s, and major reversals took place after 2000 in Argentina, Bolivia, and Venezuela as governments reintroduced a variety of price controls and international trade restrictions. In some cases entire sectors were expropriated, as in the case of Bolivia's natural gas sector.

The reform process was no less turbulent in the former Soviet bloc countries, where it was part of the larger project of state formation that followed the breakup of the USSR (making it more difficult to judge the success of the new policies). Wage and price deregulation, two of the most important components of labor and goods markets deregulation, were undertaken in most countries at the beginning of the transition process, but then stalled and even reversed in some countries after the mid-1990s. A dozen years after the collapse of the Soviet bloc, domestic markets were still almost as heavily regulated as before in Belarus, Moldova, and Uzbekistan. The liberalization of external trade, investment, and finance, on the other hand, has represented a more gradual but sustained process, although as of the first years of the 21st century that process remained incipient in Azerbaijan, Belarus, Turkmenistan, and Uzbekistan. Although the transition from communist to market

economies offered the former Soviet bloc countries ample opportunities for privatization, the reform indexes available suggest that only a handful of countries (Armenia, Bulgaria, the Czech Republic, Hungary, Macedonia, and Slovakia) have privatized the vast majority of their economic activity. As of 2001, the process had barely progressed in Slovenia and Turkmenistan and had suffered drastic reversals in Russia and Uzbekistan.

The process of microeconomic reform varied even more across time, country, and area of reform among the African countries. In the area of financial liberalization, Africa went from a completely dirigiste stance in the mid-1980s to freely moving interest rates and greater flexibility in bank operations in the late 1990s. State-owned financial institutions still intermediated a sizable portion of domestic credit, however, and restrictions on the allocation of credit abounded. Trade liberalization also advanced substantially, but many countries continued to impose high import tariffs and import and export licensing restrictions in the late 1990s. African countries were likewise reluctant to engage in capital account liberalization during the 1980s. Around the mid-1990s most countries undertook at least partial reforms, but many countries continue to require some form of authorization for the acquisition of firms by foreign investors and for portfolio investments by foreigners. Countries in Africa privatized less and more reluctantly than Latin American or transition countries. Less than 40 percent of Africa's state-owned enterprises were affected by privatization, and only four countries Ghana, Côte d'Ivoire, Nigeria, and Zambia accounted for a third of all transactions between 1991 and 2001, worth just $9.1 billion.

Assessment Washington consensus policies have been widely criticized for their ineffectiveness in delivering more macroeconomic stability and higher growth their two main objectives as well as for their social and distributional effects.

Although macroeconomic stability vastly improved in the developing world in the 1990s, it failed to reach developed-country levels, and countries remained vulnerable to extreme macroeconomic events such as banking crises, currency crashes, and

sudden interruptions in capital flows, or "sudden stops." Argentina, a close follower of the Washington consensus recommendations, nonetheless experienced a severe economic crisis in 2001 and 2002: the exchange rate was devalued by more than 300 percent, the government defaulted on its debt obligations, and economic activity and employment collapsed. The inadequate policy conditions imposed by the IMF on the countries affected by the Asian crisis of 1998 are also offered as evidence of the failure of the Washington consensus to prevent macroeconomic instability.

Among the main shortcomings of the policies advocated are sequencing problems (particularly the premature liberalization of capital flows without adequate financial regulation), excessive reliance on high interest rates to contain aggregate demand, price and exchange rate pressures (at the risk of worsening or precipitating a financial or a debt crisis), and inadequate fiscal adjustment that exacerbates busts and weakens economic recovery. The Washington consensus is further criticized for inadequate international financial architecture to respond to the needs of countries in crisis or facing speculative attacks and to prevent "sudden stops."

All of these objections, however, are subject to intense debate. There is no widespread agreement on whether capital controls are effective in moderating or stabilizing capital flows, or whether financial systems isolated from international competition can be adequately regulated. When fiscal sustainability is at risk (for instance, as a result of a sudden interruption in credit access or a decline in the country's terms of trade), interest rate increases or public expenditure cuts may be necessary in order to prevent further capital outflows, currency depreciation, and inflation. Finally, there is intense debate regarding the role the IMF and other international financial institutions should play in preventing and responding to crises, as bailouts and other forms of support may encourage lack of macroeconomic discipline.

The effects of Washington consensus policies on growth have been a contentious issue since their outset. The lackluster performance of Latin America in relation to other regions, especially the fast-growing countries of East Asia, is often offered as evidence of their modest effect. Econometric evidence for Latin America and the transition economies of the former Soviet bloc suggests that Washington consensus policies had positive, but only weak and transitory, effects on growth. The main explanations for this modest growth effect include insufficient depth and completeness of policies and reforms, excessive use of macroeconomic policies to achieve price stability rather than promote growth, sequencing problems (capital account liberalization, domestic financial liberalization, or privatization prior to the regulatory reforms needed to prevent financial instability and market manipulation), and a host of other implementation problems, due especially to lack of institutional support to administer trade reforms, facilitate resource reallocation, prevent corruption, and implement regulatory reforms. Other critics contend that stimulating and sustaining growth requires removing only the most binding constraints, rather than completing the ambitious list of reforms prescribed by the Washington consensus or its augmented versions, which incorporate a variety of institutional or "second-generation" reforms as well as social policies.

The view that Washington consensus policies have deleterious social effects is presently so widespread as to seem beyond discussion. But the empirical evidence is mixed at best. In many countries in Latin America and Africa, trade liberalization had a negative effect on employment in the sectors affected by import competition, which was not compensated by employment creation in the exporting sectors. Nonetheless trade liberalization and privatization produced both winners and losers among the poor, depending on their sectors of activity and their consumption baskets, and there is virtually no empirical support for the view that aggregate poverty was increased by these reforms.

Much more debate attends the distributional consequences of Washington consensus policies. The fact that trade openness may increase inequality in developing countries seems to go against standard economic theory (or at least theory rooted in the simplest version of the Heckscher-Ohlin model of

international trade), since trade should increase the income accruing to the relatively abundant factor, presumably unskilled labor. This effect may be muted or even reversed, however, where trade protection before liberalization was focused on labor-intensive products, as in the case of Mexico, or where the most abundant factor of production is natural resources, as could be the case in Russia or some of the South American countries. Contrary to popular belief, privatizing utilities did not hurt the poor, as the quality and coverage of services improved, while the impact of privatization on income distribution was moderate in Latin American countries, but substantial in some of the ex-communist countries.

An Evolving Concept The terms *Washington confusion* and *Washington contentious*, among others, have been used to convey the state of disarray of the economic, institutional, and social policies advocated by international financial institutions more than a decade after the original Washington consensus. Among the international financial organizations and some Washington-based think tanks, the view prevails that the Washington consensus can deliver growth, stability, and equality if it is "augmented" with a variety of institutional reforms to strengthen state capabilities and with more encompassing and ambitious social policies. In academia, however, as well as in some segments of the World Bank and other organizations, it is argued that a more comprehensive list of policy requirements can hardly be a useful guide for governments short of political support, technical expertise, and administrative capabilities. Furthermore, although no one disputes the importance of macroeconomic stability, secure property rights, market-oriented incentives, outward orientation, and government provision of basic public goods, it is becoming widely accepted that there are no standard prescriptions for achieving these goals. If a new consensus is emerging it is based on the recognition that economic policy reform is always constrained by institutional and political economy factors, which are even harder to reform.

■ World Bank

The World Bank (henceforth "the bank") is a multilateral institution devoted to the promotion, worldwide, of sustainable economic development and poverty reduction. The bank was established as the International Bank for Reconstruction and Development (IBRD), in Bretton Woods, New Hampshire, in July 1944, and its Articles of Agreement entered into force in December 1945. The International Monetary Fund was set up at the same time: together, the fund and the bank became the "Bretton Woods institutions." The role of the fund in the Bretton Woods system was to administer the international monetary system, initially in the form of a system of fixed but adjustable exchange rates (House, Vines, and Corden 2008). The initial rationale for the bank, in a world where dollars were in short supply and international capital flows were limited, was the provision of low-interest finance for postwar reconstruction.

The rapidity of the postwar recovery, and decolonization in the 1960s, meant that IBRD activities came to be refocused on development and in particular on infrastructure investment. The IBRD operated, as it still does, by borrowing in its own name and then lending on to borrowing governments for public sector projects at a small margin. However it was soon found that, despite evident needs, it was difficult to justify investments on these semicommercial criteria in many developing economies. As a result, the International Development Agency (IDA) was established in 1960 to lend capital from IBRD profits, augmented by funds donated by "Part I" governments to poor "Part II" countries, on an interest-free basis with long grace periods. IDA is a development agency, not a financial institution. The post-1960 bank is therefore a more complex hybrid agency than the one established in 1944.

This more complex bank does three things.

The Bank as a Multilateral Lending Institution. The bank borrows at AAA rates on international markets and then on-lends the funds to countries. This remains the largest of the bank's activities. IBRD lending, financed from this source, averaged $12.8 billion per annum out of a total lending av-

eraging $21.5 billion per year over fiscal years 2002 7. The bank's actual lending (i.e., the total of its disbursed and outstanding loans) stood at $98 billion in 2007; its outstanding IDA development credits amounted to $102 billion, making a total of $200 billion (World Bank 2006).

The bank is able to borrow funds at rates lower than the London interbank offered rate because countries are reluctant to default on loans from an international institution, because the bank is able to provide additional lending to prevent default arising from inability to pay, and also because it has a buffer of "callable capital" money that member countries have an obligation to contribute if the bank were ever to get into financial difficulties. The bank lends funds to governments with a margin over the cost-of-funds, which makes a contribution to the bank's operational costs. This margin includes a commitment fee and has typically been in the region of 25 to 40 basis points. The bank is able to make this margin because of its advantages, compared with private banks, in having much lower default risk. IDA credits are interest-free but are subject to a commitment fee and a service charge which, in 2007, amounted to 95 basis points.

The Bank as Development Agency. The most basic rationale for development policy is to rectify market failures in the development process. In the early stages of development, these arise particularly because of the complementarity between activities, many of which become profitable only when other activities are already established. As a result of these failures, private sector enterprises may be unable to capture the social returns from potential investments. Governments can assist by undertaking investment projects in which private returns fall short of social returns. This can raise potential returns on private sector projects, thereby stimulating private sector investment.

Undertaking such policies would normally be identified as a role for domestic government. The bank, as a global, multilateral institution, has been involved in these activities partly because its knowledge and experience of development allow it to identify and address these needs more effectively than

can governments themselves. In many of the poorest of developing countries governments lack the capacity to operate such policy, and in addition, governments are often constrained by the politics of rent seeking. This government-failure view leads the bank to impose conditions on its loans and to monitor the projects in which it invests.

There are also global public-good aspects of good development policies. "Global commons" problems exist when a situation negatively affects many countries simultaneously. Examples are environmental pollution, the management of global capital flows, and the elimination of drug trafficking. Because the costs of global commons problems are so widespread, they require global solutions. The bank has played a significant role in work of this kind.

The Bank as Provider of Aid. Through its IDA arm, the bank carries out international development assistance directed toward the reduction of poverty. In doing this it provides concessional loans with a large aid component. Arguments for such aid rest on the idea of countries being stuck in a poverty trap from which escape is difficult without assistance from abroad (see Sachs 2005). The use of a multilateral institution such as the bank to provide these funds allows richer countries to give aid to poorer countries without this leading to direct bilateral political power relations with them. Channeling aid through a multilateral agency enables donors to precommit not to impose political conditions or economic conditions such as tying the aid to purchases of the donor country's goods.

The bank's ambition is to promote growth and alleviate the *causes* of poverty, rather than just to alleviate the *symptoms* of poverty. Reduction of poverty in this way came to the fore during the tenure of James Wolfensohn as bank president from 1995 to 2005. It is now widely accepted that poverty reduction through capability building is a necessary precondition for sustainable development.

Criticisms The bank has been heavily criticized by a wide range of people. Their criticisms generally fall into five categories. The first two criticisms are associated with left-wing critics and, more recently, with the anti-globalization movement. The third and

fourth have been associated with professional economists and the right wing of the political spectrum. The final criticism has been voiced by both political scientists and anti-globalization activists.

1. Is the Bank "Neoliberal"? The bank has been accused of imposing "neoliberal" economic policies on countries under the guise of structural adjustment. *Neoliberal* is a label widely attached by international relations scholars to those who see economic development as arising from the pursuance of free market policies (of the kind recommended by neoclassical economics) in conjunction with liberal, democratic political processes. John Williamson coined the term *Washington consensus* to describe those who think about economic development in this way. The majority of professional economists trained in British and U.S. universities over the past two decades would position themselves broadly within such a paradigm, and this is reflected in the bank's staff. Non-economists often see such a position as ideological; professional economists justify their position using both theory and evidence.

These debates are central to an understanding of the structural adjustment policies used by the bank since the 1980s. Prior to that time, the bank had lent almost exclusively for projects, but with the drying up of private flows to developing countries in response to the default by Mexico in 1982, and subsequently elsewhere in Latin America, countries' foreign exchange requirements outstripped the availability of attractive projects. On the "neoliberal" view that countries' abilities to respond were inhibited by over-large public sectors and lack of competition, the bank started to lend to finance reform (see Gilbert and Vines 2000; Mallaby 2004). The critics are correct in arguing that governments were pushed into adopting reforms that they would not otherwise have chosen. But most economists would argue that the critics are incorrect in suggesting that alternative policies might have enabled countries to cope with these problems with greater success or at lower cost. Evidence supporting this position comes, for example, from Tanzania, which attempted to go it alone until the mid-1990s but since reforming has seen much faster growth.

2. Conditionality The bank makes reform of policy a condition for its lending. Hopkins et al. (2000) set out the rationale for the bank's conditionality. The bank's status as a multilateral development agency enables it to impose these conditions, which are designed to improve outcomes. As described earlier, the bank's status allows it to lend at a rate that safeguards its debt servicing and repayment, reducing its risk premium and lowering costs of funds so that they are only marginally above its borrowing rate and less then the rate at which countries would be able to borrow from private markets. The imposition of conditions is a feature of the bank's operations that allows it to lend in circumstances that the private sector avoids.

Critics focus on how these conditions interfere with the sovereignty of the borrowing governments. If the critics' arguments were accepted and the bank was prevented from conditioning its lending on what it regards as appropriate policies, it would be unable to act as a financial intermediary in the way that it does.

But conditionality can lead to policy incoherence, since it results in time inconsistency. Recipient governments may agree ex ante to policy conditions if they see this as a means of attracting future loans or aid support. However, once the aid is disbursed these incentives are diminished, the reforms agreed to in the conditions will not be "owned," resulting in weak implementation, and in certain cases, governments may renege on the conditions to which they had previously agreed. The bank's response to a problem of this type has been to restructure its decisions as a repeated game by designing aid programs that include shorter horizons and more detailed conditions. But governments then have the incentive to hold back from reform and exaggerate its costs. An agile government may be able to sell the same reform several times (see Collier 2000).

As a result, there is a widespread view that bank policy conditionality has been not only undesirable but ineffective as well. Evidence comes in three forms   from case studies, from the bank's own assessments, and from econometric studies (see World Bank 2005 for a concise summary of the large liter-

ature). The failure of conditionality can be put down to a number of difficulties: implementation problems and the impact of external shocks (weather, commodity prices, etc.) that can throw plans off course, the overriding importance of domestic politics in determining policy and a failure of "ownership" of reforms, and the inadequacy of penalties and rewards that the bank can impose in the context of these political imperatives.

These negative findings have prompted the view that the bank should give up on the kind of policy conditionality described above (Burnside and Dollar 2000; Collier 2000). Instead the bank should recognize that there are "good" types and "bad" types of countries, and it should direct aid at the "good" types rather than trying to control the behavior of its clients. The bank should advocate and push for the adoption of policies that are consistent with its accumulated knowledge and practical experience. Governments will have an incentive to pay heed to this advice, because the bank bases its advice on its accumulated knowledge and because following this advice will induce future assistance from the bank: the bank should direct its lending and aid selectively toward countries that have demonstrated that they have good policies. A large component of bank activity in countries with poor policy environments would then become educational.

3. Aid Dependency The aid dependency thesis has been most cogently argued by Easterly (2006) and, in more qualified terms, by Collier (2007). It is an attack on the development agency role of the bank, or at least the way this role has been implemented hitherto. The bank lends to governments but, in Easterly's view, it is individuals and firms who promote development. Lending to governments reinforces the power of groups who have little to gain from development and who in any case can contribute little to that process. Collier particularly focuses on how bad governance and corruption can prevent development. He criticizes the provision of aid, both in countries where it is in danger of being used to further political conflict and in resource-rich countries in which the pursuit of resource rents can come to stifle development.

Both Collier and Easterly seek a substantial redirection of multilateral aid efforts. In part, this might mean a shift of resources within the bank toward the IFC, but it also requires new thought on what aid is effective. Much of the policy debate over the past two decades has been directed toward the question of "Where is aid effective?" We now need to ask, "In those countries in which aid has not hitherto been highly effective, what sort of aid may be effective?"

4. Lending to Emerging Market Economies Critics on the right have argued that the bank should withdraw from lending to middle income countries, because they are now able to access international capital markets on their own. These critics want the bank to retreat to being a development agency concerning itself purely with low-income countries that lack this access (see International Advisory Commission 2000). Ironically, moving in this direction would produce the same effects as those sought by left critics who wish to deny the bank the ability to impose policy conditionalities

The critics of bank lending to emerging markets fail to understand that without its lending to middle income countries, the bank would find its development assistance role in low income countries severely restricted the bank's current mode of operation depends on this lending. In the absence of a major increase in multilateral funding for development assistance, this financial intermediation function is required to generate the funds for development assistance. For example, in 2007, the bank received about $1 billion in income from its $40 billion of reserves. It also received profits on market-based lending of about $800 million and $800 million from fees charged to countries that borrow from the soft-loan IDA operations. If the bank were to cease market-based lending, then, even if it kept its reserves, it would forgo $800 million or so in annual revenue. According to Mallaby (2004, 409 10), that would not be enough to cover the administrative budget ($1.7 billion) plus the annual transfers that the bank now makes to the IDA ($300 million) and the HIPC debt relief fund ($240 million).

5. Representativeness The final set of criticisms relates to the bank's governance. The bank is governed by a 24-member Executive Board. Although board decisions are almost always consensual, the threat of a vote makes the distribution of votes important. This distribution in part reflects financial contributions to the bank's activities but even more, the status and power of countries in the 1944 Bretton Woods meeting. Uniquely, the United States has veto power on this board. European countries and Japan, together with the United States, make up a significant proportion of the voting strength. Sub-Saharan Africa, which is now the bank's most important client constituency, has the smallest share of votes 19 percent of IDA votes (2007) in relation to 48 percent of IDA credits (2002 7 average). By unwritten convention, the United States has the power to appoint the president, something which proved unpopular both when Paul Wolfowitz was appointed to replace James Wolfensohn in 2005 and when Robert Zoellick was appointed after Wolfowitz was forced to resign in 2007. There is now considerable pressure to reform the governance and voting structure of the organization, to make it more representative (see Woods 2006).

There is general agreement that both the board voting structure and the procedures for appointment of a president need to be overhauled, but as with the similar debates relating to the IMF and the UN Security Council, there is less agreement on the precise reforms, and in particular on which countries should be the beneficiaries of the reforms. The paramount danger in these reform proposals is that, in becoming more representative and democratic, the bank may also become less effective. Concretely, if a reformed bank were to advocate policies that donor country governments considered likely to be ineffective or counterproductive, they would reduce support for multilateral assistance. UNCTAD provides an example of a development institution in which all countries have equal voting power, and which has provided an effective forum in which developing countries can express their views. It has never enjoyed sufficient funding to have a major developmental impact.

The Bank as a "Bundled" Institution The bank has led global development research and has been

important in promoting debate, and fostering consensus, on the conditions and policies that will result in sustainable growth. A famous example is the role played by the bank in the early 1980s in the promotion of more open trade policies. This remains true in such diverse areas as poverty reduction strategies, governance, and financial regulation. Although few argue that the bank has originated major new ideas or directions in development economics, bank staff have generated a large volume of empirical research that has been fundamental in the assessment of the scale of problems (e.g., levels and changes in world poverty), the importance of different responses, and the applicability of possible policy reforms (e.g., on aging and HIV/AIDS) (see Squire 2000). World Bank (1998) brings together the results of a large body of important research in the bank on the effectiveness of aid. Gilbert and Vines (2000) refer to this as the "Knowledge Bank."

The bank's operation requires it to "bundle" together this knowledge of development work with its profitable lending to middle-income emerging market economies. This lending enables the bank to generate profits to support its other activities. We can think of the bank as rather like a large private American university, which uses its endowment income and income from lending to subsidize its research and teaching (see Gilbert and Vines 2000).

Squire (2000) clearly describes the value of this bundling: "Without an in-house capacity, integrating the results of research into the World Bank's everyday operations and making those results available to policy-makers in developing countries does not happen. This usually requires an in-house champion, and the best champion is usually the best researcher." Thus the bank brings both research and money. Accountability in relation to the expenditure of public money forces research applicability. And the bank's research culture ensures that projects are directed more closely to developmental and poverty reduction objectives than would otherwise be the case: money carries ideas.

It is hard to see how else this bundling of knowledge and money could be provided. In private banks, or private consulting companies, there will always be cost-minimizing pressures to cut the knowledge overhead, subject merely to satisfactory product (i.e., research) quality. Furthermore private banks have no incentive to disseminate knowledge and make their experience widely available, and consulting firms do so only at a price substantially in excess of the marginal cost of dissemination. By contrast, university research departments produce knowledge, but not necessarily of the kind needed for good policy. In addition knowledge about best-practice development policy is a global public good, requiring a global solution to the provision-problem of the kind that the bank provides. Many reforms of policy that work in one country will tend to work elsewhere; there are significant economies of scale and scope in the development of knowledge about development. It is difficult for individual governments to provide these goods.

Gilbert and Vines (2000) argue that such bundling can also help one to better understand bank conditionality. Conditionality may be necessary if the bank is to be able to lend where commercial banks are unwilling to enter. But the bank's knowledge is necessary to determine what constitutes good development policies and also to identify conditions for the reform of policies of a kind that governments will be willing to "own."

The conception of the bank as a Knowledge Bank is central to this account of what the bank does. The bank's lending provides income from endowment and revenue earned in the provision of loans. This funds the activities of the bank as a development agency, including the production of research that increases the effectiveness of both the lending and the aid that the bank provides.

As emphasized earlier, it is important that countries get the *right* combination of money and knowledge. In the countries with good policies and strong institutions the emphasis should be on money. In countries where the policy environment is poor, either because of an unsatisfactory macroeconomic and trade framework or because of poorly performing public institutions, the emphasis must be on getting these policy and institutional prerequisites right.

CHRISTOPHER L. GILBERT AND DAVID VINES

■ World Economic Forum

The World Economic Forum (WEF) is one of the major instances of informal power influencing the world economy. Incorporated as a Swiss not-for-profit foundation whose members are among the world's 1,000 largest companies, the WEF is best known for the annual meetings, attracting around 3,000 participants, that it organizes in Davos, Switzerland, where chief executive officers (CEOs) meet world leaders, government officials, and a broad range of media, cultural, and academic executives identified as opinion leaders. It also organizes yearly meetings with more regional focuses, as well as ad hoc meetings related to the various initiatives it hosts under its Center for Public-Private Partnership.

The WEF has its origins in the Centre d'Etudes Industrielles of Geneva, one of the four executive business schools that had a key role in the managerial revolution following the Marshall Plan in postwar Europe. A junior faculty member, Klaus Schwab, was asked to prepare the 25th anniversary celebration of the institution, which was planned for 1971. He suggested celebrating by organizing a large conference in Davos mingling U.S. experts in management with European businessmen. He also conceived an artful legal artifice to keep control of the event and future initiatives. Thanks to the worldwide reputation of the Centre d'Etudes Industrielles, the conference attracted big names from American business schools and high-profile European industrialists. It is against this background that Klaus Schwab is known as the founder and president of the WEF. The scope of the forum quickly expanded beyond managerial questions to develop an agenda including macroeconomic, political, and strategic issues.

Since the early 1990s, the large increase in the number and prestige, as well as in the geographical and sectoral origins, of the participants has transformed the WEF into the world rallying point for which it is now known. The number of participants grew from fewer than 1,000 in 1971 to around 3,000 by 2007, more than half of whom are invited by the foundation to participate in panels, lend a high profile to the network, and ensure the greatest possible impact. While regular members pay around $20,000 a year to take part in the events, several dozen WEF partners pay more than ten times this amount to be entitled to direct input into the agendas of the meetings by setting up panels, choosing participants, and providing strategic positioning for their industries. Guests include several hundred political leaders and high-ranking officials, including around 20 chiefs of state or government each year; ministers; governors of central banks; directors of international organizations; Forum Fellows chosen from among academic scholars; executive officers of research foundations; some social, religious, and cultural celebrities; as well as around 500 editors and columnists from large press groups around the world. The apogee of the prestige of participants to the forum was probably reached in 2000 when for the first time the president of the United States, William J. Clinton, took part in the event with nine other political leaders of the Organisation for Economic Co-operation and Development (OECD).

Although the WEF advertises itself as an international organization committed to improving the state of the world by engaging leaders in partnerships on key issues to shape global, regional, and industry agendas, critics are prone to identify the WEF as nothing but a meeting place for world masters planning neoliberal globalization behind closed doors. Of course, those closely associated with the forum are inclined to deny its power, while those fiercely opposed are likely to emphasize

its overarching influence. More broadly, however, these contrasting views of the influence and power of the WEF in global politics and economy express disagreement on one outstanding feature of the changes associated with globalization: the significance of the power exercised on a global scale by informal and weakly institutionalized nonstate actors.

The WEF presumably reflects the archetype of the most exclusive and powerful transnational elite club. Other groups include the Bildeberg conferences, the Trilateral Commission, the Clinton Global Initiative, or on a more regional basis, the U.S.-based Business Council and the European Round Table of Industrialists. The WEF is an extremely efficient infrastructure for piling up in three days appointments that would otherwise take three months, solving urgent matters among numerous actors, adding up pressure on the public agenda, and ensuring a large impact in elite circles, the media, and wider public opinion. Situated at the interface between economic and political aspects of the world order, it also embodies a strategic function in seeking to find a synthesis between the territorial basis of a legal and political order and the global reach of the world economy. This is why, for instance, key actors in the Middle East conflict such as Mahmoud Abbas, president of the Palestinian Authority, and Simon Peres, top Israeli politician for decades, can mingle with Eric Schmidt, cofounder and CEO of Google, or Matthew J. Cadbury, heir of the British Cadbury Schweppes agribusiness company. The WEF meetings and backup services provided by its secretariat play a crucial role not only in developing common strategies but also in raising collective consciousness among elites from different countries who get better acquainted and influence one another.

The contribution of elite groups like the WEF to the structure of power in the world economy takes two interrelated courses. On the one hand, they reinforce the formation of an overall class consciousness that transcends national and industry-based rivalries and embraces the global dimension of capitalism. On the other hand, they constitute a privileged locus for expanding this worldview to subordinated interests. Media and other dissemination channels target issues easily identified with the general interest. It is against this background that pleas for historic changes from top women and men in Davos should be understood. The WEF, however, faces intrinsic limits to its power. Its actual practices and organizational principles impair its power. It will always lack a recognized institutional basis. The bigger its suggested influence, the greater the problems it faces in legitimizing its informal power. The sheer size of the meetings, the huge media coverage, and the at times better-organized opposition requiring massive security measures have also tarnished the public image of the club atmosphere that made the WEF so successful.

Despite its continued attractiveness to world leaders for reinforcing their class consciousness, shaping the global agenda, and cutting deals, the WEF has tried to overcome these internal and external challenges since the early 2000s. Officials of the foundation have given a twist to its activities in order to bridge the gap between the loose influence of a closed club and a more focused engagement with states, intergovernmental organizations, and society at large in supporting the launch of various initiatives. Foundation officials and guests target a large range of commitments, from health to the digital divide, including education, gender, corruption, religion, energy challenges, and global warming. Although many of the participants drift apart eventually, some of them vie with other initiatives to concretely influence the policy agenda.

One of the self-proclaimed flagships of the WEF in this regard is the GAVI Alliance (Global Alliance for Vaccines and Immunization). Created as a global network of international development organizations, national governments, multilateral development banks, philanthropic organizations, and large corporations involved in vaccines and immunization, it was officially launched at the 2000 annual meeting at the initiative of the former World Health Organization director-general Gro Harlem Brundtland, in association with Bill Gates, CEO of Microsoft and

cofounder of the Bill and Melinda Gates Foundation, and other regular participants to the WEF meetings. In December 2006, the amount actually disbursed since its creation reached $1.3 billion.

The Global Competitiveness Report is another well-advertised product of the WEF. It was created in 1979 in conjunction with the International Institute for Management Development, the top European executive business school located in Lausanne, Switzerland. The report uses a large quantity of data to build an index that ranks states according to the environment they provide for supporting the economy. The yearly release of the report in advance of the WEF annual meetings makes headlines. Although not at the same level as the conditionality imposed by international financial institutions on developing countries or the recommendations included in the OECD country and sectoral reports for industrialized countries, WEF competitiveness reports still operate at a distance. By shifting the focus away from management issues related to firm performance to competitiveness concerns in national business environments, they explicitly fulfill an agenda-setting function and contribute to harnessing state capacity to define overall economic orientations.

In conclusion, the WEF has achieved long-standing prominence among the various organizations designed to provide informal platforms for meetings, networking, lobbying, and strategic planning among an impressive list of world leaders. Like other platforms, the WEF claims wide public recognition on various issues as a forum of transnational private governance. Yet its loose and large influence is not without limits, as its so-called club atmosphere has faded away with the growth of its events, and it will always offer a privileged target for protesters and all those contesting its legitimacy. The future of the WEF clearly lies in the narrow path between persisting with its massive communication campaign supporting its public image and returning to a more intimate format that would preserve the discrete atmosphere for business leaders to meet with one another and with government officials.

JEAN CHRISTOPHE GRAZ

■ World Intellectual Property Organization

The World Intellectual Property Organization (WIPO) is the key international organization dealing exclusively with intellectual property rights. As such, and with more than 180 member states, it plays a pivotal role in the negotiation and establishment of intellectual property norms. It was founded in 1970 under the terms of a convention signed in Stockholm in 1967. Under a 1974 agreement, WIPO became a specialized agency of the United Nations.

History The origins of the organization lie in the 1893 merger of the secretariats (or "international bureaus") of the Paris and Berne unions, which made

up the contracting parties to the two oldest and most important intellectual property treaties: the 1883 Paris Convention for the Protection of Industrial Property and the 1886 Berne Convention for the Protection of Literary and Artistic Works. The merged organization was known as the Bureaux Internationaux Réunis de la Protection de la Propriété Intellectuelle (BIRPI).

The idea of transforming BIRPI into an international intellectual property organization arose at a 1962 meeting of the Permanent Bureau of the Paris Union and the Berne Union. The meeting recommended the setting up of a Committee of Governmental Experts in order to consider administrative and structural reforms to the Paris and Berne Union systems and prepare for a diplomatic conference.

It is important to note that, during this time, the decolonization process that began just after World War II was gathering pace. Many new, developing countries were becoming independent and seeking to join the United Nations and other international organizations. The United Nations itself was undergoing a period of transformation as it sought to accommodate a rapidly increasing membership with a wide range of interests and concerns. Which parts of the UN system should have jurisdiction over complex and politically contentious matters such as intellectual property rule-making remained unresolved. In consequence, it was obvious that BIRPI could no longer remain as a developed-country "club" and needed a more multilateral character that could attract developing countries, including the newly independent ones.

Some developing nations had their own ideas about international intellectual property norm-setting, however, and were becoming assertive in expressing them. This was cause for concern in some quarters. Indeed, the proposal to establish a new organization based on BIRPI was intended in part to ensure that politicized organizations, including those known for accommodating the specific concerns of the developing countries, would not be chosen as the forum for negotiating intellectual property norms.

According to Stephen P. Ladas (1975), the intent was "to head off any attempt by outsiders, such as the United Nations Economic and Social Council or the United Nations Conference on Trade and Development, to deal with the subject of intellectual property and eventually to form a Specialized Agency of the United Nations in this field."

A second meeting of the committee took place in 1966 and was attended by representatives from 39 nations, of which 9 were developing countries. The rest were developed or European communist countries. The draft convention prepared by BIRPI on the basis of the views expressed by the committee at these two meetings was presented to a diplomatic conference in 1967 in Stockholm, where a final text was approved. The WIPO Secretariat, located in Geneva, Switzerland, is still known as the International Bureau.

Activities, Governance, and Mandate As of late 2007, WIPO administered 24 multilateral agreements. These were of three kinds:

1. *The standard-setting treaties*, which define agreed basic standards of protection for the different intellectual property rights. These include the Paris Convention; the Berne Convention; the 1961 Rome Convention for the Protection of Performers, Producers of Phonograms, and Broadcasting Organizations; the 1996 WIPO Copyright Treaty; and the 2006 Singapore Treaty on the Law of Trademarks.

2. *The global protection system treaties*, which facilitate filing or registering of rights in more than one country. These include the 1970 Patent Cooperation Treaty, the 1891 Madrid Agreement Concerning the International Registration of Marks, and the 1958 Lisbon Agreement for the Protection of Appellations of Origin and their International Registration.

3. *The classification treaties*, which are essentially administrative and concern the management and organization of information concerning patents, trademarks, and

industrial designs. These include the 1957 Nice Agreement Concerning the International Classification of Goods and Services for the Purposes of the Registration of Marks and the 1971 Strasbourg Agreement Concerning the International Patent Classification.

WIPO has three main governing bodies, which are the General Assembly, the Conference, and the Coordination Committee. There are also standing committees and working groups. It is an intergovernmental organization, but official observers are allowed to attend meetings subject to their compliance with certain criteria and procedures. These observers include other intergovernmental organizations and nongovernmental organizations. The latter category comprises not only groups representing business, intellectual property owners, and legal practitioners, which tend to favor intellectual property protection and support WIPO, but also groups whose views range from the very pro intellectual property to the extremely critical.

What is WIPO's mandate? The organization's two objectives as stated in Article 3 of the convention are: (1) to promote the protection of intellectual property throughout the world through cooperation among states and, where appropriate, in collaboration with any other international organization; and (2) to ensure administrative cooperation among the unions. However, the 1974 agreement between the United Nations and the World Intellectual Property Organization balanced the goal of promoting intellectual property protection by recognizing WIPO's responsibility "for facilitating the transfer of technology related to industrial property to the developing countries in order to accelerate economic, social and cultural development, subject to the competence and responsibilities of the United Nations and its organs."

Recent Challenges WIPO briefly lost influence between 1986, when intellectual property was included in the Uruguay Round of trade negotiations, and 1994, when the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) became part of the Agreement Establishing the World Trade Organization, and also for a short time afterward. But since then, WIPO has become a high-profile actor, raising levels of intellectual property protection in developing countries and driving the evolution of international intellectual property lawmaking in response to the opportunities and challenges arising from new technologies. For example, WIPO has proffered technical assistance to developing countries implementing TRIPS and provided a forum for the negotiation of new intellectual property treaties, including four since 1996. In addition, it has become a forum for substantive discussion of emerging intellectual property issues, including ones of interest to developing countries, such as protection of traditional knowledge and cultural expressions. Significantly, it is now a well-funded organization on account of the fees charged for services it provides to the private sector.

From time to time, WIPO is criticized for being biased, either in favor of the interests of the developing countries or in favor of those of industry and the developed countries. In the past few years, complaints have been made that it promotes intellectual property protection in ways that benefit transnational corporations but do not suit developing countries. For example, some critics, including governments, claim that WIPO's technical assistance programs for developing countries give insufficient attention to public interest exceptions to intellectual property rights.

Since 2004, 14 developing country WIPO members, led by Brazil and Argentina, have sought to establish a Development Agenda at WIPO to address the perceived bias. These countries, collectively known as the Friends of Development, argue that as a UN agency WIPO should be guided by the Millennium Development Goals, adopted by the UN General Assembly in 2000. To the 14 countries, the agenda should cover such issues as WIPO's mandate and governance, norm-setting, technical cooperation, and transfer of technology. As of late 2007, the agenda had not yet been approved. Nonetheless, the organization has had to position itself publicly as one whose work is dedicated to fostering economic development.

WIPO plays a substantial role in the world economy by dint of its involvement in promoting intellectual property rights internationally. The high commitment of so many governments and businesses to influence negotiations at WIPO is testament to the high economic stakes involved in the regulation of intellectual property rights at the global level. Because of the more obvious economic significance of the World Trade Organization, however, and the huge attention given to the TRIPS Agreement, WIPO tends to receive less attention from trade analysts than it probably should.

GRAHAM DUTFIELD

■ World Trade Organization

The World Trade Organization (WTO) is *the* international institution governing virtually all trade among its 151 members. As such, it serves two primary functions. First, it provides a set of multilaterally agreed rules that govern policies affecting (1) countries' trade in goods and services and (2) the protection of intellectual property of foreign nationals in member countries. By imposing certain disciplines on countries' trade-related policies, the rules covering trade in goods and services encourage international trade by making future access to foreign markets more predictable. Second, it provides a forum for (1) the day-to-day administration of the various WTO agreements, (2) the settlement of trade disputes among members, and (3) negotiations to further liberalize trade as well as to strengthen and extend the multilateral rules.

Between 1947 and 2007, first under the General Agreement on Tariffs and Trade (GATT), and then under the WTO, world merchandise trade expanded markedly faster than world production (6.2 percent a year on average versus 3.8 percent). It is no coincidence that this period of increasing international specialization, facilitated by the two rules-based multilateral agreements, was also a period of unparalleled prosperity for the world economy, with average per capita income growing more than twice as

fast (2.1 percent a year versus 0.9 percent) as in the previous "boom" period of 1820 1913.

Around the time the WTO came into being, the growing share of output traded across national frontiers, coupled with expanded flows of foreign investment and technology, gave rise to what has become the economic catchword of our times: *globalization* (Wolf 2004). With the world's economies progressively more integrated the essence of globalization and economic prosperity more and more dependent on developments in world trade, the WTO is both the preeminent international economic organization and, inevitably, the international organization most closely linked in the public's mind with globalization.

Origin of the WTO After more than seven years of often arduous negotiations, the Uruguay Round the eighth and final round of trade negotiations under the auspices of the GATT ended successfully in December 1993. In April 1994 trade ministers meeting in Marrakesh, Morocco, signed the Uruguay Round Agreements, including the agreement establishing the WTO, and on January 1, 1995, the WTO came into being. With the subsequent entry of China an event of major importance for the global economy Chinese Taipei (Taiwan), and Saudi Arabia, and with the expected entry of Russia, the WTO's members will include all of the major trading nations (at the end of 2007 an additional 28 countries were in various stages of the accession process).

Although the WTO grew out of the GATT and embraces nearly all of the GATT's principles and practices, it is a distinctly different entity. In contrast to GATT's status as a provisional agreement among governments, the WTO is a formal international organization. The rules, which under the GATT covered only trade in goods, were extended to cover trade in services (telecommunications, banking, tourism, etc.) and the protection of intellectual property. Whereas the GATT had included limited membership agreements dating from the Tokyo Round negotiations (1973 79), all the major WTO agreements are binding on all the members.

The GATT, updated by the Uruguay Round, was absorbed by the WTO and became the umbrella treaty for trade in goods (the new agreement is referred to as GATT 1994, the original one as GATT 1947). As noted earlier, the principles that guided the original GATT, along with virtually all of the key rules and procedures of the original GATT, can be found in the WTO.

Basic Principles Five time-tested basic principles carried over from the GATT some explicit, some implicit inform the rules and guide the activities of the WTO.

Nondiscrimination. The most-favored-nation (MFN) clause prohibits a WTO member from discriminating between imports of goods or services from other WTO members. By requiring a country to treat imports from all WTO members equally, the MFN rule depoliticizes trade (it also ensures that a country buys its imports from the cheapest foreign source). In the case of services (but not goods), countries could obtain at the inception of the services agreement, or on accession for new members, "MFN exemptions" to cover measures that would otherwise breach the MFN rule.

Some key exceptions to the MFN principle included in the GATT were carried over to the WTO, most notably the provisions for (1) free trade areas and customs unions among small groups of countries and (2) preferential treatment of imports from developing countries. With the rapid spread of preferential trading arrangements especially free trade areas beginning in the late 1980s, many trade experts openly question the practical relevance of the MFN rules (see, for example, Srinivasan 2005).

While the MFN clause enforces nondiscrimination at the border, the national treatment principle prohibits discrimination between imported *goods* and domestic products once the imports have entered the country. A retail sales tax applied to imported automobiles but not to domestically produced automobiles, for example, would violate the national treatment principle (however, imposing an import duty on foreign-made automobiles as they enter the country is not a violation of national treatment). For imported *services*, in contrast, application of national treatment is required only to the extent that a country has undertaken an explicit commitment to do so on the service in question.

Tariffs only. The WTO is not a free trade organization. Member countries are not required to participate in trade liberalizing negotiations, and they are free to protect domestic producers by imposing restrictions on imported goods and services. In the case of goods, however, if they do protect they are required to use tariffs only rather than import quotas or other nontariff restrictions to provide the protection. This is good economics tariffs are a less distorting (less inefficient) way of granting protection, and the level of protection provided by a tariff is more transparent than that provided by nontariff barriers.

Consensus decision making. Although there are provisions for majority voting on a one-country, one-vote basis, the WTO has continued the strong tradition, developed under the GATT, of making decisions by consensus defined as no country present at the meeting when the decision was taken formally objecting to the proposed decision. Although this often slows the decision-making process, it has important advantages, including adding to the intellectual and diplomatic "legitimacy" of the decisions, many of which result in legally binding obligations for all members.

Special treatment for low-income countries. Following a practice that evolved under the GATT, the WTO rules and procedures include special arrangements for developing countries. These include special provisions in WTO agreements (for example, longer implementation periods for new obligations), activities of the Committee on Trade and Development, and technical assistance (mainly training). Responding to a widening income gap among these countries a number of successful "developing" countries now have per capita incomes approaching those of developed countries, while many others remain very poor the WTO uses a two-part grouping: developing countries and least-developed countries (a UN grouping of the 50 poorest countries, 32 of which are WTO members), coupled with an increasing focus on helping the latter group of countries (see Part Five of WTO 1999).

Small Secretariat with a limited mandate. The member countries have also continued the tradition, developed under the GATT, of having a Secretariat that is *very* small in terms of budget and staff as compared with the other major international economic organizations, such as the World Bank and the International Monetary Fund (IMF). The limited mandate is reflected not only in the limited budget and staff, but also, for example, in the fact that the Secretariat is not allowed to interpret WTO rules, nor can the Director-General initiate a dispute settlement case, no matter how blatant the rule violation. More generally, the head of the WTO has much less authority in relation to both the member countries and the organization's activities than do his counterparts at the World Bank and the IMF.

The result is a Secretariat whose activities are largely limited to servicing meetings and other activities of the member countries. This "member-driven" nature of the WTO, which has become even more pronounced than it was under the GATT, can be traced to the fact that trade policies are highly politicized at the national level. No government especially no government of a large or medium-size country can be seen advocating a Secretariat with any real independence and power. (Some analysts argue that the member-driven nature of the GATT was an important factor in its success; see Hudec 1993; Winham 1998.)

Administering the Agreements and Other Day-to-Day Activities Aside from the agreement establishing the WTO, virtually all of the more than 50 agreements, annexes, decisions, and understandings agreed to in the Uruguay Round, as well as the organization's day-to-day activities, fall into one of five broad areas: administering the agreements on trade in goods, on trade in services, and on intellectual property protection, plus dispute settlement and periodic reviews of countries' policies under the Trade Policy Review Mechanism (TPRM). Technical assistance and training activities for officials from low-income countries round out the list of usual activities.

The member-driven nature of the work, plus the fact that all of the nearly 30 councils, committees, working parties, and working groups are open to all WTO members (there are no limited membership "executive groupings"), means that national

delegations in Geneva typically have to cope with a heavy schedule of meetings dealing with a variety of often technically complex issues. This can be burdensome for delegations from the smaller developing countries and especially so for the least-developed countries (Blackhurst, Lyakurwa, and Oyejide 2000).

Dispute Settlement A rules-based agreement can function only if it includes an effective system for resolving disputes between the member countries. Although the GATT's dispute settlement system worked well for much of nearly five decades that the GATT provided the legal framework for world trade, by the early 1980s serious problems were beginning to appear. In particular, there was a noticeable decline in the willingness of countries to "protect" the system by (1) allowing the dispute settlement process to run its course (under GATT rules, any member including the defendant country could block the process at any stage) and (2) removing policies that were found to be inconsistent with the country's GATT obligations. Everyone agreed that negotiations to reform the dispute settlement system were a high-priority part of the Uruguay Round agenda.

While most of the GATT's rules and procedures were taken over by the WTO with relatively little or no substantive modification, an important exception to this generalization occurred in the Uruguay Round understanding on dispute settlement. The previous practice of requiring that decisions by the panels that hear cases be adopted by consensus was turned on its head under the WTO, panel decisions are automatically adopted unless there is a consensus *not* to do so. A second key change was the creation of a new institutional element the Appellate Body to which the parties to a dispute can appeal the panel's decision, with the Appellate Body's decision being final. Under the heading "Strengthening of the Multilateral System," the understanding also explicitly prohibits the use of *unilateral* actions in trade disputes between WTO members.

The WTO's dispute settlement system was remarkably successful during its first decade, producing more than 150 panel and Appellate Body reports which, in turn, generated a rich case law. While not disputing that assessment, many countries especially developing countries believe the system can be improved and have offered specific proposals for reform (WTO 2004, chapter VI; Sacerdoti, Yanovich, and Bohanes 2006).

Negotiating Rounds The underlying "ethos" of the WTO is that the pursuit of *freer* trade is a desirable goal. During the GATT years that goal was pursued through a series of formal negotiating rounds (eight in total). Despite some support for the view that more progress might be possible through lower profile "continuous" negotiations, during its first decade the WTO embraced the big round approach with the launch in Doha, Qatar, in November 2001 of the Doha Development Agenda, encompassing both a new round of trade liberalizing negotiations and work on other issues, especially problems many developing countries were encountering in implementing existing commitments agreed to in the Uruguay Round.

At the end of 2007 the outlook for a successful conclusion of the Doha Round remained clouded. This, in turn, has given rise to claims that a failure of the round would seriously, perhaps fatally, harm the WTO. As a ploy to get countries to make the politically difficult decisions needed to conclude the round successfully, there is nothing objectionable about such claims. At the same time, they overlook at least two important sources of strength and stability in the WTO system. First, existing WTO rules and contractual obligations, together with the well-functioning dispute settlement system, impose severe constraints on the ability of countries to *increase* current levels of protection. Of course countries could be tempted to flout the WTO, but then the second source of strength comes into play, namely the fact that politically powerful multinational corporations and other export-oriented firms from many countries, together with their millions of employees, have a very large financial stake in world trade continuing to flow smoothly and be governed by enforceable multilateral rules.

Other Challenges Facing the WTO An international organization with a mandate as broad and complex as that of the WTO is bound to find itself

confronting a seemingly endless series of challenges. Very briefly, these include:

- *Dispute settlement.* It was noted earlier that, although the dispute settlement system is working very well, a number of proposals for improving the system are on the table. In addition, there is a fear that a failure of the Doha Round could put additional strains—perhaps very serious strains—on the dispute settlement system if countries sought to obtain through litigation what could not be achieved through negotiation—for example, the reduction or elimination of agricultural subsidies. It is helpful to recall, in this context, that the WTO has no police force and no jails. The dispute settlement system works only if the member countries want it to and are willing to protect it.

- *Preferential trading arrangements.* The continuing proliferation of preferential trading arrangements, in particular free trade areas, is believed by many to be a serious problem for the WTO. However, 20 years of debate and analysis have failed to bring about a consensus among either economists or policymakers on whether, in practice, such agreements—many of which extend to issues not covered by the WTO—support or harm the multilateral trading system (see WTO 2004, chapter II; WTO 1995). It is widely assumed that a failure of the Doha Round would give an added stimulus to the spread of such agreements.

- *Decision making.* The WTO's various councils, committees, and negotiating groups are loosely analogous to what in a national government would be the "parliamentary" branch of government. It is generally accepted in the trade policy community that the practices and procedures in this area—especially the ones surrounding the negotiating activities—are functioning badly and need to be reformed. Along with built-in procedural and structural shortcomings, other factors that have been blamed for the disappointing pace of negotiations and decision making include the increased WTO membership, the increased sensitivity of the issues being considered, the lack of a more regular presence in Geneva of senior policymakers from capitals, and the across-the-board reliance on consensus decision making (see WTO 2004, chapters VII and VIII).

- *Anti-globalization.* The WTO is a major target of the anti-globalization movement—the high point or low point, depending on one's perspective, being the "Battle of Seattle" at the December 1999 Ministerial meeting when an estimated 40,000 to 50,000 people showed up to protest a very wide range of issues (Jones 2004). Aware that such attacks on the WTO can erode public support for further trade liberalization, the WTO has taken a number of steps in the years since 1999 to counter what it believes to be the misconceptions and distortions spread by the anti-globalization movement. These include improving the transparency of WTO activities and the dialogue with nongovernmental organizations (NGOs), expediting the derestriction of documents, providing regular briefings for NGOs in Geneva, holding symposia, and allowing NGO attendance at ministerial meetings (see WTO 2004, especially chapter V; also chapters I and III).

The WTO's Contribution Douglass North shared the 1993 Nobel Prize in economics for his work on the role of institutions in early European and American economic growth and in the experience with postwar growth in developing countries. His focus was on human cooperation that allows societies to capture the gains from specialization and trade stressed by Adam Smith in the *Wealth of Nations* (North 1990). He argues convincingly that an important determinant of a country's rate of economic growth is the extent to which institutions, as they evolve, create or fail to create a favorable environment for cooperative solutions to complex economic exchange.

Although North's analysis of differences in growth rates among countries, and within the same country over time, focused on the role of institutions at the subnational and national levels, there is little doubt that global economic integration spurred by ever more complex production and distribution chains has progressed to the point that his findings apply with equal force at the international level. If economic growth is a priority, a global economy requires multilateral economic institutions that can perform the essential institutional functions that, in successful economies, are carried out at the national level by national institutions. The WTO is the preeminent example of such a multilateral institution.

RICHARD BLACKHURST

■ World Trade Organization, accession to

Policymakers give a range of reasons for wanting their countries to join or accede to the World Trade

Organization (WTO). For some the rationale is to further integrate their country into the world economy. Here often the hope is that the better access to foreign markets that WTO membership can bring will result in higher exports. Another economic rationale is to encourage greater foreign direct investment and, more generally, to use WTO accession as a seal of approval recognized by the international business community. It is also the case, however, that many nations join the WTO for political reasons. Transition economies, for example, often see WTO membership as a means to join the international community of nations. Some see WTO accession as facilitating both political as well as economic reform processes within their countries.

There is some overlap between these stated rationales and the potential benefits of WTO accession identified in economic research, in particular as they relate to bolstering exports and foreign direct investment inflows. Economists would also point to the benefits that flow from better foreign access to the acceding nation's markets, specifically in terms of lower prices for and a greater variety of imports. By binding national tariffs, committing to eliminate quotas on imports, and reforming other state measures, an acceding nation can enhance the credibility of its policies and reduce the uncertainty facing the private sector. In principle, then, WTO accession can improve important components of the national business environment which, in turn, has sizable domestic payoffs.

The Process of WTO Accession Most WTO members were also contracting parties to the General Agreement on Tariffs and Trade (GATT) and automatically became founder-members of the WTO when it was established on January 1, 1995, because they had either signed the Marrakesh Agreement Establishing the World Trade Organization in April 1994 or because they had joined the GATT after April 1994 but before the WTO was set up. The Marrakesh Agreement also made provision for "any state or customs territory possessing full autonomy in the conduct of its external commercial relations and to the other matters provided for in this Agreement" to accede to the WTO. From January 1, 1995, to July 2007, 23 new members, including two least-developed countries (LDCs), have acceded to the WTO. At the time of writing, another 28 jurisdictions, 10 of which are LDCs, are in the process of acceding to the WTO.

Article XII.1 of the Marrakesh Agreement permits new members to accede on "terms to be agreed" between the applicant and the WTO. No guidance is given in the Marrakesh Agreement on the "terms to be agreed." However, the WTO Secretariat, in consultation with WTO members, has drawn up a set of procedures for accession that are closely modeled on those followed by contracting parties to the GATT. In brief, these procedures require that:

1. an applicant must send a communication to the Director-General of the WTO indicating its desire to accede to the WTO under Article XII;
2. this communication is then circulated to all WTO members and a decision is made whether to approve the establishment of a working party;
3. once a working party has been established and a chairperson has been appointed, the applicant submits a memorandum on its foreign trade regime;
4. the working party meets to examine the memorandum and the applicant provides further information and answers;
5. a Working Party Report is prepared;
6. at the same time, bilateral negotiations are undertaken on concessions and commitments on market access for goods and services (as well as other specific terms of accession);
7. a goods schedule and a services schedule are prepared;
8. thereafter, a draft decision and a draft Protocol of Accession (containing commitments listed in the Working Party Report and the goods and services schedules) are prepared;
9. the working party, and then the WTO's General Council or the Ministerial Conference, approves the accession package;

10. thereafter, the applicant formally accepts the accession package;
11. the applicant notifies the WTO Secretariat of its formal acceptance; and
12. 30 days later the applicant becomes a member of the WTO.

For the countries that joined the WTO most recently this process took on average 10 years.

The "Price" of WTO Accession Throughout the WTO accession process the onus is on the applicant to satisfy the demands of existing WTO members. This apparently one-sided procedure has given rise to the following perceptions about the accession process (Evenett and Primo Braga 2005):

- The WTO accession process is costly and complex.
- The WTO accession process is taking longer and longer to complete.
- The price of joining the WTO now includes commitments that go beyond the GATT/WTO agreements.
- The price of joining the WTO is steadily rising.
- The WTO accession process takes little account of the specific circumstances of applicant countries or their needs for special and differential treatment.

With respect to the evidence on the "price" of accession, it is important to distinguish between the two broad types of commitments made by acceding countries: those relating directly to market access (for goods and services) and other commitments on rules. Acceding countries may benefit from transition periods or exceptions to existing WTO rules, but these are rarely granted by existing WTO members. Concerning commitments to open national markets to foreign trade, in the areas of agricultural and non-agricultural (typically manufacturing) products there is clear evidence that the price of accession is growing over time. For both agricultural and nonagricultural goods the average tariff binding that acceding countries were allowed has fallen over time (to approximately 15 and 6 percent, respectively) and is now at levels well below those agreed by developing countries in the Uruguay Round (Evenett and Primo

Braga 2005). In short, from a mercantilist perspective the relative price of WTO accession is high (in comparison with Uruguay Round commitments made by peer nations) and growing over time.

From the first 20 completed WTO accessions the picture that emerges concerning service sector commitments tells a similar story. Taking the number of services subsectors (of the 160 identified in the WTO's classification list) committed by countries as a proxy for the "price" to be a WTO member, LDCs that were founding members of the WTO committed on average 20 subsectors. The averages for founding members in the developing and industrialized country categories, in turn, were respectively 44 and 108. Countries that have acceded since 1995, in turn, have on average committed around 104 subsectors. Needless to say, this is a crude measure of the "services-related" price of accession as this figure does not capture the depth (e.g., the scheduling of explicit limitations) or the breadth (e.g., the modes of delivery covered) of the commitment. Still, it is illustrative that countries that went through the WTO accession process typically committed a much higher number of subsectors than GATT contracting parties at a similar level of development did in the context of the Uruguay Round negotiations.

Turning to commitments on other policies that countries have adopted when joining the WTO, the picture is more mixed. With the exceptions of China and Taiwan accession countries signed around 25 such commitments. These commitments typically concern a wide range of state measures, some of which are not obviously trade related. Bulgaria, for example, made commitments with respect to domestic price controls, the privatization of state-owned enterprises, and excise taxes on alcohol, as well as many other traditional trade policy related measures. A controversial question is whether this class of accession obligation goes beyond the commitments agreed during the Uruguay Round (constituting so-called WTO-plus commitments) or involves an accession country agreeing to forgo the rights available to other WTO members (the so-called WTO-minus commitments).

Whether an accession obligation goes beyond an existing WTO agreement depends in large part on how the latter is interpreted, and so it should not be surprising that disagreement is rife on the extent of WTO-plus commitments. Moreover, some WTO-plus obligations may only involve consultation with, or reporting to, existing WTO members and thus are of limited developmental significance. Others may be more significant, such as Jordan's commitment that if any of its laws or state acts are subsequently found to contradict international treaties (not just WTO agreements), then the latter would have precedence. WTO-minus commitments are easier to identify, such as Ecuador's commitment to eliminate all subsidies before the date of accession and its commitment never to introduce them afterward. China's acceptance of product-specific transitional safeguard provisions, which can be more easily triggered than regular WTO safeguards, provides another example. WTO-plus and WTO-minus commitments differentiate WTO members, and they could be interpreted as contributing to a multitier multilateral trade system. This systemic concern is in addition to any of the adverse developmental effects that may result from these specific commitments.

In sum, there is evidence that the accession process is becoming more demanding in terms of market access commitments. In July 2004 WTO members recognized this trend and agreed that less liberalization be demanded of newly acceded members in the agriculture and nonagricultural market access negotiations during the Doha Round. Whether there is a trend increase in WTO-plus or WTO-minus commitments is unclear, but the very fact that existing WTO rules allow for them is a source of concern. Evidence on the latter should be interpreted with care in view of the possibility of a potential bias in the sample of recently acceded countries. After all, most of these countries were transition economies with highly distorted trading regimes to start with. Accordingly it could be argued that the higher demands of WTO members simply reflect this reality rather than a systemic trend.

The Empirical Studies of the Impact of WTO Accession The critical welfare question, however, is not whether the price of WTO accession is rising, but whether the price is worth paying in terms of its developmental impact. If it is, then the demands made by existing WTO members of acceding countries might be characterized as "tough love." Otherwise, the WTO accession process may well be seen as a one-sided power play whereby current WTO members wring commercial advantage out of weaker economic partners.

A comprehensive evaluation of WTO accession should examine postaccession performance on many metrics and should consider the state measures taken before and after the date of WTO accession. At present, few accession countries have five or more years of postaccession data to begin identifying the effect of WTO accession, so the available evidence here is necessarily limited.

The available country-specific research on WTO accession has almost exclusively focused on the case of China, an exception being an analysis of the response of Bulgaria and Ecuador's exports to their accessions (Evenett, Gage, and Kennett 2004). Other country analyses typically refer to countries in the process of accession, and a recent paper by Lissovolik and Lissovolik (2004) on Russia's potential WTO accession is a good example of this type of analysis. These authors found that after controlling for customary determinants of bilateral trade flows Russia's exports to WTO members from 1995 to 2002 were smaller than those to nonmembers. Rather than immediately attribute the export underperformance to Russia's nonmembership in the WTO, Lissovolik and Lissovolik consider four other potential explanations for this finding. Only one such explanation (the nature and extent of Russian export controls) survives scrutiny and the authors qualify their conclusions accordingly.

The second class of relevant literature includes a series of academic studies that have called into question widely held and long-standing views about the economic effects of WTO membership. Having documented numerous claims made by scholars,

officials, and international organizations about the beneficial consequences of WTO membership (and of membership in its predecessor, the GATT), Andrew Rose used conventional econometric tools to assess these claims in a series of papers. In one study he found no statistically significant effect of GATT/WTO membership on the value of bilateral trade flows over a 50-year period, a finding he regards as mysterious (Rose 2004). In another study he found that GATT/WTO accession increased the value of bilateral trade flows, but WTO membership itself does not (Rose 2005a). Moreover GATT/WTO membership was found in a third study not to have a statistically significant effect on the volatility of trade flows, as measured by the coefficient of variation of bilateral trade flows over a 25-year period (Rose 2005b). In these three studies GATT/WTO membership is captured in econometric specifications by the use of dummy variables, rather than directly identifying the changes in trade policies that followed from membership or accession.

Rose's findings have prompted others to revisit the questions he posed and the methods he employed. Subramanian and Wei (2003) diverge from Rose's earlier articles in two respects. First, they differentiate between the effects of GATT/WTO membership on industrialized and developing countries. More generally they note that there is no presumption that the effects of GATT/WTO membership are common across all goods and trading partners, hence calling into question the pooling of certain types of trade data. Second, they employ some of the latest techniques for estimating bilateral gravity equations that try to control for country-specific characteristics. These two departures appear to have led to substantially different findings. Subramanian and Wei find that WTO membership raised trade between industrial countries by 40 percent, whereas such membership only increased a developing country's trade if it joined the WTO after the completion of the Uruguay Round. Asymmetric results were found across sectors, and GATT/WTO membership is associated with greater effects on goods trade (which typically faces lower trade barriers than other

sectors). The authors note that these findings are consistent with the reluctance of industrialized economies to liberalize trade in food and clothing under the auspices of the GATT and WTO, and the fact that developing countries were not asked to undertake many liberalizing commitments before the completion of the Uruguay Round.

Noneconomists have also contributed to the literature on the effects of WTO accession. Goldstein, Rivers, and Tomz (2003) draw on the insights of the international relations literature to assess the effects of international institutions on trade patterns. They note that many customs territories (which need not be nations) participated in the GATT and WTO before formally becoming members of these institutions. The date of accession, therefore, may not accurately reflect the point at which a nation begins to align itself with multilateral trade rules. Another interesting observation is that the effects of GATT and WTO membership are likely to be conditional on prevailing preferential trading arrangements and on the nature and history of certain state-to-state ties, such as former colonial links. These authors also undertake a gravity equation analysis and find that, although the GATT/WTO appears to have increased trade among members, these institutions have contributed to faster growth of trade among nonmembers.

To summarize, there is a dearth of empirical evidence on the effects of WTO accession on the developmental prospects of developing countries. This weak evidential base has created a vacuum that has been filled by doubts about the case for opening markets and taking WTO obligations and negotiations seriously. Some have questioned whether developing economies, especially least-developed countries, should be encouraged to use the WTO as a forum to structure national development efforts. Moreover it is difficult to see how technical assistance programs, especially those initiatives that enable firms to capitalize on postaccession export opportunities, can be effectively designed without a better understanding of the economic consequences of WTO accession. One challenge for the scholarly

and policymaking communities in the coming years is to fill this knowledge gap.

■ World Trade Organization dispute settlement

The dispute settlement system of the World Trade Organization (WTO) is the mechanism through which members thought to be in violation of their trade agreement commitments present their cases to a third-party panel for decision. The system evolved from the dispute settlement process of the WTO's predecessor, the General Agreement on Tariffs and Trade (GATT), which first embarked on the process of resolving disputes among its signatories in 1948. GATT's dispute settlement process was initially re ferred to as a process of "conciliation," not arbitra tion, and was supervised by a panel of experts that generally consisted of diplomats, not lawyers.

The goal of this process was to reach a solution mutually agreeable to the parties rather than to es tablish and apply binding legal principles. It did this reasonably well, but there was one major shortcom ing. GATT, as its name makes clear, was a multi lateral agreement. Indeed, strictly speaking, GATT had no "members." Signatories were known as "Contracting Parties." Since GATT was simply a

contract among a group of parties, any action required a consensus of all of those parties. This allowed parties whose practices were challenged to block the establishment of a dispute settlement panel or the adoption of an adverse panel report. There was considerable dissatisfaction with this aspect of the system.

Although some amendments to improve the GATT dispute settlement system were made over the years, it took the establishment of the WTO's dispute settlement system in 1995 to put in place an effective legal system, including an Appellate Body to which panel decisions may be appealed.

The WTO dispute settlement system is governed by the Understanding on Rules and Procedures Governing the Settlement of Disputes, known as the "Dispute Settlement Understanding" or "DSU," and is administered by a Dispute Settlement Body (DSB), which consists of representatives of each WTO member. The DSB is the sole WTO body with authority to establish panels, to adopt their reports and those of the Appellate Body, to maintain surveillance of the implementation of the rulings and recommendations it adopts, and to authorize the suspension of concessions or other obligations under WTO agreements if its rulings and recommendations are not acted on by members in a timely fashion.

The power of the DSB is, perhaps, the biggest difference between the GATT and WTO systems. Consensus is still required, but it is "reverse consensus." Consensus is required *not* to establish a panel when a request is made, reversing the GATT practice of requiring consensus to do so. Since at least one member, the complaining party, always wants the panel to be established, this effectively means there can be no reverse consensus. This reverse consensus rule also applies to the other major functions of the DSB, including the adoption of reports and the authorization of the prevailing member to impose the WTO remedy of suspension of trade concessions or other obligations on a losing member that does not implement the DSB's recommendations.

Jurisdiction The WTO agreements are between governments and impose obligations only on gov-

ernments. Therefore access to the dispute settlement system is limited to member governments   private interests have no right of access. Although panels and the Appellate Body sometimes accept amicus curiae submissions from private interests, they have rarely accorded much weight to these submissions in their analysis.

The subject matter jurisdiction of panels and the Appellate Body is limited to the interpretation of the provisions of the WTO agreements cited by the complaining party. Although there is much discussion of whether WTO panels and the Appellate Body should consider other international agreements and principles of public international law as part of their work, they have done so only to assist in interpreting the WTO agreements. The DSU instructs panels to interpret the agreements in accordance with the "customary rules of interpretation of public international law." This has been understood to refer to the Articles 31 and 32 of the Vienna Convention on the Law of Treaties, which places primary emphasis on the role of the ordinary meaning of a treaty's text rather than the history of its negotiation.

The Panel Process The WTO panel process is, unexpectedly, a legalistic one, with rules providing for the establishment and composition of panels and for the procedures they are to follow. The system's diplomatic heritage in GATT is reflected at the outset, however, by the requirement that the process begin with a formal request from one member to another for consultations concerning the subject of the dispute. Only after these are held may a member with a grievance move on to request the establishment of a panel and its procedures to resolve the dispute.

Consultations The consultation requirement concerns those "measures affecting the operation of any covered agreement taken within the territory" of one member that are deemed by another member to contravene WTO commitments. In most cases, however, informal bilateral consultations between the parties have already taken place; consequently, the formal request for consultations is often seen as an effort by the requesting member to signal to the other member that the matter at issue is serious.

The purpose of consultations is to enable the parties to gather relevant, and correct, information both to assist them in reaching a mutually agreed solution or, failing that, to assist them in presenting accurate information to the panel. Many disputes do not proceed beyond the consultations stage.

The request for consultations plays an important role in defining the jurisdiction of the eventual panel in the dispute. The DSU requires that the complaining party give the reasons for the request, identify the measures at issue, and indicate the legal basis for the complaint. This forms the basis for a subsequent request for the establishment of a panel, although there need not be an exact identity between the measures identified in the request for consultations and those identified in a request for the establishment of a panel. Consultations are confidential and take place bilaterally without any WTO involvement. What transpires during the consultations is not the concern of a panel.

Other WTO members have a limited role in consultations. A complaining member may draft its request for consultations so that even third-party members with a substantial trade interest may not participate. Tactical considerations usually dictate the complaining member's decision on this point. Of course, those third-party members may participate in the panel procedure itself even if they have not been permitted to participate in consultations.

Requests to Establish a Panel The complaining member's request for the establishment of a panel is a fundamental, jurisdictional document. It is incorporated into the panel's terms of reference and, therefore, determines the subject matter jurisdiction of the panel. It also fulfills the due process objective of notifying the responding party   and other WTO members as potential third parties   of the claims at issue. Because of its jurisdictional importance, disagreements over the scope of terms of reference arise frequently.

The formal requirements of a request for the establishment of a panel are set out in the DSU: the request must be in writing, indicate whether consultations were held, identify the objectionable measure taken by the other member, and specify the

"legal basis for the complaint." A measure typically is a law or regulation, or an action that applies a law or regulation. The cited measure, together with the legal basis for the complaint, that is, the provisions of the relevant WTO agreement cited in the panel request, constitutes the "matter" over which the panel has jurisdiction.

Composition of Panels Panels normally are composed of three persons, with one serving as chair. Panelists usually are present or former members of nonparty delegations to the WTO or academics who are not paid for their service. Unless the parties agree, panelists may not be nationals of parties or third parties to the dispute. They serve in their individual capacities, not as government representatives or representatives of other organizations. A developing country that is a party to a dispute may request that at least one panelist shall be from a developing country.

Usually panelists are nominated by the WTO Secretariat from member delegations and from a roster of governmental and nongovernmental individuals who are deemed qualified by virtue of their training or experience. If the parties do not agree on panelists within 20 days of the establishment of the panel, either party may request the Director-General of the WTO to name the panelists. Although the DSU instructs members not to oppose nominees of the Secretariat except for compelling reasons, parties frequently have proven unable to agree on the composition of the panel, leaving the Director-General to appoint the panel.

Procedures Panels normally issue their own detailed working procedures soon after their members have been named. These procedures supplement the more general Working Procedures set out in the DSU and may cover topics ranging from the panel's schedule and deadlines to the required format for submissions. Although the DSU sets out some time limits for panels' work, these often prove too short, and panels frequently depart from them, usually with the agreement of the parties and notice to the DSB. Despite these delays, WTO dispute settlement is widely seen as comparatively rapid for litigation as complex as most WTO disputes are.

Although normally all of the relevant information is submitted to a panel by the parties, panels are not confined to the parties as sources of the information they need. They have the right to seek information and technical advice from any source they deem appropriate. They may obtain opinions from experts and, with respect to scientific and technical matters, may request an advisory report from a more formal expert review group.

Other WTO members may participate to a limited extent in panel proceedings as third parties. When a panel is established, the chairman of the DSB usually specifies that members wishing to participate as third parties should file their notifications within 10 days. Third parties are normally entitled to receive only the first submissions of the parties to the panel and to participate in a special session of the first meeting of the panel with the parties. However, members have been granted enhanced third-party rights in several instances.

Meetings of WTO panels with the parties are normally confidential, but, with the agreement of the parties, some panels have opened their meetings to the public or permitted the rebroadcast of portions of the hearings that do not involve confidential information.

Few individuals have served on more than one or two WTO dispute settlement panels. Accordingly, the role of the WTO Secretariat, which provides legal and secretarial advice to panels, cannot be overstated. Not all panelists feel qualified to disagree with the Secretariat on points of law. Although there have been proposals to create a permanent roster of panelists, these proposals have not yet achieved consensus approval.

Panels normally conduct two separate meetings with the parties. At these meetings, the parties present formal statements of their arguments or rebuttals, after which the panel questions them on the details of their arguments. Panels vary greatly in their degree of activity during meetings with the parties. Some will interrupt presentations to ask questions as they arise; others will question after a presentation is concluded; still others do so only after both sides have finished their presentations; and a few present no oral questions at all, but rely entirely on written questions.

Prior to the issuance of their final report, parties are given the opportunity to review an interim report. They may submit comments on this report and may request a meeting with the panel to discuss these comments. In most instances, parties do not request a meeting with the panel, but simply submit written comments on the report. The interim review stage is not intended to present an opportunity to reargue the issues. Generally panels do not revise their substantive findings following the interim review stage, although there have been some exceptions. Although interim reports are supposed to be strictly confidential, their release to the parties provides the first disclosure beyond the Secretariat of the outcome of the proceeding. The gist of the panel's findings frequently makes its way to the press at this point.

The Appellate Process The creation of a standing Appellate Body, staffed by its own secretariat and therefore largely independent of the rest of the WTO, was one of the two most important additions to the GATT dispute settlement system by the WTO. The other, of course, was "reverse consensus." About half of the reports of panels are appealed to the Appellate Body.

The WTO Appellate Body consists of seven members appointed for four-year terms, which may be renewed once. Members serve on a paid, part-time basis. The DSU requires that members be persons of recognized authority and demonstrated expertise in law, international trade, and the subject matter of the WTO agreements. Members may not be affiliated with any government. For the most part, the members have been experienced trade negotiators and lawyers. Generally they have been appointed with a view to ensuring a broad geographic representation on the Appellate Body.

Cases are heard by a Division of three of the seven members of the Appellate Body who are selected on the basis of a rotation system intended to ensure random selection and unpredictability. Unlike panelists, Appellate Body members may serve on any case, including those involving their own country. The Division selects a presiding member, whose

responsibilities include coordinating the overall conduct of the proceeding, chairing oral hearings and meetings, and coordinating the drafting of the appellate report. The Appellate Body has adopted its own working procedures, which specify the schedule for each proceeding as well as the required format and content of notices of appeals and other submissions. The Appellate Body's proceedings, like those of panels, are confidential and closed to the public.

Reports of the Appellate Body are signed by all members of the Division. The DSU provides that opinions expressed by individuals shall be anonymous. At the time of this writing (in late 2007), there have been two separate (dissenting) opinions contained in reports of the Appellate Body.

The jurisdiction of the Appellate Body is limited to issues of law covered in a panel report and to legal interpretations developed by a panel. The Appellate Body may uphold, modify, or reverse the legal findings and conclusions of a panel. If it modifies or reverses the findings, however, the Appellate Body may not remand the matter to the panel for further proceedings.

Perhaps the greatest impediment to the work of the Appellate Body is the requirement that it must normally complete the entire appeal process within 60 days and, according to the DSU, in not more than 90 days. Since the panel process normally averages approximately a year to complete, this is an extremely restrictive deadline. On occasion the Appellate Body has found it simply impossible to complete the task within this deadline and the parties have agreed to extend this deadline.

Adoption and Implementation of Reports Panel reports are formally adopted by the DSB within 60 days of their circulation to all members unless a party gives notice of its decision to appeal the report or the DSB decides by consensus not to adopt the report (which has never happened since the creation of the WTO). Appellate Body reports are normally adopted within 30 days of circulation, again unless the DSB decides by consensus — which must include the prevailing party — not to do so.

Generally, where they find in favor of a complaining party, panels and the Appellate Body simply recommend that the defending party bring its measure into conformity with the relevant WTO Agreement. The defending party must normally state its intentions in this regard at a DSB meeting within 30 days of the adoption of the report. The defending member then has a "reasonable period of time" within which to bring its measure into conformity. Ideally the duration of this "reasonable period of time" is negotiated between the parties to the dispute. If agreement cannot be reached, the DSU provides for an arbitration process, to be completed within 90 days, as to the duration of this period. These arbitrations are conducted by a sole arbitrator agreed on by the parties or, absent agreement, appointed by the WTO Director-General. Arbitrations are relatively infrequent.

In implementing the panel or Appellate Body rulings, the defending member need only ensure that its measures and actions are WTO-consistent with *prospective* effect. There is no obligation to take any action to redress the past effects of any WTO-inconsistent actions.

If the defending member fails to act within the reasonable period of time or the complaining member is not satisfied with the manner in which the defending member has acted, the complaining member may refer the matter back to the original panel. Following a truncated version of the normal process, the reconstituted panel issues a further report — nominally within a 90-day deadline but in practice within about 6 months — as to whether the defending member properly implemented the original panel or Appellate Body's report and is now in compliance with the relevant provisions of the WTO Agreements.

The DSU contains a procedural inconsistency in this area that has led to the so-called sequencing problem. In addition to providing for review of disputes concerning a defending member's compliance with rulings in adopted panel or Appellate Body reports, the DSU also grants complaining members rights (described later) to take certain retaliatory actions in the event of inadequate implementation. The deadline for both actions begins when the time for the defending member to comply has expired,

however. The DSU allows, as noted, 90 days for a review of compliance. But it calls for the retaliatory action to be taken within 30 days of the expiration of the time for the defending member to comply 60 days before the members can even know what the compliance ruling will be. In other words, a member wishing to retaliate is called on to do so 60 days before it can know whether it is entitled to do so. This "sequencing" problem has generally been resolved by bilateral agreements between the parties suspending and preserving the retaliatory rights of the complaining member pending the outcome of the review proceedings.

Remedies Where a defending member fails to implement properly an adverse panel ruling, both the GATT and WTO dispute settlement systems provided for remedies in the form of compensation or suspension of concessions. *Compensation*, in GATT/ WTO parlance, refers not to monetary compensation, but to a reduction in the defending member's tariff rates or other trade barriers designed to offset the trade harm to the complaining member resulting from the impugned measure. *Suspension of concessions* refers to the imposition by the complaining member of additional tariffs or other trade barriers against imports from the defending member.

The DSU provides that the level of suspension of concessions shall be "equivalent" to the level of nullification or impairment of benefits due to the complaining. This can be difficult to quantify, so the DSU provides the possibility of arbitration, by the original panel or an arbitrator appointed by the WTO Director-General, to determine the appropriate level of retaliation. Economists have frequently pointed out that these "remedies" do not benefit the member taking retaliatory action. Others have pointed out that they also do not benefit the complaining member's exporting industry, which presumably was the intended beneficiary of the action. Both of these points are correct, but they overlook the political statement that retaliatory action, or the credible threat of such action, makes in both the domestic politics of the members concerned and in the internal politics of the WTO. It is also noteworthy that, on several occasions, members have

obtained the right to retaliate but have refrained from doing so, presumably because they have realized that not only would such action not benefit their economies but, on the contrary, could harm them.

WTO members continue to negotiate to revise and improve the system. The issues under negotiation largely concern procedural matters, such as the sequencing problem and the panel selection process. Some members see the Appellate Body's lack of authority to remand a dispute back to a panel for further proceedings as a shortcoming. Others see the limited remedies available as a shortcoming, while still others are unwilling to accept a regime with stronger sanctions.

Nevertheless, since its inception the WTO dispute settlement system has been one of the most active forums, if not the most active, in the entire field of public international law. It has produced an extensive body of jurisprudence, and has, for the most part, been highly effective in its stated mission of "providing security and predictability to the multilateral trading system."
