Internships offer benefits to the intern, the sponsoring organization, and the academic institution. The intern gains valuable work experience that reinforces classroom training, usually earns money, and can earn school credit at the same time. The work experience imparts knowledge of the industry: the specific terminology and work atmosphere. The intern gains confidence in his or her social skills, critical-thinking skills, and specific work-related skills. The experience provides the intern with an enhanced knowledge of self and the potential to achieve career aspirations. The internship experience helps the intern determine genuine interest in a particular career path. Most important, the capable intern is in a strong position for future full-time employment with the sponsoring organization, clearly ahead of other candidates for available job openings.

The sponsoring organization gains an opportunity to build rapport with the school while getting a close look at specific job candidates. Internships offer the employer an opportunity to develop a pool of talented individuals in its own industry. If the intern is properly supervised, the employer will get real work accomplished at reasonable expense. Interns can bring a refreshing level of enthusiasm to an organization.

Internships provide schools with an opportunity to enrich academic programs with practical applications to theoretical concepts. Strong relationships between sponsoring organizations and schools serve to improve curricula by keeping academic programs in sync with industry changes, and sponsoring organizations can provide fertile soil for ongoing academic research at the university or college.

To achieve optimum results for all concerned, both the sponsoring organization and the intern need to be prepared. The internship supervisor should manage this preparation. The preparation includes writing an internship agreement, briefing coworkers, preparing the intern, and creating intern-specific evaluation criteria.

The internship agreement delineates the responsibilities of the intern, the sponsoring organization (as represented by the workplace supervisor), and the

school (as represented by the internship supervisor). The agreement also specifies what is to be accomplished by all of the parties: work to be completed by the intern plus interpersonal and technical skills to be introduced and/or improved. The agreement clarifies behavioral requirements of the intern, including personal demeanor and business dress requirements.

Coworkers and the immediate supervisor(s) need to be apprised of the internship, including its goals and duration. Work assignments must be able to be completed within the time frame of the internship and must be in support of the educational goals established in the internship agreement.

The intern should research the sponsoring organization, the work discipline, and the industry within which he or she will be working. This research enhances the educational effect of the internship, helps set realistic expectations, and highlights required job skills to be learned in preparation for the experience.

Evaluation criteria should be established to help ensure that the objectives of the sponsoring organization and the intern are met. A formal evaluation should be completed at the end of the intern experience to provide feedback to all parties. Intermediate evaluations are useful to keep the intern and the sponsoring organization on track and allow for suggested course corrections as required. The evaluation criteria should comprise a mix of objective observable milestones and an analysis of interpersonal characteristics.

The key to successful career management is the development of a clear self-identity supported by career strategies and goals. If properly supported by high-quality sponsoring organizations and internship supervisors, internships have proven to be an invaluable career-management tool for college students in the development of both a clear self-identity and the setting of career goals. Furthermore, internships deliver tangible results because they provide the intern with an advantage in securing employment at the time of graduation in the chosen discipline and industry. Supporting organizations should continue to offer internships to ensure a steady flow of qualified and interested future employees. Schools should encourage and support internship programs in light of their practical and educational value. Students should avail themselves of such opportunities to gain a better self-understanding and a distinct advantage in the work world.

JOB CHALLENGE

Job challenge can be described as the extent to which a job is stimulating and interesting. Challenging jobs provide an opportunity to strengthen, develop, and learn skills applicable to the work world. A common theme in the research literature is that employees desire work experiences that include challenging jobs and that such jobs increase employee and organizational effectiveness.

Job challenge highlights the importance of considering job factors or job characteristics in understanding many aspects of organizational life. A focus on job factors enables organizations to develop and design practices and programs that will enhance employee performance. Job factors include a number of dimensions, some of which (such as a high level of variety and substantial autonomy on the job) combine to produce job challenge. Job challenge is a powerful characteristic that is closely linked to career development, intrinsic job satisfaction, organizational commitment, motivation, empowerment, and personal goal achievement.

The career-development programs of some organizations include recruiting college student interns who upon graduation become employed by the organization. For both parties to benefit from the work relationship, organizations need to design jobs that allow interns to develop, strengthen, learn, and apply new skills. Job challenge is among the key variables that have contributed to successful work experiences among undergraduate college interns. In fact, interns who are given challenging jobs report higher organizational commitment when they join their respective organizations

upon graduation and continue with challenging assignments. Researchers suggest that the confirmation of the interns' preentry expectations contributes to their commitment and loyalty to the organizations within the first six months of their employment.

Newcomers into an organization, especially recent college graduates, desire challenging jobs. One study of how recent graduates view their jobs revealed that the graduates' highest initial expectations were for on-the-job challenge and diversity, as well as opportunities for technical or managerial career advancement. Job challenge has long been established as particularly important for employees at the early stages of their careers. Organizations should be cognizant of the fact that providing employees with challenging jobs at the early career stage can be critical to achieving later career success.

It is also important to recognize that recent trends such as globalization and advances in information technology have contributed to an uncertain and mobile labor market, wherein employees may experience several entry stages into various organizations during their work lives. In the current work environment, individuals bear the primary responsibility for managing their careers and seeking challenging jobs during their entry into different organizations. Some organizations' career-development programs reflect this changing work landscape by focusing on activities that allow employees to continually add to their skills, abilities, and knowledge. Hence, career-development responsibilities of organizations include providing employees with opportunities to acquire new, interesting, and professionally challenging work experiences.

Job design has contributed to our understanding of motivation. Job design directs attention to the job itself, matching job factors with employees' skills and interests. Studies have found that incorporating varying degrees of five core job dimensions—skill variety, task identity, task significance, autonomy, and feedback—into employees' work will enhance the achievement of personal and organizational outcomes. Creating jobs that require employees to use a wider variety of skills will result in more challenging work assignments that subsequently serve to motivate employees.

The way jobs are structured contributes to employees' intrinsic motivation and creative performance at work. Employees are more likely to break cognitive mind-sets and develop creative responses to job demands if they have challenging work. Research has found that individuals who perceive their jobs as challenging are intrinsically satisfied with their jobs, work harder and smarter, and enhance their performance on the job.

Job challenge has been studied both by itself and in combination with other job factors. For example, job challenge and job significance are major factors in producing job satisfaction and in motivating an individual to learn on the job. In a similar vein, research-and-development professionals who have challenging jobs and freedom to determine how to do their work have been found to increase their creativity.

Practices that promote job challenge have been linked to employee empowerment and the achievement of personal goals. When organizations incorporate or adopt policies that increase job challenge, employees build self-confidence as they learn and utilize new skills to accomplish a task, choose among alternative ways of accomplishing the task, and alleviate feelings of helplessness. Possessing challenging jobs and receiving training to perform them successfully empower employees toward satisfying both individual needs and organizational goals. Having empowered employees can translate into multiple benefits for both parties.

In light of recent developments in the work of work (e.g., globalization, information technology, reorganization, transition to a knowledge economy), a focus on work experience is becoming inevitable. This has increased interest in job factors such as job challenge, which has recently been considered to be a dimension of an organization's culture. Moreover, for organizations to fulfill their career-development responsibilities to employees in the changing work world (e.g., encouraging self-reliance and continuous learning), a focus on employees' work assignments and job experience is essential.

We should note that although job challenge is rarely studied in isolation, research suggests that challenging jobs or work experiences are fundamental to achieving a number of positive individual and organizational outcomes. We also need to acknowledge that individuals may differ in their responses to challenging jobs (that is, not every employee thrives on challenging work) and to be aware of individual differences in discussing the benefits of a challenging job.

JOB DESIGN

Job design, or *work design*, refers to a process of dividing an organization's total work into various jobs and assigning tasks to those jobs. It may also involve examining the goals and interdependence of tasks as well as the interpersonal relationships involved in

accomplishing work. Because the tasks involved in doing a job and how these tasks are performed can change, managers need to know how to design and redesign jobs to make them as meaningful and productive as possible. Thus, a good job design is one that meets organizational requirements for high performance, offers a good fit with individuals' skills and needs, provides workers with challenging goals and meaningful work, and provides opportunities for job satisfaction and career advancement.

The implications of job design for employee career development are considerable. For example, organizations today are becoming "learning organizations" that value not only financial capital but also intellectual capital. Organizations must have the capacity to acquire, share, and use knowledge effectively. This includes providing workers with opportunities to learn and develop. To accomplish this, the right systems and structures need to be in place to support the management of knowledge.

The way a job is designed can also affect a worker's level of activity. For example, research evidence suggests that oversimplified jobs can lead to apathy and reduced drive and motivation. This indifference can often be reversed through increased complexity and autonomy. Other studies have demonstrated that autonomy and control can positively affect cognitive development and intellectual flexibility. Equally important is the effect job design could have on employee well-being. It is well documented that autonomy, or having control over various aspects of work, has a positive effect on health and well-being. That is, job-design factors can eliminate or minimize the negative effects that stressful job demands have on mental and physical health. Similarly, a well-designed job can actually foster learning and a feeling of mastery over time. This acts as a type of coping mechanism for workers in stressful work situations and leads to a greater capacity to learn and grow.

Another career implication concerns the opportunities for personal advancement. Many organizations have structures with reduced hierarchical levels. Instead of the traditional, rigid chain of command, employees or teams of employees are empowered to take responsibility for and control over their work. As decision-making discretion is delegated downward, there is less need for supervisors and managers. This, in turn, limits the promotional opportunities in a given organization and creates a need for new career-development choices, such as horizontal learning

options (e.g., another department's job, additional or new technical skills, short-term projects). The challenge for organizations is to provide these types of learning opportunities and create reward systems that recognize them.

Historically, the focus of job-design efforts can be traced back to what has become known as the philosophy of *job simplification* or *job specialization*, whereby complex tasks are broken down into a series of simpler tasks to enhance performance. In more recent years, however, the nature of work has changed dramatically. A number of job-redesign strategies have been adopted by organizations to counter the negative psychological effects of specialization, including job enlargement, job enrichment, and autonomous work groups. These ideas were popular during the 1960s and 1970s, and various aspects of these designs can be seen today in the form of high-performance teams, empowerment, learning organizations, and total quality production.

Information technology has also changed many jobs in the last 20 years. In some cases, workers experience increased responsibility and control through immediate access to information and resources. In other cases, however, employees perform routine work, face time pressures, are constantly monitored, and have little control over their work because of the use of computer information systems. In any event, whether the changing nature of work is brought about through technology or through increased efficiency or flexibility, there are often conflicts between an employee's motivation to work and the pressures to maximize productivity and sales.

JOB SPECIALIZATION AND WORK EFFICIENCY

Job specialization occurs when the work required to complete a product or service is divided into smaller tasks. This is often referred to as *horizontal division of labor*, whereby employees actually perform fewer tasks. The economic benefits of dividing work into specialized jobs have been described for centuries and include improved work efficiency. For example, in 1776, Adam Smith argued that work specialization leads to greater efficiency because employees have fewer tasks to complete and spend less time changing from one task to another. In addition, new machines were invented to help facilitate and automate work so that one individual could perform the work of many. Finally, workers could

practice their tasks more frequently, and thus fewer resources and less training were required.

Frederick W. Taylor, an industrial engineer, was one of the strongest supporters of job specialization and established the foundation for modern industrial engineering. In 1911, he presented his principles of scientific management. In essence, they are as follows: (a) replace rule-of-thumb work methods with methods based on scientific study; (b) scientifically select, develop, and train each worker; (c) work closely with workers and cooperate with them to ensure the scientific methods are followed; and (d) divide the work so that managers apply scientific principles to planning the work, while workers actually perform the tasks. Additional elements of scientific management include time studies, specialized supervision, standardization of work methods, standardization of tools and equipment, and a separate planning function. Taylor argued that management and workers needed a complete revolution in their attitudes toward work. He asserted that there was “one best method” of doing every job so that efficiency was maximized. Today, many of the methods used by Taylor are commonplace in many organizations and include providing incentives for workers, examining the interdependencies between people and machines, setting performance standards, setting goals, and providing employee training.

Job specialization often increases work efficiency; however, it doesn't necessarily improve job performance or employee well-being. Early research into the practice of work specialization focused on the consequences of performing low-skill, repetitive jobs for long hours. Generally speaking, this research confirmed the notion that too much specialization produces negative work attitudes, such as job dissatisfaction, fatigue, and boredom. Furthermore, psychological health and well-being can also be negatively affected if a job doesn't offer a worker the opportunity to use a variety of skills and provide a sense of accomplishment and personal growth. As a result, several work design alternatives to job simplification emerged in the workplace and are still popular today.

WORK MOTIVATION AND JOB DESIGN

Job Rotation

Job rotation involves workers moving at regular intervals from one job to another to reduce fatigue and boredom. Many organizations introduce job rotation

as part of a larger redesign effort to increase the flexibility and skills of the workforce so that there are few disruptions when a worker is absent from the job or staff shortages occur. As traditionally used, job rotation may not always have the desired effect of improving efficiency or job satisfaction, because employees often move from one routine job to another. Nevertheless, employees can benefit from job rotation because they are able to use different motions and muscles, thereby reducing repetitive stress injuries.

Job Enlargement

To counteract oversimplification, another design method commonly used in organizations is *job enlargement*. Rather than rotating employees from one job to another, job enlargement boosts the complexity of work by increasing job range or the number of tasks employees perform within their jobs. This can be accomplished by combining two or more jobs into one or by adding tasks to a given job. Either way, this approach is based on the notion that increasing skill variety will reduce the repetitive nature of the job and help reduce boredom. Job enlargement can improve efficiency and flexibility. However, it can be viewed by workers as merely adding more routine tasks to their already boring jobs. Research suggests that simply adding tasks to a job doesn't necessarily affect employee job satisfaction, motivation, or performance. To achieve these benefits, employees should have the opportunity to use a variety of skills combined with the opportunity to increase job knowledge, while having some discretion in how work is structured. These characteristics are central to job enrichment.

Job Enrichment

In general, *job enrichment* refers to the empowerment of workers to assume more responsibility for scheduling, coordinating, and planning their work. In addition, employees should be recognized for their achievements and have the opportunity to advance and grow as they perform their jobs. During the period between 1950 and 1980, there were major theoretical developments in the field of job design that continue to exert considerable influence today. One of these developments, *vertical job enrichment*, was based on the work of Frederick Herzberg, an industrial psychologist who studied the various sources of job satisfaction and dissatisfaction at work. Herzberg and his

colleagues began their research in the mid- to late 1950s by interviewing 200 accountants and engineers. Herzberg's main proposition was that job satisfaction and job dissatisfaction were independent concepts and not opposite ends on a single continuum.

Herzberg's interview data revealed that certain work characteristics seemed to influence employee satisfaction, whereas other characteristics appeared to affect worker dissatisfaction. Factors that increased satisfaction were achievement, advancement opportunities, recognition, responsibility, and the nature of the work itself. He labeled these work characteristics "motivators" and argued that they were more intrinsic to the work itself. In contrast, factors that were related to job dissatisfaction were working conditions, company policies and administration, interpersonal relations, and employees' relationships with their supervisors. Herzberg labeled these characteristics "hygiene factors," because they were believed to be extrinsic to the performance of work and could help maintain motivation but more often contributed to a decrease in motivation. Herzberg suggested that for managers to motivate employees, they should pay less attention to work conditions, company policies, and salary and instead try to design jobs that include opportunities for recognition, growth, and achievement.

During the late 1960s, Herzberg's notion of separate determinants of job satisfaction and dissatisfaction generated more empirical research than any other job-design strategy and was embraced by many practitioners. Over the years, however, many critics have questioned Herzberg's theory and methodology because other research studies failed to replicate his findings. Not surprisingly, Herzberg's two-factor theory lost credibility and has not proved to be a useful guide for practicing managers. Nonetheless, the notion of job enrichment—designing jobs that satisfy higher-order needs for responsibility, recognition, achievement, and growth—continues to influence job-design efforts and stimulate interest in motivation and job satisfaction.

Another major development in the field of job design that is one of the best-known approaches to job enrichment is the *job characteristics model*. In 1975 and 1976, J. Richard Hackman and Greg Oldham identified five core job dimensions: skill variety, task identity, task significance, autonomy, and feedback.

These five core job characteristics influence the extent to which workers experience three critical psychological states. The first of these is *experienced meaningfulness*: the belief that one's work is worthwhile or

important. Skill variety, task identity, and task significance combine to influence the experienced meaningfulness of work. The second psychological state is *experienced responsibility*: the degree to which workers feel personally accountable and responsible for the results of their work. Autonomy contributes to the worker's experienced responsibility for work outcomes. Employees must have the opportunity to control their work environments in order to feel responsible for their successes and shortcomings. The final psychological state is *knowledge of results*: the degree to which employees are aware of the effectiveness of their work or understand how they are performing. Feedback from actually doing the job determines whether a worker will have knowledge of the results of his or her work. This type of feedback comes from performing the job itself, not from a manager's performance appraisal. The critical psychological states, in turn, promote work motivation, job satisfaction, performance, and reduced absenteeism and turnover. The model assumes that autonomy and feedback are more important than the other three work characteristics and that employees with higher growth needs (e.g., desire for learning, development, challenge) will respond more favorably to enriching jobs than will employees with lower growth needs.

To date, the job characteristics model has proved to be the most widely used theoretical model for job-redesign efforts ever conceptualized. Interestingly, though, many of the specific predictions of the model have not been supported by two decades of empirical research. For example, the core job characteristics are better predictors of affective outcomes, such as motivation and satisfaction, than they are of behavioral or objective outcomes, such as performance, absenteeism, and turnover. Second, the core job characteristics don't necessarily work through the critical psychological states to predict the various outcomes. In other words, they directly predict many of the outcomes. Finally, the identified job characteristics have not always been found to be separate aspects of jobs. Nevertheless, the model continues to be a useful and valuable tool.

The job characteristics model hasn't changed much from its original theoretical development. In 1996, Hackman and Oldham omitted absenteeism and turnover as potential outcomes and added growth satisfaction. Competencies and satisfaction with contextual factors are now included with the strength of growth needs as potential individual differences.

SOCIOTECHNICAL SYSTEMS APPROACH

The models of job enrichment discussed previously have primarily focused on the individual and individual work units. They are not always appropriate for group or team-based structures. The sociotechnical systems approach to enrichment originated in the early 1950s at the Tavistock Institute of Human Relations in London and provided a foundation for group designs. Studies of coal-mining processes in Great Britain found that productivity can suffer when either technical or social factors are allowed to dictate work processes. In essence, the model advocates designing work that integrates people and technology to optimize the relationships between social systems and technology. That is, if frequent interaction is required by the production technology being used, workers should work in groups that allow them to communicate as they perform their job duties. This would enhance employee job satisfaction and performance in the workplace. The Tavistock researchers identified some general principles or requirements that are central to employee motivation and satisfaction. These requirements are similar to the work of Hackman and Oldham but were developed independently in England. They are as follows:

Workers should be able to see an identifiable product as a result of their work.

Workers should be able to see how their products affect others.

Workers should have some decision-making discretion.

Workers should be able to continuously learn while on the job.

Workers should be trained and have their work recognized by others.

The more contemporary concept of semiautonomous work groups evolved from this innovative research. In essence, work groups are given decision-making discretion over various aspects of their work, such as what methods to use and how to solve problems and allocate resources. More recently, we've seen labels such as *self-managed teams*, *self-directed work groups*, or *flexible work groups* to describe this type of work design. Without question, the sociotechnical approach to enrichment has had a major impact on group research and practice. There has been an increase in team-effectiveness models, which make

more precise propositions and specifications about how group processes and group design factors affect outcomes. In addition, the potential advantages and disadvantages of group-based designs have been studied and documented. For example, group workers often experience increased job satisfaction and commitment and are able to produce more at reduced costs. Furthermore, there are often fewer accidents, lower turnover, and improved mental health when employees are involved in group-based work.

The sociotechnical systems model has been criticized for focusing too much on production and manufacturing settings and for advocating that "groups" are the answer to most organizational problems. This approach has also neglected to recognize the effects that individual differences and organizational culture could have on employees' attitudes and behavior. Nevertheless, using this type of design does strengthen motivation, satisfaction, and similar work attitudes, and it has proved to be of great value to practitioners.

FURTHER DEVELOPMENTS IN JOB DESIGN

The job characteristics model and the sociotechnical systems approach to designing jobs remain the most popular, and there have been additional developments and extensions to both. One such development that draws on the job characteristics model is Robert Karasek's job demands-job decision latitude (i.e., control) model of stress, proposed in 1979. Essentially, the model proposes that jobs high in demands (i.e., workload) have harmful effects on mental and physical health. However, the effects of those demands are even greater when a job is simultaneously high in demands and low in control (e.g., autonomy). Karasek referred to this as a "high-strain job" because it is the most stressful. His theoretical approach has dominated job stress research for the last 30 years.

An extension to the job characteristics model was suggested by Gerald Salancik and Jeffrey Pfeffer in 1978. The social information processing perspective suggests that employees' perceptions of job characteristics are often influenced by social information provided by coworkers, managers, suppliers, customers, and even family members. Social information can include comments made during conversations, meetings, and observations. It is important to note that employees don't always respond in an accurate, reasonable manner when

asked about characteristics of their jobs. Rather, actual job characteristics and social information cues tend to interact to affect employees' perceptions of and reactions to their jobs.

At present, a popular job-design perspective is the concept of *psychological empowerment*. The concept of empowerment is defined as a psychological or motivational state in which a worker experiences more choice or self-determination, meaning, competence, and impact regarding his or her role in an organization. While job characteristics such as autonomy and feedback clearly influence psychological empowerment, the main focus is whether or not individuals perceive themselves as empowered. A worker's personality type, cues from coworkers or customers, and the work environment can affect these perceptions. Interestingly, empowerment draws from both the job characteristics model and social information processing. Individuals' assessments of self-determination, meaning, and so on are very similar to the critical psychological states in Hackman and Oldham's theory, but the state of empowerment can also be influenced by the actions and behaviors of other people in the organization. Empowerment allows employees more discretion to use their skills and knowledge to solve problems directly. Thus, in an organization that values learning and initiative, empowerment can have an impact on employee motivation, commitment, satisfaction, and performance.

THE CHANGING NATURE OF WORK

Since traditional job-design approaches were developed, there has been considerable change in the composition of the workforce as well as the way work is done in many organizations. For example, the majority of new employees will be older, more educated, women, non-Caucasian, and from ethnically diverse groups. Employees are no longer spending their entire careers with one or two organizations. Factors such as downsizing and a worker's need to be challenged mean that most employees expect to change jobs and organizations much more often. Another important change is a shift away from manufacturing and a move toward service- and knowledge-based work. Specifically, call centers have become increasingly common across a variety of industries worldwide, including telecommunications, retail, insurance, travel, mail order, and utilities. They tend to employ low-to-semiskilled workers who must

perform rather routine, stressful work under time constraints, with constant monitoring from supervision.

This has given rise to the *contingent* or *flexible workforce*. Many organizations no longer employ individuals on a full-time basis with a consistent working schedule. Instead, they employ workers on a part-time or temporary basis, and these individuals often work irregular hours. Another rapidly growing segment is referred to as the *knowledge worker*. Unlike the semiskilled jobs in customer-based call center work, the knowledge worker is a highly educated, high-level employee, who is often found performing analytical and technical work in information systems, new product development, or forecasting future business needs. Many of these employees don't work at the actual physical site of the organization; they work at home and telecommute or are part of a virtual team that assists core employees on various assignments and projects. The development of technology is a major factor in all of these movements. Work is no longer restricted by time or place. As a result, organizations can be much more flexible in their working arrangements.

Although many of the traditional approaches to job design should be applied to these new forms of work, clearly there is room for additional considerations. For example, telecommuters often have more autonomy and control, especially over the time and pacing of their work. However, there is also the potential for increased work-family conflict, particularly for women, when the demands at home interfere with getting work done. Many organizations value the knowledge that older workers possess and are redesigning jobs to include less physically demanding work—and more autonomy over how work is done and how frequently break periods occur. Without question, the introduction of technology has had a major impact on how organizations are structured. Traditional departments are disappearing; organizations are more integrated; and there is an increasing number of strategic partnerships among organizations. Furthermore, technology has helped to remove typical barriers and provide easy access to information and knowledge transfer.

Another consideration is that work designs should be expanded to include more professional occupations, such as doctors, lawyers, counselors, social workers, and some managerial positions. While these jobs contain characteristics similar to those already identified in work-design theory, they also contain

characteristics, such as emotional and ethical demands, that have received little attention in studies of job design.

To conclude, job design continues to be at the core of the work experience. Since work contexts are changing and becoming more diverse, companies are building on traditional forms of design and introducing new design options. The opportunity to create more flexible, fulfilling work in which employees can use a variety of skills and knowledge is considerable. The challenge to organizations is to maintain a motivated and committed workforce while achieving superior quality and performance.

JOB FAIRS

Job fairs serve as one of the primary connections between employers and prospective job candidates. They provide an opportunity for both the employer and potential employee to diversify their search strategies. There are many types of job fairs, but all serve a dual purpose of enabling hiring organizations to meet and screen a large number of potential job or internship candidates and simultaneously providing job or internship seekers the opportunity to meet and screen a large number of employers. Job fairs occur throughout the year and remain a popular recruiting mechanism for employers regardless of economic conditions. Job fairs can be categorized broadly into six major types, including campus based, commercial entry level, commercial professional, commercial specialty, community based, and company specific. There are also virtual job fairs, which can accommodate any of these six major types.

The *campus-based job fair* is the most popular type for college students and is normally sponsored by the college or university's career center. Employers who attend are often familiar with the college or university, and they might use the job fair as their only campus visit, or they might use it as a promotional tool in advance of their on-campus recruiting programs. Students find the campus fair a convenient method for meeting with employers who are equipped to screen and interview the potentially large number of students attending. Campus job fairs also provide an easy method for students to practice meeting face-to-face with an employer. A recent trend among career-services professionals, especially at smaller educational

institutions within close proximity to one another, is to hold a consortium job fair at a central location as a means of efficiently deploying limited resources.

Commercial entry-level job fairs are run by independent contractors and are hosted in centralized locations throughout the country. These highly advertised events typically draw large numbers of students and other job seekers from a geographical radius of at least 300 miles. *Commercial professional job fairs* are intended to attract candidates with practical work experience to fill a wide range of professional occupations. *Commercial specialty fairs* are geared toward filling openings within specific occupational groups, such as computer programmers, technical/engineering, sales, or education. Oftentimes, job seekers use these fairs as a way to gather information for later direct contact with the prospective employer.

Community job fairs are hosted by a particular town, community, or broader region, with the intent of giving interested job seekers in a specific geographic area the opportunity to meet with employers who are recruiting in that labor market. *Company-specific job fairs* are a mechanism for any given business (or industry) to offer on-site recruitment as a means of assisting in securing appropriate human capital necessary for that organization's staffing needs.

Regardless of who is sponsoring the event, job fairs provide participants an opportunity for high-visibility, efficient information gathering, alternative resource-seeking strategies, and networking. For employers, it is a low-cost method for securing a pool of candidates whose résumés and other related materials can be maintained in the human resource database. Costs and fees for running a job fair are generally borne by the hosting party or the participating employing organization participants, although in some cases candidates must pay a fee to register. Facilities housing job fairs can vary in size and venue and can include locations such as university/college unions, hotel ballrooms or conference centers, convention or expo centers, company cafeterias, community centers, gymnasiums, entertainment complexes, or any other spacious facilities with appropriate utilities and infrastructure.

Various job-seeking strategies are used by employment candidates. For example, some use the process for "window-shopping" the participating employers to see what types of jobs or career paths are available. Some candidates use a structured approach by identifying and targeting a specific number of employers for interviews. Other candidates use such unsophisticated

methods as simply visiting with the participating company that has the shortest waiting line.

The individuals representing the employers at job fairs normally are not the hiring managers. Rather, hiring companies typically use recruiters or professional screeners to identify individuals who will be tapped for future consideration by the organization and to "screen out" individuals who do not fit the profile for their organizations. Usually, the prospective employer bases the decision concerning the next step for the candidate on a brief introduction and interview that could last anywhere from a few minutes up to 20 minutes.

Some job fairs also include workshops or seminars centered on various topics surrounding the job-search process. Sample topics of these related sessions might include the art of networking, interviewing skills and techniques, résumé development, creating a job-search plan, and approaches to researching an organization. These workshops are usually offered at set times during the job fair so that job candidates can attend particular sessions while also scheduling visits or interviews with specific companies. Typically, local consultants present the workshops as a way to showcase their skills, while at the same time offering a valuable service to fair participants.

JOB INTERVIEWS

The *job interview* is one of the most popular selection techniques, and it is typically defined as an exchange

of information between interviewers and applicants. Interviewers are interested in determining whether an applicant has the necessary knowledge, skills, and abilities to do the job. They are looking for a *person-job fit*, the match between the person and the job. The applicant collects information about the organization, such as its values, culture, and policies. The interview can also be used to determine whether there is a *person-organization fit*, a good match between the personality and values of the candidate and the culture of the organization. A good fit should increase employee satisfaction, commitment, and longevity with the organization.

Job interviews can also be found as part of the recruitment or screening process. In these *initial interviews*, candidates are sought for their qualifications, and those with proper qualifications are then asked to apply for jobs. This initial interview serves as a screening process to weed out mismatches or applicants who do not have the critical knowledge, skills, and abilities required for the job. These initial interviews with an organization are generally unstructured. Initial interviews are also used to attract applicants to apply for jobs. Thus, they serve as a public relations tool for attracting applicants to the organization. These interviews can be important in providing a positive image of the organization and may be the deciding factor when applicants make choices among various organizations. Initial interviews can be held via remote video access, whereby interviewer and applicant see each other on a monitor or through the use of the computer. This latter form uses software that asks the applicant pertinent questions, and the responses are then sent to the organization to be scored and assessed. These interviews can offer a cost saving to the organization.

STRUCTURE OF THE INTERVIEW

Job interviews are typically distinguished by their structures. This means that interviews are classified as either unstructured or structured. *Structured interviews* are standardized and based on a job analysis. This means that all applicants receive the same planned questions. The questions are based on the required knowledge, skills, and abilities (KSAs) necessary for the job. Also, many of the structured interviews contain a scoring key. This means that an applicant's response to an interview question can be compared with the answer key and then given a score

on a specific interview dimension or KSA. Structured interviews can be thought of as a test, since they can be reliably scored from the scoring key. Structured interviews have been found to have more validity in predicting future job performance than unstructured interviews. Overall, the structured interview has validity comparable to some of the best selection techniques.

There are two primary types of structured interviews, based on the kinds of questions that are asked: the *situational interview* and *behavior description interview*, or *behavioral interview*, and both have demonstrated high validity. The situational interview is based on the critical-incident technique. This is a job analysis technique in which incidents related to the job that distinguish between excellent and poor performance are used to develop hypothetical situations. When the applicant responds to these hypothetical situations, the response is supposed to indicate the applicant's future intentions. A scoring guide is developed for each question, and each question is associated with an interview dimension or KSA. The first step involves stating the hypothetical situation, such as the following: A customer comes into the store to pick up an item that was to be completed several days ago. The customer finds out that the item is still not repaired, and he becomes angry. The question is: How would you handle this situation? The best response is that you will try to calm the customer down and call the repair shop. A poor response is to tell the customer that it is not fixed and that he should contact you in a couple of days.

The behavioral description interview evaluates past behavior in job or job-related situations. In this case, the interview examines what has already happened, rather than what is intended or likely to happen in a future situation. The behavioral interview does not contain questions related to technical knowledge and skills. The questions are used to assess a range of abilities, such as interpersonal relations, conflict resolution, judgment, planning, and organization as well as other qualities, such as motivation, punctuality, and commitment. Probing questions are used after the initial question to find out exactly how the applicant behaved and what the consequences of that behavior were. Even when an applicant has not encountered the specific situation, probing questions may ascertain what the applicant has done in similar situations. A key provides a score for each quality that is assessed (e.g., judgment) rather than for each question that is asked.

INTERVIEW BIAS

Much of the interview research is related to the problems or biases associated with the unstructured or conversational interview. Since these traditional unstructured interviews are more likely to be unplanned conversations, they may not always focus on job-relevant factors. However, they are generally preferred by both the interviewer and the applicant. Many interviewers feel that the structured format is too limiting because they are unable to assess various aspects of the person. They believe that they can better evaluate the applicant if they can probe or challenge the applicant. Applicants, on the other hand, prefer the unstructured format because they feel they are able to give a better impression of themselves in a conversational format. Still, unstructured interviews are less valid and seem to provide poorer judgments based on factors that are not job relevant.

Evaluations of applicants tend to be biased favorably when the applicants are more physically attractive, are of normal weight, and are well groomed. Nonverbal behaviors also seem to influence the interviewer's decision. This includes the applicant's eye contact, smile, and general body posture. These behaviors are part of one's impression management and can alter the interview. Another bias is related to the weight given to information. More weight is given to negative than to positive information. For example, one negative attribute can result in a rejection even though the applicant displayed numerous positive behaviors. This is probably related to the idea that interviewers seem to be searching for reasons to reject rather than accept an applicant.

One of the major biases is called the *first-impression error*. Probably the two most important sources of this bias are information known about the applicant prior to the interview and the physical appearance of the applicant. Information prior to the interview includes résumés, references, test scores, work experience, and scholastic standing. Although some of this information is important in evaluating the applicant, the problem is that many interviewers use this information and the relative attractiveness of the applicant to register first impressions that are very subjective and sometimes not very accurate in predicting future job performance. Furthermore, the first impression will bias subsequent information so that information gleaned later in the interview could be ignored if it is inconsistent with the first impression. This is likely to

create inconsistencies among interviewers, as different interviewers are likely to place more importance on some types of information than on others. For example, if a particular interviewer believes that the applicant's handshake and attractiveness are important while another believes that the applicant's grade point average is important, there are likely to be different first impressions regarding the same applicant. It is also likely that the first impression will dictate how the interview will be conducted and will change the types of questions given to the applicant. That is, applicants who convey a favorable first impression are more likely to be given easier questions than those given to seemingly less favorable applicants. In this way, interviewers conduct the interview to confirm their first impressions.

Research also indicates that interviewers tend to like applicants who are more similar to themselves, especially those with similar interests, attitudes, and demographics. This is likely to have implications for interviewers who may discriminate against those who are not similar to them. Although research findings are not very clear about discrimination with regard to race, gender, age, and disability, some bias has been found, for example, against women applying for jobs that are traditionally male dominated.

DISCRIMINATION AND THE LAW

Interview questioning practices play an important role in discrimination cases. Although there are only a few questions that are prohibited by federal equal employment law, interviewers' inquiries related to age, sex, religion, marital status, nationality, and ethnicity that can be shown to discriminate can be a liability for the employer. There are questions regarding disability and specific health inquiries that are prohibited by the Americans with Disabilities Act of 1990. There are also state fair employment practice laws that explicitly prohibit questions concerning the applicant's race, color, religion, sex, or national origin.

In most cases, the standard for discrimination in the interview is based on *disparate-treatment theory*. This means that the party discriminated against must show that he or she was treated differently than persons of the majority or another group and that the reason for the discrimination was group membership. To prove disparate treatment, the key element is whether an employer intended to discriminate. For example, if evidence were found that women were

asked different questions than were asked of men regarding employment, this would be evidence that the employer intended to discriminate.

MULTIPLE INTERVIEWERS

Although most interviews involve a single interviewer, there can be multiple interviewers. The most popular form is the *panel interview*. In most situations, the panel interview is similar to a structured interview; members of the panel ask the same questions to all the applicants. It is thought that having a panel of interviewers may enhance the reliability of the interview because the questions are usually very structured and job related. Furthermore, the use of multiple interviewers is more likely to reduce the impact of idiosyncratic biases described previously. It also means that the information recalled by the interviewers is likely to contribute to more accurate evaluations and predictions. Validity evidence indicates that panel interviews tend to be more valid than unstructured interviews but may not always be more valid than good structured interviews. The negative side to the panel interview is the cost of using multiple interviewers.

DECISION-MAKING PROCESS

To better understand the process by which interviewers make decisions, it is important to describe Robert Dipboye's cognitive model of decision making. Interviewers rely on knowledge structures, which take the form of categories, stereotypes, and implicit personality theories that constitute the interviewer's beliefs about the requirements of the job and the characteristics of the applicants. In the preinterview phase, the interviewer uses information about the candidate and these knowledge structures to form initial impressions. Then, the interviewer is likely to compare these initial impressions with his or her stereotype of the ideal candidate. During the interview, the interviewer continues to evaluate and reevaluate the applicant based on the interviewer's knowledge structures and initial impressions of the applicant, and tends to seek information to confirm the initial impressions.

Interviewers also make attributions about the causes of the applicant's behavior during the interview. The interviewer may initially attribute an applicant's behavior to a trait (e.g., the applicant's anxiety or extraversion) or to a situational factor, such as the interviewer's conduct during the session. A large

amount of information is presented to the interviewer, and an interpretation of this information may be biased because it is based on his or her knowledge structures and initial impressions or on the way the interview was conducted, rather than on the applicant's qualities. Later in the interview, the interviewer uses all the information to make an evaluation of the applicant, and even at this stage, the interviewer's knowledge structures are used to assist in the evaluation, especially when the information regarding the applicant is not clear.

CONCLUSION

A number of suggestions could improve the interview and make it more reliable, valid, and legally defensible. First, much of the interview process should be structured and standardized. This likely means the use of job-related questions, more specifically the use of either situational or behavioral questions or both. Since these questions are derived from a job analysis, they are likely to be job related—and more valid and legally defensible.

Second, the interviewer should determine which knowledge, skills, abilities, and other characteristics should be assessed during the interview. Much of the research has shown that interviewers try to assess too many characteristics. Thus, instead of using the interview as a general measurement device, only those characteristics measured accurately by the interview should be considered for evaluation. Furthermore, multiple questions should be asked concerning each characteristic. The characteristics that should be measured are sociability or interpersonal skills, verbal fluency or oral communication skills, dependability, conscientiousness, and other citizenship skills. Some job knowledge may also be assessed with an interview in those situations in which a test of job knowledge is difficult to develop. Moreover, as described previously in the context of the situational interview, interviews are not well suited to assessing technical skills.

Third, the responses to the questions should be formally scored. This can be done for each question or for each characteristic that is evaluated. Scoring systems are preferable in terms of reliability, validity, and legal defensibility. An interview guide can be used to assist in the scoring and for assistance in the questioning. Finally, it is suggested that the interviewers be trained in the proper procedures for conducting the interview, including techniques such as role-playing

exercises, practice in scoring, or instruction in pointing out decision errors and methods for overcoming them.

JOB INVOLVEMENT

Throughout the research literature of the past four decades, a number of different terms have been used to describe an employee's level of involvement in his or her job; among these are *work as a central life interest*, *occupational involvement*, *work role involvement*, *ego involvement*, *morale*, *job commitment*, and, of course, *job involvement*. Furthermore, in the discussion of the extreme ends of an individual's relationship (or lack of relationship) to his or her job and work, one may find discussions focusing on workaholism or alienation. This entry briefly reviews the historical, conceptual, and methodological issues related to job involvement and presents various profiles of the job-involved person. Finally, several suggestions are offered for further exploration of this concept.

CONCEPTUAL ISSUES

Thomas Lodahl and Mathilde Kejner introduced the construct of job involvement in their seminal article on the definition and measurement of job involvement. This work presented two conceptualizations of job involvement:

The extent to which an individual's self-esteem is affected by his or her level of job performance

The degree to which an individual identifies psychologically with his or her work, or the importance of work in an individual's total self-image

The researchers' belief that job involvement has two different aspects or dimensions (job performance/self-esteem connection and psychological identification with work) justified the presentation of both definitions in their article, which set the tone for decades' worth of criticism and research on this concept.

Samuel Rabinowitz and Douglas T. Hall offered perhaps the first systematic review of the job-involvement literature. Within this review, they observed that the literature continued to describe job involvement as the two different concepts presented in Lodahl and Kejner's pioneering work. This conceptual ambiguity (is job involvement the connection between job performance and self-esteem, is it one's psychological identification with work, or is it both?) likely contributed to research that presented three different theoretical perspectives on how job involvement develops: (1) as a stable characteristic of a person, (2) as a reaction to the work situation, or (3) as an interaction between the person and the situation.

Rabindra Kanungo's work identified a number of concerns raised by scholars (including himself) conducting research on job involvement. He noted that the precise meaning of job involvement lacked consensus among the researchers. This conceptual ambiguity started with the question of whether job involvement represents a psychological identification with work versus a connection between job performance and self-esteem. It continued with the confusion between job involvement and intrinsic motivation on the job; between viewing job involvement as a cognitive belief versus an affective, that is, emotional, state; and between seeing job involvement with reference to a generalized work context as opposed to one's specific job context. Kanungo's work ultimately led to a refinement in the way that

job involvement was measured, a topic described in the next section.

METHODOLOGICAL ISSUES

In addition to introducing the concept of job involvement, Lodahl and Kejner presented both a 20-item and a 6-item short form of a job-involvement scale. The use of this scale or a variation of it has generated similar criticisms to those expressed regarding the conceptual issues discussed earlier. Kanungo evaluated the measure developed by Lodahl and Kejner, identified problems with it, and developed new scales designed to overcome his methodological concerns. For example, he noted that the words *work* and *job* were used rather loosely and interchangeably, thus leading to separate scale development for “job involvement” and “work involvement.” In addition, his scale clearly measured job involvement as a cognitive state of psychological identification with the job, while avoiding items tapping concepts outside of this definition as well as separating job involvement itself from other factors (e.g., job satisfaction) that either cause or result from job involvement. A quantitative review of the literature by Steven Brown in 1966 concluded that although there were a small number of substantive differences between the findings of studies using Lodahl and Kejner’s measure and Kanungo’s measure, the latter offered greater conceptual clarity and was preferable for future use.

PROFILE OF THE JOB-INVOLVED PERSON

A number of different profiles of the *job-involved person* have been presented in the literature. Based on their initial research on several samples, Lodahl and Kejner presented a hypothetical profile of a job-involved person as one who (a) is older; (b) is less considerate as a leader, with a preference for administrative or coordinating activities; (c) identifies with good supervisors and scores high on initiative and intelligence; (d) has more highly interdependent (team-type) jobs, while seeing a large number of people during the day; (e) expresses satisfaction with the work itself, promotional opportunities, supervisors, and coworkers; (f) feels his or her supervisor is technically proficient; (g) believes he or she has a good chance of getting two or more promotions; and (h) went to high school elsewhere than in the Eastern portion of the United States.

In the decade that followed, a considerable number of studies attempted to determine the factors that are correlated with job involvement. This led Rabinowitz and Hall to present a newer profile of the job-involved person as one who (a) is a believer in the Protestant work ethic; (b) is relatively old; (c) has an internal (versus external) locus of control; (d) has strong psychological growth needs (e.g., need for achievement); (e) has a stimulating, “enriched” job; (f) participates in decisions affecting him or her; (g) is satisfied with the job; (h) has a history of success; and (i) is less likely to leave the organization.

Some two decades passed before two additional studies applied more quantitative, meta-analytical techniques to the body of research conducted on job involvement and updated the profile of the job-involved person. In one such study, Brown concluded that the job-involved person displays the personal characteristics of a strong work ethic endorsement, a high level of internal motivation, and high self-esteem. In addition, the job characteristics and supervisory behaviors desired by the job-involved person (especially one with high growth needs) were meaningful, challenging, complex, and varied work (i.e., an enriched job) containing opportunities for participation in setting performance standards and a good relationship with an immediate supervisor who provided considerable feedback. The job-involved person is committed not only to the specific job but also to work in general, his or her career, and the organization itself. Turnover intentions are less likely to occur with the job-involved person. The job-involved individual is generally satisfied with the job situation, particularly the content of the work itself.

The other quantitative review of the literature by David Allen and Rodger Griffeth portrayed the job-involved person as being satisfied with the job in general and specifically with the work itself, promotions, the supervisor and the coworkers. The job-involved person also participates in work-related decisions, desires a job with autonomy and feedback, and is at a higher level in the organization. Finally, the job-involved person believes in the Protestant work ethic and is less likely to voluntarily quit the job.

CONCLUSION

The conceptual and methodological concerns expressed in the earlier stages of the research on job involvement appear to have lessened with the more

consistent use of the “psychological identification” definition and the Kanungo measure of job involvement. The profiles of the job-involved person do not reflect a significant relationship between job involvement and demographic variables but do continue to show, as Rabinowitz and Hall and Brown had indicated relationships between job involvement and personal/individual difference variables (e.g., work ethic endorsement); situational factors (e.g., enriching job characteristics); and correlates/outcomes (e.g., satisfaction with various job components, commitment on multiple levels, turnover intentions). Most recently, Aaron Cohen spoke of the need to integrate the study of multiple commitments (e.g., job involvement, work involvement, career commitment, and organizational commitment) rather than study any one of these variables without considering the larger picture. Further avenues of potentially interesting research might lie in understanding the distinctions between high levels of job involvement and the addictive (and negative) aspects of workaholism.

JOB LOSS

Outsourcing, offshoring, downsizing, rightsizing, and reorganizing: Every day, local and national headlines proclaim events that mean just one thing to workers—their jobs are at risk. *Job loss*, as discussed here, is the

involuntary removal of paid employment from an individual. Those who experience job loss are known by many different names: they are “laid off,” “redundant,” “dislocated,” or “displaced” workers. Regardless of the label, experiencing job loss is a stressful event, on par with the death of a spouse in terms of potential life impact. Moreover, not only does job loss affect individual workers, but its impacts also through relationships with spouses and children and into the communities affected by the precipitating events.

In the United States, as around the globe, a declining unemployment rate signals a recovering economy. The unemployment rate, the ratio between the number of people looking for work and total employment, underestimates the impact of job loss in two ways: First, only those actively looking for work are included in the computation. The unemployment rate does not include “discouraged” workers, those who have stopped looking for work because they think that their chances of success are slim. Second, the unemployment rate fails to account for the number of lost jobs that are offset by the creation of new jobs—jobs that tend to be lower-paying service jobs. Hence, while the overall economy experiences a net gain, people continue to experience displacement in an expanding economy. Such broad-scale trends of economic recovery thus mean little to the individual who has to bring home a pink slip instead of a paycheck. The ever-increasing competitive pressure within the global marketplace shows no sign of abating, suggesting that workers around the globe will continue to lose their jobs and face the challenge of looking for a new job. The risk of layoffs now extends to all sectors, affecting unskilled manufacturing workers and white-collar professional employees alike.

The remainder of this overview is organized around five sections: Section 1 includes an outline of the potential negative effects of job loss. Section 2 focuses on how displaced workers cope with losing their jobs, and Section 3 identifies some individual differences that may account for the differential impact of job loss by looking at the importance of identifying the “personal meaning” of job loss. Section 4 summarizes interventions targeted at getting employees back to work and minimizing the detrimental effects of job loss and identifies resources and benefits that may be available to unemployed workers. Section 5 looks briefly at issues related to downsizing. The entry ends with a conclusion and summary.

EFFECTS OF JOB LOSS

Financial

The most obvious and pervasive effect of job loss is the loss of income. Highly paid executives may have lucrative layoff packages that provide a financial cushion, but many displaced workers find themselves without adequate income to cover the necessities: rent or mortgage, utilities, food and clothing, transportation, health insurance, and the like. Financial resources—in the form of a monthly income, savings, retirement accounts, credit cards, and friends or family from whom to borrow money, for example—may provide a protective resource from the negative impacts of job loss. These resources vary in terms of accessibility, however, and a more important consideration seems to be the degree of financial strain or worry that the worker experiences. That is to say it is not just having or not having money available, but the perception of money problems that affects the displaced worker. Financial strain tends to become more severe over time. As unemployment duration extends, unemployment insurance benefits or severance packages run out, savings are spent, and reserves are depleted. Finally, those who experience acute financial stress are often more likely to take the first job they are offered, which may not be the best long-term strategy.

Career

There are also effects on the displaced worker's career. This section discusses the effects of job loss on employee wages and career trajectories, the subtle but important differences between reemployment and quality of reemployment and underemployment, and the importance of career stage in the impact of displacement.

First, economics research consistently demonstrates post-job loss wage reductions. Laid-off workers' salaries at their new jobs tend to be lower than in their previous positions. In declining or cyclical industries in which employees are likely to face repeated downsizings and layoffs, these wage reductions can significantly diminish an employee's lifetime earning potential. Along with salaries come other intangibles, such as position titles and prestige, leading to an additional impact on the employee's career trajectory coupled with the financial implications.

Traditional unemployment research focused on the outcome of finding a new job or reemployment.

Research is accumulating, however, that suggests that it is not just finding a job that is important but also the quality of the new job. The distinction thus is made between *reemployment* and *quality of reemployment*. Some workers may take jobs that pay less, that are at a lower level in the organization, that are less prestigious or are outside the employee's area of expertise and training, that require working during nontraditional hours or shift work, that are part time or of limited duration, or that do not require the use of the worker's full skill set. These workers rejoin the ranks of the employed, but their jobs are of low quality, leaving them dissatisfied with their *underemployment*. Such employees do not realize the psychological and practical benefits of employment that their fully employed counterparts experience, causing them to continue coping with the stresses of their displacement by continuing to look for another job or experiencing negative psychological states such as dissatisfaction, anxiety, and depression. Workers who experience acute financial stress are more likely to take the first job that is offered to them, regardless of quality, and thus are more at risk for the effects of underemployment.

The impact of a layoff differs according to the basis of the individual's career stage. For example, middle management often bears the major brunt in a downsizing event as the company seeks to flatten its organizational structure. These employees are likely to have been in their jobs or careers for several years, with significant investments in their professions and careers and correspondingly high salaries. These employees may also have company-specific skill sets that are not easily transferable to another company and command higher salaries. As a group, this set of employees also tends to be at midlife, with large mortgages and children either in the home or in college, and they may be at an age where they begin to experience subtle age discrimination (which is exceedingly difficult to prove). This combination of factors may explain the U-shaped relationship between psychological health and career stage that has been found in unemployment research, whereby workers at midcareer are "harder hit" by unemployment than those who are earlier or later in their careers. Although early-career employees face an additional burden of establishing their career and professional identities, they are also less likely to have significant financial obligations and thus have greater flexibility. For example, this group is less likely to have constraints on relocation.

At the other end of the spectrum, those who are near retirement may also have additional options, such as taking an early retirement or voluntary severance package. Of course, these broad trends do not apply to every individual within the classification, but they do provide insight into the differing effects of displacement at various life and career stages.

Psychological and Physical Health

Job loss also takes a toll on a person's sense of well-being, affecting both psychological and physical health. Compared with fully employed workers, displaced workers experience anxiety, depression, distress, emotional withdrawal, and illness or health complaints, as well as reduced self-esteem, satisfaction with life, and physical health. Job loss has also been linked to high-risk health behavior, such as smoking and substance abuse. Some workers exhibit a grieflike response to unemployment, shame from being out of work, or threatened identity following job loss. When workers are subjected to repeated layoffs, the stress appears to accumulate, rather than building a protective effect or resiliency for facing future layoffs. Despite the well-documented differences in mental health and unemployment, some controversy remains over the causal direction between unemployment and reduced well-being. That is to say, does unemployment cause poor psychological health (the social causation effect), or are those with poor health more likely to experience displacement (a social selection effect)? Evidence exists for both explanations, so the jury is still out on this question. Population studies have linked higher unemployment rates to increased mental health hospital admissions and suicide rates.

Spouse, Family, and Social Networks

The person who has lost a job is not the only one in a household affected by the layoff. Family members also bear the brunt. For example, a working spouse or partner may buffer the financial burden of job loss because a steady income continues to come into the household. However, this shift in financial responsibility may play out in unanticipated changes in the power structure or in domestic responsibilities within the household. As couples adjust to restructured roles, other detrimental effects of job loss can include domestic violence, partner depression and

physical health symptoms, children's problems at school, reduced relationship quality and satisfaction, and even divorce. The social support provided by a close family or a network of friends can provide an important resource on which to draw when faced with displacement. Unfortunately, those same families and friends may "undermine" displaced workers or place undue pressure on them to find new jobs. Social networks may also shrink following job loss, leading to less contact with others.

In sum, the negative outcomes associated with job loss are pervasive and well documented. These outcomes range from the obvious loss of income, to the psychological well-being and physical health, to the relationships within families and into the community. The next section looks at how displaced workers cope with unemployment.

COPING WITH JOB LOSS

One way to examine the effects of job loss is to examine it as a stressful event with which the displaced worker must cope. The coping process begins with a perception or an appraisal that the situation requires more resources than the individual has available. Some workers possess coping resources such as an optimistic outlook, a supportive spouse, or financial reserves that make them less likely to form a strong negative appraisal to displacement, while others' lack of resources puts them more at risk. Those who fall into this latter category are more likely to appraise displacement as a harm (damage has already been done) or a threat (damage is likely to occur) rather than as a challenge (which can be used for good). Once the appraisal has been made, efforts to cope begin.

Displaced workers must deal with the fact that they are now unemployed and with the accompanying psychological and emotional responses to being without work. Research on coping with job loss focuses simultaneously on attempts to manage both components, typically by examining the dimensions of problem-focused or control-focused coping directed at rectifying the source of the problem, in this case unemployment, and emotion-focused, symptom-focused, or escape-focused coping aimed at managing the emotional response to the stressor. *Problem-focused coping* entails efforts to alter the source of the problem, such as enrolling in a retraining program, relocating somewhere with greater employment opportunities, or cognitive reappraisal to change one's thinking about being

unemployed. It also includes job search. *Emotion-focused coping* encompasses thoughts and behaviors focused on decreasing the isolation or hardship from being unemployed and making oneself feel better, including activities such as seeking support from one's social network and getting involved in community activism to create more awareness and services for unemployed workers, as well as escape-oriented strategies such as devaluing the importance of holding a job or distancing oneself from job loss.

An active job search is a critical factor in becoming reemployed following displacement, and thus looking for a job is the most obvious form of coping with job loss. Job search behavior includes activities such as preparing a résumé, filling out job applications, reading the want ads or searching online job postings, visiting a career counselor, and participating in mock interviews. Those with high self-esteem, an internal locus of control, high job-search self-efficacy and greater financial need, employment commitment, and social support are more likely to engage in job-search behaviors; and a significant relationship exists between job search and reemployment. Job-search intention and job-search behavior appear to be important intervening variables between individual differences and attitudes (as antecedents) and reemployment (as an outcome).

There is a somewhat counterintuitive negative relationship between job search and well-being, given the strong relationship between job search and employment. Looking for a job is a stressful process, often filled with rejection that can lead to self-doubt and frustration. Indeed, job search takes a greater toll on well-being for the most motivated and engaged searchers, leading some to experience job-search burnout and others to become discouraged and stop looking. There is also some evidence that looking for a job too soon is detrimental to the displaced worker, highlighting the need to examine a broader range of behaviors for coping with job loss.

THE PERSONAL MEANING OF JOB LOSS TO THE INDIVIDUAL

Unemployment research has typically focused on identifying broad trends related to how displaced workers react to unemployment. As summarized in the previous section, there are a variety of ways to cope with job loss, and no two displaced workers react identically to job loss. For example, as mentioned previously, research indicates that workers who lose their

jobs at midlife tend to be impacted more negatively than those just beginning their careers or nearing retirement. Several alternative scenarios provide potential explanations for this trend. Perhaps the impact comes from the financial implications of job loss: As mentioned previously, workers at midlife are more likely to have children in the home or attending college, with large mortgage payments and high living expenses. As such, they may have larger expenses than new entrants and fewer investments and savings than those near the end of their careers. Alternatively, it could be that the impact of unemployment stems from strongly identifying one's sense of personal identity with one's occupation or career. The worker may not be able to secure a new job that is similar to the one he or she lost in terms of prestige, level in the organization, or salary and compensation. Thus, the layoff may be seen as a "slip" down the corporate ladder. Another plausible explanation centers on the development of company-specific skills that are not transferable. Midcareer workers, given their likelihood of having longer tenure with a company, may have skill sets that are not marketable to other companies or across industries. Moreover, losing one's job at midlife could impact the family and the roles within the family. Perhaps the displaced worker was the primary wage earner, and his or her job loss means that the other spouse must return to the workforce. This change could send shockwaves through the family as new daily routines emerge, household responsibilities shift, and interpersonal dynamics adjust.

Any one of these scenarios could alternatively explain the relatively stronger impact of displacement on midcareer employees, or it could be that these issues accumulate in an additive or multiplicative way. Research to date has been unable to test complex models that would be suggested here, but recent attention focuses on explaining the variation within groups of unemployed workers. More research is needed to develop more complex and highly individual models that account for this variability of dislocated workers' responses to unemployment.

INTERVENTIONS AND RESOURCES FOR THE UNEMPLOYED

Job Loss Interventions

Job loss interventions typically focus on (a) facilitating reemployment, (b) diminishing the negative emotional and psychological effects of displacement, or (c) both.

These programs include components such as providing resources (e.g., help writing résumés, computers to type résumés and for e-mail access), enhancing job-search skills, aiding participants in identifying their own transferable skills and setting job-search goals, having realistic job-search expectations, improving the self-efficacy and motivation of job seekers, and providing a social support network of career counselors or trainers as well as other displaced workers who empathize with the job seeker. Participants typically experience positive outcomes from these interventions, including higher rates of reemployment, higher salaries, shorter unemployment duration, and better psychological well-being. Finally, interventions tend to disproportionately benefit those who are most at risk for the negative outcomes of job loss, such as those with low self-efficacy or high levels of depression, suggesting that interventions should be specifically targeted to at-risk groups of displaced workers to maximize effectiveness.

Resources for the Unemployed

Severance packages and unemployment insurance or unemployment compensation are designed to provide replacement income for a short time while the displaced worker seeks replacement employment. Benefits vary by country and state, and not all workers are eligible to receive assistance. Those who receive unemployment benefits may also be eligible for additional resources, such as retraining and wage subsidies if the layoff was certified for Trade Adjustment Assistance because jobs were lost due to import competition or to offshoring, for example.

Higher-level and professional employees are also likely to have access to outplacement services. Outplacement programs serve to help displaced workers regain a sense of well-being, plan for their careers and the future, and find new jobs. These programs vary in their comprehensiveness and support and include resources such as help writing résumés, training modules, career counseling, networking, negotiating job offers, and the like. Outplacement programs are not used by all to whom they are available, suggesting that this avenue should be added to coping-strategy research.

DOWNSIZING AND REORGANIZING

The detrimental effects of downsizing are not limited to laid-off workers. Those who manage to keep

their jobs face increased workloads and responsibilities, compounded by the uncertainty and fear that surround layoffs and guilt that they kept their jobs while friends and colleagues were let go. This combination of factors causes some remaining workers to exhibit symptoms of “survivor syndrome” or “survivor sickness.” Among other detrimental outcomes, survivors may have low levels of organizational commitment, job satisfaction, and trust in management, along with high levels of stress, hostility, and intention to quit.

A great deal of prescriptive advice is available for those required to implement layoffs in their companies due to downsizing or reorganization. In general, following this advice provides benefits to both those who are laid off from the organization and the survivors who remain employed with the company. Recommendations to managers include ensuring a procedurally fair and transparent process; providing timely, complete, and accurate information; giving advance notice when possible; and making resources available to deal with the practical and psychological issues brought about by the event, such as providing survivors opportunities to air their concerns in a safe environment and supplying displaced workers with severance packages and outplacement services. Additional resources to dislocated workers may be available through governmental services provided under the Worker Adjustment and Retraining Notice (WARN) Act or through Trade Adjustment Assistance, but the services and eligible populations vary by state, industry, and the cause of the downsizing event.

CONCLUSION

Millions of workers face involuntary job loss every year in the United States and around the globe. These workers are laid off, downsized, rightsized, reengineered, dislocated, or redundant. The negative effects of job loss and unemployment are pervasive and well documented and intensify over time as unemployment persists. Beyond the immediate economic impact of the loss of income, displaced workers also potentially experience detrimental career effects, such as lower wages or underemployment, or employment in a job that does not utilize all of the individual’s education, skills, and experience. Psychological troubles such as anxiety, depression, reduced self-esteem, and threatened identity may also manifest following displacement, along with physiological symptoms such as trouble sleeping, substance abuse, weight gain or loss, headaches, or other illness.

Job loss also affects the spouse, family, and community of the dislocated worker.

Given the potential life disruption from job loss, displacement has been identified as one of the most stressful life events an individual can face. The process of coping with job loss begins with the individual's perception or appraisal of the event. This entails taking mental stock of one's resources in relation to the demands of the situation. Those who possess coping resources such as a healthy self-concept, a supportive spouse, and financial resources are less likely to perceive job loss in harmful or threatening terms and thus tend to fare better than those who lack resources. Displaced workers face two sets of issues with their unemployment: the lack of a job and the emotions and psychological reactions that goes along with it. Coping with job loss includes both problem-focused coping, such as looking for a job or relocating, and emotion-focused coping, such as seeking social support or distancing oneself from unemployment. Both strategies can be helpful at different times following job loss, and the coping process changes over time. A counterintuitive relationship exists between job search and well-being, on the one hand, and reemployment, on the other. The process of looking for a job is stressful and full of rejection, resulting in a negative relationship between searching and well-being. At the same time, research consistently shows a positive link between engaging in active job search and reemployment. These seemingly incongruous results highlight the importance of simultaneously examining the dual outcomes of (a) personal well-being and the quality of reemployment and (b) testing complex models that account for individual variability in response to job loss and unemployment.

Interventions designed to diminish the detrimental effects of job loss have shown promise, particularly when used in at-risk populations such as those who lack coping resources. These interventions typically focus on speeding reemployment or managing the psychological effects of displacement. Unemployment insurance and severance packages provide a financial cushion following job loss. Companies can also provide outplacement services for dislocated workers as an additional resource. Organizations conducting layoffs must also be mindful of the effects of a layoff on the employees remaining with the company and guard against survivor sickness. In general, clear, effective, and open communication and implementing a fair, transparent process are important components of ensuring effectiveness in the postdownsizing organization.

In conclusion, the current competitive environment suggests that employees and companies alike need to prepare and plan for the potential of employee displacement. Employees are advised to focus on their employability and maintaining a current portfolio of transferable skills.

JOB-POSTING PROGRAMS

Organizational initiatives focused on supporting employees' careers, also referred to as "organizationally supported career management practices," are geared toward career planning and development. Using *job-posting programs*, organizations can play a critical role in their employees' career-development efforts by providing accurate and updated information about promotion and growth opportunities within the organization. Organizations can proactively focus on their employees' careers by using job-posting programs and, in some cases, by selectively making these programs available to specific individuals.

Job-posting programs serve as an information service in assisting organizational employees in career-development endeavors and in generating a pool of internal candidates. Job-posting programs were initiated in the early stages of affirmative action, when organizations began publicizing available jobs internally. These programs offered organizations the possibility of providing equal opportunities for women and minorities to compete for existing job openings and were viewed as measures for circumventing the traditional "old-boy" networks existing in organizations.

Organizations can post job openings on bulletin boards, in organizational newsletters, through recorded phone messages, by e-mail messages, or, increasingly, using organizational intranets. Job openings are published, and interested employees are expected to respond within a stipulated time period. Some job postings apply to specific organizational locations or offices, whereas other postings are organizationwide openings applicable to multiple locations or offices. Increasingly in a virtual world, organizations are connecting their intranets to external job-search engines to cast a wider net for their job-posting programs.

CHARACTERISTICS OF WELL-CONSTRUCTED JOB-POSTING PROGRAMS

A well-constructed job posting, critical to the success of the program, should delineate the competencies required for the position, information about compensation, performance standards, the supervisory structure, the work schedule, and the job-selection criteria. If possible, a well-constructed job posting is framed within the larger context of the organizational goals and objectives, enabling employees to determine whether they are qualified for the position and to assess the "fit" between their goals and the organization's goals. Sometimes employees are skeptical about whether the recruitment efforts resulting from the job posting are political processes or genuine searches for the best internal candidates. When a posting clarifies how the open position will be filled and what the job selection criteria are, it is likely to alleviate employees' apprehension concerning the credibility of the recruitment process.

In addition to its comprehensiveness, the success of well-constructed job postings is determined by its scope or reach. No matter how the job-related information is disseminated, it is important for information in any job-posting program to be available to all employees who are eligible for the position. Some unions require that job postings reach their members first for any new positions opening up within the organization. Job postings are an excellent idea even for nonunionized organizations, as they assist organizations in employees' career development by transferring and/or promoting suitable internal candidates to appropriate positions.

OUTCOMES OF JOB-POSTING PROGRAMS

Well-designed job-posting programs are a tremendous asset to organizations as they reinforce the notion that the organization promotes from within and is focused on developing employees' careers. This notion enhances employee retention and boosts employee morale because it signals to the employees that they do not need to go elsewhere to find opportunities for career development. Posting jobs also creates an open-recruitment process, which helps give all employees equal opportunity for advancement and helps in recruiting for jobs from a pool of existing employees with proven track records.

Job-posting programs are also advantageous with reference to employees' career development, as astute

employees observing postings over time soon learn a great deal about their organizations. They realize that following job postings yields information about turnover rates in different departments and information about skills and competencies in high demand within their organizations. Equipped with these data, employees are likely to be able to better shape their careers by getting additional and relevant training and/or experience to advance their careers.

Not all job-posting programs' outcomes are positive, however, as mismanaged programs are likely to have more detrimental effects. A critical threat plaguing internal recruitment from job-posting programs originates from supervisors' or managers' reluctance to allow their employees to be interviewed for potential promotions and/or transfers. This reluctance stems from the fact that supervisors and managers have invested tremendous resources in training their employees for their current positions. When trained employees apply for other positions, their supervisors/managers are encumbered with the predicament of selecting and training new employees to replace their existing employees. To assist and prompt supervisors/managers to overcome this reluctance, organizational policies allowing and encouraging employees to seriously contemplate internal job opportunities must have top-management support. Job-posting programs that have not overcome this managerial reluctance are likely to result in political selection decisions and distrust in the employees applying for internal jobs.

Job-posting programs may also be vulnerable as some employees, to gain a better job title or salary, try to outsmart the organizational system by transferring to new positions that do not necessitate any varied or incremental skills beyond what their current jobs require. This temptation may be counterbalanced by organizations establishing consistent compensation structures and policies across varying jobs and in different locations. Job-posting programs can also be expensive in terms of additional administrative costs unless organizations have rules and policies about applying for jobs posted. For example, some organizations do not accept applications from employees who have been in the organization for less than a year and/or in their current positions for less than six months. Finally, the outcomes of job-posting programs are critically dependent on the postselection follow-up and feedback process in place. Unless organizations provide employees with honest, precise, and factual

feedback about their applicant screening and selection, unselected employees may feel slighted and distrust the organization in the future. In summary, well-constructed job-posting programs enhance employees' careers and organizations' abilities to retain good employees.

JOB ROTATION

In recent times, a number of fundamental changes have taken place in production technologies, the nature of physical and human capital, and ideas about how to organize firms. The precise nature of the reorganization process naturally varies from firm to firm, but the evidence is now sufficiently clear to recognize some prominent features of ongoing reorganizations. These include an increased role for *job rotation* and *teamwork*, a reduction in the number of management levels, continuous learning and the development of complementary skills, decentralization of responsibility within firms, and direct participation of employees in decision making on multiple fronts. It appears that the various features of this process have a common thread: emphasis on learning multiple tasks, the blurring of occupational barriers, and the use of experience gained at one task to enhance performance at another.

A number of interrelated forces have driven these changes. One of these forces is the introduction of

computerized information and communication systems. This has provided employees with greater access to information about other employees' work within the organization and made it easier to communicate with others. Teamwork and job rotation have become important ways to respond to customers' changing needs.

A second force is the introduction of flexible machine tools and programmable equipment. This has made the capital stock more versatile, capable of performing a wide variety of tasks. A third force has been the steady growth of human capital per worker. This has been generated by education systems, vocational training programs, and on-the-job training.

As workers have acquired better general education and a wider variety of skills, they have come to prefer jobs that permit the exercise of diverse skills. More and more employees have come to resent the monotonous fragmented jobs of traditional organizations and prefer more varied, multifaceted work. Greater emphasis is now placed on continuous learning and skill development, all-round knowledge, the potential to acquire multiple skills, and the ability to learn how the experience gained from one skill enhances another skill. Multitasking, job rotation, and the blurring of occupational barriers are not the only consequences of the ongoing reorganization of work. Of particular note is the expansion of the scope for learning and the returns from it in the new organizational environment.

One definition of *job rotation* suggests that it is a systematic movement of employees from job to job or project to project within an organization, as a way to achieve certain human resource objectives, such as employee orientation, retention, training, and preventing burnout. Traditionally, job rotations move people between distinct business units in order for them to explore a wider range of experiences. For example, a technical engineer who moves to a business position, can get a better sense of a customer's need. By being situated in the actual work environment, job-rotation programs increase the employee's interest in learning. In addition, employees who have worked with so many diverse people through a job-rotation program about may become more flexible and agile in their job assignments.

Some argue that the job-rotation process is better framed in the context of organizational learning. The multiplication of economic networks worldwide assures the individual that many paths for testing and accumulating new learning can be pursued simultaneously. The greater the number of paths and the more

sharing of knowledge, the more progress worldwide. It has also been noticed that on-the-job learning is much more effective than traditional instructor-based learning. Companies need to be aware that people have different ways of learning. Some learn by doing, some by seeing, and some by hearing. As many companies transition from products to services to outcomes, learning is at the heart of a successful transition. Employees who internalize effective practices in the workplace will lead the business to productivity and profit and gain satisfaction.

When people move between geographic regions or countries, they obtain an increased understanding of different cultures and business strategies. From the beginning, however, the organization needs to recognize that the rotation process generally creates more generalists than specialists.

A close look at the global economy indicates that success is based on the ability to understand and utilize loosely connected economic and social processes. The dynamic of economic progress in the new economy is based on learning. Innovation is at the heart of this process. It accounts for the bulk of improvements in productivity, and quality is at the heart of the flexibility that allows for variety, customization, convenience, and speed. Agile, multitasking individuals are needed to serve on cross-functional teams to direct this process. Some hold the opinion that increased wage dispersion is a result of technological change, education, and training. It seems, however, that in countries in which real wages respond flexibly to changes in labor demands and supplies, the move from job specificity to a more holistic view of work may lead to a widening of the wage dispersion within groups that vary by job education, occupation, and job tenure.

Job rotation is a mechanism that makes it possible for the firm to observe employees in action in different positions and thus learn which job is the best fit for each employee. This implies that human capital theory is at least partly job specific. It could be argued that only through job rotation can the firm get the information necessary to create the most efficient job assignments. The organization must make sure its skill needs correspond to those likely to be learned through job rotation.

The advantage of a rotation policy over a job-specialization policy increases when there is some uncertainty regarding employees and the activities in which they are or may be engaged. On a micro level, it is better for a firm to rotate new employees among

different jobs, because the firm can find out how well suited different persons are to different activities. On a macro level, it is more profitable for an innovative firm to rotate employees because this will induce more innovative learning among employees. In this view, job rotation helps a firm focus on improvement and on the future, rather than looking at the past and placing blame. Since individuals who rotate jobs associate in new work groups, job rotation may promote team-based management.

Learning provided by the organization helps the team members achieve at the level sought by management. Teams carry the responsibility, authority, and accountability for the performance of their members. Teams can then create, acquire, and transfer new knowledge. Today, much employee training has been transferred to electronic learning, or *e-learning*. Companies today that rely on e-learning enhance the opportunity for employees to interact through chat rooms and with mentors. In this model, teams become the “resource persons,” and clerical, production, and service employees develop a sense of self-worth, ownership, and satisfaction in their work. This employee development is considered the heart of organizational development.

JOB SATISFACTION

Job satisfaction (JS) is one of the most widely discussed and studied dimensions of employees’ work lives, with research dating back to the dawn of the twentieth century. Early definitions conceived of JS as a global affective or emotional reaction to one’s job.

More recently, JS has been defined as comprising two distinct yet related components: an individual’s *affective* orientation toward the job (e.g., I enjoy my job; I look forward to going to work each day) and an individual’s *cognitive* evaluation of the job and how well it meets personal needs (e.g., I think that I am adequately compensated for the work I do; this job provides me with the recognition I deserve). A large number of job facets (or dimensions) have been identified as underlying these cognitive evaluations, including social aspects of the job (e.g., appreciation or recognition by the supervisor or organization); compensation and benefits; working conditions (e.g., safety); and opportunities for personal growth (e.g., promotion). Thus, many measures of JS ask specifically about these various facets.

The relevance of JS attitudes to career-development issues lies in the fact that JS is an important (arguably the most important) outcome for assessing the effectiveness of career-development activities and decisions. That is, the ultimate goal of most career-development activities is to ensure that individuals end up in careers and jobs that they find maximally satisfying. Thus, it is important to understand how JS is measured, the determinants of JS (both individual and situational), and outcomes typically associated with higher levels of JS. Each topic is reviewed in the following sections.

MEASURING JOB SATISFACTION

There are a number of different scales and techniques available for measuring one’s level of JS. Most involve eliciting responses on a self-report questionnaire or in an interview (with the former being much more common). For example, to understand how satisfied individuals are with their jobs or with a particular aspect of their jobs (e.g., benefits), employers can ask them to complete a survey (or participate in an interview) that directly asks them the extent of their satisfaction. These scales have a number of benefits, including high reliability (i.e., consistency of responses across time and different items); face validity (i.e., they appear to measure what they are measuring, which is important for employees’ willingness to complete such measures); and practicality (i.e., questionnaires are relatively quick to complete and inexpensive to create or obtain). Limitations to this assessment method include variability in individuals’ motivation to report how they truly feel and think and their ability to accurately describe what they are feeling or thinking.

The various scales designed to measure JS can be sorted according to the following distinctions: (a) verbal versus pictorial, (b) global versus facets, and (c) cognitive versus affective (or a combination of both). With regard to the first distinction, the vast majority of JS scales ask participants to respond to a series of items on a Likert-type scale, usually ranging from *very dissatisfied* to *very satisfied* (or *strongly disagree* to *strongly agree*). However, the Faces Scale forgoes this verbal response system in favor of a series of faces depicting varying levels of satisfaction. Employees are then asked to choose the face that most closely reflects how they feel about their jobs. In general, the Faces Scale has been shown to be as good a measure of JS as scales that rely on Likert-type response formats.

Regarding the second distinction among JS scales, global (or general) measures of JS are characterized by their relatively small number of items (sometimes as few as one item) and their avoidance of asking about specific aspects of a job. Usually, global measures of JS include items such as “Overall, I am satisfied with my job” or “In general, I enjoy working here.” These types of scales offer a number of advantages, including their relative practicality (it may take only a minute or two to complete the measure) and strong relationships with multidimensional JS scales (i.e., those including several facets). JS scales that assess multiple facets of an individual’s JS are commonplace and vary widely in their length and the number of distinct facets assessed. These JS measures offer the advantage of greater specificity in the assessment of JS, which can be useful for gaining a greater understanding of employees’ satisfaction regarding specific aspects of their jobs. For example, although an employee may be generally satisfied with a job, examination of facet-level JS may reveal that he or she is dissatisfied with the supervisor, a situation that could potentially lead to performance problems or even result in the employee’s leaving the organization. Thus, both global and facet measures of JS have unique advantages and limitations that should be balanced with the purpose(s) for collecting the JS information.

The third distinction among JS scales involves that between cognitive and affective components of JS (previously defined). The vast majority of extant JS measures are more cognitive in nature, asking employees what they *think* about various facets of their jobs. However, a few JS measures are more affective in nature, asking employees how they *feel* about their jobs. Although these two types of measures

do not tend to differ much in terms of their reliability or validity (i.e., their relations with other variables), recent JS research building on basic attitude theory has demonstrated the importance of measuring and considering both components of JS. That is, job incumbents have been shown to have distinct affective and cognitive perceptions of JS that may be quite different. For example, individuals may cognitively understand that for the work done, they are well compensated, yet at the same time not like the type of work they are doing (thus, a cognitively focused measure of JS might show them to be satisfied, whereas an affectively oriented measure might show the opposite). In addition, it is known that when cognitive and affective components of attitudes align, they are much more useful as indicators of subsequent behavior and attitudes (and this has recently been shown in the JS research specifically).

More recently, there have been some “new directions” in JS attitude measurement, using some techniques that are qualitatively different from verbal reports on JS scales. The first involves a more “interpretive” approach, an emphasis on employees’ reports of their JS and its important components (using the employees’ language) rather than reliance on predetermined facets of JS (using the researcher’s language). This approach involves asking employees to write unstructured accounts of satisfying and dissatisfying job experiences, and research using this approach has found that the language employees use to describe such experiences largely converges with the facets reflected in the more traditional JS scales.

Second, an interesting new methodology has developed that can be used for measuring employees’ job satisfaction, particularly its affective component. This methodology, referred to alternatively as *experience sampling methods* or *ecological momentary assessment*, allows researchers to capture momentary behaviors and psychological states in context and then track those behaviors and states over time. For example, an employee whose job satisfaction would be measured in this way would most likely receive a personal digital assistant (PDA) to carry for several days or weeks. This employee would be periodically cued throughout the day from the PDA and asked to report on his or her affective state. This very new approach to measuring JS has the advantage of being able to assess JS at a very detailed level and in “real time,” allowing for examination of changes in JS over time.

DETERMINANTS OF JOB SATISFACTION

Given that JS is believed to be an important outcome of career-related actions, it is particularly relevant to review what factors contribute to an individual's level of JS. These factors can be grouped into three categories: the individual, characteristics of the job and organization, and the intersection of the two.

Individual Determinants

Although it may seem intuitive that JS is primarily a function of the job, there are, in fact, a number of characteristics of individuals that, independent of the jobs they hold, will influence their general levels of JS. Among these factors are relatively stable personality traits, such as self-esteem, self-efficacy, and positive/negative affectivity, with research suggesting that people with greater self-esteem, greater self-efficacy, greater positive affectivity, and lower negative affectivity tend to report higher levels of JS. Investigation of the relationship between JS and personality traits has also focused on the five-factor model of personality, which comprises five traits: Neuroticism, Extraversion, Openness to Experience, Agreeableness, and Conscientiousness. Of these five traits, Neuroticism has the strongest relationship. Perhaps not surprisingly, this relationship shows that the more neurotic individuals are, the less likely they are to be satisfied with their jobs; thus, this is characterized as a *negative* relationship. Extraversion and Conscientiousness, on the other hand, are both related *positively* to JS; more extraverted and more conscientious employees tend to report higher JS.

From this evidence, it is clear that individuals' perceptions of JS are reflective of not only their jobs but also who they are as people. In fact, levels of JS may even have a genetic component to them. Specifically, research based on identical twins shows that up to 30 percent of JS may be heritable, and identical twins reared apart have been shown to have very similar levels of JS as adults, even though they may hold very different jobs. In essence, research on the individual determinants of JS suggests that some people are more likely to be satisfied with their jobs regardless of their actual employment conditions (and therefore, across the career span). This is not to say, however, that employment conditions do not play any role at all, and those effects are reviewed next.

Situational Determinants

The examination of the effects of job characteristics on JS perceptions is, historically, perhaps the most studied aspect of JS. At the core of this idea is the belief that different working conditions will cause individuals to feel motivated and satisfied with their work or unmotivated and dissatisfied. Support for the doctrines of empowering workers, redesigning jobs, and building variety into task work arose from the assumption that employees would not be satisfied if they felt they were in boring and highly repetitive jobs. Decades of research in this area have reported mixed findings. In general, improving job characteristics such as autonomy, feedback, and skill variety does result in increased levels of JS. However, these relationships depend in large part on the personality of the individual employee, with some employees enjoying added flexibility and responsibility and others disliking it. This dependence on the characteristics of the individual employee brings us to perhaps the most recently and widely agreed-upon important determinant of JS: *fit*.

Fit Determinants

Fit between an individual and the employment situation can be conceptualized at both the job level, *person-job (P-J) fit*, and organizational level, *person-environmental (P-E)* or *person-organizational (P-O) fit*. Fit can be assessed in terms of demographic, personality, or values characteristics, and, in general, it is believed that persons who fit with the job and organization should experience more positive work outcomes, including higher levels of JS. For example, a highly competitive employee should be more satisfied in (a) a job that requires little cooperation and much intergroup competition and (b) an organization characterized by a highly competitive culture that rewards individual performance and tends to attract other competitive individuals. In general, research has supported these predictions regarding the important role of fit in determining JS.

OUTCOMES OF JOB SATISFACTION

Over the course of nearly 100 years of research, JS has been linked to a number of important workplace outcomes, including job performance, withdrawal behaviors, burnout, and health.

Job Performance

Intuitively, the relationship between JS and job performance makes sense (that is, a happy worker should be a productive worker). However, the majority of research has not borne out this relationship, with studies generally finding only weak to moderate relations between JS and job performance. These findings are being continually revisited, however, with claims that (a) the older reviews of this relationship have been misinterpreted and (b) either JS or job performance has been conceptualized and/or measured in ways that do not expose this relationship. For example, recent research has shown that when JS attitudes are “strong” (i.e., an alignment between the cognitive and affective components), the relationship between JS and job performance increases significantly. Findings such as these, as well as the continued expansion of the definition of job performance to include contextual performance and organizational citizenship behaviors (i.e., employees going above and beyond the call of duty) have led to a renewed interest in understanding the role of JS in determining job performance.

In addition, it appears that the relationship between JS and job performance or career success may change somewhat over the course of an individual’s career. Careers are often identified using a three-stage approach: establishment, maintenance, and decline. During the *establishment stage*, there is little relationship between JS and job success, as JS can change as a person explores his or her career options (likewise, career success is generally low, but rises as the person finds the career in which they will remain). In the *maintenance stage*, JS and career success begin to align more closely, and both reach career high points. The *decline stage* is also marked with high consistency between JS and career success, with both levels slowly declining until retirement.

Employee Withdrawal

Withdrawal attitudes and behaviors such as commitment, absenteeism, intention to quit, and turnover have long been linked both empirically and theoretically to JS. The rationale behind these relationships is the commonsense notion that if you are dissatisfied with your job, you will (a) be less committed to your organization, (b) seek to avoid your job whenever possible (increased levels of absenteeism), and (c) possibly, if your dissatisfaction is strong enough, intend to or actually leave your job. In many models of employee turnover, JS is

considered to be a primary determinant of employees’ forming the intention to quit their jobs, thus setting into motion a process that will result in their eventually leaving the organization. This is an important distinction, as research has shown that although JS is a weak predictor of actual turnover, it is a strong predictor of *intention to turnover* (i.e., quit). Thus, organizations interested in retaining their employees are well-advised to consider their employees’ JS.

Psychological Burnout and Health

In recent years, burnout and emotional exhaustion have been identified as important problems in the workplace, and research has shown that both stressful job conditions and employees’ low levels of JS can lead to an increased risk of burnout or emotional exhaustion (this type of research has focused almost exclusively on careers involving medical services or direct care, so additional research needs to be done on these relationships in other occupations). Interestingly, in many models of the burnout process, low JS is not by itself a direct cause of burnout; rather, it is a factor that can amplify the effects of a stressful or highly emotionally demanding job and/or workplace. In this context, therefore, low JS can be seen as an indicator of which individuals may be more susceptible to burnout. These established links between JS and burnout and experienced stress on the job become especially problematic when considered in conjunction with findings that levels of JS can “spill over” to affect general life satisfaction.

JOB SEARCH

Job search is a process that consists of gathering information about potential job opportunities, generating and evaluating job alternatives, and choosing a job from the alternatives. It is a self-regulatory process that begins with the identification and commitment to pursuing an employment goal and ends when the employment goal has been achieved or is abandoned.

The job-search process involves a logical sequence of activities that consists of two phases: (a) planning job search and (b) job search and choice. Job search begins with an extensive search to gather information and identify job opportunities, followed by a more intensive search that involves the acquisition of specific information about jobs and organizations. Job search has also been described as consisting of preparatory and active phases. Preparatory job-search behavior involves information gathering about job opportunities, and active job-search behavior involves applying for positions.

Models of job search include the antecedents and consequences of job search behaviors. Job-search behaviors include (a) job information sources, (b) job-search intensity, and (c) job-search effort. *Job information sources* refer to the means by which job seekers learn about job opportunities. Formal sources

involve the use of public intermediaries, such as advertisements, employment agencies, and campus placement offices. Informal sources are private intermediaries, such as friends, relatives, or persons who are already employed in an organization.

Job-search intensity refers to the frequency with which job seekers, during a set period of time, engage in specific job-search behaviors or activities, such as preparing résumés or contacting employment agencies. *Job-search effort* refers to the amount of energy, time, and persistence that a job seeker devotes to his or her job search. Unlike measures of job-search intensity, job-search effort does not focus on particular job-search behaviors, but rather, refers to the time and effort one devotes to the search.

Two more specific types of job-search behavior are assertive job seeking and networking. *Assertive job seeking* applies the concept of assertiveness to job search and refers to the ability to identify one's rights and choices during job search and to act on them. *Networking* involves contacting friends, acquaintances, and referrals to obtain information and leads about job opportunities.

The antecedents of job search include (a) biographical/demographic variables, (b) individual-difference variables, (c) employment and job-search attitudes, and (d) situational variables. With respect to biographical/demographic variables, older, non-White, female, less-educated, and more-tenured individuals have been found to conduct less intense job searches than younger, White, male, more-educated, and less-tenured individuals. In addition, younger, more-educated, and male job seekers are more likely to find employment, and more-educated and White job seekers experience a shorter period of unemployment. Grade average has also been found to positively relate to job-search behavior and job-finding success. In general, biographical variables tend to be only weakly related to job-search behavior and to a lesser extent than the other antecedents.

Individual-difference variables that are important for job search include personality variables, motivational variables, and affective variables. Among the personality variables, self-esteem has been found to relate positively to job-search intensity and assertive job-seeking behavior and to a shorter period of unemployment, more job offers, and a greater likelihood of obtaining employment. Dimensions of the five-factor model of personality such as Extraversion and Conscientiousness have been found to be strong

predictors of job-search behavior, followed by Openness to Experience and Agreeableness. In contrast, Neuroticism is negatively related to job-search behavior. Extroversion, Conscientiousness, Openness to Experience, and Agreeableness are associated with a shorter period of unemployment, and Conscientiousness also predicts employment success.

Attitudes have also been found to predict job search. *Employment commitment* refers to the importance or centrality to the job seeker of employment beyond its financial return. It has been found to positively relate to job search intensity. *Job-search attitude*, or the extent to which a person has a positive or negative evaluation of job search behavior, has been found to predict job-search intention.

A motivational variable that is especially important is *job-search self-efficacy*, or the confidence one has in his or her ability to perform specific job-search tasks and activities. Job-search self-efficacy has been found to predict job-search intensity, assertive job-search behavior, and job source usage, as well as search duration, number of job offers, and employment success. Another motivational variable is job-seekers' *perceived control* over job search outcomes. Perceived control is positively related to job-search intensity and finding employment.

Recent research has examined whether affective traits are related to job-search behaviors. This research suggests that individuals who tend to experience positive emotions set employment goals that, in turn, lead to high job-search intensity. Individuals who tend to experience negative emotions, however, are less successful in their job search because they have lower self-efficacy than their counterparts. Another study found that emotionally intelligent job seekers start employment more quickly than individuals with low emotional intelligence. Taken together, these studies reveal that the way job seekers feel, and their abilities to process emotional information have important effects on job-search behaviors and job-search success.

Situational variables that are important for job search include financial need and social support. *Financial need* is the extent to which a job seeker is experiencing economic hardship. Job seekers who have a greater financial need tend to be more intense in their search for employment. In addition, those with higher benefit levels or a longer duration of benefits tend to remain unemployed for longer periods. *Social support* refers to the network of friends and family

who provide counseling, assistance, and encouragement to job seekers. It predicts job-search behavior and employment success and is particularly important in assisting individuals following job loss.

The consequences of job search include (a) job-search outcomes (outcomes that occur during the search process), (b) employment outcomes (outcomes that are a result of one's job search), and (c) employment quality (outcomes that occur on the job).

Job-search outcomes include the number of job interviews and job offers that a job seeker receives and the speed with which one obtains employment. Job-search intensity is positively related to the number of job interviews and offers received and is negatively related to search duration.

Employment outcomes assess the result of one's job search and refer to whether or not a job seeker obtains employment and the nature of that employment. The most common outcome measure of job search is *employment status*, or whether or not the job seeker has found a job. Job-search intensity, effort, and the use of informal information sources (i.e., friends and personal acquaintances) predict employment status. Other employment outcomes predicted by search intensity include person-job fit, person-organization fit, and initial compensation.

Employment quality refers to job-search outcomes that occur once the job seeker assumes a position and begins work (e.g., job satisfaction). Job seekers who find employment through informal sources tend to have more positive job attitudes and lower turnover. There is also some evidence that job-search intensity leads to more positive job and organization attitudes because of its positive effect on perceptions of job and organization fit.

In summary, individual differences and situational variables predict job search behaviors, and job-search behavior is related to the probability, speed, and quality of employment that one obtains.

JOB SECURITY

Job security is the stability and continuance of one's current employment as one knows it to be. An appraisal of one's job security involves an assessment of both one's position and one's employment within an organization. In other words, job security can be affected by the potential loss of employment and/or the potential loss of valued aspects of one's position within an organization. Related concepts include economic stress, job insecurity, job stability, underemployment, and unemployment.

Job security is closely related to the issue of career development. It is estimated that the average employee will follow approximately seven different career paths during a typical 30-year span of employment. Analyses of *Current Population Survey* data suggest that the average tenure in a job in the United States is 7.4 years, among the lowest in industrialized nations. Often, career changes can be a direct result of involuntary turnover, layoffs, outsourcing, or shifts in the national economy. During the 1990s, there were over 15 million layoffs. A comparison of 21 industrialized nations found that the United States ranked among the lowest in employee perceptions of job security.

CONCEPTUALIZATIONS OF JOB SECURITY

Job security can be thought of as a subjective experience or an objective state. Objectively, the Bureau of Labor Statistics within the U.S. Department of Labor (DOL) provides biennial estimates of the job outlook

for hundreds of occupations within the United States. The job outlook for these occupations is based on whether employment opportunities within these occupations are growing, stable, or declining over the next decade. Occupations with declining employment can be objectively categorized as having less job security than those with growing employment. Organizations can also objectively identify positions within the company as being more or less likely to be outsourced, eliminated, retained, or expanded on in the future. Often, this assessment can be made by upper-level management based on annual strategic planning and company economic forecasts.

While job security can be described objectively, it is more commonly conceptualized and measured as a subjective perception on the part of the employee. Using this methodology, a job can be defined as *insecure* if an employee perceives his or her job to be unstable or at risk regardless of any actual objective level of job security. Thus, it is possible to have a job that is objectively considered to be secure but is subjectively perceived to be insecure by the employee holding that position. The reverse situation may also occur, whereby an individual perceives his or her job to be secure but organizational or DOL estimates would categorize that position or occupation as having a poor job outlook.

There are advantages and disadvantages to both approaches of conceptualizing and measuring job security. The objective approach removes individual perceptions from the equation and relies on government or organizational forecasts of job security. This can be advantageous if one's purpose is to accurately categorize a position or occupation as having (or lacking) job security. On the other hand, the subjective approach explicitly relies on individual perceptions of job security, which can be colored by economic, social, organizational, and individual characteristics. However, many outcomes of job security are best predicted by such subjective individual perceptions rather than more objective assessments. Thus, if one's purpose is to predict individual outcomes, assessing job security subjectively may be more informative.

ANTECEDENTS OF JOB SECURITY

There are many known antecedents and consequences of having a secure or, conversely, insecure position at work. The predictors of job security can be summarized into four categories: organizational

change characteristics, worker characteristics, employment characteristics, and economic factors.

Formal announcement of layoffs, an upcoming merger or acquisition, organizational restructuring, and/or downsizing are all potential *organizational change characteristics* that may decrease employee job security. Annually, over 1 million U.S. workers can expect to lose their jobs as a result of these transitions. In addition to actual job loss, organizational change characteristics have also been shown to predict employee reports of job loss fears, perceived psychological contract violations, and lowered expectations regarding job security, compensation, and opportunities for advancement.

An additional antecedent of job security may be related to changing organizational technology. A change in the technological systems of an organization can have a profound effect on the security of positions experiencing the technology change. As the level of technological complexity required in an organization changes, so do the worker requirements, which can, in turn, affect the security of individuals who cannot adapt to the change or whose skills are no longer required (i.e., obsolescence). Thus, technological change can decrease job security and eventually lead to job loss for workers whose skills and/or positions are obsolete.

Worker characteristics refer to a variety of individual-difference variables that can affect an individual's perception of job security. These variables include employee gender and race, absenteeism rates, grievance filing, organizational tenure, career history, and education level. Government data provided by the Bureau of Labor Statistics show that the rate of unemployment is traditionally higher among racial minorities than among Whites. Although the actual rates of unemployment for women are not higher than for men, research indicates that women tend to suffer from greater downward mobility than do men. Workers who are frequently absent are less likely to be secure in their positions and are more likely to face involuntary turnover than workers who do not absent themselves as often. Research has also shown that workers who file grievances are less likely to be promoted, receive lower performance evaluations following the grievance activity, have higher voluntary and involuntary turnover rates, and have lower job-security perceptions than workers who do not file grievances.

Job longevity or organizational seniority often provokes feelings of security; in particular, due to seniority protections, older workers are less likely to be laid

off than their younger counterparts. An employee's career history may also be related to job security. Employees who have been laid off in the past, have been laid off for longer periods of time, or are at career plateaus are more likely to face underemployment and job insecurity, perhaps due to a marketplace stigma associated with having been laid off. Finally, workers with more education tend to experience fewer layoffs than their less educated counterparts. Thus, education appears to provide some protection against job insecurity.

Employment characteristics refer to the contractual relationship that an employee has with his or her organization. This includes whether the worker is employed on a temporary or contingent basis versus a permanent one, whether the worker is employed part time versus full time, and whether the job falls under union jurisdiction. Nonbinding, temporary, or part-time contracts typically result in lower job security, because these characteristics implicitly suggest a briefer tenure with the organization than would a binding, permanent, full-time contract. In addition, these types of contractual arrangement also tend to pay less and offer fewer employee benefits, such as retirement and health benefits, than permanent or full-time arrangements.

Economic factors are the last set of antecedents of job security. When the state of the economy is poor, rates of unemployment and underemployment increase. As news of mass layoffs, low levels of job creation, and a scarcity of high-wage jobs loom large in the public eye, employee perceptions of job security typically decline. Research suggests a link between media reports of mass layoffs and employee perceptions of job insecurity. Thus, regardless of any planned layoffs in one's organization, exposure to media accounts of mass layoffs occurring in other organizations can stimulate anxiety regarding one's own job security.

Although organizational change characteristics, worker characteristics, employment contractual arrangements, and economic factors can serve as useful predictors of employee job security, far more research attention has been paid to the individual, organizational, and societal consequences.

CONSEQUENCES OF JOB INSECURITY

According to the "vitamin model" of work and unemployment, individuals require nine environmental "vitamins" to maintain their psychological health:

opportunity for control, opportunity for skill use, externally generated goals, variety, environmental clarity, availability of money, physical security, opportunity for interpersonal contact, and valued social position. Many of these aspects are threatened or compromised under conditions of job insecurity. For example, a loss of control over one's employment security, low environmental clarity, and an anticipation of a loss of income often accompany employee job insecurity. Based on this model, one would expect that the consequences of job insecurity would be negative as a result of these "vitamin" needs being compromised, and, indeed, research has borne this out.

Research from as early as the 1970s suggests that concerns about job security can have a detrimental effect on employee health outcomes. Employees with low job security report a greater incidence of physical health conditions, elevated levels of blood serum cholesterol, elevated blood pressure, and elevated levels of stress hormones. Job insecurity has also been associated with higher levels of general psychological distress, increased medical consultations for psychological distress, and increases in depression, somatization, anxiety, and hostility.

Research suggests that in addition to affecting the workers themselves, concerns over job security may have implications for the families of affected employees and society at large. Work and family research suggests that these two spheres of life do not operate independently of each other. Therefore, it is perhaps not surprising that the economic worries of one member of a couple cross over to predict the job security of the other partner. In addition, in couples who experience job insecurity, the individuals display more negative affect, evaluation, and behaviors toward one another. Children of parents who are experiencing job insecurity at work are also not immune from its negative effects. Children's perceptions of work, work beliefs, and work attitudes are influenced by their parents' job insecurity. In addition, student grades are related to parental perceptions of job security.

Extensive research has also focused on the job-related outcomes associated with job-security concerns. A recent meta-analysis reported that insecure employees experience decreased job satisfaction, are less involved in their jobs, are less committed to the organization and more likely to quit their jobs, place less trust in management, and have lower levels of performance than do workers with more job security. Other studies report significantly higher levels of

job-related stress; more work withdrawal behaviors, such as absenteeism, tardiness, and work task avoidance; lower levels of creativity; and more work-related accidents and injuries among less secure workers.

FACTORS THAT INFLUENCE THE OUTCOMES OF JOB SECURITY

Despite the evidence indicating that concerns over job security have negative implications for individuals, organizations, and society, certain variables can serve to moderate (or influence) the effects of job insecurity by either mitigating or exacerbating its consequences. These moderators fall into two categories: individual-difference moderators and organizational-level moderators. *Individual-difference moderators* refer to characteristics that vary from person to person, whereas *organizational-level moderators* refer to differences within or between organizations.

One individual-difference moderator, cultural values, may influence the extent to which employees react negatively to perceived job insecurity. Individuals with collectivist cultural orientations or from collectivist cultures appear to be more likely than their individualistic counterparts to report lowered job satisfaction, more job stress, and more turnover intentions as a function of job insecurity.

Workplace control (i.e., the ability to protect oneself from negative events at work) may also be an important moderator of the stress associated with job insecurity. Research has found that employees who perceive they have little control over their workplaces exhibit more somatic symptoms and higher blood pressure in response to job insecurity, whereas employees who perceive they exert greater control over their workplaces do not experience these outcomes. Thus, individuals who perceive that they are able to protect themselves from negative events at work may be less vulnerable to the effects of job insecurity.

Another variable that has been theorized to buffer the effects of job insecurity on employee outcomes is emotional intelligence. Because emotional intelligence regulates the way in which individuals manage emotions, it is argued that emotional IQ will moderate the effects of job insecurity on emotional reactions and behaviors. Specifically, high-emotional-intelligence employees should be less likely to experience negative emotional reactions to job insecurity or use negative coping strategies than low-emotional-intelligence employees.

Finally, job involvement has also been shown to moderate the effects of job insecurity on employee outcomes. Employees who are highly invested in their jobs appear to be more adversely affected by job insecurity than their less involved counterparts, reporting more negative job attitudes, more health problems, and higher levels of psychological distress when they perceived their jobs to be threatened. This implies that individuals who consider their jobs to be quite important and whose jobs may be significant to their self-identity or financial security are more at risk for negative outcomes as a result of job insecurity than are individuals who are relatively indifferent to their jobs.

Although the individual-difference moderators may explain who is most likely to negatively react to job insecurity, these variables are not easily modified. For example, one cannot change an employee's cultural values or level of job involvement in an effort to ward off the negative effects of job insecurity. However, research has shown that a number of organizational interventions may be effectively utilized toward this end.

One of the major sources of stress during times of organizational change is the uncertainty associated with such events. Whether an organization is restructuring, merging with another organization, or downsizing, research has shown that employees face concerns regarding their job security during those periods. In addition, during times of organizational transition, the "rumor mill" often plays a large role in employee perceptions. Reliance on the rumor mill and the absence of factual information can exacerbate employee anxiety. On the other hand, increased organizational communication may reduce the consequences of such uncertainty. Offering "realistic merger previews," "realistic downsizing previews," and increasing upward and downward communication may counter the negative effects associated with job insecurity. These types of interventions may be more attractive when one considers that providing increased communication within an organization is a relatively low-cost endeavor.

A slightly more involved organizational intervention found to reduce the negative effects of job insecurity is to increase employee participative decision making. Whereas job insecurity is associated with a lack of control perceived by employees, participative decision making has been found to be effective within organizations precisely because it allows employees to have a substantial voice in job-related decisions.

Organizations that provide their employees with participative decision-making opportunities may offer their employees the chance to regain control over important aspects of their jobs, which is otherwise lost under conditions of job insecurity.

A final organizational intervention that shows promise in attenuating some of the safety-related effects of job insecurity involves the organizational safety climate under which employees work. As noted earlier, research suggests that job insecurity has a detrimental effect on employee safety attitudes, behaviors, and outcomes. However, the effects of job insecurity on safety appear to be moderated by the extent to which the organization is seen as valuing and emphasizing safety. Thus, during times of organizational transition and employee economic stress, it may be wise for organizations to consistently send a strong message regarding the importance of safety to their employees.

JOB SHARING

Job sharing is a flexible working arrangement in which two or more individuals voluntarily share the responsibilities, pay, and benefits of a full-time position. In essence, job sharers convert one full-time job into two permanent part-time positions by coordinating task responsibilities while sharing the full-time equivalent of pay and fringe benefits. Job sharers may work split days, split or alternate weeks, or their hours may overlap. Pay and benefits are typically divided proportionately to the hours worked. Other similar yet distinct flexible working arrangements include regular part-time work, flextime, V-time, and work sharing.

Research has suggested that successful job-sharing arrangements have beneficial effects for both employees and organizations. Job sharing is believed to broaden the depth of organizational knowledge, facilitate the achievement of human resource management objectives, and enhance organizational flexibility. Moreover, job sharing has implications for individual careers, as it has been found to reduce stress associated with juggling work and family demands and increase job satisfaction. In addition, because job-sharing employees perceive their organizations as recognizing and accommodating their personal lives, the practice has been found to increase organizational commitment and loyalty and reduce turnover and absenteeism.

Job sharing originated in the 1970s as a creative solution for career-minded individuals balancing work and life responsibilities. Job sharing permits part-time opportunities in career-oriented jobs that are not conducive to reduced hours or traditional part-time employment. An employee seeking to spend less time at work yet maintain status within a career can remain in the workforce by splitting his or her workload with a job-sharing partner. This arrangement allows individuals to work reduced-hour schedules yet maintain job skills, preserve job status, and remain eligible for advancement within their careers.

Job sharing is increasingly being offered by employers as part of a package of family-friendly or work-life balance policies geared primarily toward parents. In fact, approximately 90 percent of job-share partners are women with parental or elder care responsibilities. However, more frequently, individuals are requesting job-share arrangements for reasons other than family responsibilities, such as to continue education or to phase into retirement.

A job-sharing arrangement is typically initiated by employees who make a written proposal to management. This proposal may include issues such as the advantages to the employer if the job is restructured; the strengths and weaknesses of the proposed job-sharing team; the specifics of the work plan, including how the responsibilities and work time will be divided; and the proposed communication techniques. The success of the job-sharing arrangement is dependent on gaining supervisory support and maintaining open lines of communication, not only between job share partners but also between the partners and management. In addition, it is critical for the division of responsibilities to be seamless and for balance to be maintained in the sharers' partnership.

Empirical research with respect to job sharing is limited; however, a number of organizational benefits have been identified. For example, organizations offering job-sharing arrangements have the ability to recruit and retain highly skilled and valuable employees who may be unable or unwilling to work on a full-time basis. In addition, job sharing has been found to increase organizational flexibility and continuity by allowing sharing partners and management to develop work schedules that satisfy both parties, thereby providing continuity when one partner is unavailable or unable to work. Successful job-sharing arrangements are further said to broaden organizational knowledge by bringing two or more diverse sets of skills, experiences, and perspectives to a position that would traditionally be occupied by only one person. Moreover, it has been suggested that the creative pairing of job-sharing partners can help in the achievement of human resource management objectives, such as training, phased retirement, and upward mobility.

In addition to allowing employees to gain flexibility in balancing their work and personal commitments, job sharing has other beneficial effects for individuals. Research indicates that the heightened control over one's working life can reduce stress and anxiety levels and lead to more highly motivated and satisfied

employees. Moreover, individuals involved in job-sharing arrangements have been found to be more committed and loyal to their organizations than their coworkers, presumably because they feel that their personal needs are being recognized by their employers.

Despite the potential benefits, job sharing remains the least utilized flexible working arrangement. Research has suggested that the most common organizational concerns include increased administrative and training costs and extra time requirements for supervision and communication. Additional concerns include the impact of job sharing on other employees, the difficulty in hiring a replacement if one partner leaves the organization, and an overall change in organizational culture.

Advocates argue that organizations view job sharing as more difficult than it really is. It is suggested that the success or failure of the arrangement is dependent on the people who compose the team and on management's willingness to accept and foster the arrangement. With commitment, compromise, and open communication, job-sharing arrangements can benefit

both the organization and the job-sharing partners. Employees gain flexibility to balance their work and personal lives, and organizations benefit from highly satisfied and motivated employees, lower absenteeism, and reduced turnover.

K

KNOWLEDGE WORK

The term *knowledge work* refers to a profession that utilizes intellectual capital to create, teach, and problem solve. Knowledge work requires significant cognitive activity and dedication to continuous learning on behalf of the practitioner. Day-to-day knowledge work consists of nonroutine and nonrepetitive activities. Examples of knowledge workers include, but are not limited to, doctors, lawyers, researchers, engineers, and consultants. Knowledge workers have expertise in their fields, and they stay current on theoretical and practical applications in their fields. They add value to their professions and to others through the creation of new theories, information, services, and products. Knowledge work requires formal education and incorporates theoretical knowledge in the creation of new information. Knowledge work is not solely applied tacit knowledge. For example, an experienced waitperson is not a knowledge worker even though he or she may know the menu and the customers at the restaurant very well.

Knowledge work is part of a larger economic shift. The transition from the industrial age to the information age has caused a shift in the labor market from the production of material goods to the production and management of services, many of which are based on the acquisition, transformation, or application of information. This economic shift has increased the number of knowledge workers and has also highlighted issues specific to knowledge work and knowledge workers.

Some of the issues being addressed include how to manage knowledge workers individually and in teams and how to better prepare students for work of the future. The increase in knowledge-work professionals and knowledge-based organizations has also raised issues about the measurement and management of intellectual capital. For example, in the past, many businesses owned buildings, equipment, and inventories of goods. A knowledge-based company, for example a consulting firm, may not own any buildings, equipment, or tangible goods. Instead, its assets lie in the intellectual capital held by its professionals, who provide consulting services to clients. Because managing human capital is different from managing other capital assets, knowledge-based companies face managerial challenges different from those that confront industrial companies.

KNOWLEDGE, SKILLS, AND ABILITIES (KSAS)

Knowledge, skills, and abilities are often referred to as “KSAs.” They are part of many methods used to analyze jobs and work for purposes such as staffing and vocational counseling. All three terms concern human attributes needed to complete work tasks successfully. In other words, KSAs are cognitive and psychomotor informational digests and processes stored in memory that people need to succeed at work. The first two of these, knowledge and skills, are largely developed through life experiences, often through hard work. The third, abilities, are thought to be relatively enduring capacities of an individual that are helpful in developing knowledge and skills. The acquisition of knowledge and skills is the main goal of education and training. Abilities typically predict who will benefit most from a certain kind of training. Measures of all three factors are often used by employers to inform decisions about whom to hire, because employers are looking to hire the people who know the most, can do the best job, and can be most easily trained to do the work.

Knowledge is mostly concerned with the “what” of a task. Things that one learns from books, structured demonstrations, trial and error, and classrooms are most often knowledge. Knowledge is commonly thought of as factual and procedural information as well as action sequences kept in the head mainly for brain work but also to execute skilled activities. For example, most people reading this already know the meaning of a large number of words in English and the names of the capitals of most states in the United States. The knowledge that is most commonly associated with careers usually belongs to a specific discipline, such as chemistry, forestry, music, cooking, or graphic design. Knowledge that is helpful for a career comes from both general education and specific vocational preparation. Many jobs, for example, require one to read and write (general education). To be able to read and write, however, one must know the meaning of many commonly used words. Most jobs also require additional specific knowledge (e.g., cell biology). Thus, in addition to general knowledge, one would need specific knowledge of, for example, cell biology to read a technical report on cloning and write an evaluation of the report.

Skills are more closely associated with using the body than with using the head. Motor skills allow one to do things quickly and relatively effortlessly, such as shifting gears or using the steering wheel while

driving a car, truck, or forklift. Other examples include operating a sewing machine, tying a knot, or properly serving a tennis ball into the court. Perceptual skills may also be developed. Examples of visual perception include color perception used for picking custom colors for interior design, and contrast and brightness perception needed for video camera operation. Sound perception is used for tasks such as analyzing the performance of an orchestra. Many heavy equipment jobs require both motor skills and perceptual skills (especially depth perception), such as moving pallets with a forklift or landing an aircraft.

Most skills are very specific to a job or occupation. Experience in landing an airplane, for example, is not particularly helpful in using a forklift to load a truck, nor is such experience particularly helpful in docking a ship. Such is the case even though all the previously mentioned tasks involve using the hands and feet to cause large machines to move in certain ways. For a rather different example, skill in rolling cigars will not prove terribly helpful in playing the piccolo, even though both tasks involve skilled movements of the fingers. Skill acquisition is typically rather slow in developing, especially for difficult tasks such as playing the violin or figure skating. For this reason, highly skilled performance is usually found in people who have practiced the skill in question for months or years.

Abilities are relatively enduring, mainly intellectual capacities that distinguish one person from another. An ability long studied by psychologists is *cognitive ability*, which is related to how quickly and how well people learn new material. The two most commonly assessed distinct cognitive abilities are verbal and mathematical (quantitative) abilities. There are other, more specialized cognitive abilities, such as space relations and the ability to solve anagrams. Other abilities may be thought of as talents, such as musical ability, artistic ability (ability to draw or paint), and the ability to dance. There are several different systems for describing and analyzing different human abilities. Abilities are special characteristics that allow people to become good at tasks quickly compared with other people. Some people show particular facility in reading and understanding a book on philosophy, while others can quickly learn to play the piano, others to paint well, and still others to figure-skate gracefully. People with special ability are said to be “naturals” at some tasks. Unlike skills and specialized knowledge, the same ability can often be used for different tasks. For example, someone gifted in verbal ability might be

a good poet or a good lawyer. Someone with musical talent might become a good speech pathologist, orchestral soloist, or acoustical engineer.

KSAs are sometimes called KSAOs because people want to refer to “knowledge, skills, abilities, and other characteristics.” “Other characteristics” can be thought of as capacities or work habits. For example, one might imagine the capacity to resist monotony. In a very repetitive task, such as putting golf balls into packages or loading boxes onto trucks, many people become bored and fatigued. Others are resistant to monotony and do not seem to mind doing the same thing over and over (musicians also need some of this capacity because they have to practice the same piece many times). “Other characteristics” include personality traits (e.g., punctual, persistent, courageous, unconventional) and describe how people typically behave. However, like abilities, “other characteristics” are thought to be relatively enduring individual-difference characteristics; that is, they meaningfully distinguish people in ways that are useful to know when one is considering the fit of an individual for a job or for a career.

KUDER CAREER ASSESSMENTS

Frederic Kuder published his first career interest assessment in 1939. The Kuder Preference Record was different from the other vocational assessments of the day in that it asked respondents to indicate their

preferences for everyday activities rather than their occupational preferences. The 1943 version became the standard career assessment used to assist World War II veterans with their educational planning under the GI Bill. The next generation of Kuder career interest assessments began in 1966, with the Kuder Occupational Interest Survey. This version contained 10 interest scales and provided test takers with scores that indicated their similarity to workers in 100 occupations and 40 college majors.

In the late 1990s, the latest version of Kuder brought the most change to the assessment since its conception. The name of the interest assessment was changed to the Kuder Career Search with Person Match, and the approach to matching test takers with employed others also changed. The publisher now offers two additional career assessments, the Kuder Skills Assessment and Super’s Work Values Inventory, Revised. In keeping with the times, all three Kuder assessments are available online at <http://www.kuder.com>. From the Kuder Web site, individual or group test takers can obtain and print their assessment results in seconds. Yet another innovation is the Kuder Electronic Career Portfolio, which offers the option of loading results from the Kuder assessments, along with the demographic information and résumés required by most prospective employers.

The Kuder Career Search with Person Match (KCS), the Kuder interest assessment, contains three sections. The first section depicts the test taker’s interests in each of the six Kuder Clusters (Arts/Communication, Business Operations, Outdoor/Mechanical, Sales/Management, Science/Technology, and Social/Personal Services). Results on each cluster are depicted on the profile in a bar graph format from highest similarity to lowest. The second section of the KCS assists individuals in exploring careers by educational levels, making it possible for the test taker to consider exploration of careers requiring post-high school training through college degrees. The third and newest section, Person Match, is based on a matching system first introduced by Kuder in 1980 as person-to-people matching. This approach matches individuals to people in jobs, rather than the traditional approach of matching people to job titles. To select the most similar matches, a modification of Spearman’s rank order correlation is used to compare the test taker’s KCS responses with the KCS profiles of more than 2,500 individuals in the Person Match reference pool.

The Person Match scale is depicted as a list of the top matches. As the test taker clicks the mouse on each

person in the list, they obtain a mini-autobiography written by that individual. Donald Zytowski, principal KCS researcher and developer, suggested explaining these matches to clients by stating that each identified match has preferences highly similar to their own preferences and that those listed as person matches may be in a variety of jobs or occupations worth further exploration. The actual job titles of the top person matches may not immediately appeal to the test taker, but the similarities may be found in the details contained in the autobiographical sketches. The mini-autobiographies easily lend themselves to the use of stories during the assessment interpretation process. In 1993, Mark Savickas explained that twenty-first-century career counseling will be about stories, not scores, and the Person Match scale of the KCS can help clients with the formation of their own career stories. The variety of job titles represented by the person matches also promotes the notion of *multipotentiality*, or the idea that all workers have the potential for job satisfaction in many work environments.

The Kuder Skills Assessment profile depicts the test taker's self-reported skill levels (low, medium, high) for the same six Kuder Clusters contained in the KCS. The second section, Exploring Careers by Educational Level, matches the second section of the KCS. The results of the Kuder Skills Assessment and the Kuder Career Search with Person Match can be depicted on a combined profile for comparison of skill and interest levels. Online career exploration is facilitated via links to middle school, high school, college, and adult levels of the Kuder College and Career Planning site. Other links provide access to occupational information (O*Net), job search opportunities (America's Job Bank), Résumé Builder, and information about colleges (College Search). The test taker has all the materials of a career resource library available online.

The third Kuder assessment, Super's Work Values Inventory, Revised, assesses the test taker's preference for 12 work-related values: achievement, coworkers,

creativity, income, independence, lifestyle, mental challenge, prestige, security, supervision, variety, and work environment. Results are listed in order of preference. A definition of each value is provided.

Results from the three Kuder assessments are available to administrators (such as the school counselor, career counselor, or advisor) in an administrative database. The database can be arranged in a variety of useful ways, such as by name, age, gender, or Kuder Career Cluster. Administrators can easily identify groups of test takers for special programs, guest speakers, college visits, or career guidance sessions. These recent innovations have made the Kuder career assessments readily accessible to administrators and test takers all around the world.

Donald Zytowski has published extensively on the various versions of the Kuder interest assessments. He is currently responsible for further research and development of the Kuder Career Search with Person Match, the Kuder Skills Assessment, and the Super's Work Values Inventory, Revised, for their publisher, National Career Assessment Services, Inc.

L

LATE CAREER STAGE

As individuals age, the possibilities for age and career stage to be asynchronous are numerous. Many workers over age 50 are about to graduate from school to start new careers, and many individuals in their late 40s are retiring after 30 years of service. Following common usage in the area, the general boundaries of this entry are career issues that typically affect individuals who are over age 50 or who have been in the workforce 30 years or longer.

SATISFACTION WITH JOBS AND CAREERS

Research suggests that both older workers and late-career employees have more positive attitudes toward their jobs (e.g., job satisfaction and job involvement). One explanation for this finding is that late-career workers have more realistic expectations for their jobs than do their younger, less experienced peers. As a result, they experience a smaller discrepancy between what they hope to get from their jobs (in terms of both tangible rewards and intrinsic satisfaction) and what they actually receive from them. They are old enough to have gotten over the “entry shock” of the world of work and senior enough to be less troubled by minor psychological contract violations.

Another potential explanation of these results is that late-career employees and older workers have jobs that pay more and provide more exciting work duties. Often as a consequence of increased seniority, older workers accrue jobs that provide greater job security and pay higher fringe benefits (e.g., pension

benefits, vacation, and sick leave), particularly since many organizations distribute such benefits on the basis of years of service. Using this rationale, then, older workers are more satisfied with their jobs than are younger employees not because of the aging process per se but because older workers have fundamentally more rewarding work situations than their younger colleagues.

Whether late-career employees are happier with their *careers* (as opposed to their *jobs*) is less clear. Certainly, consistent with the logic described above, there are multiple reasons why senior people would have more positive attitudes toward their careers than their younger, less experienced colleagues. Being a partner of a major law firm or accounting firm is typically a more satisfying experience, in terms of both salary and hours worked, than being an associate. In addition, cognitive dissonance may play an important role in the higher career satisfaction of later-career employees. Thirty-year veterans in one career may have internal pressure to self-justify their professional investments as being more worthwhile than do early-career individuals.

Nonetheless, there is at least some indirect evidence that satisfaction with careers tapers off in late career. For example, when older people retire and then come back into the workforce in some type of “bridge employment,” more than 25 percent choose a new career altogether. There are several potential explanations for this phenomenon.

Part of the explanation may rest with the issue of burnout; after 30 years in a vocation, individuals may experience boredom and lack of emotional involvement in their daily activities and psychologically distance themselves from their occupations. Another potential

explanation is that older workers may start devaluing their careers as a means of adjusting to retirement. As workers become more aware of impending retirement, they may start devaluing their vocations to reduce the amount of cognitive dissonance they might experience when they leave them—for example, “I’m not leaving such great a career after all.” Third, career paths can change dramatically over the course of a 30-year period, and individuals may look backward and find the changes in their career paths unappealing.

PERCEIVED AGE DISCRIMINATION AND WORK-RELATED SELF-ESTEEM

A particularly important job attitude to consider here is *perceived age discrimination*. In trying to explain this phenomenon, researchers have drawn a distinction between *normative age* and *chronological age*. This research suggests that it is not only chronological age that can create bias but also an individual’s age relative to expectations of others. Thus, even within a cohort of individuals at the same chronological age, some can be described as being ahead of schedule, on track, or falling behind—and this last group is the most vulnerable to age discrimination.

Along similar lines, the research of organizational demographers suggests that the more discrepant an individual’s age with the dominant coalition in a group, the more likely he or she is to be discriminated against. Thus, late-career individuals working primarily with other older employees are less likely to be subjected to bias than those working primarily with young employees.

As a result of perceived age discrimination, organizationally based self-esteem tends to decline over time as well. As the result of negative comments from coworkers and supervisors about the value of older workers, senior employees often experience lower life satisfaction, more frequent feelings of depression and learned helplessness, and less sense of being valued by the organization. These feelings of lower self-worth frequently appear in reaction to performance appraisals from supervisors, whose subjective evaluations of older workers tend to be harsher than objective performance indicators might suggest.

ABSENTEEISM AND TURNOVER

In light of the evidence presented above, it is not surprising that older workers, as a group, have lower

levels of absenteeism than their younger colleagues. Although negative stereotypes of older workers suggest they would have more illnesses that require absences from work, older workers are, in fact, less likely to take days off. One explanation for this finding is that older workers, because they are more highly paid and may have more responsible jobs, are less likely to take days off except when absolutely necessary. Another explanation is that younger workers, particularly those with school-age children, are more susceptible to getting sick or having to miss work to care for sick children. There is yet another potential explanation for this relationship, namely, that older workers with significant health problems are more likely to exit the workforce altogether via retirement. Consequently, older workers with the worst health problems are less likely to be included in studies of age differences in absenteeism because they are no longer in the labor market.

Similarly, previous research has found that older workers have lower levels of voluntary turnover. Again, because late-career workers may be more likely to have jobs that pay well and have higher levels of job responsibility, they may be less likely to seek out alternative employment. In addition, many firms distribute benefits such as pension contributions and vacation days on the basis of organizational tenure, further enhancing the financial inducements to stay. Furthermore, many older workers fear age discrimination in the labor market and worry that they wouldn’t be able to get good replacement jobs if they quit their current employment. Thus, late-career employees often have fewer “push” factors to get them to leave their present employers and fewer “pull” factors that impel them to enter the open job market.

JOB LOSS, REEMPLOYMENT, AND UNDEREMPLOYMENT

The preponderance of research on turnover among older workers has focused on voluntary exits from current positions. Some recent research on involuntary turnover caused by downsizings highlights the particular problems older workers face in the job market. In many ways, the experiences of laid-off older workers are similar to those of their younger colleagues. That is, older workers, too, typically experience feelings of depression, anxiety, irritability, and hopelessness.

However, their probability of losing their jobs via layoff and their success in finding new employment

are quite different. In the case of blue-collar workers, workers with high seniority are actually less likely to lose their jobs. Blue-collar workers who are members of unions typically enjoy some seniority-based protections, and even in the case of nonunionized workers, companies may be more willing to use seniority as grounds for layoffs than subjective performance ratings, which may not hold up well in litigation for wrongful discharge. The situation is largely opposite in the case of “exempt” white-collar workers. With the push to eliminate whole levels of management to save money, organizations have been disproportionately eliminating middle- and upper-middle-level management positions that are not readily seen as adding tangible value. The impact of this management strategy clearly negatively impacts older and late-career employees, who hold the majority of such positions.

Whether they are blue-collar or white-collar, though, the evidence is fairly strong that older workers have a more difficult time finding reemployment. As noted above, many supervisors have negative stereotypes of older workers anyway, and hiring older workers who have been let go by another firm is an even less appetizing proposition to them. In still other cases, older workers are so embedded in their communities (by virtue of home ownership, family responsibilities for parents, or a spouse’s job) that geographical relocation to obtain new employment is seen as an unacceptable option.

Older workers also seem to be more vulnerable to becoming underemployed in their replacement jobs—and for many of the same reasons that make it harder for older workers to get new jobs at all. That is, even when older workers become reemployed, they often have to take positions that pay much less money than their last jobs paid, provide substantially poorer benefits, or entail far less challenging or less responsible job duties. While generic outplacement services tend to have little impact on older workers’ abilities to become reemployed, some recent research suggests that individualized career planning is particularly instrumental in sustaining older workers’ energy for job hunting and in identifying the most appropriate replacement jobs for them.

JOB PERFORMANCE

The topic of job performance of older workers has been attacked from two different perspectives. The first examines whether late-career employees are

more likely to receive lower “subjective” performance appraisal ratings from supervisors than are their younger colleagues. The second examines whether the “objective” skills of older workers tend to decay over time; here, the research has traditionally examined the degree of decline in “cognitive” skills (such as memory) and “physical” skills (such as gross strength or fine-motor control) over time. We discuss each of these issues in more detail below.

SUBJECTIVE PERFORMANCE RATINGS

A major review of studies that looked at the relationship between age and job performance in the 1980s found approximately equal numbers of studies reporting that job performance increases with age, decreases with age, and remains the same. These results suggested that the relationship between age and job performance may very well depend on other factors, such as the type of work late-career employees perform and the reliability of performance appraisal instruments. Reexamining these qualitative assessments with a statistical meta-analysis, subsequent researchers have discovered some interesting patterns of results. When employees are evaluated on objective indices of productivity, older workers actually significantly outperform younger workers. However, when older workers are evaluated by supervisors with global rating scales, they receive significantly lower evaluations than do younger workers.

Thus, rater bias and age discrimination, rather than older workers’ productivity levels themselves, seem to account for the widespread belief that job performance declines with age. Older workers whose jobs are primarily managerial in nature, whose job outcomes tend to be less tangible, and whose job duties tend to be less visible may be particularly vulnerable to this kind of age discrimination. In such cases, superiors have more latitude to discriminate against older workers in their evaluations because there is less objective, observable data with which to refute superiors’ assertions.

Labor economists have used an *implicit-contract model* to explain another potential reason for age bias in subjective performance ratings. Younger workers are often paid below their marginal rates of productivity, while older workers are often paid above their marginal productivity. Labor economists hypothesize that this compensation practice evolved to motivate younger workers to put more effort into their jobs and

to be more loyal organizational citizens, with the hope that, they, too, will be able to cash in when they get older. However, when faced with the reality of paying older workers wages that are above their marginal productivity, managers want to change the deal in order to cut costs.

In more recent work on the political nature of performance appraisals, several other potential explanations for this divergence in ratings have become evident. First, supervisors may be giving late-career employees lower evaluations in order to give young employees higher pay raises. Thus, the primary motivation for giving late-career employees lower evaluations may not necessarily be discrimination, but rather to justify distributing scarce pay raise dollars to younger workers who might otherwise leave the firm. Alternatively, supervisors of late-career employees may give low evaluations to older workers to block potential rivals from being promoted over them or from being promoted into their own jobs.

OBJECTIVE PERFORMANCE INDICATORS

Aging can negatively impact the information-processing capabilities of older workers in two ways. First, there is some evidence that older workers process new information less speedily than their younger colleagues and, consequently, can't make decisions as quickly. Second, there is some evidence that older workers have smaller working memories than younger people. That is, older workers cannot keep track of as many variables at the same time and, consequently, have more trouble making complex decisions under time pressure.

While these age-related effects have been found quite consistently, the magnitude and consequences of these deficits may not be as severe as widely believed. Many of the experimental tasks used in these kinds of studies have been rote-memory tasks (e.g., recalling paired-word associations). Whereas memorizing rote lists is a common task for younger people, it is a much less frequent activity for older workers, and it may not be the most appropriate way to test their working memories. When the new knowledge to be acquired is linked to existing knowledge, age differences in memory are quite small and frequently inconsequential.

In terms of physical skills, the literature on gerontology suggests that older workers do experience declines in gross motor strength, fine-motor control, visual acuity, and auditory acuity. However, declines

in these capabilities are quite modest and occur after age 70, when most older workers have already left the workforce.

What is much harder to get a handle on is how less visible deficits in physical well-being (such as arthritis, diabetes, high blood pressure, chronic pain) impact job performance. Certainly, these physical conditions are both more common and more likely to be severe with older workers, but tightly controlled studies measuring their impact on performance are rare. Research from the retirement literature, though, does suggest that workers with severe health problems are more likely to retire "early" (before reaching 30 years of service), so the main effect of poor physical health may be on workforce exit rather than on workforce performance.

Another issue that comes into play is the objective performance criteria on which older workers are being evaluated. Several researchers suggest that age-based differences in performance are attenuated when quality is taken into consideration as an outcome variable. Taken collectively, their results indicate that older workers have a propensity to pursue quality in performance tasks and may be more willing to sacrifice quantity to achieve that goal. There is little evidence to date on the relationship between age and extra-role or citizenship behavior, and what evidence does exist suggests a nonsignificant age effect.

In sum, then, the global relationship between age and performance is quite modest in magnitude. Moreover, it is highly dependent on which tasks are being performed, how performance is measured, and who measures it.

LEADERSHIP DEVELOPMENT

Careers unfold over time. Leadership also develops over time and often over an entire career. For these reasons, when discussing *leadership development* (as with careers), there is an inherent longitudinal focus. Development implies change and growth. Leadership development is mainly concerned with the intrapersonal change and growth of individual leaders, as well as the relational aspects associated with interpersonal leadership processes. Compared with the disciplines of work careers and leadership, the field of leadership development is weak on theory. There are no recognized theories of leadership development, but a great deal has been published on various practices. Thus, a primary focus has been on using and, to a much lesser extent, evaluating different ways of developing leadership.

CONCEPTUAL ISSUES AND DEFINITIONS

Leadership has proved impossible to define in a way that is universally accepted. Different leadership approaches emphasize specific behaviors (e.g., initiating structure, providing support); aggregate leadership styles (e.g., task- and relationship-oriented); trait like characteristics (e.g., charisma); the relationship between a leader and a follower (e.g., leader-member exchange quality); and so on. Leadership can include any of these emphases but is most holistically characterized as a process involving leaders, followers, and

situations. Thus, contemporary approaches view leadership as a dynamic process, not as a static formal position.

Leadership development can be described as the longitudinal process of expanding the capacities of individuals, groups, and organizations to increase their effectiveness in leadership roles and processes. Increased effectiveness from this perspective pertains to anything that would improve the ability for groups of people to work together in productive and meaningful ways. Thus, leadership development is inherently multilevel in that the developmental focus can be on the individual, group or team, or the entire organization—or some combination of all three levels. Taking into account group and organizational levels is important to the goal of building a sustainable leadership-development system that supports continuous and ongoing individual self-development processes.

Although the best leadership-development processes include multiple levels, there is a long-standing confusion between *leader development* and *leadership development*. What is typically called leadership development is usually more accurately conceptualized as leader development, as it is targeted at developing individual leaders. This distinction goes beyond mere semantics, because it gets at the core of the important role that social context plays in leadership. A social context is necessary in that no leadership can occur without at least one other person (i.e., “follower”) who is influenced, directed, supported, or otherwise affected by the leadership process. Nonetheless, most so-called leadership-development efforts are focused entirely on enhancing individual leaders’ knowledge, skills, and abilities (or broader competencies) in ways that are expected to improve their overall individual leadership capabilities. Developing individual or intrapersonal capabilities (i.e., human capital) can enhance the potential for effective leadership at some future point, but it does not ensure more effective leadership without attention to the social context. The broader concept of leadership emerges through social interaction and is based on the pattern and quality of networked interpersonal relationships in an organization (i.e., social capital).

Effective leadership development requires attention to both human and social capital concerns. Developing individual capabilities without any attention to the social context ignores the fundamental tenet that leadership is based on interactions among leaders, followers, and the social environment. Attempting to develop the pattern and quality of networked

relationships that defines the social capital component of leadership without preparing individual leaders with the requisite skills to communicate, influence, inspire, and otherwise participate effectively in leadership processes could risk putting people into situations in which they are unprepared individually to lead effectively. Critical to developing effective leadership is designing and implementing developmental systems that link intrapersonal leader development with networked interpersonal leadership development in ways that build both the human and social capital components of leadership.

DEVELOPMENTAL PRACTICES

Many different types of interventions have been used to facilitate leadership development. They vary in degree of intensity, organizational embeddedness, and temporal scope. An important distinction across various interventions is the extent to which they emphasize the development of intrapersonal skills (e.g., self-awareness, self-regulation, or other individual skills), interpersonal skills (e.g., social skills, social awareness, or other relational skills), or both. An especially important but often overlooked aspect of successful leadership development is linking the development of intrapersonal skills (human capital) with the development of interpersonal skills (social capital).

Formal Classroom Programs

The most common approach to leadership development is the formal classroom program in which basic principles of leadership are presented, discussed, and reflected on. It has been estimated that approximately 85 percent of companies engaged in leadership-development efforts use some version of classroom programs. Frequently, these programs are designed to promote self-insight and enhance self-awareness through the application of leadership principles to participants' personal experiences. Another version is the assessment-for-development approach that was pioneered by the Center for Creative Leadership, in which participants complete self-assessment (e.g., personality) inventories and receive feedback about their personal characteristics and behavioral profiles. Often, formal programs occur over the course of several days and are held off-site. *Open-enrollment programs* are classroom courses in which participation is open to all qualified participants (usually determined

by job level) regardless of their organization affiliation. *Custom programs* are specifically designed for a particular organization to enhance the relevance of the course with regard to the business objectives of the client firm.

Although popular, formal classroom programs are limited by high development costs (especially in custom work) and issues with the transfer of knowledge from the classroom to the job (especially in open-enrollment programs). Thus, many organizations are coming to realize that formal classroom programs are valuable but not completely adequate for effective leadership development. As leadership tends to be most effectively developed through the enactment of leadership, a majority of the more cutting-edge approaches emphasize the role of hands-on experiences in development. In particular, experiences that occur in the context of ongoing work may provide the most meaningful development and are often used as follow-up efforts to formal classroom programs.

Multisource Feedback

Also known as *360-degree feedback*, *multisource feedback* seeks to enhance self-knowledge of leadership ability and one's impact on others by providing leaders with multiple assessments of their performance from different role perspectives. In this method, ratings of a target's performance are systematically collected from multiple sources—including supervisors, peers, subordinates, and self-perceptions—in order to compile a comprehensive, "360-degree" picture of a target's ability and behaviors. The underlying philosophy of multisource feedback is that people in different reporting roles in relation to a target may experience different aspects of that person's personality and behavior. Widening the lens to include perspectives other than one's boss is thought to develop a more complete understanding of the impact of one's behavior on others across different role relationships. Multisource feedback can help leaders enhance the intrapersonal skill of self-awareness by illustrating the effects they have on others and by highlighting any discrepancies between various perceptions of performance. But simply providing feedback does not necessarily translate into enhanced leadership. In many cases, other elements are added to the process to help someone make better sense of the feedback and to use it to create and implement a developmental plan. An *executive coach* is often used for this purpose.

Mentoring

Whereas executive coaches are often hired as external consultants to help people develop necessary leadership competencies or address specific leadership challenges, developmental relationships (i.e., mentoring) can also be fostered formally or informally within organizations. Mentoring usually occurs as a more senior member interacts with a more junior protégé (typically at least two organizational levels below the mentor) to advise, share lessons learned, and enhance career development and advancement. Through observing and interacting with mentors, developing leaders can expand their perceptions of key organizational challenges and strategies as well as enhance more microlevel interpersonal skills. Mentoring relations run the risk of failure, however, if the protégé becomes too dependent on the mentor. A Other important components of effective mentoring are the quality of the mentor and the mentoring experiences. Only recently have researchers begun to examine the effects of “marginal mentoring” (that is, mentors limited in terms of effectiveness but who still have value) on the performance and development of protégés.

Networking

To facilitate communication among functional areas and to build better social capital, organizations have implemented initiatives to foster the development and maintenance of work-related relationships. Initiatives such as regular lunches, electronic dialogue, and other social events at work can help individuals build their networks. Broad social networks are advantageous to leaders in expanding their resources with regard to knowing who has expertise in which particular domains (called *transactive memory*). Individuals can also develop broader and more complex ways of viewing problems and ways of working with others and can challenge basic assumptions through network relationships.

Outdoor Challenges

Outdoor challenges or wilderness training include challenging experiences, such as high- and low-ropes courses, orienteering, rappelling, and whitewater rafting. These experiences are designed to require collaboration, trust, and participation for successful performance and are aimed at encouraging individuals to

overcome risk-taking fears (intrapersonal) while enhancing teamwork skills (interpersonal). As such, they have a heavy affective component in terms of their effects on participants. While these initiatives are popular, little empirical evidence exists of the effectiveness of enhanced leadership on the job. One important obstacle to successful transfer is the difference between a wilderness setting and typical business environments.

Challenging Job Assignments

Challenging assignments within one’s current role as well as expatriate assignments, job rotation, and cross-unit rotation encourage the development of new skills, such as team building, strategic thinking, and social-influence skills. Complex cognitive and social skills can be developed when individuals are challenged or pushed beyond their comfort zones. These “stretch assignments” can facilitate self-awareness that can challenge how an individual learns, thinks, and interacts. Challenging job assignments are effective for development only when they are intentionally developmental and learning oriented, rather than solely focused on performance. An important consideration is to avoid potentially putting people “in over their heads,” resulting in feelings of helplessness, rather than encouraging development. Some attention should be given to the developmental readiness of the person to take on a new and significantly challenging job assignment, as well as helping the incumbent learn and develop from the challenge.

Action Learning

Often used in conjunction with challenging job assignments, action learning involves development through work-related organizational experiences. The approach is grounded in the assumption that people learn most effectively when dealing with work-related issues in real time, which heightens the relevance of the learning. Action learning is best described as a structured, continuous process of learning and reflection that also addresses a complex challenge of strategic importance to an organization. It is typically group or team based, includes aspects of coaching and mentoring, and has a specific focus on learning. The overall spirit of action learning is to help people learn and develop from their work, rather than taking them away from work to learn and develop. Techniques such as

journaling are often used in conjunction with action learning to facilitate reflection and keep the learning process intentional.

Because leadership is a complex interaction between the individual leaders and their social and organizational contexts, comprehensive developmental efforts need to be directed at (a) developing individual leaders, (b) developing broader interpersonal leadership capacity, and (c) linking the two. Leadership development practices also are generally more successful when linked to key strategic business imperatives. Effective development is less dependent on which specific practices are employed relative to how tightly tied the efforts are to intentional and consistent implementation. To implement effective developmental programs, organizations must overcome a tendency to allow development to become a haphazard process. This haphazard tendency can be addressed through intentionality, evaluation, accountability, and adopting a long-term focus.

INFLUENCING FACTORS

It is presumptuous to assume that the rate or nature of change will be the same for all leaders for any given developmental experience, and it certainly cannot be expected to be identical across entire careers. *Developmental readiness*, or how prepared an individual is to benefit from developmental experiences, provides a preliminary point for understanding development. Factors such as cognitive ability, motivation, and maturity influence an individual's preparedness. Some researchers suggest that developmental readiness may be related to a person's moral reasoning. More complex moral reasoning is associated with a greater reflexive capacity through which leaders are better able to "step back" to perceive how their actions affect others. In this sense, developmental readiness is related to one's capacity for self-awareness. Given individual differences in developmental readiness and existing abilities, some experiences or interventions might be better suited only to certain individuals. To maximize success of a leader developmental practice, a match may be required between an individual's readiness and existing abilities and specific experiences.

Environmental factors, within both the formal training context and work environment, are also important for facilitating the *transfer of training*, or the degree to which trainees apply to their jobs the knowledge, skills,

behaviors, and attitudes gained in training. Developmental experiences in the context of ongoing work provide an advantage over classroom programs because what is learned more readily transfers to the job. A supportive environment, in which individuals are encouraged to apply learned leadership skills, allowed to reflect on and adopt various leadership styles, and supported to continue their development, is critical for success. A recipe for failure includes sending a changed individual into an inflexible and unchangeable environment. Similarly, leadership is best developed in an environment characterized by safety and trust, support for learning and change, and a sense of purpose in which members are encouraged to work closely with each other.

CONCLUSION

A key to the effective development of leaders and leadership depends a great deal on implementation. All of the various developmental practices have some evidence of effectiveness. What is of utmost importance in making them work is how they are implemented. One consideration is how consistently and broadly the developmental initiatives are practiced. Instead of limiting development to top levels or "high-potential" executives, a more effective implementation strategy may be to introduce versions of the focal practices throughout all levels of an organization as a means of developing deeper leadership capacity. Another key to effective implementation is to link initiatives so that leadership development builds on leader development. Grounding developmental initiatives in an overall purpose tied to key strategic business challenges is one way to heighten the relevance of leadership development for better organizational performance. One caution is that development is a relatively long-term investment in the human and social capital of an organization. There are no proven shortcuts to leadership development, but the potential payoffs from a well-designed initiative with consistent implementation across organizational levels can provide a key for better overall individual, team, and organizational effectiveness.

LEARNING ORGANIZATION

The *learning organization* is a concept describing organizations in which learning and work are integrated in an ongoing and systematic fashion to sustain continuous improvement of the organization at three levels: individuals, work groups or teams, and the organization. A learning organization has the capacity to continuously learn and develop toward a collective vision. Learning is viewed as a strategic process that is embedded in the organization's system.

The concept of the learning organization has gained an increasing popularity since the early 1990s. There are many reasons explaining why it has attracted so much attention by both organizational scholars and practitioners. The first reason is the ever-changing environment faced by most organizations. Modern organizations operate in a world of growing technology, increased knowledge and skills, and global competition. They must continuously learn in order to survive and grow in this dynamic and competitive environment. Learning organization thus

describes an organization that has the capability to develop and renew itself on the basis of learning.

The second reason for the popularity of the concept of the learning organization relates to a changing economy. It has been widely recognized that society has entered into a "knowledge economy" in which the most sustainable competitive advantage for organizations comes from learning-related assets such as innovation and intellectual capital. Organizations previously relied on tangible assets, such as land, machinery, and financial capital, to compete in the marketplace. Although these tangible assets remain necessary resources in a knowledge economy, intangible assets such as innovations and new technologies have become increasingly valuable. Organizations must effectively utilize and develop human resources and make them more valuable than the traditionally valued physical and financial resources. Organizations have realized that acquiring and generating knowledge is a major means of enhancing competitive capability, as important to organizational performance as acquiring physical and financial resources. Meanwhile, many societies have embraced the concept of the learning organization, seeing it as essential in the transformation from a traditional labor-intensive economy to one that is based more on knowledge work.

The third reason that the learning organization has gained popularity has to do with the changing view of organizations. At one time, organizations were viewed as machinelike entities, with few tangible and fixed goals. For example, it was once thought that the ultimate goal for a manufacturer was to maximize profit for the owners by producing quality commodities, with little attention paid to the interests of other stakeholders, including consumers, the local community, and the broader society. In today's environment, organizations have multiple and even competing goals and interests and are properly viewed as organisms with different life cycles. Organizations with strong learning capabilities are more likely to survive in a fierce competitive environment and to fully develop themselves to meet their missions. Consequently, the concepts of learning and development become a key to better understanding organizations.

Closely related to the concept of learning organization is the notion of *organizational learning*. Although both of these concepts share the same terminology—learning and organization—they are used for different purposes and thus have different implications. Learning organization normally refers to specific

characteristics for an ideal organization, while organizational learning describes the processes or activities that are part of organizational change. Organizational learning occurs in all organizations, and it indicates how individuals, teams, and organizations learn and transform. In a learning organization, there is an enhanced capacity to adapt, learn, and develop. The learning organization is effective in managing, analyzing, developing, and strategically aligning with the goals of improvement and innovation. In addition, these two concepts can also be differentiated by their perspectives of organizations. The learning organization tends to be prescriptive, as it focuses on building an ideal organization with certain characteristics, whereas organizational learning tends to be descriptive. While organizational learning may merely require individuals in an organization to engage in continuous-learning activities, the learning organization demands a conscious effort of the organization to facilitate learning activities and build the capabilities of adaptation and development.

EVOLUTION OF THE LEARNING ORGANIZATION

The concept of the learning organization evolved from the tradition of organizational learning. The latter concept can be traced back to the early 1900s, when modern management theory started to establish its foundation. Frederick Taylor's theory of scientific management suggested that learning can be transferred to employees and subsequently improve the efficiency of the organization. Systematic research on organizational learning started as early as 1936, when researchers began studying organizational learning curves. The concept of a learning curve has demonstrated the value of learning for organizations.

In 1978, Chris Argyris, of Harvard University, and Donald Schön, of MIT, published the seminal *Organizational Learning*, which marked a new era in this field of study. These authors argued that organizations are not simple collections of individuals. Organizations are best viewed as systems of collective agents. Argyris and Schön suggested that learning involves the detection and correction of errors. When people face a situation in which something has gone wrong, their common initial reaction is to look for another strategy that can solve the problem. They tend to identify the solution within the governing framework. The problem-solving process can be characterized as

discovering the error source, inventing new strategies and problem-solving methods, and generalizing the new approach to other situations. This problem-solving process is called *single-loop learning*, in which people work within given goals, values, plans, and rules, and their task is to operationalize within a given governing framework rather than challenge or change it. An alternative approach is to question the governing framework, to subject it to critical scrutiny. This approach is described as *double-loop learning*. Such learning may then change the organization's existing culture, values, and norms and typically involves a transformative change of employees' frame of reference for their daily work.

During the early 1980s, studies on organizational learning focused on the types of learning and the behavioral changes resulting from the learning. Various studies were conducted, and models were proposed to explain the outcomes of learning. It was recognized that the outcomes of learning are highly associated with both the content and level of learning. In the mid-1980s, a new concept of lower- and higher-level learning was proposed, similar to the concept of single- and double-loop learning. It was recognized that behavioral change can occur without any cognitive influence. Similarly, employees can gain knowledge without any behavioral changes occurring. Higher-level learning involves the changes of cultures, values, and social norms within the organization. It has been revealed that long-term changes can be brought about only by higher-level or double-loop learning.

The concept of the learning organization really began to flourish in the late 1980s. Peter Senge added to the momentum with a widely read book, *The Fifth Discipline: The Art and Practice of the Learning Organization*, published in 1990. Senge defined the learning organization as one in which individuals' capacities to create desired results continually expand, new patterns of thinking are nurtured, and people learn together. By applying systems theory to the learning process in organizations, Senge formulated the core disciplines of building a learning organization: (a) team learning: emphasis on the learning activities of the group rather than the development of team process; (2) shared visions: the skill of finding shared "pictures of the future" that foster genuine commitment and enrollment, rather than compliance; (c) mental models: the deeply held internal images of how the world works; (d) personal mastery: the discipline of continually clarifying and deepening personal

vision, focusing energies, developing patience, and seeing reality objectively; and (e) system thinking: the ability to see interrelationships rather than linear cause-effect chains. The study of the learning organization has since received escalating attention in both business and academic fields.

The dawn of the twenty-first century has marked a new era in the study of the learning organization concept. A number of scientific studies have been conducted to operationalize, measure, and validate the concept; to examine its associations with other important organizational variables; and to incorporate this idea systematically into organizational change and development. Early on, many practitioners in organizations immediately grasped the idea of the learning organization and applied the concept in a pragmatic way. Such applications by and large tended to rely on intuitive approaches that lacked empirical evidence supporting their effectiveness. Over a decade later, a handful of empirical studies have suggested positive relationships between the learning organization and desirable outcomes, including financial performance, innovation, employees' job satisfaction, motivation to transfer learning, and less likelihood of employee turnover.

The new century also witnessed a significant conceptual advancement in understanding learning in organizations. Learning is no longer viewed as some simple behavioral or cognitive change taking place in isolated domains. The literature on organizational learning and learning organization traditionally covered two distinct streams, cognitive learning and behavioral learning, but paid little attention to the role of affect and emotion in learning. More recent research has given attention to affect and spiritual aspects of learning. This more holistic perspective posits that learning involves three interrelated learning domains—*affect, cognitive, and behavior*—driven by three distinctive forces—*liberty, rationality, and reality*. Learning as one kind of human action serves as a function of maintaining equilibrium among these driving forces. A learning organization is a dynamic system that involves different domains of learning and diverse types of knowledge. This perspective views organizations not only as information-processing and decision-making systems but also as social and political entities. Organizations are established on certain values, and they strive for specific visions and aspirations. Holistic theory identifies three key dimensions for organizational knowledge: the critical dimension

(as reflected in value and vision), the technical dimension (as indicated by formal system and strategy), and the practical dimension (as embedded in practice and process). It points out that it is more important to facilitate the dynamic interactions among the dimensions to foster a change in isolated domains. A learning organization is capable of integrating different domains of knowledge across the multiple of levels of the individual, the team, and the organization.

BUILDING A LEARNING ORGANIZATION

What does an organization have to do to become a learning organization? There are numerous writings on the process and strategies for building one. Research has identified seven distinct features of a learning organization at the individual, team, and organizational levels. These features and their implication are described in the following paragraphs.

First, a learning organization strives to create continuous learning opportunities for all members. Organizations wanting to embrace the learning organization ideals need to structure learning as part of the work so that employees can learn on the job. They also need to provide opportunities for ongoing education and growth. Learning organizations have a culture that values continuous learning and development and encourages people to discuss mistakes openly in order to learn from them. Employees not only help each other but also identify skills and knowledge needed for future work. In addition, the organization supports learning by providing time and rewards for it. Under a strong culture of learning, people view problems in their work as opportunities to learn, instead of as obstacles.

Second, a learning organization promotes inquiry and dialogue and thus creates a culture of questioning, feedback, and experimentation, in which people give open and honest feedback to each other. They listen to others' views and different perspectives. They are encouraged to ask "why?" regardless of their rank in the organization. A culture of respect and trust is needed to build a learning organization.

Third, a learning organization encourages collaboration and team learning. To build a learning culture, organizations must design work using a team or group structure to access different models of thinking. Teams and groups are expected to learn and work together. A learning culture values and rewards collaboration and uses a team approach to problem solving. Teams and

groups can revise their thinking as a result of group discussion or information collection. They also have the freedom to adapt their goals as needed.

Fourth, a learning organization empowers people toward a collective vision. The organization is strongly motivated to create and share a collective vision and to obtain feedback from its members about the gap between the current status and the new vision, and its members are involved in setting, owning, and implementing the common vision. The organization recognizes individuals for taking initiative and supports employees who take calculated risks. Employees have control over resources they need to accomplish their tasks, and they are willing to contribute to the organization's vision.

Fifth, a learning organization establishes appropriate systems to capture and share learning and gather and share information. To nurture a learning culture, the organization must make the lessons it has learned available to all its members. It creates systems for measuring the gap between current and expected performance and transfers that gap into learning.

Sixth, a learning organization connects well to its internal and external environments. It works with the outside community to meet mutual needs and helps its members scan the environment and use information to adjust work practices. A learning organization encourages people to see the effects of the environment on the entire organization.

Last, a learning organization provides strategic leadership for learning. Leaders model, champion, and support a strong culture of learning. Leadership of the organization uses learning strategically to fulfill its mission.

To summarize, a learning organization has a strong capacity for integrating people and structures in order to move toward continuous learning and development for a shared vision.

LEARNING STYLES

The term *learning styles* refers to the preferences that an individual has regarding the organization of information. How people actually learn is a question that is best answered by considering a particular person's preferred learning style. There are many instruments available that can guide individuals in identifying their preferred learning styles. Furthermore, research with those instruments has potential for identifying some "best practices" for teaching students with specific learning preferences.

Learning-style research has its roots in the work of Carl Jung and David Kolb. Both psychologists developed models useful for classifying learning styles; however, much of the contemporary work on learning styles developed from Kolb's 1983 study of "Learning supports learning" as a cyclical process. He described a process through which concrete experience is followed by reflection and observation, which then leads to the formulation of abstract concepts and generalizations, the implications of which are tested in new situations through active experimentation.

Kolb identified four main styles of learner and developed his Learning Style Inventory (LSI) to establish an individual's relative emphasis on each of the four styles. Kolb's LSI is based on the work of John Dewey, Kurt Lewin, and Jean Piaget. John Dewey emphasized the need for learning to be

grounded in experience. Kurt Lewin stressed the importance of active learning, and Jean Piaget articulated a theory of intelligence as the result of the interaction of a person and his or her environment.

Kolb's learning style model separated learners on the basis of four steps of learning defined from a two-dimensional model. The first dimension is based on task, and the second dimension is based on the soul or ego. The dimension based on task ranges from performing tasks to observing tasks. The soul or ego dimension ranges from logical (left brain) to creative and emotional (right brain). The model is usually shown with the task dimension displayed horizontally and the soul dimension displayed vertically. The four resulting quadrants are labeled with four steps to learning and four personal learning styles. The four steps to learning are labeled (1) concrete experience, (2) reflective observation, (3) abstract conceptualization, and (4) active experimentation. The four personal learning styles are (1) theorists, (2) pragmatists, (3) activists, and (4) reflectors.

An LSI high score on *concrete experience* represents an open, experience-based approach to learning that relies on feeling-based judgments. These learners generally find theoretical approaches to be unhelpful and prefer to treat each situation as a unique case. They learn best from specific examples. The instructor serves as a coach/helper for this self-directed autonomous learner. Students scoring high on *reflective observation* indicate an impartial and reflective approach to learning. They prefer lectures and look for an instructor who is both a taskmaster and a guide. A high score on *abstract conceptualization* indicates an analytical, conceptual approach to learning relying on logical thinking and rational evaluation. These learners prefer authority-directed, impersonal learning situations that focus on theory and systematic analysis. Case studies, theoretical readings, and reflective-thinking exercises are the best vehicles to use with these learners. Finally, a high score on *active experimentation* indicates an active "doing" orientation relying heavily on experimentation for learning. These learners prefer projects, homework, and group discussions and show a clear dislike for lectures.

The personal learning style labeled *theorist* represents a person who likes to learn using abstract conceptualization and reflective observation. Theorists' strength lies in the ability to create theoretical models. They prefer case studies, theory readings, and thinking alone. This learning style is characteristic of those

gravitating toward basic science and mathematics. The theorist adapts and integrates observations into complex but logically sound theories. They think problems through in a vertical, step-by-step, logical way and assimilate disparate facts into coherent theories. They tend to be perfectionists who won't rest until things are tidy and fit into a rational scheme. They like to analyze and synthesize and are keen on basic assumptions, principles, theories, models, and systems of thinking. Their philosophy prizes rationality and logic. Questions they frequently ask are "Does it make sense?" "How does this fit with that?" and "What are the basic assumptions?" They tend to be detached, analytical, and dedicated to rational objectivity rather than anything subjective or ambiguous. Their approach to problems is consistently logical. This is their "mental set," and they rigidly reject anything that doesn't fit with it. They prefer to maximize certainty and feel uncomfortable with subjective judgments, lateral thinking, and anything flippant.

Pragmatists like to learn using abstract conceptualization and active experimentation. Their strength lies in the practical application of ideas. They prefer laboratories, fieldwork, and observation. This learning style is characteristic of individuals specializing in the physical sciences. The pragmatist is keen on trying out ideas, theories, and techniques to see whether they work in practice. They positively search out new ideas and take the first opportunity to experiment with applications. Within organizations, pragmatists are the people who return from management courses brimming with new ideas that they want to try out in practice. They like to get on with things and act quickly and confidently on ideas that attract them. They tend to be impatient with ruminating and open-ended discussions. They are essentially practical, down-to-earth people who like making practical decisions and solving problems. They respond to problems and opportunities "as a challenge." The pragmatist's philosophy says, "There is always a better way," and "If it works, it's good."

Individuals with an *activist* personal learning style use concrete experimentation and active experimentation. Their strength lies in doing things and involving themselves in new experiences. They prefer practicing a skill, problem solving, small-group discussions, and peer feedback. This learning style is characteristic of individuals who choose technical or practical fields, such as business. Activist learners involve themselves fully and without bias in new experiences. They enjoy

the “here and now” and are happy to be dominated by immediate experiences. They are open-minded and not skeptical, and this tends to make them enthusiastic about anything new. Their philosophy is, “I’ll try anything once.” They tend to act first and consider the consequences afterward, and they tackle problems by brainstorming. As soon as the excitement from one activity has died down, they are busy looking for the next. They tend to thrive on the challenge of new experiences but are bored with implementation and longer-term consolidation. Activist learners are gregarious people constantly involving themselves with others, but in doing so, they seek to center all activities on themselves.

Reflectors use reflective observation and concrete experience. Their strength lies in their ability to imagine. They prefer lectures with much reflection time and an instructor who provides expert interpretation. This learning style is characteristic of individuals who choose humanities and liberal arts. Reflectors like to stand back to ponder experiences and observe them from many different perspectives. They collect data both firsthand and from others and prefer to think about information thoroughly before coming to any conclusion. The thorough collection and analysis of data about experiences and events are what counts, so they tend to postpone reaching definitive conclusions for as long as possible. Their philosophy is to be cautious. They are thoughtful people who like to consider all possible angles and implications before making their own points. They tend to adopt a low profile and have a slightly distant, tolerant, unruffled air about them. When they act, it is part of a wide picture that includes the past as well as the present and others’ observations as well as their own.

Although many specific recommendations can be derived from the work on learning styles, the most important factor to consider in designing and delivering education is to provide products that tap multiple learning dimensions for a particular content area. The following represent some of the most utilized instruments for assessing and understanding individual differences in learning. Components of Kolb’s work can be identified in most of the instrument descriptions that follow.

The Gregorc Differentiator is designed specifically for adult use. It was developed as a self-analysis tool to aid individuals in recognizing and identifying the channels through which they receive and express information effectively and efficiently. Anthony Gregorc’s model uses a Concrete-Abstract continuum, representing

perception, as well as a Sequential-Random continuum, representing ordering, which results in four identified learning style preferences: (1) Concrete/Sequential, CS; (2) Concrete/Random, CR; (3) Abstract/Sequential, AS; and (4) Abstract/Random, AR.

CS individuals see themselves as objective, persistent, careful with detail, realistic, thorough, and logical. They tend to be perfectionists and choose order and seek proof or multisolutions. The CS is product oriented rather than person oriented. Hands-on learning and accredited experts are helpful to learning.

CR individuals see themselves as intuitive, experimenting, creative, troubleshooting, and risk taking. They are concerned with multisolutions and innovation. Demonstrations and personal proof, rather than outside authority, are helpful to learning.

AS individuals see themselves as evaluative, analytical, logical, concerned with ideas, and oriented to research rather than perfectionism. They are concerned with quality and see themselves as judges. Knowledge facts and documentation are helpful to learning.

AR individuals see themselves as sensitive, evaluative, intuitive, aware, not careful with detail, and spontaneous. They are concerned with research and risk taking. They are person oriented rather than product oriented. AR individuals appreciate self-directed learning.

The Myers-Briggs Type Indicator (MBTI) is another tool for measuring personal learning preferences. The first of the four preference scales measured through the MBTI is Extraversion (E) versus Introversion (I). This preference indicates how people “charge their batteries.” *Introverts* find energy in the inner world of ideas, concepts, and abstractions. They can be sociable but need quiet to recharge their batteries. *Introverts* want to understand the world. *Introverts* are concentrators and reflective thinkers. For the introvert, there is no impression without reflection. *Extroverts* find energy in things and people. They prefer interactions with others and are action oriented. *Extroverts* are interactors and “on-the-fly” thinkers.

The second scale is Sensing (S) versus Intuition (N). *Sensing people* are detail oriented, want facts, and trust them. *Intuitive people* seek out patterns and relationships among the facts they have gathered. They trust hunches and their intuitions and look for the “big picture.” They see patterns where others see randomness or chaos.

The third scale is Thinking (T) versus Feeling (F). *Thinking individuals* value fairness. They choose to

make decisions impersonally based on analysis, logic, and principle. *Feeling individuals* value harmony, and they focus on human values and needs as they make decisions or arrive at judgments. They tend to be good at persuasion and facilitating differences among group members.

The final MBTI scale is Judging (J) versus Perceptive (P). *Judging people* tend to be decisive, planful, and self-regimented. They focus on completing the task, want to know only the essentials, and take action quickly. *Perceptive people* are curious, adaptable, and spontaneous. They start many tasks, want to know everything about each task, and often find it difficult to complete a task.

An instrument helpful to studying learning in a college-student environment is the Grasha and Reichmann Student Learning Style Scales. Anthony Grasha and Sheryl Reichmann developed the Grasha-Reichmann Learning Style Scales (GRSLSS) in 1974 to determine college students' styles of classroom participation. Their model focuses on student attitudes toward learning, classroom activities, teachers, and peers. Six styles are identified: (1) *avoidant students* tend to have high absenteeism, organize their work poorly, receive grades at the lower end of the grade distribution, and take little responsibility for their learning; (2) *participative students* are characterized as willing to accept responsibility for self-learning, and they relate well to their peers; (3) *competitive students* can be described as suspicious of their peers, leading to competition for rewards and recognition; (4) *collaborative students* enjoy working harmoniously with their peers; (5) *dependent students* typically become frustrated when facing new challenges not directly addressed in the classroom; and (6) *independent students* prefer to work alone and require little direction from the instructor. There are two forms of the instrument; one for general class responses and one for use with a specific course. Each instrument has 90 questions, 15 questions per style. Subjects respond to each statement on a 5-point *disagree-agree* scale, with *agreement* being 5. Scale scores range from 15 to 75, where the highest score is considered to be the preference for a student. As with most scales, it is noted that anyone can demonstrate any style given an appropriate environment. Nonetheless, the scale identifies a preference for classroom behavior.

Howard Gardner provided a framework that recognizes several intelligences and suggested that people use one or two to maximize their personal learning. The U.S. culture teaches to, tests, and rewards primarily two

kinds of intelligence: verbal-linguistic and logical-mathematical. However, Gardner asserts that there are at least six other kinds of intelligence that are equally important. The full list includes verbal-linguistic, logical-mathematical, musical, spatial, bodily kinesthetic, interpersonal, intrapersonal, and naturalist.

Verbal-linguistic intelligence is marked by individuals, such as poets, being sensitive to the meaning and order of words. *Logical-mathematical intelligence* is defined as the ability to handle chains of reasoning and recognize patterns and orders, as scientists do. *Musical intelligence* is recognized as sensitivity to pitch, melody, rhythm, and tone, as composers do. *Spatial intelligence* is defined as the ability to perceive the world accurately and to trying to re-create or transform aspects of that world, as do sculptors and airline pilots. *Bodily kinesthetic intelligence* reflects the ability to use the body skillfully and handle objects adroitly, as do athletes and dancers. *Interpersonal intelligence* reflects an understanding of people and relationships, as salespersons or teachers have. *Intrapersonal intelligence* is demonstrated by those who possess access to their emotional lives as a means of understanding themselves and others, exhibited by individuals with accurate views of themselves. Finally, *naturalist intelligence* is connected to the intricacies and subtleties in nature.

According to Gardner's multiple intelligences theory, the intelligences are not necessarily dependent on each other, but they rarely operate in isolation. According to Gardner, all normal individuals possess varying degrees of each of these intelligences. However, the ways in which intelligences combine and blend are as varied as the personalities of individuals.

Putting learning styles together, it must be noted that no single measurement of style ensures that a learner's needs will be met. Those who wish to teach with student learning as their goal need to build an adaptable learning environment that presents material in a variety of methods.

LEISURE INTERESTS

Generally, the study of *leisure interests*, unlike the decades of work with vocational interests, has been confounded by the way in which such interests are measured. Instruments designed to assess vocational interests (e.g., Strong Interest Inventory, Self-Directed Search, Campbell Interest and Skill Survey) ask respondents to indicate the extent to which they like or do not like work-related activities. The instructions for these instruments encourage respondents not to worry about (a) their ability to do the activity, (b) how often they have done the activity in the past, or (c) how often they expect to engage in the activity in the future. The study of leisure, on the other hand, often focuses on the assessment of leisure needs and leisure participation, which, in turn, are used to infer leisure interests.

The stream of research related to leisure needs typically asks people why they participate in or why they enjoy various leisure activities. Responses then are used to identify clusters or factors of needs. These studies show that different types of activities meet different needs. Leisure needs that frequently emerge in these analyses include social interaction, altruism, status, excitement, achievement, and independence. The Leisure Activity Questionnaire (LAQ), a 334-item instrument that measures 45 need-satisfier dimensions,

has been shown to have potential as a measure of leisure needs.

Certainly, the need-gratifying property of leisure activities is an important component of understanding the impact of leisure participation on well-being and life satisfaction. However, research in vocational psychology has shown that interests and needs make a unique contribution to differentiating among people even though they are moderately related constructs.

Another stream of leisure research has relied heavily on cluster or factor analyses of self-reports of leisure participation to develop a classification system for leisure activities. These studies typically have been limited by the presentation of a relatively restricted number of activities. Nonetheless, some common themes do emerge from this line of research. For example, a factor representing artistic, intellectual, and cultural activities usually emerges. Likewise, sports and outdoor activities often are identified as a factor. Other factors, such as social/affiliative interests, replicate less often across studies, perhaps because of deficiencies in the initial pool of activities to which individuals respond or because actual participation in activities is used as a stand-in for the construct of leisure interests. The Leisure Activities Blank (LAB) is an example of an instrument that measures past participation as well as expectations for future participation in leisure and recreational activities.

More recently, efforts have been made to assess leisure interests in the same manner used to measure vocational interests. In this approach, participants are instructed to indicate the degree to which they like, are indifferent to, or dislike a wide variety of leisure activities. The leisure interest scales were constructed first using a series of cluster analyses to reduce the initial large-item pool and then using factor analyses to identify the underlying structure of the item pool. The resulting inventory, the Leisure Interest Questionnaire (LIQ), has 20 leisure scales derived from 250 items.

STABILITY OF LEISURE INTERESTS

One of the well-known characteristics of vocational interests is their stability over long periods of time. One might expect, then, that leisure interests also will be stable over long periods and that these interests, analogous to vocational interests, will represent a component of an individual's psychological identity. Stability in the leisure context has been examined in several ways, including studies that

assess the extent to which leisure participation is stable over seasons of the year or the degree of stability of leisure participation across settings. A few studies also have looked at the stability of leisure interests of individuals over various time intervals. The stability coefficients vary depending on the specific leisure interest. For example, the most stable leisure interests (test-retest correlation over a 2-year interval of about .70) center on individual and team sports, camping and outdoor activities, hunting and fishing, dancing, partying, cultural arts, and shopping. Modest stability ($r = .50$) over the same time period is found for socializing, community activities, culinary pursuits, adventure sports, and cards and games. Vocational interests, in contrast, show relatively uniform stability across the domain, and over a three-year period of time, test-retest coefficients hover around .80. This suggests that leisure interests may be more age related than vocational interests and that leisure interests may be affected more by circumstances (e.g., financial resources or physical health).

STRUCTURE OF LEISURE INTERESTS

Factor analyses of leisure scale scores generally identify four underlying factors: (1) artistic and intellectual (e.g., cultural arts, arts and crafts, culinary pursuits, gardening and nature, literature and writing, dancing, and community involvement); (2) competition and sports (e.g., cards and games, team sports, individual sports); (3) social (e.g., socializing, partying, and shopping); and (4) outdoors (e.g., hunting and fishing, camping, and adventure sports). These factors seem to capture some but not all leisure needs (e.g., intellectual aestheticism, companionship, physical exercise).

Research that has examined the relation between leisure interests and Holland's six vocational personality types generally finds convergence of leisure interests on three of the six types (i.e., correlations of .40 to .75): Realistic (outdoor and mechanical activities), related to building and hunting and fishing; Artistic (aesthetic activities), related to cultural arts, literature and writing, arts and crafts, and dancing; and Social (helping others), related to community involvement and socializing. Leisure interests that have modest correlations (i.e., correlations of .30 to .35) with Holland's vocational types include gardening and nature and cards and games, related to Investigative (science and research); individual and

team sports and partying, related to Enterprising (business); and Conventional (attention to detail), related to computer activities.

Research using multidimensional-scaling analysis to map the pattern of relationships among leisure activities suggests a two-dimensional solution. One very robust dimension reflects expressive versus instrumental activities. The interpretation of the second dimension suggests either social affiliative versus nonaffiliative activities or active versus sedentary activities.

LEISURE, CAREERS, AND LIFE SATISFACTION

Over time, theorists such as Donald Super, whose work is in the vocational domain, and Douglas Kleiber and John Kelly, whose work is in the leisure domain, have viewed leisure as an important component in their developmental models. More recently, vocational and occupational health psychologists have come to understand the importance of leisure for well-being and life satisfaction and the role that leisure counseling can play in career counseling. The assessment of leisure interests can play an important role in this counseling process, providing the tools necessary for clients to better understand themselves and their own proclivities for recreation.

LIFE STYLE INVENTORY

The Level I: *Life Style Inventory* (LSI) was originally developed by J. Clayton Lafferty in 1973. The Level I: LSI is described as a self-assessment of 12 different thinking and behavioral styles of interest to members of work organizations. This form of the LSI has a total of 240 items, with 20 items assessing each of the 12 thinking and behavioral styles. The responses range from 0 (*essentially unlike you*) to 2 (*strongly like you—most of the time*). This inventory has been used by career counselors to assess the relative emphasis a client places on work-related cognitive and behavioral styles. This instrument is also employed by management consultants to enhance the performance of groups by providing a method of assessing and selecting leaders based on their interpersonal orientations. Furthermore, the Level I: LSI has been used to perform a longitudinal assessment of beneficial attitudinal change in students enrolled in a professional master's program in managerial leadership.

Lafferty theorized that there are 12 lifestyles and based the development of his instrument on Abraham Maslow's hierarchy of needs as well as on the views of other needs theorists and psychologists. Instead of using Maslow's proposal that needs are organized hierarchically, Lafferty theorized that his 12 lifestyles formed a circumplex; thus, the hypothetical structure could be construed as a circular ordering of the variables, similar to the way in which hours are positioned on a clock. The variables were ordered as follows: Humanistic/Helpful was found at 1 o'clock, followed by Affiliative, Approval, Conventional, Dependence, Apprehension, Oppositional, Power, Competitive, Perfectionist, Achievement, and, finally, Self-Actualization at the 12 o'clock position. The lifestyles placed adjacent to each other are considered to be highly related. More recent studies have demonstrated that the 12 scales load on three factors: people/security, satisfaction, and task/security orientations.

In 1976, Lafferty developed the Level II version of the LSI: *Description by Others*, a parallel inventory allowing four to five other individuals to assess the individual of interest with reference to the same 12 thinking and behavioral styles. Lafferty developed this second inventory to respond to findings that people may confound self-perceptions with an idealized style of thinking and behaviors; in other words, people tend to report that they act in the way that they feel they

“should” act, rather than report their actual behavior. The Level II: LSI allows for the individual of interest to receive feedback from others, making available to the individual information about how his or her behavior is perceived by others. As a result, the individual can compare his or her intentions with the perceptions of others. When used for the purpose of management training and development, feedback generated from the Level II form adds an important dimension to the information provided by the Level I form. This feedback from coworkers and subordinates can provide individuals with insights regarding the inferences made by others pertaining to their thinking and behavioral styles.

LIFE-CAREER RAINBOW

Career-development theorists tend to ignore one of the most basic facts of life—that while people are busy making a living, they are living a life. The result is that many theorists describe career development as if it occurred in isolation from human development. Isolating life roles creates a false scenario that does not reflect life as people live it. Career interventions emanating from false scenarios have limited usefulness as clients leave career counseling and attempt to implement their work-related decisions within a complex web of life-role activities. When career counselors ignore their clients' multiple life-role activities, they also ignore the fact that life roles can interact in ways that are supportive, supplementary, complementary, or conflicting. Life roles can enrich life or overburden it. Donald Super noted that for each person, the social

elements that constitute a life are arranged in a pattern of core and peripheral roles. This pattern is defined as the *life structure*. The life structure organizes and channels the person's engagement in society. To understand an individual's career, it is important to know and appreciate the web of life roles that embeds that individual and her or his career concerns.

Increasingly, career-counseling clients, especially adult clients, present for career counseling due to life structure concerns. For example, in career counseling, an adult client may come to understand that her conflict regarding selecting a more satisfying career option is connected to the pressure she experiences as a parent of young children. Similarly, the young adult college student may desperately desire to switch her academic major from engineering to education but is afraid to do so because she does not want to disappoint her parents, who seem intent on their daughter's becoming an engineer. Rarely do decisions about work occur in isolation from other life-role experiences.

Life-structure concerns can involve normal developmental processes (such as the college student attempting to sort out career decisions within the individuation process), but they can also involve unexpected and traumatic life events (e.g., unexpected job loss). Developmental life-structure concerns are predictable (e.g., the graduating college student must prepare for "life after college") and therefore can be addressed via career counselors constructing developmental career-intervention programs. Professional counselors in the schools take this approach when they offer evening programs for parents and students regarding topics such as financial aid for postsecondary education, college planning, and career fairs. Counselors in higher education do the same when they offer workshops on selecting a major for first- and second-year university students and job-search workshops for fourth-year students. Career interventions such as these seek to address the predictable career-development tasks Super outlined in his life stage theory segment.

Life-structure concerns can also be unpredictable, as when a partner or parent dies unexpectedly, a serious illness arises, an unplanned job loss occurs, or an injury requires a substantial shift in life-role activities (although these examples are not necessarily equal in the trauma they generate, they each require adjustments to one's life structure). Interventions at these times tend to be more therapeutic (than what is typically required to address developmental concerns) and

often require individual career-counseling interventions. Collectively, developmental and traumatic events influence the life structure throughout the life span, making life-role choices and adjustment to choices continuous processes.

In describing the life structure, Super identified nine primary life roles: child, student, worker, partner, parent, citizen, homemaker, leisurite, and pensioner. He also noted that each life role tends to be played in a particular theater, such as the home, school, work, or community. In today's environment, life roles are often played in multiple theaters. For example, laptop computers make it possible to work in a park or at home. The role of student can be played at school or at home, as in the case of Web-based training courses. Thus, the fluidity of life-role activities has increased to the point where individual theaters commonly contain multiple roles. This fluidity makes balancing life-role activity an even greater challenge.

The blurring of boundaries between roles and theaters also requires us to be intentional in our life-role behavior and, at times, to communicate our intentions to others. For example, engaging in conversation with a friend may be acceptable when we are enjoying a leisurely latté in a coffee shop, but not acceptable when we have chosen the coffee shop as the location for completing a business report in a timely manner. It may be difficult for one's friends to know the life role (worker or leisurite) one is engaging in unless they are told. The blurring of boundaries between roles and theaters requires a greater emphasis on communicating our activities to others.

USING THE LIFE-CAREER RAINBOW

As implied, life roles influence each other, so the same job will hold different meanings for two individuals who live in different situations. Career counselors help their clients clarify and articulate the interests, abilities, and values they seek to express in the life roles that are important or salient to them. Role salience comprises cognitive, behavioral, and affective dimensions. Salience is strongest when we have knowledge about a life role (cognitive), participate in it (behavioral), and feel that the role is important (affective). When one dimension is weak, the implication is that salience is weaker. For example, if it is stated that a life role is important (e.g., leisure) but we know little about it and spend little time participating in it, the implication is that salience for that

role is weak. When the three dimensions of role salience hold similar levels of importance for a particular role, career interventions often focus on helping clients identify outlets for engaging in that life role. When any of the dimensions of role salience are discordant, career interventions often address the reasons for this discordance. For example, if the affective dimension is strong but the behavioral dimension is weak (i.e., the client says that he feels the role is important to him but does not spend time in that life role), career counseling focuses on factors underlying this discrepancy. Solutions for the client may lie in adjusting one dimension or the other (e.g., the role is not as important as he thought, or the role is important and he needs to find opportunities for greater engagement in the role).

To address such issues related to the life structure, Super devised the *Life-Career Rainbow*. The Rainbow provides a graphic device that merges Super's "life-span, life-space" theory segments. There are multiple dimensions to the Rainbow. The outer band of the Rainbow depicts the longitudinal dimension (i.e., life span) of career development. It begins in the lower left, with birth, and proceeds to move left to right across the Rainbow chronologically, often extending three to five years into the person's future. This reflects what Super labeled as the *maxicycle* of career development. Although this dimension of the Rainbow was initially connected to the career-development stages of Growth (childhood), Exploration (adolescence), Establishment (young adulthood), Maintenance (middle adulthood), and Disengagement (late adulthood), it is now acknowledged that career development in adulthood rarely proceeds in a linear fashion and that the stages tend to be a reflection, regardless of age, of the multiple career-development tasks confronting people (sometimes concurrently) as they attempt to manage their careers throughout the life span. Thus, age becomes more relevant than stage within the Life-Career Rainbow activity, and career-development tasks provide indications of the career resources clients need to effectively cope with the challenges they confront.

Above the Rainbow, and at the center, Super identifies the situational determinants (e.g., history, socioeconomic status, family of origin, country of residence) that influence our life-role self-concepts and life-role activities. Below the Rainbow, and at the center, Super identifies the personal determinants that influence our development (e.g., psychological and biological

factors). Collectively, personal and situational determinants remind us that context influences careers. Personal and situational factors interact to shape our life-role self-concepts and to present us with career-development tasks, with which we must successfully cope to manage our career development effectively.

Career counselors use the Rainbow in individual and group career counseling. The starting point involves asking clients to construct their personal Rainbows. Beginning with birth, clients construct individual strands for each life role in which they have participated. Clients proceed to construct the strands of their Rainbow from the past to the present. The size of a strand increases or decreases at any point in time to reflect the person's degree of involvement in the role at specific points in time (e.g., leisure may decrease as work involvement increases and parenting becomes a part of a person's life structure).

Career counselors often focus on exploring clients' experiences of their current life structures as reflected in their Life-Career Rainbows. Exploring what clients find satisfying or dissatisfying about their current life structures often provides important information as to how clients would like to move forward in their lives. Introducing interests, abilities, and values into the process can occur when the career counselor asks the client to consider the interests, abilities, and values reflected in the life-role activities depicted in the client's Rainbow. When life-role activities restrict the expression of these core client characteristics, the client is encouraged to identify outlets for increasing the expression of core interests, abilities, and values in current and future life-role activities.

Projecting the Rainbow three to five years into the future also stimulates goal-related discussions in career counseling that seek to identify opportunities for engaging in life-role activities that provide outlets for interests, abilities, and values expression. Providing the client with stimulus questions related to life-role activities the client would prefer to increase and/or decrease is an important activity for constructing the future Rainbow. Then, the counselor and client identify strategies for increasing the probability of the future Rainbow occurring. Short-term and long-term steps are identified.

Additional career-counseling questions for clients to consider when reviewing their Life-Career Rainbow include the following:

How do you spend your time during a typical week?

How important are the different roles of life to you?

What activities do you engage in to learn more about the life roles that are important to you?

What do you like about participating in each of the life roles?

What life roles do you think will be important to you in the future?

What do you hope to accomplish in each life role that will be important to you in the future?

What life roles do members of your family play?

What do your family members expect you to accomplish in each life role you play?

CONCLUSION

Effective life-role participation is difficult to achieve. Conflicting life-role demands make effective life-role participation seem like a moving target. Life is best when life roles nurture each other and offer opportunities for people to express their core interests, abilities, and values. Life becomes stressful when life roles collide and provide little opportunity for expressing core characteristics. Super contended that the life structure, once designed, is not static; it runs a developmental course and then needs redesign. The Life-Career Rainbow embraces this fact by providing a vehicle for focusing on how clients structure the basic roles of work, play, friendship, and family into a life.

LIFELONG LEARNING

Lifelong learning is the facilitation of learning, growth, and development across the life span. It has also been referred to as *lifelong education*, and it is typically seen as reflective of a "learning society" or a "knowledge society." Examples of lifelong learning include retraining adults for new jobs and new industries, informal and nonformal learning, leisure learning, activism, and continuing education. Lifelong learning is a concept embraced by most educators based on the belief that learning and growth will continue across the life span as a hallmark of adulthood; its goal is to make education accessible and involve individuals throughout the life span.

The concept of lifelong learning is at least three decades old, becoming a popular concept in the 1960s and 1970s and reemerging the 1990s. As John Field observed, lifelong learning in the 1960s and 1970s was a humanistic and even radical concept, but since the 1990s, it has become increasingly based on economic needs and conservative in its implications. Since the 1960s, many industrialized countries have seen a continued increase in adult participation in lifelong education, and in some cases, the participation has increased faster than participation in formal education programs.

Although the first major work on lifelong education was Basil Yeaxlee's *Lifelong Education*, published in 1929, it was not until the 1970s that international organizations began to advocate the ideas of lifelong learning and the learning society. And only since the 1990s have these concepts received attention in national policy.

Lifelong learning is the notion that all adults should have access to ongoing education. Researchers have long advocated the value of lifelong learning as important in professional and vocational accomplishment in an age of increasing complexity. It is viewed as a mechanism to assist individuals in obtaining the capabilities and knowledge that allows adaptation to different work situations and career and life stages. In this sense, adult and continuing-education programs form an essential link in the overall framework of lifelong learning. As William Maehl observed, lifelong learning is a functioning system of values, policies, organizations, and processes intended to provide individuals with access, opportunities, and services to support their learning from infancy to old age. Lifelong learning is viewed as

broader than adult education because of its “cradle-to-grave” focus, which incorporates both public schooling and adult and continuing education.

The objective of lifelong learning is to help adults build the skills and knowledge to help them adapt to life stages and changes. Adult continuing education is an essential and popular part of lifelong learning; indeed, adult and continuing-education enroll more individuals than K-12 and higher education combined in the United States. Although lifelong learning is often thought of as an adult enterprise, its advocates recommend that lifelong learning begin early in the public schools.

Malcom Tigh outlined Arthur Cropley’s concepts underlying lifelong education that facilitate lifelong learning:

Lifelong learning would last the whole life of each individual.

Lifelong learning would lead to the systematic acquisition, renewal, upgrading, and completion of knowledge, skills and attitudes, as became necessary in response to the constantly changing conditions of modern life, with the ultimate goal of promoting the self-fulfillment of each individual.

Lifelong learning would be dependent for its successful implementation on people’s increasing ability and motivation to engage in self-directed learning activities.

Lifelong learning would acknowledge the contribution of all available educational influences, including formal, nonformal, and informal.

Tigh noted that these concepts suggest key features about lifelong learning, including that lifelong learning is justified by keeping pace with change, linked to economic and social requirements, dependent on individuals taking charge of their learning, oriented toward self-fulfillment, and reliant on the involvement of educational providers.

D. W. Livingstone identified three dimensions of lifelong learning, including formal schooling, continuing education, and informal learning. Livingstone also noted that there are different approaches to lifelong learning, including instrumentalist, transformative, and inclusive facilitative. *Instrumentalist learning* is usually designed and controlled by groups with power. For instance, organizational management dictates much of the formal learning that occurs in the workplace. Knowledge sharing in this context serves the productivity needs of the organization but might

ignore the needs of the individual. *Transformative* approaches are initiated by the less powerful to initiate social change. For instance, labor unions might organize training programs to help workers resist management activities. The third approach, *inclusive facilitative*, designs educational programs that are representative of groups or cater to individual adult learners, such as joint labor-management education or self-directed learning.

The quest for lifelong learning is characteristic of advanced capitalist societies, and although it may have begun with a more humanistic and emancipating intent, lifelong learning today has shifted more toward the vocational in a knowledge economy. The very shift from the more traditional term *lifelong education* to *lifelong learning* indicates a move toward a more work- or worker-based view and away from the humanistic perspective.

THE GLOBAL LEARNING SOCIETY

A *learning society* is defined as one in which nearly all social institutions have a learning dimension and a responsibility for individual growth and development. The “information age” has made continuous learning more important than ever. In the United States, the Lifelong Learning Act was intended to provide hope to those who are in economically difficult or disadvantaged circumstances, including people who are unemployed or workers whose jobs are becoming obsolete. Lifelong learning is a necessary step toward making the lives of all people more rewarding and more productive.

The Devors Commission in 1996 called for the creation of a global “learning community,” with lifelong learning as a key concept. Lifelong learning is becoming more important to policymakers concerned with globalizing economies. The importance of a learning society is evident given the pace of technological and social change that must be kept up with in order to function effectively in life.

Lifelong learning helps individuals, and the global economy depends on it. Indeed, employers’ investments in lifelong learning, particularly the instrumental form, have increased dramatically. As reported by Livingstone in 1983, approximately 25 percent of U.S. employees reported receiving training after being hired. In 1991, over 50 percent reported having received training during the prior two years. By 1993, over 70 percent of employers were offering some type

of training. Today, at the start of the twenty-first century, nearly all major employers must invest in employee learning and development to stay competitive in the global economy.

Livingstone considers the interest in lifelong learning in advanced capitalist societies to have taken a “quantum leap” since the 1970s, based on the increasingly pervasive general assumption that people will have to intensify their learning efforts to keep up with the rapidly growing knowledge requirements of a new “knowledge economy.” John Holford and Peter Jarvis suggested that adult educators have become seduced by the fact that many policy documents and much of the academic literature convey a sense of inevitability that there is no alternative to lifelong learning because societies that do not become learning societies have no future. They argue that seduction into the inevitability of a learning society may prevent educators from being critical and constructive and urge that lifelong learning must incorporate the wisdom of adult and continuing education.

Although lifelong learning is widely advocated for economic goals, many advocates believe that it should involve more than strictly instrumental purposes. Some lament that learning has become more of an economic activity than a life activity. Lifelong learning continues to be a fundamental process for adults. It is imperative for educators to ensure that it honors the learning and wisdom of adult education in a fast-paced, technology-driven world that can easily lose its focus on humanistic learning goals in favor of more instrumentalist ones.

LIFESTYLE PREFERENCES

Throughout history, people’s positions in society, status, work, and worldview were dictated virtually from birth by the social class/socioeconomic status and other characteristics of their families of origin. Furthermore, men and women were ascribed different roles in society and in the family. Sex differences in lifestyle and careers were profound and largely immutable in any given society, though they varied greatly between societies and across time.

In the late twentieth century, sex differences began to erode, and women gained genuine choices as to how to live their lives—arguably for the first time in history. Two social changes were especially important.

First, the “contraceptive revolution,” from the 1960s onward, gave sexually active women reliable and independent control over their own fertility for the first time in history. This allowed women a real choice as to whether they would devote their entire lives to child-bearing and child rearing and prompted a rise in voluntary childlessness, up to 20 percent in some countries.

Second, the equal-opportunity revolution of the late twentieth century ensured that women would realize equal rights to access all positions, occupations, and careers in the labor market. Sometimes the access was extended to posts in the public sphere, including political representation. In some countries, legislation prohibiting sex discrimination goes beyond the labor market, giving women equal access to housing, financial services, and other public services.

These two fundamental social changes were complemented by other changes in society and in labor markets, which have given women in liberal modern societies new choices in careers and lifestyles. As a result, men have also acquired some flexibility, because the primary-earner role no longer invariably falls on their shoulders.

A taken-for-granted assumption in recent feminist theory was that all women would choose permanent full-time employment and careers in the market economy as soon as sex discrimination ceased to be the main barrier to women's activities in the public sphere and career success. It was assumed that given the choice, women would willingly swap a domestic role in the home for waged work in the market economy and that it was patriarchal male strategies of exclusion and segregation that had kept women out of paid work. Catherine Hakim's review of research on women's lifestyle choices in the late twentieth century in modern societies showed that this was mistaken; only a minority of women, around 10 percent to 20 percent, pursued competitive careers in the market economy in the same way as men, suggesting that only one-fifth of women preferred this lifestyle. Building on this empirical research evidence, preference theory states that women, as well as men, display heterogeneous lifestyle preferences even after social and economic changes in modern societies offer them genuine choices. Three dominant lifestyle preference groups occur among men and women, albeit in different proportions.

Work-centered women are a minority, despite the massive influx of women into higher education and into professional and managerial occupations in the last three decades. Work-centered people (men and women) focus on competitive activities in the public sphere, in employment careers, sports, politics, or the arts. Family life is fitted around their work, and many women remain childless, even when married. Qualifications and training are obtained as a career investment rather than as an insurance policy, as in other groups. A majority of men are work centered, compared with only a minority of women, even women in professional occupations.

The second group, *home-centered* or *family-centered women*, is also a minority, and a relatively invisible one in the Western world, given the current political and media focus on working women and high achievers. Home-centered women prefer to give priority to private life and family life after they marry. They are most inclined to have larger families, and they avoid paid work after marriage unless the family is experiencing financial problems. They do not necessarily invest less in qualifications, because the educational system functions as a "marriage market" as well as a training institution. Despite the elimination of the sex differential in educational attainment, an increasing proportion of wives in the United States and

Europe are now marrying men with substantially better qualifications, and the likelihood of marrying a graduate spouse is hugely increased if the woman herself has obtained a degree. Very few men currently fall into the home-centered category.

Between these two extreme groups, each with one dominant priority in life, is a large and diverse middle group labeled *adaptives* by Hakim. These women prefer to combine employment and family work without giving a fixed priority to either. They want to enjoy the best of both worlds. Adaptive women are found in substantial numbers in most occupations. Certain occupations, such as schoolteaching, are attractive to women because they facilitate a more even work-family balance. The great majority of women who transfer to long-term part-time work after they have children are adaptive women who seek to devote as much time and effort to their family work as to their paid jobs. Recent surveys in Europe suggest that two-fifths of men also fall into this group, a larger number than popular stereotypes suggest. At present, there is less latitude for men than for women to pursue adaptive lifestyles.

Lifestyle preference groups differ in values as well as preferred activities. Work-centered people have marketplace values, with an emphasis on competitive rivalry, achievement orientation, and individualism. Family-centered people emphasize sharing, caring, noncompetitive, collectivist values. Adaptive people must juggle two competing value systems.

This diversity in female and male lifestyle preferences has possibly always existed. But in the past, economic necessity was generally the primary determinant of women's employment choices. Typically, wives and children had to work in order for families to survive. Today, in prosperous liberal societies, women can choose to enter the workforce or not, and they can usually choose between part-time and full-time employment. Modern societies reveal female heterogeneity and the beginnings of male heterogeneity to their fullest extent, and lifestyle preferences are becoming a much more important factor in career and job choices.

LOCKSTEP CAREER PROGRESSION

Karl Ulrich Mayer describes institutional careers as the orderly flow of persons through segmented institutions. A number of scholars have pointed to occupational careers as providing the organizational blueprint for the adult life course, which begins with a period of education, followed by years of productive work (often in a series of related jobs) and then retirement.

Most age-graded labor-market policies and practices developed in the middle of the twentieth century reified a *lockstep occupational career path*. The lockstep imagery fostered a career mystique, touting hard work, long hours, and continuous employment as the ticket to occupational mobility and success. It also fostered a retirement mystique, “golden” years of continuous, full-time leisure as an end in itself. The resulting age-graded life course clockwork and culture legitimized the occurrence, timing, and sequencing of transitions around education, employment, and retirement, reflected in work, pension, and education policies but also in social welfare policies more broadly (Social Security and Medicare in the United States, but more forms of welfare support in Europe). Such institutionalization in the latter half of the twentieth century effectively standardized individuals’ biographical pacing, that is, the nature, timing, and sequencing of their social roles. Consider the age-graded institutionalization of education. In the United States, virtually everyone from age 6 to 16 (and increasingly to 18) is a student, enrolled in, and, ideally, attending school. This student role permeates young people’s identities, the ways others respond to them, their social location in society, and the organization of their days, weeks, and years.

Similarly, employment came to represent the quintessential adult role, providing individuals and their families with the income, status, security, and other resources (such as health insurance and pensions) essential for “the good life.” Jobs also shaped the clockwork of business, family, and social life through structured routines and timetables (for promotion,

retirement, etc.), social relationships, and opportunities for productive engagement. The hierarchical structure of business and occupation paths reinforced the notion of a lockstep career progression.

In the post–World War II economic boom, retirement from paid work was similarly institutionalized. Most U.S. workers eligible for Social Security at 65 retired if they could afford to do so, rendering retirement a “natural” component of contemporary life.

This “expected” lockstep life course is so embedded in American institutions and ways of thinking that it is hard to see it as an only relatively recent, twentieth-century invention. Scholars, as well as society at large, take as “given” the idea of career paths as part of a lockstep march from (full-time) education (as preparation for one’s career) through (full-time) employment (as career progression) to (full-time) retirement (the culmination of a lifetime of hard work). The culture that developed around the lockstep clockwork considers each of these activity domains (education, employment, and retirement) to be “naturally” segmented by age, as well as separated in time and space. Americans, along with many Europeans and Asians, have come to hold a shared definition about both what the adult life course and career progression consist of and how they should unfold.

The lockstep passage from education through continuous full-time employment in a sequence of related jobs to the continuous full-time leisure of retirement—Harold Wilensky’s concept of orderly career—has become the yardstick against which occupational expectations and accomplishments are gauged. This lockstep imagery is closely aligned with the American dream of rugged individualism, of people pulling themselves up by their bootstraps, of hard work “paying off” in financial success and job security, and of movement up ladders in particular occupational or organizational hierarchies or “ladder hopping” across occupations or organizations.

But the lockstep career path developed as very much a gendered path, effectively leaving out half the adult population. These taken-for-granted expectations captured the experiences only of mostly White, mostly middle-class, mostly married men in the middle of the twentieth century. They have never reflected women’s occupational and educational pathways (typically more contingent than lockstep), much less the occupational experiences of workers with little education or otherwise on the margins of the labor market. Still, in the post–World War II economic boom years,

most Americans aspired to this vision of the good life, buying into the lockstep career mystique for men and the feminine mystique for women as cultural ideals, twin paths to fulfillment, even if they themselves could achieve neither. In the 1950s, most Americans had finished school, found jobs, gotten married, and become parents before age 30. The cultural template—on television, in middle-class suburbs, and in grade school readers—was the breadwinner/homemaker family, with gender dividing family and career, even as age divided the lockstep career course and commutes divided paid work from the home life. Ideas about and policies developed around the conventional lockstep career shaped the life chances and life quality of (typically male) breadwinners and their families as well as those outside this favored pathway. But note that unfettered pursuit of the lockstep career mystique was dependent on having someone else—a homemaker—manage all the nonwork details of daily living.

In the 1950s, the career mystique meshed well with the feminine mystique: Men in middle-class white-collar and unionized blue-collar jobs could focus on breadwinning because their wives did the homemaking. Then, more than 40 years ago, in *The Feminine Mystique*, Betty Friedan debunked the myth that full-time homemaking offered the only road to women's fulfillment. Over the ensuing years, the women's movement opened up opportunities for women to also pursue lockstep career ladders. Many of the growing numbers of women pursuing college degrees felt they could have it all, success at home and at work. Many set about trying to follow the career mystique, not instead of, but in addition to, their obligations on the domestic front.

Today, career patterns in the United States remain one-size-fits-all, with the lockstep of continuous, full-time employment taken for granted for those "serious" about their work. The clockwork of paid work still shapes the (work) day and the (work) week, as well as the lockstep career path. Workers today are expected to work long hours (often including mandatory overtime and the "choices" of professionals to work evenings and weekends), to travel, and to relocate if their employers require it, as if they had no responsibilities outside their jobs. But most workers, men and women, no longer have the luxury of a full-time homemaker to free them from family care, and most workers are married to someone who is also in the workforce. The very diverse twenty-first-century

workforce is having to operate under lockstep rules designed for mostly married, middle-class, white-collar and unionized blue-collar men in the middle of the twentieth century. Doing so exacerbates employees' stress, along with their time overloads, work-family strains, and conflicting loyalties and pressures. Most workers—men and women of all ages and life stages—report this sense of overwork and overload.

Lockstep imagery and policies are also out of step with changing skill requirements in light of new communication and information technologies and the dislocations brought about by the mergers, bankruptcies, and layoffs endemic to a competitive global labor market. In conjunction with a global economy characterized by outsourcing and downsizing, the traditional (and typically implicit) contract between U.S. employers and their employees, rewarding hard work and commitment with advancement (or at least security), has disappeared.

Still, although it is more myth than reality, the lockstep career mystique remains in taken-for-granted polices and practices, "glass corridors" that effectively limit the options around work, education, and retirement. Almost all aspects of life in twenty-first-century America remain tied to a regime of often invisible age- and gender-graded roles, rules, and regulations fashioned from the lockstep myth. Consider how various policies—health insurance, Social Security, unemployment insurance, pensions, vacations—are all predicated on full-time, continuous employment.

The lockstep patterning of lives—education, paid work, and retirement—remains embedded in the culture of adulthood throughout Europe and Asia as well as the United States. This blueprint both shapes and is shaped by social policies still geared to (a) full-time, continuous, paid work as the key to economic and occupational stability and success and (b) the image of retirement as a one-way, one-time, irreversible exit from the workforce. The myth of orderly career progression remains the yardstick against which all workers'—men's and women's—experiences are gauged, even though it reflects the experiences of ever-fewer employees. Contemporary Americans are finding themselves increasingly vulnerable to the vicissitudes of a global economy, with its global workforce and informational technologies. While Canada, Sweden, Germany, and other countries in the European community experience high unemployment rates, they also maintain "safety nets." Still, the trends toward early retirement, corporate restructuring, women's employment, and the

changing employer/employee contract are widespread. For example, state socialism in China used to mean secure state jobs (a situation termed the “iron rice bowl”); with the introduction of capital markets, however, such state jobs are now neither as prevalent nor as secure as in the past.

Cultural expectations about the lockstep career mystique are changing at a glacial pace. Employers, men, women, and even children take for granted that regular, paid work means spending five days, 40 or more hours a week, on the job (a standard enacted in the United States in 1938 by the Fair Labor Standards Act); that education is for children and young people; that retirement is a one-way, one-time, irreversible exit; and that family care work is women’s responsibility. This sense of “the way things are” creates, perpetuates, and exacerbates inequalities—financial and emotional—between men and women. It also pressures workers struggling to start families, raise children, manage dual careers, and/or care for aging or infirm relatives. And, even as the workforce ages (with the progression of the large baby boom cohort, born 1946-1964), existing, taken-for-granted arrangements around paid work and aging foster the “rolelessness” of retirement.

The lockstep myth of career progression only reinforces gender divides. When men earn more than women and have a greater chance of moving ahead in their jobs, it makes sense for couples to invest in husbands’ occupational careers, even if it means short-changing wives’ own prospects. Thus, the weight of coordinating work and family responsibilities rests, for the most part, on the shoulders of employed wives, mothers, female single parents, and the daughters of ailing parents. Having one “good” job (with benefits) and one part-time or less demanding second job per family perpetuates gender differences in both salary and advancement prospects.

Life—and work—in the twentieth century is definitely not lockstep. Americans’ transitions into and out of school, marriage, parenting, paid work, and care work are both more contingent and more varied than ever. People today are changing not only their jobs but also their occupations; returning to school at all ages or staying in school longer; marrying later, divorcing, or staying single; delaying childbearing or having no children; and retiring early, late, not at all, or several times. The United States and, indeed, nations around the world stand in a whirlwind of demographic, economic, technological, and social

change. But policies and practices remain caught in a time warp.

The lockstep career mystique fosters a false divide between the two most fundamental life dimensions, job and family, as they play out over the life course. Americans try to follow the rules of the “career” game but on their own terms, well aware that such rules no longer guarantee achievement, autonomy, or even security. Most contemporary men and women want it all, including gender equality, but accommodate outdated and conflicting institutions through hybrid strategies, with one foot in twentieth-century practices and the other tentatively in the twenty-first, to deal with the risks and realities of twenty-first-century lives. This means that women, wives, and single mothers still do most of society’s care work without pay, even as they try simultaneously to maintain ties to the paid workforce. Men, husbands, and fathers put in long hours in paid work, even as many try to help out at home. Most Americans believe in equal opportunities for men and women but simply can’t make it happen, even in their own families.

The lockstep career mystique and the corollary policy regimes built around it also foster age divides. Most Americans in their 50s, 60s, and 70s want to remain engaged in some form of productive activity, but not without some schedule flexibility. Neither do these growing ranks of older Americans want to put in the long hours most jobs require. Conventional employment and retirement patterns make it difficult for older workers to fashion the type of arrangements they want.

The lockstep career mystique developed during very different times, for a very different workforce, in a very different economy. Yet most Americans—men and women—continue to embrace the lockstep education-career-retirement path, even though it is out of date and out of place in twenty-first-century America. This myth of the lockstep career is interwoven into the very fabric of the American way of life, making it hard to envision any alternatives in the arrangements of either work or retirement. And yet most Americans confront job or income insecurity and stress as they contend with the moving platform of change characterizing life thus far in the twenty-first century. And most older workers now moving toward retirement experience uncertainty, ambivalence, and ambiguity as they consider their future possibilities. Although lifelong education and returning to school at various ages and stages are increasingly common, most institutions of higher education cater to a clientele of young people.

While myths are important, providing a vision of what is possible, Phyllis Moen and Patricia Roehling conclude that the lockstep career and retirement mystiques are “false myths” standing in the way of creating new, alternative workplace, retirement, and career policies, flexibilities, and opportunities. Creating this alternative scenario requires putting lives and institutions back together, developing institutional arrangements that widen the circle of career options at all ages and life stages. The costs of sustaining the outdated lockstep regime—to individual and family health and well-being, to gender equality, to lifelong occupational opportunity, and to a sense of community—may well be unacceptably high.

The latter part of the lockstep life course is already in the process of being reformulated, in light of increased longevity, the aging of the large baby boom cohort, forced or encouraged (with buyouts) early retirements, and concerns about health insurance, pensions, and Social Security. Retirement is becoming a blurred transition, with considerable heterogeneity in its timing and in how lives are lived after retirement. These changes are establishing the groundwork for differentiating an emerging “third age” from the second age of “prime” adulthood and the fourth age of old age.

Most crucial are multiple exit and entry career “portals.” Existing lockstep “glass corridors” shaping occupational and career paths offer ways to get off the career train but no way to get back on, with few options between full-time (or more) employment throughout adulthood and quitting one’s job entirely. The current lockstep career path is a forked road: Follow the yellow-brick, orderly career mystique or else move “off track” to part-time, contingent, or intermittent work. The policies and practices sustaining this forked road, however, could be reformulated in ways more compatible with the multiple demands on and preferences of members of the twenty-first-century workforce. Flexible opportunities, together with alternative scaling back and “re” entry possibilities, would permit Americans to pace their occupational careers in ways that would not be at odds with their family “careers.” Older employees, burnt out or bored with one career, could begin “second acts” or revert back to an original “first-act” career at different ages and stages. Experienced and energetic employees and retirees could fashion hybrid arrangements, phasing out of or into employment and retirement—part-week, part-year, or both. Such innovative flexibility options could provide corporations and nonprofit organizations with a willing and able workforce of people of all ages

wanting flexible jobs that fit their lives and values, not ones blindly following the lockstep clockwork. True gender equality, work-family sustainability, and age integration will be possible only when the clockwork of careers becomes flexible enough to be compatible with the clockwork of the rest of life for all employees, regardless of their gender, their age, or their family responsibilities. Such innovations are feasible, once employers, unions, and governments, along with employees themselves, begin to rethink the lockstep clockwork.

LOCUS OF CONTROL

The term *locus of control* originated in the social learning approach to behavior change in the early 1960s, and

the first publication that explicitly examined this topic appeared in 1962. As originally proposed by Julian Rotter, a clinical and social psychologist, locus of control (LOC) refers to a dispositional tendency to perceive events and outcomes in one's life as being under one's own control or as being controlled by sources over which the person has little or no control, such as luck, fate, or other people. Initially, Rotter conceived LOC as being either internal or external. That is, the individuals feel either that they can control events and outcomes in their lives or that they have little control over these occurrences, which are determined more by external circumstances. In the mid-1970s, a further differentiation of external control was proposed by Hanna Levenson, between external control due to luck or fate (e.g., the individual has secured a good job simply because he or she was in the right place at the right time) and external control due to powerful other people (e.g., the job was obtained because the individual was acquainted with important people in the organization). Nevertheless, the primary distinction is still between a generalized tendency to view outcomes as being contingent on one's own efforts and abilities (internal LOC) versus factors outside one's control (external LOC).

FUNCTIONS OF LOCUS OF CONTROL

Locus of control has been implicated as playing an important role in a variety of areas in people's lives, including their health, general well-being and happiness, satisfaction with their jobs and lives overall, and (to some extent) their careers and vocational aspirations and choices. For instance, research has illustrated that people with higher internal-control beliefs tend to take more behavioral control over their health (e.g., engaging in "healthy" lifestyle behaviors), which, in turn, can lead to better health outcomes. In contrast, those with higher external-control beliefs may feel that their efforts to remain fit and healthy are somewhat futile, as their health status is more determined by luck or fate; hence, they may not persist in health-related behaviors, such as diet and exercise. Similarly, as will be discussed later, high internal control has been associated with more effort to succeed educationally and with greater career aspirations, ultimately resulting in the achievement of higher-level occupations that are more satisfying and fulfilling.

One of the reasons believing that one has a high degree of personal control over life's events is beneficial is that it is related to high levels of optimism,

self-efficacy, and self-esteem. In fact, some researchers have commented that there is sometimes little distinction between high internal control and *self-efficacy*, which is defined as a belief in one's abilities to master the environment. Nevertheless, internal control does differ from self-efficacy in that a person with high internal control may not necessarily feel mastery and in some situations may attribute failure to achieve a goal (e.g., being successful in a career) to personal limitations or lack of effort, whereas a high-external-control individual in the same situation may blame other people or just bad luck. Overall, however, research has illustrated that people who are high on internal control often exhibit higher motivation and hence performance (e.g., on the job) and that internal control is frequently associated with overall better adaptation. High-internal-control individuals are more likely to change their behavior and seem to be more adaptive. Similarly, internal control has been linked with greater persistence, which can enable the individual to persevere in the face of adversity.

MEASUREMENT OF LOCUS OF CONTROL

Several questionnaire measures of locus of control have been developed and tested in research. Rotter's Internal-External (I-E) Scale asks respondents to read two statements at a time and choose the one with which they agree more. In each case, one statement expresses internal control, while the other reflects external control over an event or situation. As mentioned above, however, other researchers have reasoned that external-control beliefs may be based on control by other people in one's environment or luck/fate; hence, other measures have distinguished between these forms of external control. Research comparing various measures of LOC has, unfortunately, found that they do not always converge, and some investigators have concluded that measurement of LOC may sometimes be confounded with two other factors: (1) the desire for control and (2) a perceived ability to exert control (competence or mastery). These problems have constrained understanding of how locus of control independently relates to variables such as motivation and performance (e.g., in a work context).

LOCUS OF CONTROL AND CAREERS

Despite its intuitive appeal and the wealth of research that has been conducted on LOC generally,

its application to vocational choice and development has been relatively sparse. Nevertheless, there is some evidence that LOC can influence individuals' career choices and, to some extent, their career progression. As noted above, individuals with high-internal-control beliefs are likely to believe that their careers are in their own hands and that occupational success will be founded on their own efforts and capabilities. Such individuals tend to pursue higher levels of education, which leads to the acquisition of more challenging, complex (and highly paid) occupations. Furthermore, if work conditions or the job itself are not satisfying, high-internal-control workers are more likely to leave their jobs or organizations, whereas high-external-control individuals seem to be less likely to search out better alternatives when they are dissatisfied with their current positions. There is insufficient research evidence at this point to conclude whether or not individuals who are high on internal control are actually better performers on the job than those who score high on external control, although this might be anticipated if, as mentioned above, there is a positive relationship between internal control and self-efficacy or mastery.

To conclude, the concept of locus of control has attracted the attention of researchers and practitioners for over 40 years, and its relevance to a broad array of life domains has been explored. Despite concerns over its measurement, researchers continue to investigate the role of LOC in areas such as health and well-being, educational performance, and career choice and success. Additional research needs to be conducted to fully elucidate the conditions under which high internal (personal) control leads to more adaptive functioning and whether there are any circumstances under which a belief in external control may be more functional.

LOW-INCOME WORKERS AND CAREERS

Employed persons living close to or below the poverty line can be considered *low-income workers*. Some examples of occupations characterized by low income are food service, retail, secretarial work, and cleaning jobs. Low-income workers face many challenges in the workplace, and traditional vocational interventions often do not meet the needs of this population. There is little theory or research that addresses the vocational development of low-income individuals. However, innovative interventions are being proposed to enable individuals to move toward greater economic self-sufficiency.

Historically, career-development theories have not focused on the experiences of low-income individuals. Several tenets of career theory that appear inconsistent with the experiences of many low-income workers include the assertions that individuals make autonomous choices regarding careers, that the goal of work is self-actualization, that work is a central component of meaning in one's life, and that all people can achieve whatever they work hard to accomplish. Pursuit of a career implies choice and a progression in one's occupation. For some low-income workers, however, economic survival (not career advancement) may be the primary goal of employment.

Within the United States, people living below the poverty line tend to include large numbers of women and people of color. Factors contributing to the high prevalence of women and minorities in low-income jobs include educational attainment disparity, racism, sexism, divorce, domestic violence, discrimination against low-income people, and responsibility for children and aging relatives. Individuals struggling with physical and mental illnesses may also be found in low-income occupations.

Low-income workers are at risk for chronic unemployment and underemployment due to obstacles at home, in the workplace, and in society at large.

Low-income workers may lack the nutritional foundation needed to perform their jobs well. Their physical health also may be compromised due to stressors encountered at home and strenuous conditions at work. Higher rates of psychological problems have been found among low-income workers, including depression, posttraumatic stress disorder, and substance abuse. Some workers cannot afford to pay for health insurance and thus lack access to adequate medical, dental, and psychological care.

In addition, minimum-wage and low-paying jobs often do not provide enough income to allow individuals to find affordable and safe housing. The neighborhoods in which low-income families live may not be safe, and the schools in these neighborhoods are often deficient. Low-income workers commonly must work multiple jobs to support themselves and their families. Working many hours may affect their ability to prepare and consume healthy meals, to parent effectively, and to be involved in the academic and social development of their children. Many low-income workers may not have access to safe child care and reliable transportation.

In the workplace and in society, low-income workers may encounter prejudice in the form of sexism, racism, and classism. Their jobs also may involve physically demanding tasks, difficult hours, and little flexibility in schedule. The structure of many low-income jobs does not promote advancement and higher wages. Low-income workers and their children may feel trapped in a cycle of poverty that is difficult to escape.

Recently, vocational interventions have been developed for welfare recipients, high school students, and children in at-risk environments to promote job readiness and employment attainment. As a result of legislative changes limiting the amount of time that individuals may receive welfare assistance, several programs focus on attaining economic self-sufficiency prior to the cessation of financial assistance from the government. The purpose of most of these programs is to promote long-term economic self-sufficiency, and most of the programs utilize an interdisciplinary approach to providing comprehensive services to all family members. Individual case management, job training, job transition, and access to education are included. In addition, assistance in obtaining supportive services is provided (e.g., quality child care, affordable and safe housing, and reliable transportation).

The school-to-work transition movement attempts to minimize the barriers that many low-income youth encounter when they leave high school and enter the labor market. In 1994, the School-to-Work Opportunities Act was enacted, with the goal of facilitating the transition from high school graduation to employment for non-college-bound youth. Federally funded programs enable students in public school systems to access community-based organizations through joint ventures of educators, parents, and labor unions. Such programs typically involve career counseling and the integration of school- and work-based learning. Students are given the option of preparing for technical-preparatory and college career paths and have the opportunity to learn outside the classroom through internships or apprenticeships in the community. These programs are especially encouraging for non-college-bound youth, who receive training in high school and, if deemed necessary, in the workplace, community colleges, or other vocational schools.

Several school interventions aim to facilitate the academic and vocational success of children living in at-risk environments. Notably, school-to-career interventions in Boston public schools address students' uncertainty about their education and career options, while helping them access resources for achieving their goals. For instance, interventions often engage students in self-exploration, identifying resources and barriers, connecting school and work, and enhancing personal strengths. In collaboration with parents, psychologists, administrators, teachers, and the community, such programs empower students to effectively cope with economic, academic, and social hardships they may encounter.

To conclude, economic struggles adversely affect the quality of life among low-income workers. Recently, scholars have proposed that additional attention be directed to the vocational experiences of low-income workers. Socioeconomic class is beginning to be examined in research studies, and career counselors are starting to address how their biases might influence their work with low-income clients. Additional work is needed to ensure that all individuals have access to educational and occupational opportunities.

MACHIAVELLIANISM

The notion of *Machiavellianism* is based on the writings of the sixteenth-century writer Niccolò Machiavelli. In his most famous work, *The Prince*, Machiavelli describes an Italian prince who is willing to do anything, no matter how unscrupulous, to gain and maintain political power. Furthermore, in his writings, Machiavelli argued that successful leaders need to be cold and calculating and must never be bound by feelings of guilt or shame. Building on this idea, Richard Christie and Florence Geis introduced the construct of Machiavellianism and conceptualized it as a measurable, individual-difference variable. In their work, these researchers made a distinction between high “Machs,” who tend to agree with the ideas that “the best way to handle people is to tell them what they want to hear,” “anyone who completely trusts anyone else is asking for trouble,” “sometimes you have to cheat a little to get what you want,” and “it hurts more to lose money than to lose a friend,” and low Machs, who tend to disagree with such assertions.

In short, Machiavellianism is the extent to which individuals are willing to behave in ways that are manipulative, believe that the ends justify the means, are emotionally detached from others, view others as dishonest and untrustworthy, and have disregard for traditional moral standards and ethics. Since its introduction in the late 1960s, a great deal of research has sought to learn more about this trait.

Given that Machiavellianism is associated with a lack of concern for conventional morality, several studies have sought to understand how this trait might

relate to unethical behavior. The findings of such investigations seem to suggest that high Machs tend to behave less ethically than low Machs but only in certain situations. For example, researchers have found that Machiavellianism is not associated with cheating in general but that high Machs are more likely (than low Machs) to cheat when there is a low probability of being caught. Along the same lines, research suggests that the tendency for low Machs to steal from others is influenced by their affect for those from whom they are stealing; in contrast, high Machs seem to be less discriminating in their stealing behavior. Also, while Machiavellianism appears to be unrelated to the actual frequency of lying, high Machs tend to be more convincing liars than low Machs. Surprisingly, perhaps, high Machs and low Machs do not seem to differ in the frequency or degree to which they engage in impression management. Relative to low Machs, though, those with Machiavellian personalities do seem more willing to engage in more deceptive and self-serving forms of impression management and have the ability to project an image of confidence even when they might lack certainty or resolve. Moreover, high Machs are more likely to advocate the use of ingratiation in organizational settings and tend to be very persuasive as well.

In terms of career choice, organizational scholars have found that those who are more Machiavellian tend to prefer careers in business-related fields and to avoid professions that involve helping others. Several studies have also sought to understand the link between Machiavellianism and leadership styles. The principal findings of this line of inquiry are that high-Mach leaders tend to be more autocratic and initiate

more group interaction than do low-Mach leaders. The data also suggest that Machiavellianism is unrelated to leadership effectiveness or to the emergence of group leadership. In studies of U.S. presidents, though, it has been argued that Machiavellian presidents tend to have greater legislative success during their presidencies, are more likely to be seen as charismatic leaders, and are rated as more effective presidents overall.

With regard to job performance and career success, high Machs generally seem to fare no better than low Machs; however, there is some evidence that high Machs are more successful than low Machs when they are working in organizational environments that are less regulated or structured. Some research also suggests that high Machs often do well in settings that encourage employees to act opportunistically. With regard to other work outcomes, researchers have consistently found that Machiavellianism is positively related to job stress and inversely related to job satisfaction. In terms of these findings, it has been argued that high Machs are often dissatisfied because they tend to be more anxious in general and typically dislike settings that might constrain their ability to be manipulative.

A great deal of research on Machiavellianism has actually focused its attention on the instruments and specific items commonly used to measure the construct. By and large, such studies have emphasized the weaknesses of these instruments and have been especially critical of the Mach-IV and Mach-V scales. The principal criticisms here are that these measures of Machiavellianism are too highly correlated with measures of socially desirable responding, that these instruments lack adequate internal consistency or reliability, and that these Machiavellianism scales are, in fact, multidimensional and thus tap several different constructs rather than just one. Nevertheless, researchers continue to use the Mach-IV and Mach-V scales in their research, and these instruments have been vigorously defended by some scholars.

According to citation counts, it appears that research on Machiavellianism has generally been declining since 1982, when it reached its peak. Indeed, more recent research on Machiavellianism has been less focused on identifying differences between high Machs and low Machs and more concerned with understanding how this construct may fit in with theories and constructs that have been more commonly examined outside of the organizational and

social psychological literatures. For example, clinical psychologists have sought to learn more about the potential overlap between Machiavellianism and psychopathy. Evolutionary psychologists and biologists are interested more generally in the link between Machiavellianism and the ability to manipulate others as an important aspect of human evolution. Researchers have also called for more cross-cultural investigations of Machiavellianism as, by and large, most of the research in this area has been conducted within the United States.

MENTORING

Mentoring within the workplace is typically described as a relationship between two individuals, usually a senior and junior employee, in which the senior employee takes the junior employee “under his or her wing” to teach the junior employee about his or her job, introduce the junior employee to contacts, orient the employee to the industry and organization, and address social and personal issues that may arise on the job. The mentoring relationship is different from other organizational relationships (e.g., supervisor-subordinate) in that the mentoring parties may or may not formally work together; the relationship is typically

not sanctioned by the organization; the relationship usually lasts longer than most organizational relationships; the issues addressed during the course of the relationship may include nonwork issues; and the bond between the mentor and protégé is usually closer and stronger than those of other organizational relationships.

Mentoring relationships are by nature developmental and therefore are thought to be a critical career development activity. For example, mentoring relationships play a prominent role in career and life stage theories. Establishing mentoring relationships with others is a critical developmental task faced by individuals during the early career years. The advice and guidance of a mentor can be an invaluable resource as individuals seek to establish themselves during this career stage. Mentoring is also a key task during later stages of career development. Specifically, serving as a mentor to others during the later career years provides a sense of accomplishment and serves as a means for the older worker to contribute to future generations.

The power of mentoring relationships has also been widely discussed beyond the academic literature. Popular business leaders such as Jack Welch and Lee Iacocca have publicly credited their success to having a mentor. In addition, reports suggest that over 75 percent of executives indicate that having a mentor played a key role in their careers. Career counselors often advise individuals to cultivate a relationship with a mentor, and many organizations encourage the formation of mentoring relationships between organizational members.

MENTORING FUNCTIONS AND STAGES

Mentors provide two major functions to their protégés. *Career-related functions* focus on success and advancement within the organization and include sponsorship, coaching, exposure and visibility, protection, and challenging assignments. *Psychosocial functions* focus on the enhancement of sense of identity, competence, and effectiveness in the professional role and include role modeling, acceptance and confirmation, counseling, and friendship. Empirical research based on factor-analytic studies supports the existence of these two overarching mentoring functions.

Mentoring relationships are theorized to progress through four distinct stages over time. The first stage is *initiation*. In this stage, the mentor and the protégé are just beginning the relationship and learning about

each other. If the relationship matures into a mentorship, the second phase, known as *cultivation*, begins. This is the most active phase of the mentorship, during which the greatest amount of career and psychosocial mentoring is thought to be provided. It is during the cultivation phase that the most learning occurs. This is the longest phase of the mentorship and is expected to last from two to five years. As the needs of the mentor and the protégé evolve, the partnership enters the *separation* phase. During this phase, the protégé begins to assert independence, and the mentor comes to believe he or she has no additional knowledge to share with or guidance to provide to the protégé. This phase is thought to last from 6 to 24 months. The final phase of the mentoring relationship is referred to as *redefinition*. This is when the relationship changes into one of peers or colleagues. Little research has been conducted that provides a direct test of these phases. However, there is some evidence that psychosocial and career mentoring does increase from the initiation phase of the mentorship into the subsequent phases.

THE MEASUREMENT OF MENTORING

Much of the mentoring research is based on two types of studies. One type compares those with mentoring experience (protégés or mentors) versus those without mentoring experiences (nonprotégés or nonmentors) on some variable of interest. Mentoring experience is typically operationalized as a dichotomous variable (yes or no) based on responses to a screening question that includes a definition of a mentoring relationship. That is, research participants are provided with a definition of mentoring and then are asked to respond yes or no as to whether they have ever been in such a relationship.

The second common type of mentoring study examines the relationship between mentoring provided and other variables of interest. In this case, those that report mentoring experience also report on the degree to which mentoring was provided during the course of the relationship. Several measures exist in the literature to assess mentoring provided. Mentoring provided is usually examined at the level of Kathy Kram's two primary mentoring functions described earlier, psychosocial and career mentoring. However, exceptions to this exist. Several measures separate mentoring behavior into more discrete categories (e.g., role-modeling is examined as a separate

function), while others combine career mentoring and psychosocial support into a single measure.

MENTORING BENEFITS

Much has been written about the benefits of mentoring. Mentoring relationships are touted as beneficial for protégés, mentors, and organizations. To date, most research has focused on career success outcomes and benefits for the protégé. Career success outcomes can be grouped into those that are objective and those that are subjective. Objective career outcomes are tangible, such as promotion and compensation. In contrast, subjective outcomes are affective and less tangible, such as career and job satisfaction. Recent meta-analytic research supports the notion that mentoring relates to both objective and subjective career benefits for protégés. Specifically, individuals who are mentored advance more rapidly in the organization, earn higher salaries, have greater job satisfaction, and have fewer intentions to leave the organization. Being mentored also has been associated with other career-related variables. Specifically, those who have been mentored report greater career planning, career involvement, career motivation, and career self-efficacy than those who have not been mentored. Mentoring also serves as a form of social support and has been positively associated with employee socialization. Although limited research exists regarding other outcomes, being mentored has been also associated with less stress, more organizational citizenship behavior, and less family interference with work.

Although the benefits of mentoring for protégés seem to have been firmly established, it is important to keep in mind that most research has been cross-sectional. It is commonly assumed that mentoring leads to advantages such as greater career outcomes, but the direction of the relationship is uncertain. For example, it is also possible that those who possess the skills to obtain greater career benefits also possess the skills to attract a mentor. Until more long-term longitudinal studies are conducted, alternative causal directions cannot be ruled out.

Much less research has focused on the benefits of mentoring for the mentor. Qualitative studies examining the benefits of mentoring others suggest that mentors achieve personal satisfaction from passing knowledge and skills on to others, exhilaration from the fresh energy provided by protégés, improved job performance by receiving a new perspective on the

organization from protégés, loyalty and support from protégés, and organizational recognition. The few quantitative studies that have been conducted yielded similar findings, indicating that mentors report that mentoring others provides personal satisfaction and improved workgroup performance. In a study of the expected benefits of being a mentor, five categories of benefits were identified, including rewarding experience, improved job performance, loyal base of support, recognition by others, and generativity (that is, leaving a legacy to future generations).

Researchers are only beginning to examine how mentoring others may relate to more tangible career benefits to the mentor, such as increased promotion rates and salary. Preliminary research shows that after controlling for variables commonly associated with objective career success, those who have mentored others report greater salary and rates of promotion than do those without any experience as mentors. Similar to research regarding protégés, longitudinal studies are needed to better ascertain the causal direction of the relationship.

Mentoring is also thought to provide benefits to the organization. However, organizational benefits have primarily been inferred based on individual benefits. For example, mentoring can have organizational benefits by reducing individual employee turnover, enhancing employee productivity, and increasing the retention of women and minorities. There are no empirical data demonstrating that mentoring relates to organizational-level outcomes, such as firm performance. In addition, while formal mentoring programs are frequently touted as a way to attract employees to the organization and as an effective mechanism for facilitating succession planning, research supporting this assertion does not exist in the published literature. In short, much work remains to be done examining the impact of mentoring at the organizational level.

NEGATIVE ASPECTS OF MENTORING

Recent research has demonstrated that like any form of interpersonal relationship, mentorships can also have dysfunctional aspects. Even generally effective and healthy mentorships may be marked by negative experiences that range from the relatively minor (e.g., petty disagreement) to the malicious in nature (e.g., revenge or sabotage). Protégé accounts of negative mentoring experiences include tyrannical or manipulative behavior on the part of the mentor,

mentors who lack technical or interpersonal skills, a mismatch in terms of values and personality, overprotection and paternalism by mentors, and neglect by the mentor. Protégés who report negative mentoring experiences also report less learning within the relationship, less relational quality, and weaker perceptions of relational complementarity. Negative experiences are not limited to the protégé, as mentors also report encountering problems related to mentoring others. These include a drain on time, difficulty dealing with protégés who have performance problems, protégés who are unwilling to learn, protégé deception and betrayal, and concerns regarding jealousy or favoritism. This line of research is important in that it serves as a useful reminder that although mentoring is generally a beneficial career development process, it also has potential drawbacks and challenges that should be recognized.

FACTORS RELATED TO MENTORSHIP PROCESSES

Gender

A considerable amount of research has been devoted to examining the impact of gender on mentorships. Lack of access to mentors has been offered as one explanation for the disparity between men and women in terms of advancement into senior leadership positions. However, men and women generally report similar levels of experience as protégés. Although men and women may have similar access to mentorships, once in a mentoring relationship, the type of mentoring provided may differ. The results of research examining this issue are mixed, with some studies finding differences and others finding none. When gender differences are detected, the results lean toward women reporting more psychosocial mentoring than men and men reporting more career-related mentoring than women.

There is some evidence that the gender of the mentor may matter in terms of the type of mentoring provided and the benefits accrued. For example, female mentors have been found to provide more psychosocial mentoring than have male mentors. In addition, having a male mentor has been associated with greater career outcomes, such as compensation, than having a female mentor. One explanation offered for this finding is that male mentors are more likely to be in power positions in the organization and thus have greater opportunity to aid the career development of their protégés.

The dyadic composition of the mentorship is also an important consideration. Theory concerning diversified mentoring relationships suggests that the specific dyadic composition of the mentorship impacts the level of mentoring support provided and satisfaction with the mentorship. That is, not only the gender of the mentor or of the protégé is important but also the interaction between the two. For example, although findings are inconsistent across studies, there is some evidence that greater psychosocial mentoring occurs in same-gender mentorships than in cross-gender mentorships. However, it is interesting to note that the majority of cross-gender mentorships comprise male mentors with female protégés. Female mentors with male protégés are typically a small percentage of mentorship pairs.

Race

There has been considerably less research examining race and mentoring than that examining gender and mentoring. Similar to the findings regarding gender, there is little evidence that minorities are less likely to have mentoring experience than are nonminorities. There is no consistent evidence to suggest that the amount of career or psychosocial mentoring provided differs across race. However, the race of the mentor does appear to make a difference. Research has shown that Black employees with White mentors earn more compensation than do Black employees with Black mentors.

Research also indicates that protégés in same-race mentorships report greater psychosocial support than do protégés in cross-race mentorships. There is some evidence that individuals experience more interpersonal comfort in same-race and same-gender mentorships than in cross-race and cross-gender mentorships and that this accounts for the greater psychosocial mentoring reported by protégés. It should also be noted that when cross-race mentoring relationships are studied, the majority comprise nonminority mentors paired with minority protégés.

One factor that should be considered regarding the research on race is that often because of small samples, different minorities are grouped together and analyses are conducted that examine minorities versus nonminorities. Thus, the extent to which findings generalize to all minorities is not certain. In addition, research that has focused on a single race has been almost exclusively on Black Americans. We have

limited knowledge regarding cross-race issues for other minority groups, such as Asian Americans and Hispanics/Latinos.

Protégé Attributes

Some research has indicated that dispositional characteristics relate to the likelihood that one will engage in a mentoring relationship. Mentoring researchers have identified several personality characteristics related to protégé-initiated mentorships. Individuals who have an internal locus of control (those who believe that they are in control of life events) and are high self-monitors (those who modify their behavior to fit the situation) have been found to be more likely to initiate mentoring relationships than have individuals who have an external locus of control and are low self-monitors. Research also indicates that individuals higher in need for achievement are more likely to report having a mentor than are individuals lower in need for achievement. Relatedly, the ambition-to-succeed aspect of the Type A personality has been positively related to protégé-initiated mentoring.

While some protégé attributes relate to their likelihood of being mentored, some research also suggests that mentors look for certain attributes in protégés to be mentored. Social exchange theory suggests that mentors will look for protégés thought to bring desirable attributes into the relationship in an effort to maximize their rewards from the relationship. Consistent with the social exchange perspective, research has found that mentors prefer protégés who possess strong potential for achievement, show favorable past performance, and are willing to learn and accept feedback.

Mentor Attributes

Research has shown that several factors relate to the propensity or willingness to serve as a mentor to others. One consistent finding is that someone with previous mentoring experience, either as a protégé or as a mentor, is more willing to be a mentor to others than someone with no previous mentoring experience. There is also evidence that dispositional factors relate to the willingness to mentor others. Individuals who possess a more pro-social personality (are generally helpful and empathetic toward others) are more likely to have experience as mentors and are more likely to report willingness to mentor others. In addition, internal locus of control and upward striving have been

associated with willingness to mentor others. The relationship between gender and willingness to mentor others has also been examined. Although women have reported more barriers to becoming a mentor to others than have men, most research shows that they are equally willing to do so.

A limited amount of research has examined mentor individual differences that relate to the degree of mentoring provided. One study has found that individuals higher in openness to experience report providing more mentoring than those lower in openness to experience. Learning goal orientation by mentors (the propensity to view challenges as opportunities for growth and development) also has been positively linked with mentoring provided. Recent research has examined the motives that mentors report for mentoring others and how this relates to mentoring behavior. Mentors motivated to mentor others for self-enhancement reasons appear to be more likely to provide career-related mentoring, whereas mentors motivated by the intrinsic satisfaction that mentoring brings report providing more psychosocial mentoring.

Very limited research has been conducted to examine what attributes protégés look for in mentors. The research that does exist suggests that protégés prefer mentors with strong interpersonal skills, a broad knowledge of the organization, and powerful positions within the organization.

Perceived Similarity

In addition to examining the impact of mentor-protégé similarity in terms of demographic characteristics such as race and gender, some mentoring research has examined perceived similarity in terms of attitudes, values, personality, interests, and work styles. Perceived mentor-protégé similarity has been consistently associated with greater mentoring provided and relationship quality. Results show that protégés who perceive that their mentors are more similar to themselves are more satisfied with the relationships and report receiving more mentoring than do protégés who perceive that their mentors are less similar to themselves. Likewise, mentors with protégés perceived to be more similar to themselves report more high-quality mentoring relationships than do mentors with protégés perceived to be less similar to themselves.

It is important to emphasize that this research is based on perceptions of similarity. Research that examines actual similarity in terms of values, personality,

and interests is scarce. One exception is that protégés in mentor-protégé pairs who shared similar levels of learning goal orientation reported greater psychosocial and career mentoring. It is also important to note that because most existing research regarding perceived similarity is cross-sectional, it is possible that mentors and protégés in successful relationships attribute the success of the relationship to having a similar mentoring partner rather than similarity actually resulting in a more effective mentorship.

Organizational Factors

Some aspects of the organizational environment can inhibit or facilitate the occurrence of mentoring relationships. Organizations can foster mentoring relationships among employees by encouraging an organizational learning and development climate. Mentoring relationships are more likely to naturally occur and be successful when the organization fosters an environment that encourages employees to take active roles in learning from and teaching others. This can be done by recognizing and rewarding the efforts of those who mentor others, providing opportunities for junior and senior employees to interact, and helping employees develop the tools needed for coaching and counseling others.

FORMAL MENTORING

To capitalize on the known benefits of mentoring, many organizations have developed *formal mentoring programs*. Various reports estimate that up to 66 percent of companies may have some form of structured mentoring. Formal mentoring programs can help organizations develop and advance the careers of women and minorities who may have limited access to informal social networks, can be used as a recruitment and retention tool, can be used to help groom employees for positions of greater responsibility and expose high-potential junior employees to senior leadership, and can be used to foster cultural change.

Formal and informal mentoring relationships differ in two primary ways. One is that formal mentoring relationships occur through an assignment or matching process instigated by a third party within the organization. In contrast, *informal mentoring relationships* develop spontaneously through the process of mutual attraction. Second, formal mentoring relationships are usually shorter in duration than are informal mentoring

relationships. While informal mentoring relationships typically last three to six years, formal mentoring relationships generally last for six months to one year.

The design and purpose of formal mentoring programs can vary greatly. For example, some programs are geared primarily toward organizational newcomers, while others target high-potential employees. Some programs are highly structured, while others take a more casual approach. Most literature regarding best practices for developing and designing a formal mentoring program is based on conjecture rather than empirical data. However, some preliminary research evidence indicates that formal mentorships are most effective when mentors and protégés have some input into who will be their mentoring partners, training is provided to the mentoring parties prior to the start of the relationship, and guidelines are provided regarding meeting frequency.

One of the most critical issues for the design of formal mentoring programs is determining what specific mechanism to use for matching mentors and protégés. Research concerning actual practices within industry indicates that a variety of methods are used. In some cases, programs purposefully match partners who are similar to each other, and in other cases, partners who are dissimilar are intentionally matched. Organizations also vary in their philosophies with regard to issues such as matching mentors and protégés from different departments, geographic locations, and functional areas. Although research on this issue is needed, it is probably safe to assert that the purpose of the program should be taken into account when deciding on the matching approach to use. For example, if a program is designed to enhance the understanding of different areas of the business, matching individuals from different functional areas would likely help accomplish such goals.

Interest in formal mentoring has also resulted in research examining differences in outcomes for protégés involved in formal versus informal mentorships. Generally speaking, the research tends to show that formal mentoring relationships are less effective than informal mentorships but better than no mentoring. However, it is important to keep in mind that most formal mentoring programs are not designed with the intention that participants will achieve greater objective career outcomes, such as promotion and salary, over nonparticipants. As noted above, programs may be designed with distinct purposes such as enhancing newcomer socialization or increasing diversity awareness.

Hence, the effectiveness of formal mentoring programs might be better evaluated in terms of how well the program meets its stated objectives rather than how well informally mentored protégés compare with formally mentored protégés. It is also important for formal mentoring participants to recognize that formal mentorships are no substitute for informal mentorships. Finally, research shows that the quality of the relationship matters more than does the manner in which the relationship was initially formed. All formal mentorships are not created equally, and high-quality relationships can emerge from formal programs.

NONTRADITIONAL FORMS OF MENTORING

Although mentorships have been traditionally thought of as dyadic, face-to-face relationships with hierarchical distance between an older mentor and a younger protégé, recent research has focused on other mentorship forms. One newer approach beyond the traditional dyadic focus is viewing mentoring relationships in terms of a constellation of different developmental relationships that vary in terms of strength and diversity. The *developmental network* is made up of concurrent relationships with others that occur at a particular point in time that are important to the career development of the individual. The developers may come from a variety of settings (e.g., employing organization, professional association, religious institution), and each relationship may vary in terms of the strength of the relationship bond. Some research indicates that having multiple mentors can be beneficial beyond the effects of a single traditional or primary mentor.

Related to the developmental network perspective is the recognition that developmental support can be provided by a variety of sources. For example, in some cases, more experienced peers may be able to provide some of the same functions provided by senior members of the organization. Peers may be particularly suitable for providing support that aids in the socialization of newcomers. Moreover, given that individuals are more likely to have multiple jobs or even careers during their lifetimes because of today's boundaryless-career landscape, there is an increasing likelihood that older individuals may be organizational newcomers. This sets the stage for mentoring relationships to occur between younger mentors and older protégés.

Another nontraditional approach to mentoring is online or electronic-mentoring, or e-mentoring.

E-mentoring, also known as *virtual mentoring*, refers to the use of electronic media, such as e-mail, as the primary means of communication between mentors and protégés. In recent years, there has been a proliferation of online networks designed to facilitate virtual-mentoring relationships. One example is that of MentorNet, a program that pairs professionals working in industry and academia with women studying engineering or science at participating universities and colleges, postdoctoral students, or untenured faculty. There are several potential benefits to e-mentoring. It can help increase the pool of mentors available. This can be particularly helpful in small or rigidly structured organizations that provide limited opportunities for mentoring relationships to develop. Because e-mentoring does not occur in a face-to-face context, it can also reduce the impact of social cues or salient features, such as race and gender, that can play a part in the dynamics of a mentoring relationship. Although there are a number of potential benefits to e-mentoring, research is needed to support the effectiveness of its use.

DYADIC RESEARCH

Most mentoring research examines issues from the individual perspective of the mentor or of the protégé. An interesting new area of research examines mentor and protégé agreement with regard to mentoring provided. Research that has collected data from mentor-protégé dyads and obtained reports of mentoring provided from mentoring parties show minimal consistency across reports. That is, correlations between mentor and protégé reports of mentoring provided are typically small in magnitude. Similarly, correlations small in magnitude have been observed with regard to mentor and protégé reports of relationship quality. This suggests that mentors and protégés typically do not hold shared views of the nature of their relationships. This is important in that there appear to be benefits to shared perceptions. One study found that both protégés and mentors in mentorships with greater mentor-protégé agreement regarding psychosocial mentoring provided reported greater job satisfaction and organizational commitment than did protégés and mentors in mentorships with less agreement. Examining dyadic-level processes within mentoring relationships should be a promising new area for continued research.

MERIT-BASED PAY

Organizations often seek to link pay to a measure of performance in order to attract, motivate, and retain the best employees. The organization can link pay increases to the performance of an individual, a group, or the whole company. There are many forms of individual performance-related pay, the most

popular being *merit-based pay*, because it can be applied to many jobs and covers a broad range of performance criteria. Under a merit-based pay system, an employee's pay increase is based on a supervisor's assessment of performance over a previous time period, usually the prior 12 months. Reward for past performance is intended to increase performance in future time periods. Pay increases made under a merit-based pay system accumulate in base pay, so that subsequent increases build on the increase of the previous year. In some organizations, the merit-based pay system is the only means for achieving a pay increase. It also serves as the mechanism for moving employees through the pay range for the job.

The annual cycle of a merit-based pay scheme commences with the establishment of performance objectives, either by the supervisor or jointly between the employee and the supervisor. Progress toward these objectives is monitored over the ensuing months, although the formal rating of the employee usually occurs at the end of the evaluation cycle. The supervisor is required to rate the performance of an employee against the objectives established at the beginning of the cycle, typically on a three-, five-, or seven-point scale. Each of these rating points is then associated with the amount of a pay increase (usually expressed as a percentage), so that the higher the rating, the higher the amount of the merit-based pay increase. The size of the pay increase can also vary depending on the position in the pay range. Typically, employees at the bottom of the pay range with high performance ratings will get a larger increase than an employee near the top of the pay range with a high-performance rating. In some cases, the intention is to enable the employee to reach the top of pay range at the same time as he or she is ready to be promoted (and therefore eligible for further merit-based increases).

The magnitude of the merit increases will also be a function of the merit-pay budget made available by the organization, which reflects not only the financial circumstances of the organization but also their view of how much of a merit-pay increase is necessary to affect employee behaviors. There has been some research that has attempted to determine this "optimal" amount, though there is no agreement on the quantum. A further difficulty is that merit-based pay is not supported by all employees. Past research has demonstrated that merit-based pay is attractive to some occupations (for example managers) and to certain demographic groups (such as white-collar

workers, high-income earners, and younger employees), but it might not be the best remuneration approach for all occupations, individuals, or organizations.

METAPHORS FOR CAREERS

When people talk, or even think, about careers, they typically use metaphors. A *metaphor* is a figure of speech in which one concept, usually a relatively abstract one, is substituted by another, usually more concrete, to provide clarity and dramatic effect. Thus, Nelson Mandela did not title his autobiography *My Career* or *My Life*, but *Long Walk to Freedom*. In this metaphor, his career becomes a journey, on foot, to a known destination. The metaphor gives clarity, additional meaning, and color to the subject matter.

In their career discourses, people employ metaphors frequently. Many of these are variations on the journey metaphor: for example, *career path*, *career trajectory*, *career plateau*, *career ladder*, *fast track*, *rat race*, *getting to the top*, *zigzag career*, *roller-coaster ride*. All of these attribute "journeylike" characteristics such as movement and direction to the career, and some of them provide cues as to the kind of career that one should have (moving upward, fast, in competition with others, etc.). Career talk is not confined to journey metaphors, however. There are many different associations that people habitually employ when talking about their careers. Each of these metaphors reveals particular truths, and by considering each one in turn, we can develop a multifaceted

view taking us closer to understanding some total truth about careers.

The focus here is on (a) the influence of metaphor, not just on language, but on ways of thinking about careers; (b) the strengths and weaknesses of the metaphor as a means of understanding and gaining insight about careers; (c) the metaphors and their implications most frequently employed in discourse about career; (d) the recent development of new metaphors in response to new characteristics of the career environment; and (e) the use of metaphor in career practice.

METAPHOR: A WAY OF THINKING

A metaphor is not just a "figure of speech." Scholars of the relationship of language to thought advise us that metaphor is more than an affectation, more than a smart way of talking, and more than a means of persuasion: It is a representation of how we think. Consider the metaphorical implications of the common career-related phrases, *wrong side of the tracks*, *silver spoon in his mouth*, *story of my life*, *self-made man*, *playing a part*, *square peg in a round hole*, *loyal company servant*. Each phrase depends on the literal meaning of the words that constitute it but also conveys more than that literal meaning. People's metaphors embody and betray their internal images of the world around them. Using metaphors in our speech, we influence others to share our pictures of the world, and by listening to others' metaphors, we modify our own internal images and develop new ones. While some might worry that metaphors are inherently deceptive—Nelson Mandela did not literally *walk* to freedom—they are apparently inevitable. If that is the case, it is important to understand both the strengths and limitations of metaphors.

STRENGTHS AND WEAKNESSES OF METAPHORS

One strength of the metaphor as a tool of thinking and talking is its ability to represent difficult abstract concepts by means of clear, familiar, often concrete, parallels. People find it easier and more interesting to work with such images.

Another advantage is that metaphors, particularly novel ones, can enable us to gain new insights and to use these to solve problems. Generating multiple metaphors for the same phenomenon may enable people to see things in a new light and thereby act innovatively to solve career problems.

The advantages of the metaphor can be observed in the common representation of the career as a journey. Most people can identify in their own lives career associations with travel-related phenomena such as planning the trip ahead, having a smooth or bumpy ride, making choices of direction, trying to keep up a good pace, overcoming obstacles, losing momentum, getting stuck, going astray, and reaching a destination. Recognizing the parallels between physical journeys and career journeys may therefore bring fresh insight. On the other hand, excessive and dramatic focus on the career as a journey might inhibit alternative potentially helpful images. Much imagery relating to careers, such as fast track, rat race, winners, getting to the top, and so on, constitutes a rhetoric of progression, competition, and pressure that may fairly represent some careers but make unwarranted assumptions about many others. A metaphor can be used not just to assist comprehension and to extend vision but also to persuade and politicize.

Seldom is a metaphor a complete and perfect representation of the concept that it stands for: Carried to their logical conclusion, most metaphors eventually break down. But metaphors should be judged not just by how accurately they appear to describe the reality they are supposed to represent but also by the extent to which they facilitate productive and new thinking. For those seeking to understand their own careers or careers in general, the method of multiple metaphor is recommended: Each new metaphor enables complementary layers of understanding and meaning to be added, until a more complete and balanced understanding of the phenomenon is reached.

PREDOMINANT CAREER METAPHORS

A number of major metaphors for careers have special significance in career studies. Most likely, they represent generic ways of thinking about careers both by theorists who frame their concepts of career through them and laypeople grappling with their own careers.

For example, much theorizing on the sociology of occupations and careers is based on an inherent metaphor of the career as an *inheritance*. This metaphor reminds us how much of our career behavior and success is predetermined by characteristics such as gender, social class, education, and genetically inherited abilities. Understanding careers in this way might lead career actors to accept the status quo

and the inequality it may entail or to attempt to improve people's career chances by altering the social structure or protecting "disinherited" individuals from it—rather than by empowering people to overcome their inherited handicaps through proactive behavior.

Another common way of considering careers is as a *cycle* or cycles. This metaphor tells us about cyclic stages and transitions that careers typically go through in sequence. The cyclic metaphor *the seasons of a life*, for example, provides the message that careers take place in inevitable stages that are uniform across different individuals. Acceptance of this metaphor might lead individuals to plan their careers carefully in light of their expectations that their priorities and career issues will change (predictably) as they age. However, it might also handicap them under conditions in which either unpredicted changes in their own experiences (for example, seeking to leave an established occupation and "start again") or radical change in the environment (for example, organizational failure leading to layoff) have disrupted the expected cycle. A cycle metaphor emphasizing that the career is not a single cycle but a sequence of transition cycles between employment experiences might provide a more flexible outlook.

The metaphor of the career as *action* or *construction* adds to both of the above by emphasizing the power that individuals may exercise over their careers as they create them through proactive action and "construct" them cumulatively in their own ways, regardless of the constraints of either inheritance or sequence in the cycle. Individuals who hold this model of career might emphasize the planned development of their careers through the careful, self-directed construction of new experiences and achievements on the basis of what has gone before. A variant metaphor, careers as *jazz*, proposes that careers, rather than being preplanned, are actively improvised around particular themes in response to changing conditions.

The *fit* metaphor sees the career as resulting from an interaction between the individual and the work environment aimed at achieving a good match between the two. An individual with an implicit fit model of career might become preoccupied with understanding both himself or herself as well as the environment of work within which a good fit must be found and maintained as the career progresses. Indeed, this metaphor appears to underpin much of the work of those in the career development and guidance movement who are concerned with providing

clients with good self-measurement devices and advice on “adjustment.”

The *resource* metaphor emphasizes the career as a repository of the person’s accumulating energy, talents, and skills that can be utilized in combination with other resources in the efficient production of goods and services. The career management theories developed in business schools and the human resource management and organizational commitment-building practices of many business organizations implicitly adopt this metaphor, seeking to engage the career resource productively. This may be accomplished through the encouragement of “organizational careers” in which the individual’s resources are developed and his or her progression in the organization is planned and implemented according to operational and strategic company requirements, yet in a way that utilizes human potential and provides individual fulfillment. This very common metaphor raises interesting issues about the ownership of the resources embodied in a person’s career and about the long-term mutuality of interests between people and their employers. Whatever the benefits to organizations, individuals who consider their careers to be company resources may gain benefits (e.g., pensions) from reciprocal company patronage but risk overdependence on the sole controller of the resource. On the other hand, conceptualizing one’s career as an accumulating repository of knowledge and consciously building the resource as a form of tradable “career capital” may be a smart career strategy.

As mentioned, the *journey* metaphor for careers is the most common of all in public use and emphasizes that careers involve movement toward destinations that sometimes emerge only as the journey proceeds. The metaphor’s main strength—and weakness—is its wide applicability. There are so many different kinds of journeys (short-long, fast-slow, planned-unplanned, upward-downward) that career experiences might be hard to find that do not have convincing “journey” parallels. This perhaps makes the journey metaphor conventional and commonplace, but at the same time, it creates a common imagery for discussion about careers and may, for example, enable counselors to assist their clients to find new forms of travel imagery (e.g., “So, your vehicle has broken down on the road. Could you jump-start it? Could you get out of the vehicle and explore the surrounding country?”)

As indicated earlier, one criticism of the journey metaphor is that its associated imagery often appears

preoccupied with vertical movement, such as climbing ladders and getting to the top. This possibly idealizes hierarchical journey making to an extent that alternative models, such as horizontal movement, free movement, and nonmovement, appear to be stigmatized. In that respect, the recent recognition of the validity of “downshifting” is to be welcomed.

NEW CAREER METAPHORS

Recent changes in structures of employment opportunities, particularly for organizational restructuring, downsizing, and outsourcing, and the rise of contingent forms of work have apparently led to changes in the typical forms of careers and their general destabilization. This has created a need for new metaphors to represent new career realities.

Two important metaphors developed by theorists are the *protean career* and the *boundaryless career*. The protean career is based on Proteus, a character from Greek mythology who could change shape at will; it represents the notion of career as being self-directed by the individual based on a strong inner identity plus the adaptability to be able to make good career changes in a rapidly changing environment. The boundaryless career crosses boundaries and barriers, for example, between organizations, occupations, and industries, enabling the individual to keep his or her career essentially independent of external control. The boundaryless career is based also on a “boundaryless attitude” by the individual. The shape-changing and boundary-crossing virtues inherent in these metaphors make them attractive as idealized formulae for career development in a changing society, but if pushed too far, they may appear intolerant of alternative models (for example, those whose under-privilege prevents them from being self-directed or mobile).

Another increasingly common career metaphor, driven by the development of postmodern approaches to social science and the recognition that careers may be socially constructed rather than having objective reality, is of the career as a *narrative* or *story*. The storylike characteristics of most accounts of careers is striking, whether they are individual monologues, vitae, material elicited by counselors, or barroom boasting—as are differences of “fact” and emphasis in accounts of the same career given by different individuals or by the same individual to different audiences and for different purposes. Talking about one’s

career as a constantly developing and changing story may enable individual adjustment, rationalization, and perhaps even sublimation in fantasy and self-mythologizing. For this reason, there is an increasing recognition of the potential of narrative approaches to career guidance.

METAPHOR AND CAREER PRACTICE

It is likely that the interactions of career guidance counselors and their clients are characterized by much metaphorical discourse indicating interesting built-in career models. However, so far this remains unresearched. The material in question is not confined to generic models of career. Often a client will use a metaphor to describe a momentary part of the career, for example, "I'm in a rut" or "I want to fly." Can these spontaneous metaphors be utilized by the counselor to facilitate the client's development? Some progress has been made on the deliberate utilization of metaphor as part of the guidance process. One question is whether the process should always be based on the metaphors spontaneously used by the client or whether it is legitimate for a counselor to attempt to stimulate a client's thinking by providing a new metaphor for the client to consider.

Another imposition of metaphor in career practice comes in the publication of metaphor-based "self-help" books urging the reader to "Reinvent yourself," "Be a brand," "Become Supermom," "Pack your own parachute," and so on. The attractiveness and popularity of such books is a testament to the power and rhetoric of metaphor, but a single powerful metaphor may constrain one's breadth of thought. Readers of such books need to think through the validity and limitations of the metaphor carefully and to consider how it might be supplemented by others.

CONCLUSION

Career metaphors are more ubiquitous and powerful than most people realize. Those interested in careers need to surface and explore their own characteristic metaphors. They may benefit, too, from giving thought to alternative metaphors and being creative about generating possible new metaphors.

MIDDLE CAREER STAGE

Early career theorists studied careers as a linear progression that generally corresponds to a person's life span. They focused primarily on men who worked for one or two organizations, with a ladder of opportunities for promotion. In a typical career, the *middle career stage* is the point at which an individual attains a level of successful accomplishment recognized by both oneself and one's peers. This usually occurs approximately at middle age.

According to careers researcher Douglas T. Hall, the middle career stage may occur at different times depending on a person's pattern of entering and leaving work situations as well as when he or she experiences various work events. Although the middle career stage may be referred to as *midcareer*, *midlife*, and *midworklife*, they are not the same. Hall defines midcareer as a subjective experience of attaining a level of achievement and establishing an occupational or career role. However, if a person changes careers several times or has a sporadic work history due to, for example, the need to care for children, then what we consider the point of a middle career may occur

several times, before and after middle age (i.e., midlife). A person with a job or occupation rather than a career might experience midworklife earlier than the accepted age 40 midlife point. For example, men in industrial jobs showed an earnings peak at age 35. According to John C. Rife, women often show a different work pattern than men; they are more likely to have a more sporadic work history, to work part-time, and remain in the workforce longer. A woman might not embark on a career until a much later age than the average man and thus would attain a middle career stage in a later age range.

Furthermore, it would be difficult to define a middle career for these less-than-linear career engagements. More recent research acknowledges the similarities and differences between careers of men and women and those who make several career changes. These changes may be due to individual choice, such as a woman or man who returns to school to train in a new field or stays out of the workplace to care for family members. Career changes may also be precipitated by circumstances such as downsizing and economic downturns. The idea that careers evolve throughout a lifetime in a series of stages has received much attention and produced an enduring framework.

STAGE THEORISTS: PSYCHOLOGICAL APPROACHES AND THE MIDDLE CAREER STAGE

Stage theorists take a life course approach. They evaluate an individual life across time, which they then aggregate to discern patterns. One of the most well-known theories of career stages was developed by Donald E. Super. He proposed four career stages. In the first stage, *exploration* (teen years to 20s), individuals engage in self-examination and preparation for a career. During the second stage, *establishment* (late 20s to mid- to late 30s), a person finds employment and works to be a successful contributor to the organization. During the third stage of *maintenance* (late 30s to mid-40s), a person maximizes his or her capabilities and may be a mentor to others. The maintenance stage may be considered the middle career stage. Some people in this stage continue to grow in their careers; others reach career plateaus; while still others stagnate if they fail to learn new job skills and remain professionally active. The fourth stage is *disengagement*, in which the individual may leave the organization to find personal fulfillment outside of a

career. Super later identified a *recycling phase*, in which individuals may change career paths.

Building on his stage model, Super developed the Life-Career Rainbow, a “life-space, life-span approach.” He identified the early 30s and late 40s as the period in which one allocates the most time and effort to the worker life role. Thus, the middle career stage would be the point at which one attains a clear level of competence and devotes the most life space to career issues.

The stages identified by Super were also supported by the work of Daniel Levinson. Levinson studied men in a variety of occupations (e.g., hourly workers, business executives, biologists and novelists) to discern developmental periods of stability and transitions that correspond to age. Using the “life structure” of self, family, affiliations, career, and community, he observed the following: an Early Adult Transition from age 17 to 22; the era of Early Adulthood, spanning age 17 to 45, with an Age 30 Transition commencing between age 28 and 32 and concluding between age 33 and 40; the Era of Middle Adulthood, from age 40 to 65, with a Midlife Transition somewhere between age 40 and 45 and another transition between age 50 and 55; and the Era of Late Adulthood, commencing at age 60.

The Transition periods involve a reassessment of the life structure with a special focus on work and family. Specifically, the Age 30 Transition involves the man identifying the benchmarks of success—a ladder of accomplishments—and creating a strategy to attain them. If the man determines that his life structure is not satisfying, he may be prompted to change jobs. During this stage, the man reaches for his dreams; he desires to win and gain recognition. Whether one changes an occupation or not, the Age 30 Transition sets the stage for the Age 40 Transition. During the latter transition, the man reviews his past and prepares for the future. At this point in his life, he becomes more concerned with his own internal markers of success than with approval from others. He is more concerned with using power to lead and help others, forming a legacy, and having more caring relationships.

Thus, in Levinson’s framework, the middle career stage occurs at the end of early adulthood (age 33-40), when the man has devoted much of his energies to establishing himself in his chosen occupation with associated markers of success. The individual is more likely to attain a balance between internal and external markers of success through the process of the

Midlife Transition (age 40-45). Although commonly associated with a "midlife crisis" of disillusionment with one's life structure, especially career status, the Midlife Transition may also be a time of flexibility, creativity, and developing new goals and aspects of the self. A person perhaps shuns externally driven rewards, choosing those he prefers; he takes delight in the intrinsic rewards of his career. He is in a position to make positive organizational changes, mentor others, and decide the terms of his attachment to his career as an independent person. He assesses his legacy as the value of his life that he leaves to subsequent generations.

Levinson's later work included women, and he found that similar eras of stability and transition exist for both men and women. The homemakers, businesswomen, and academics he studied also experienced Midlife Transitions. Some women found that their "careers" as homemakers, wives, and mothers did not contribute to their self-development. They faced the work world with fewer resources at an older age. However, some homemakers were able to turn to occupations for new avenues of personal satisfaction. They were able to dedicate themselves to work pursuits as the demands of home and family decreased and became less preferable. In contrast, career women experienced more conflict among their dreams of being the "successful career woman," "antitraditional figure," and "traditional homemaker figure." They entered the Midlife Transition with the realization of the difficulty of having a career, a marriage, and a family.

Both men and women engaged in career change by moving from external rewards, such as promotions and salary, to examining internal gauges of success. The successful respondents realized that they had attained success in one area but were starting at the bottom of a new area in the MidLife Transition. Almost all the women studied by Levinson changed their life structures during this transition, especially when they realized the deleterious impact of gender discrimination. A longitudinal study of MBA men and women by Joy A. Schmeer and Frieda Reitman supports this idea. Schmeer and Reitman found that although there were no gender differences in early careers, by midcareer, women had experienced lower levels of satisfaction, difficulty in progressing in their careers, being unappreciated by their managers, and gender discrimination.

Stages are useful in understanding individual career choices and attitudes, especially in occupations

with clear career paths. For instance, Susan A. Lynn, Le Thi Cao, and Betty C. Horn studied male and female accounting professionals at different career stages. They defined these stages by professional tenure (years in the accounting profession since college graduation, with 10 years considered the maintenance or middle career stage for the profession). Professional tenure was significantly related to intrinsic and extrinsic reward satisfaction, job involvement, and organizational commitment and negatively associated with intention to leave for the men, but not for the women, in this sample. A study by Rajiv Mehta, Rolph E. Anderson, and Alan J. Dubinsky examined the effect of career stage in sales managers, also considering tenure to measure career stage. Middle stage was considered to be the period of working in the field for 8 to 15 years. Reward preferences varied with career stage. Middle stage sales managers ranked the attitudes of superiors toward them as being the highest preference (compared with those in early and late career stages), followed by salary and commission bonus, achievement of market goals, respect of fellow salespeople, and opportunities for promotion. Significant differences were found between middle stage managers and late stage managers in achievement of market goals and middle stage and early stages managers in opportunities for promotion and earning the respect of salespeople. David A. Jepsen and Hung-Bin Sheu, using a sample of working-class adults, found that midcareer status predicted job satisfaction for men, but not for women. Thus, an organization may be better able to establish rewards, set policies, manage employees, develop leaders, and understand employee career decisions if managers examine how preferences and attitudes may vary by career stage and the interaction of stage and gender.

Although these stage models are intuitively appealing and are based on longitudinal in-depth studies, they may not apply to individuals who do not fit the traditional career model of working for one or two employers in a stable environment of promotion opportunities (i.e., career ladders). Careers scholar Edgar H. Schein proposed a career cycle that encompasses both an internal and external career regardless of career opportunities or type of work. The external career reflects the characteristics of work itself, such as opportunities and limits. Although still perceived by the individual, it provides markers that influence the internal career assessment, which is the individual's subjective ideas of a career and one's role in it.

Schein recommended that aspects of career development be viewed as a series of issues or tasks irrespective of age or life stage. In his framework, an individual enters the work world and receives training between the age of 16 and 25. An individual attains full membership in an early career anywhere between age 17 and 30. Schein identified full membership in a career or midcareer from age 25 on. In this middle career stage, the major issues for the person to consider are choosing between being a generalist or specialist, retaining skills through learning, developing visibility, becoming more responsible for work tasks and managing others, being productive, and formulating a long-range career plan. At this point, a person is also gaining independence, developing personal standards, and forming a clearer self-assessment and the ability to evaluate opportunities. He or she is also becoming a mentor and seeking family/work balance. From age 35 to 45, a possible midcareer crisis has the individual seriously reassessing attainments versus goals to determine whether to change careers, keep the status quo, or move ahead. He or she also considers desired versus actual outcomes, examines the weight of a career in life, and becomes a mentor to others. This middle stage also includes a realistic appraisal of economic and family needs as well as how to maintain skill competencies.

Schein acknowledged that people move through these stages at different rates and that personal and family factors also play a role in career decisions. In illustration, Dawn S. Carlson and Denise M. Rotondo examined MBA graduates to determine whether there was a difference between external and internal careers in terms of promotion stress. They found no difference in career stress based on internal career stage, but did find that early external career individuals showed the highest levels of promotion stress, followed by midlevel career stage. The higher career stages showed lower levels of promotion stress.

Despite the appeal and research findings of the stage theorists, we need to look beyond their assumptions of organizational stability and job security to understand careers in contemporary work life. In our present-day work environment, organizations are under continual pressure to change and adapt to their environments. Similarly, individuals employed in organizations as well as those outside of them face the need to change with their environment to have a meaningful connection to work. The learning, experience, and motivation that brought a person to the

middle stage of a career path will help the person navigate career and personal change as well as develop innovations and new business ideas. Sally J. Power and Teresa J. Rothausen observed that when an individual scans the external environment for work information, it indicates a readiness for midcareer development. Power and Rothausen extended our knowledge of the midcareer or maintenance stage by proposing a middle-career development structure in which individuals consider work in a broader context, rather than as a specific job; engage in continuous learning to avoid obsolescence by surveying the environment to determine the future requirements of their work; and analyze their organizational roles to make lifestyle decisions, such as how to maintain their skill value to their present employer while remaining marketable. Using these three concepts, they identify three levels of midcareer development with developmental tasks and cycles.

According to Power and Rothausen, the first level of midcareer development is *job oriented*, in which the person is dependent on the employer and reactive, an early midcareer situation. Most people at midcareer who work for large organizations are probably at this stage. They either cannot or do not realize that the need for organizational adaptation may influence their future employability. The second level is *work maintenance*, in which a person has attained job satisfaction and internal and external rewards but is cognizant of the need to become a lifelong learner to remain marketable. An example of this is a person who has good “people skills” but may need to learn the more commonly used software applications. The third level is *work growth development*, in which a person proactively fashions growth and learning opportunities to satisfy new internal and external rewards as part of a long-term career development plan. This would involve self-assessment, retraining, and changing the organization-person role agreement.

ALTERNATIVES TO STAGE APPROACHES: AN ARRAY OF CAREER PATTERNS

Whereas traditional stage theorists assume a long-term career within the same stable organizational environment, with development of organizational-specific skills to climb the hierarchy and career decisions made more likely by the organization (or at least in tandem with the individual), other theories consider less linear paths and emphasize the need for the

individual to take control of his or her career. Kenneth R. Brousseau, Michael J. Driver, Kristina Eneroth, and Rikard Larsson described a multiple-career concept model. In addition to the “traditional” linear career, they explain an *expert career*, in which there is little movement and one stays in one career for life; a *spiral career*, in which a person moves into different careers every 7 to 10 years; and a *transitory career*, in which a person changes jobs every 3 to 5 years, usually in unrelated areas.

Experts such as self-employed health care professionals, lawyers, and skilled craftspersons with their own businesses may experience midcareer analyses differently than does the traditional organizationally employed person. Little is known about the expert career pattern because we have only just begun to study these types of work situations. Because experts are motivated to continually develop professional competency, it may be that these individuals seldom experience a middle stage or midcareer reevaluation. In contrast, a person with a spiral career pattern may have several midcareer experiences at different points within each career experience. While those with a spiral career pattern are motivated by developing new knowledge and skills that enhance personal development and creativity, these individuals move every three to five years to unrelated areas, in search of variety and independence. Similarly, those with transitory careers may have midcareer evaluations at different points in each career experience, or they may not even experience midcareer reevaluations because they move on to the next exhilarating experience once they start feeling bored.

Contemporary organizations are more likely to include the expert, spiral, and transitory career patterns. Firms need to build their human capital while considering these nontraditional patterns, using strategies including contracts for long- and short-term assignments; career development, training, counseling, and cafeteria-type rewards and benefits tailored to different trajectories and patterns; engagement of workers in forthright discussions and strategy-building sessions; and mentoring across career patterns not only to meet organizational and individual needs but also to sustain motivation, as a person may move through several midcareer issues.

BOUNDARYLESS AND PROTEAN CAREERS

In response to the “new economy” and accompanying organizational changes, Michael A. Arthur and

Denise Rousseau have proposed that a career is now the converse of the organizational career in terms of individual independence from organizational employment. This unbounded state can be determined by moves across employers, organizational levels, functional areas, occupations, or industries; validation by the market; reliance on external networks; emphasis on personal reasons over organizational imperatives; or the individual’s perception of himself or herself as unbounded. In these circumstances, an individual may adopt any of Brousseau and colleagues’ career concepts described earlier and become the architect of his or her own career. This shifts more of the focus from external career success indicators to the internal markers.

In the boundaryless career setting, the individual would be determining midcareer attainment in terms of skill proficiency and marketability. Instead of an organization, the market and the inner self provide feedback as to career status and success. For example, boundaryless careerists such as filmmakers, consultants, and self-employed skilled craftspersons often start out working as an apprentice, develop a reputation, engage in networking, gain work based on referrals, work on different projects with various clients, and decide when and where to work. These individuals gain knowledge and skills as they move from project to project and can use their career capital when they desire new career challenges. We have all read about successful actresses who switch to directing or entertainers who use their visibility to highlight social issues.

A similar reliance on internal indicators of success is found in the “protean careerist,” a term identified by Hall. Although related, the protean career is conceptually distinct from the boundaryless career. Like the middle-career psychosocial development issues described by Super, Levinson, Schein, and Brousseau, Hall described a career driven by an “internal compass” of satisfying internal rewards. Protean careerists are in charge of their careers; seek growth, mobility, and psychological success; and are committed to a profession while maintaining balance with other life issues. The protean careerist seeks continuous learning, is open to exploration and change, and engages in learning cycles that constitute a career.

CONCLUSION

An individual in the middle stage of his or her career has developed an array of knowledge, skills, abilities, and experiences and recognized accomplishments in a

chosen career or occupational area. Middle careerists are repositories of organizational learning, mentors, and present and future leaders in and out of organizations. They function as change agents in the work environment. However, if the middle career stage does not reflect desired accomplishments, it may be associated with demotivated or plateaued workers, the loss of talent, and psychological distress and despair, all of which impact individual and economic development. We need to recognize that individuals in and out of organizations may have diverse middle-career experiences at different ages. These experiences may also vary with occupation and with individual factors, such as gender, interests, and abilities. Given the importance of work to self-esteem, social standing, and perceived success in our society, we need to examine ways to maintain the psychological satisfaction, creativity, productivity, skills, and experiences of people in the middle stages of their careers.

MIDLIFE CRISIS

The term *midlife crisis*, or *midlife transition*, is generally defined as a period in an adult's life, believed to occur at or around the age of 40, in which there is a reappraisal of life's accomplishments, a more poignant recognition of health issues and ultimate mortality, and the potential for a change in lifestyle or behaviors. "Midlife crisis" is instantly recognized in the United States and increasingly in other Western nations. The recognition is most likely due to its prominent use in novels, movies, art, and advertising. People tend to use the term negatively, associating it with stereotypes about physical aging, career stagnation, and midlife marital boredom. The term is also most often associated with men's experiences, although recent research on popular beliefs about the term suggests that some women also believe that they have experienced midlife crises. In the United States, therapists, popular writers, and people outside the academic and therapeutic professions connect the midlife crisis to the strong cultural expectation that a successful and self-fulfilling work career is central to achieving success in life. The assumption is that if by age 40, career growth and development has stagnated, men (and increasingly women) will experience crises.

Although there is some evidence that age 40 held special cultural significance before the twentieth

century, the term midlife crisis is a recent creation first introduced in 1965 by Elliott Jaques. In his article "Death and the Midlife Crisis," Jaques argued that there is a critical stage of development among creative male artists in their late 30s, taking three forms: the cessation of creative activities, a marked change in the quantity or quality of the creative output, or death. The term crossed quite rapidly into popular usage, applied well beyond the original sample of observation.

Another major milestone was the work of Daniel Levinson and his colleagues. Their work *Seasons of a Man's Life* described a stage theory of adult development that gave prominent play to crises associated with transitions between key decades in life, including the transition into full middle age around age 35 to 40. Predictable stages of adulthood and throughout midlife were also popularized by Gail Sheehy in the book *Passages*.

The aging of the baby boom generation into midlife has brought the concept of midlife crisis to the fore in popular culture. It is important to note that scientific studies of emotional well-being at midlife have never established the midlife crisis as a universal or expectable stage of life in the general population. In fact, the scientific literature tends to reject the idea. There is also considerable scientific skepticism as to whether the traditional definition of the midlife crisis applies to middle-aged people at the beginning of the twenty-first century. Some researchers, such as O. G. Brim and David Chiriboga, have argued that the concept may never have been an accurate description of the expectable course of midlife development. Marjorie Lachman found that the midlife crisis was reported by those who had life histories characterized by serious life events and adjustment disorders. Stanley Rosenberg has recently observed that it is more useful to think of the midlife crisis as an "ideal type" concept that has evolved into a popular myth and a staple of literary treatments of midlife. In sum, the influence of the midlife crisis in the scientific literature on adult development was relatively brief; already in the 1970s, researchers such as George Vaillant had published studies challenging the idea that midlife crises were expectable crises of life or universally experienced. The concept itself has psychiatric and therapeutic roots, and thus it was probably predictable that scientific skepticism would emerge.

Three major social trends now also tend to undercut the idea of a predictable midlife crisis connected with careers. First, the years that are popularly

believed to constitute midlife have shifted upward and have extended further as longevity has increased. People believe that midlife begins at age 40, rather than age 30. Second, many more women are pursuing careers. Jaques theorized that the midlife transition would be "obscured" in women because of the timing of menopause. Women's mixed-life paths, with child-bearing interruptions, have transformed what midlife (and midcareer) looks like for the average American woman: midcareer may be in the 40s for a man, but in the 50s for a woman who invests in her work career after having children or has her children in her 30s, interrupting early career progress. Third, the idea of a lifetime career is disappearing as well. How does a crisis involving boredom or stagnation in a "career job" apply to workers who are necessarily switching companies, careers, and work opportunities several times throughout their adult lives?

Another related issue is a theoretical one: Developmental stage theories of adult development have fallen into disfavor in both psychology and sociology. Major new works on the midlife in the United States, such as the recent work supported by the MacArthur Foundation Research Network on Successful Aging (*How Healthy Are We? A National Study of Well-being at Midlife*) call the expectation of a midlife crisis into serious question. This edited volume suggests that midlife and midcareer are increasingly diverse among Americans—and that most Americans in the 1990s experienced midlife positively rather than negatively. Thus, a "crisis" model seems outdated, as researchers develop models of midlife that emphasize process, diversity, adaptation, and the effective use of accumulated resources to solve problems rather than lockstep progression through universal stages.

Because scientific research on the midlife crisis is scarce, lay definitions rule the day. Lay definitions are inherently elastic. Recent studies of midlife and attitudes toward midlife by Stanley Rosenberg and by Elaine Wethington have found that the general public defines the midlife crisis broadly: as a period of reevaluation or regret sometime in middle age. This is evidenced by Wethington's recent study of American use of the term *midlife crisis*, conducted for the previously mentioned MacArthur Foundation research network. In general, the study found that people used the term as a way to explain the meaning of severe life events in their lives. People reported a fair degree of uncertainty about what the term actually meant; it was

common for a respondent to ask the interviewer whether a recent life event "counted" as a midlife crisis. Equal proportions of women and men reported that they believed they had experienced midlife crises. Almost half of the self-reported crises were situations that occurred before or after the age range of 39 to 54. The types of events that were nominated as midlife crises were those that prompted a reevaluation of life priorities; however, there was no evidence that this type of reevaluation was distinguishable from the types people make at other points in the life span. Echoing Rosenberg, the popular use of the term midlife crisis is more accurately described as the appraisal people give to crises that happen to occur to them when they are in their 40s and 50s.

Does the term midlife crisis hold any future relevance for the career literature? Rosenberg makes a valid point that the term gives meaning to career and other changes in midlife. Thus, it serves as a useful heuristic for everyday people describing the meaning and impact of severe life events or career transitions. Yet the outlook for the term will probably be more mixed in the scientific literature on career development. Current scientific research embraces a process-and-continuity view of adult development through changing circumstances in adulthood. Why maintain a concept that paints a very negative view of midlife, when the reality is that at midlife, people are at the peak of their capacities to master problems in their lives?

MINNESOTA CLERICAL TEST

The *Minnesota Clerical Test* (MCT) first was published under the title of the Minnesota Vocational Test for Clerical Workers in 1933 for use in the selection of clerical personnel and to provide career guidance information. The instrument has remained unchanged since its first publication.

The MCT is a brief test, taking 15 minutes to complete. The test itself comprises two parts that measure numerical and verbal acuity. These skills are assessed by asking respondents to identify identical pairs of numbers or words. The two sections, Numerical Comparison and Name Comparison, yield separate scores calculated by adding up the number of correctly identified same pairs minus any pairs incorrectly marked as similar or similar pairs that are not marked. For each section, the maximum raw score possible is 200.

The most recent MCT manual, published in 1979, provides updated information on the instrument's reliability and validity. Information on the test-retest reliability of the MCT is provided on a sample of female business school students at both a northeastern university and a midwestern university. The test-retest reliability of the Numerical Comparison section, with four days between test sessions, was .81 for the northeastern sample and .83 for the midwestern sample. For the Name Comparison section, the test-retest reliability was .86 and .87 for the northwestern and midwestern samples, respectively. Evidence of reliability for the MCT also shows stability in scores over long periods of time. The manual provides data on bank bookkeeping machine operators and two samples of clerks, who were retested during a span of 8 to 54 months. Correlations between the first and second testing ranged from .56 to .69 for Numerical Comparison and .62 to .81 for Name Comparison.

The two parts of the MCT have been shown to be highly correlated. For male and female samples of

mixed ethnicity, correlations between the Numerical and Name sections ranged from .58 to .73. The samples included students, job applicants for clerical positions, and experienced clerical workers.

Data supporting the validity of the MCT also are provided in the manual. For example, scores on the MCT for samples of employed clerks and secretarial and business students were correlated with a variety of other clerical tests for verbal and numerical ability. Correlations between verbal tests and the MCT Name section ranged from .36 to .52. Correlations ranged from .38 to .59 between numerical tests and the MCT Numerical section.

The MCT has been used in research and selection procedures. For example, reports have been published using the MCT as a predictor of job performance and clerical task performance. The MCT also has been used in employee selection. Last, research on the MCT has focused on creating norm comparison groups, and research also has focused on practice effects.

MINNESOTA MULTIPHASIC PERSONALITY INVENTORY-2 (MMPI-2)

The *Minnesota Multiphasic Personality Inventory-2* (MMPI-2) is a 567-item, true-or-false measure of personality and psychological symptoms. It can be administered individually or in a group format, via booklet or on a computer. It requires roughly a sixth-grade reading level. Audiocassette versions are available for individuals with reading difficulties, vision

problems, or physical disabilities that affect their abilities to manipulate the test materials. It is intended for individuals age 18 or older; an adolescent form (the MMPI-A) is available for individuals between the age of 14 and 18. Under standard conditions, the MMPI-2 requires approximately 60 to 90 minutes to complete. It can be scored by hand, optical scanner, or computer processing. Computer-based interpretations of the results are available as well. Nonetheless, MMPI-2 results should be interpreted only by individuals who are thoroughly trained in test theory, personality, psychopathology, and psychodiagnosis.

DEVELOPMENT OF THE MMPI

The original version of the instrument, the MMPI, was published in 1943. It had been developed at the University of Minnesota by psychologist Starke Hathaway and psychiatrist J. Charnley McKinley to aid in the diagnostic screening of clinic patients. The original items were selected for the inventory because they discriminated statistically between psychiatric patients and individuals without identified psychiatric problems. This method of test construction, known as *empirical keying*, reduced the subjectivity of the interpretation of the test results.

Initially, the inventory included eight clinical scales, which measured psychoneurotic concern with bodily health (Hypochondriasis, now known as Scale 1); symptomatic depression (Depression, Scale 2); conversion hysteria (Hysteria, Scale 3); antisocial tendencies and psychopathic behavior (Psychopathic Deviate, Scale 4); suspiciousness and mistrust (Paranoia, Scale 6); anxiety with obsessive and compulsive features (Psychasthenia, Scale 7); symptoms of the four recognized subtypes of schizophrenia (Schizophrenia, Scale 8); and the tendency to act in euphoric and hyperactive ways (Hypomania, Scale 9). Two more scales were later developed from the items, at the time being intended to measure "male sexual inversion" or homosexuality (Masculinity-Femininity, Scale 5) and social introversion-extroversion (Social Introversion, Scale 0).

In addition, four scales were created to evaluate the validity of the test taker's report: Cannot Say (?), to track the number of items that were omitted or to which both true and false were answered; Lie (L), to detect unsophisticated attempts to portray oneself overly favorably; Infrequency (F), to reflect item responses that deviated from typical ones; and Correction (K), to

measure clinical defensiveness. The K scale was later used to weight scores on Scales 1, 4, 7, 8, and 9, which were thought to be most susceptible to underestimation in the context of a defensive test-taking approach. Evaluating the validity of respondents' profiles is critical for understanding their degree of cooperation with the assessment process and their possible attempts to distort responses, such as by minimizing problems or exaggerating symptoms.

In the years following the publication of the MMPI, it was subjected to extensive and rigorous scientific study. The research showed that the instrument was not reliable for differentially diagnosing discrete psychiatric groups, as it was originally intended to do. However, the research produced a collection of empirical correlates of high and low scores on the clinical scales and corresponding classification rules for describing behavior and personality traits. Over time, the MMPI became the most widely used personality instrument in the United States, and the MMPI-2 holds that same designation today.

THE MMPI-2

In 1982, a committee was formed to modify the original test booklet and develop new norms for the MMPI. The restandardization project was initiated because (a) many of the 40-year-old MMPI items were out-of-date, and some were objectionable in content; and (b) the original normative sample of White, rural Minnesotans was not regarded as representative of the U.S. population in the late twentieth century. In 1989, the restandardization project culminated in the publication of the MMPI-2. Extensive validation research has documented the MMPI-2 as an effective replacement for the original MMPI for assessing adults.

The MMPI-2 contains the same clinical scales and validity indicators as the original instrument. However, there have been changes in the interpretation of some scales (for example, Scale 5 is now considered a measure of degree of deviation from stereotypical gender roles). There also are several new validity indicators, including two additional scales of infrequent responses (F_b , measuring endorsement of aberrant items in the latter portion of the test; and $F(p)$, measuring endorsement of problems that are uncommon even among psychiatric inpatients); two response-inconsistency scales (Variable Response Inconsistency, or VRIN, and True Response Inconsistency, or TRIN); and means of assessing “faking

good” among nonclinical samples (such as Superlative, or S). Awareness of the benefits of paying attention to the content of the inventory items prompted the development of clinical scale subscales, so-called content scales, and myriad supplementary scales. Most recently, a set of restructured clinical scales has been introduced and proposed as another means of facilitating profile interpretation.

The MMPI-2 can be used in a variety of settings. It is valuable for assessing psychiatric inpatients and outpatients, and it is also favored for use in forensic settings. It provides important information for non-clinical purposes as well, including screening for high-risk employment positions in the airline industry and public safety. It is valid for use with people representing a range of ethnic and cultural backgrounds, and it has been translated into dozens of foreign languages to extend its usefulness beyond English-speaking populations. Serving as a rich source for empirical investigation, its body of literature is ever increasing. Potential new and advanced uses include computerized adaptive testing to tailor the instrument to the individual while it is being taken. Numerous texts and other reference materials provide further information about these innovations (as well as about useful interpretation strategies), and frequent national workshops and conferences afford training opportunities and expose attendees to the latest research on the MMPI-2 and its applicability.

The MMPI-2 can add to evaluation in career counseling assessments in several ways. First, the MMPI-2 item pool contains many items that address the assessment of emotional adjustment, a factor that is pertinent to many careers that require high emotional stability and good judgment (for example, in airline pilot selection, nuclear power plant operation, police and fire departments). The test also provides information about a potential candidate's general personality functioning, including factors such as interpersonal relationships, impulse control, responsibility, and potential substance use problems. The MMPI-2 is one of the widely used personality measures in personnel selection and can add valuable information to the decision as to whether a client shows the emotional stability and responsibility needed for some occupations.

MINNESOTA THEORY OF WORK ADJUSTMENT

The *Minnesota Theory of Work Adjustment* (TWA), developed by Rene Dawis and Lloyd Lofquist, provides a way of conceptualizing the fit between an individual and a job or organization. It was initially influenced by research into the job placement problems of the physically disabled, which was the focus of a consultancy undertaken at the University of Minnesota as part of the Work Adjustment Project commenced in 1957. Much of the early research leading to TWA was published with the Minnesota Studies in Vocational Rehabilitation. In developing the TWA, the authors drew heavily on the strong measurement tradition at Minnesota. This emphasis resulted in a theory that provides a set of clearly testable hypotheses, which has stimulated many decades of research and associated development of instruments and measures.

TWA consists of both a structural model and a process model. Much of the research has focused on the components of the structural model, thereby failing to capture the underlying influence of learning theories on the development of the model and, more important, missing the richness of the dynamic aspects of the theory that deal with how both individuals and environments change. However, the dynamic component of TWA has increasing relevance because of the way in which the theory accommodates the current focus on adaptation and change in the work environment.

STRUCTURAL MODEL

The TWA describes both people and work environments in terms of the demands they impose on or ways they can reinforce each other and in what each can offer, or supply, the other. Commensurate measurement of the individual and environment along two broad dimensions captures the extent of the match between demands and supply.

Knowledge, Skill, and Abilities (KSAs)

TWA requires a detailed understanding of the environmental requirements in terms of the KSAs (perceptual, cognitive, social, and physical), education, and experiences that are necessary for optimal functioning. The measurement of these requirements derives from the job analysis literature.

A principle of symmetry embedded in TWA requires that the individual be assessed on the same KSA dimensions as those used to describe the environment. Commensurate measurement provides information not only on what the individual has to offer but also on how well his or her supplies match the work requirements. This emphasis on stable individual differences is unique among career development theories, and although it implies certain limitations, it does not deny the influence of the situation or the potential for change.

Further evidence of symmetry can be seen in the focus on the demands the environment places on the individual, and vice versa.

Needs, Values, and Interests

The importance of assessing an individual's needs, values, interests, and preferences illustrates TWA's link to fundamental learning principles. The concept of individuals seeking environments that will reinforce their values or the potential of an occupational reinforcer to reinforce behavior was heavily influenced by the early learning theory traditions of Edward Tolman and B. F. Skinner. Originally, measurement of needs and values occurred through the Minnesota Importance Questionnaire (MIQ), which included 20 need dimensions thought to be common to the majority of working people. These 20 needs were summarized into the five work values of achievement, autonomy, status, safety and comfort, and altruism, which, according to TWA, are higher-order needs.

Similarly, the environment is assessed in terms of the opportunities it has to offer individuals as motivational incentives, that is, its capacity to fulfill an individual's identified needs, values, and interests.

Work adjustment is the outcome of a match, or correspondence, between requirements and supplies from both the individual and the work environment on the two dimensions described above. Three major criteria are viewed as indicators of work adjustment: satisfaction, satisfactoriness (i.e., satisfactory performance), and tenure.

Satisfaction

Satisfaction is the outcome from the match between the individual's vocational interests, motivational needs, and values and the extent to which the organization is able to provide appropriate rewards and reinforcement of these. The authors of TWA argued that satisfaction was more than an overall component and therefore incorporated satisfaction with specific aspects of one's job such as supervision, coworkers, working conditions, hours of work, pay, and types of work. Importantly, they also highlighted the more intrinsic aspects of work, including satisfaction arising from the fulfillment of aspirations, expectations, and needs.

Satisfactoriness

Unlike other theories of career development that focus solely on the individual's perspective, TWA also incorporated the employer perspective through the inclusion of *satisfactoriness* (satisfactory performance). Resulting from the correspondence between the environment's need for specific KSAs and the individual's capacity to supply these, satisfactoriness covers efficiency, productivity, the ability to get along with a supervisor and coworkers, and a willingness to follow company policies. The early measure of this construct, The Minnesota Satisfactoriness Scales (MSS), asks the employer to rate how well the individual is performing compared with others in his or her work group on dimensions parallel to current conceptualizations of *task performance* (quantity and quality of work); *contextual performance* (e.g., accepts direction from supervisor, works as a member of a team); and *adaptive performance* (e.g., adapts to changes in procedures or methods, adjusts to different interpersonal approaches). The MSS also has sections that address what is currently called "counterproductive behavior" (e.g., comes late for work, becomes upset and unhappy, and requires disciplinary action).

Furthermore, TWA proposes that the extent to which correspondence between person and environment results in satisfactoriness is moderated by (that is, dependent on) the level of an individual's satisfaction. Specifically, the prediction of satisfactory performance from the match between an individual's KSAs and those required by an organization is stronger for satisfied employees than for unsatisfied employees. Likewise, satisfactoriness moderates the

extent to which satisfaction is predicted from a match between an individual's needs and the reinforcers provided by the environment.

Tenure

Tenure, that is the length of time an individual and environment interact, is a function of both satisfaction and satisfactoriness. While TWA originally operationalized tenure as a period of time before voluntary or involuntary removal from the workplace, more recently, the concept of withdrawal behavior has been used to include voluntary turnover as well as absenteeism, lateness, and other behaviors that indicate a reduced affective commitment to work.

PROCESS MODEL

The dynamic component of TWA was developed to explain the process by which either the person or the environment adjusts or adapts to minimize deterioration in fit.

Based on control or systems theory, it is proposed that a lack of correspondence acts as a trigger for a behavioral response aimed at reducing the tension that is created by the associated dissatisfaction. The extent to which this behavior is initiated depends on the so-called response style of either the person or the environment. *Response style* is classified in four dimensions: *celerity*, or speed of response; *pace*, or strength of response; *rhythm*, or pattern of response; and *endurance*, or length of sustaining the response.

The actual behaviors that reduce the level of mismatch can be enacted by either the person or the environment. There are four kinds of behaviors or *adjustment styles* that describe this process of maintaining or improving correspondence: activeness, reactivity, flexibility, and perseverance. Taken from the perspective of the person, *activeness* is when the individual attempts to reduce the mismatch by acting to change the environment to better suit himself or herself. An example of activeness on the part of the person would be negotiating job changes or a salary increase. Conversely, *reactiveness* occurs when the individual changes or modifies himself or herself to better suit the environment. Examples of reactive behavior include learning new skills, adapting interpersonal relating, and cross-cultural adaptability. *Flexibility* is tolerating a mismatch, such as being able to cope with higher-than-desired levels of stress and

ambiguity in the workplace. Finally, *perseverance* describes the degree to which an individual will enact adjustment behaviors before giving up. In the same way that individuals act in these four adjustment styles, so do environments. For example, an organization can provide feedback and training to actively change its employees' KSAs and reactively changes itself by instituting work redesign initiatives.

RESEARCH

The structural and process models of TWA combine to produce 17 research proposals. Propositions X to XVII relate to the style variables and, due mostly to inadequate measures of these, have attracted scant empirical attention. Likewise, there has been little testing of the hypotheses concerning the moderating role of satisfaction and satisfactoriness (Propositions IV and V).

In contrast, a large body of research has been consistent in supporting the prediction of satisfaction from the congruence between an individual's needs, interests, and values with the corresponding environmental reinforcers.

Similarly, there has been extensive support for the proposed relationship between satisfaction, satisfactoriness, and tenure. However, recent research has highlighted the complexity of measuring tenure and the recently identified need to include work withdrawal behaviors other than resignation or termination (such as absenteeism and lateness).

Support for the propositions regarding the prediction of satisfactory performance is found directly in research investigating TWA as well as indirectly through the large body of selection research of the last decade, particularly that showing a link between cognitive ability and job knowledge and performance. Admittedly, much of this research shows the direct link between KSAs and performance, failing to account for the requirements of a specific job. However, the identification of a number of moderators of the relationship between cognitive ability and job performance, such as task complexity and novelty, does suggest that the more a task requires cognitive ability, the stronger its prediction of performance.

UPDATED VERSIONS

Although the TWA was originally developed to assist people to choose careers and to adjust in a rehabilitation

context at a time when work environments were relatively stable, the theory has shown itself to be readily amenable to being updated to cater to changing work conditions and ongoing research developments.

As mentioned, the concept of tenure has evolved with the recognition of the importance of both work and job withdrawal behaviors. Aharon Tziner and Elchanan Meir expanded TWA to take account of this research and also included the notion of organizational commitment. Attention has also been paid to the other TWA criteria of satisfaction and satisfactoriness. Peter Warr identified the need to account for mental health and well-being along with satisfaction. He emphasized the measurement of job-related well-being, and much of the subsequent support is found in the stress and coping literature. Other seminal work showed that job performance (satisfactoriness) is, in fact, a multidimensional construct and that its dimensions are differentially predicted, suggesting that future investigations of TWA consider measurement of these separate aspects of performance.

The role of personality factors was not a focus of the original TWA. Although considered as higher-order variables derived from the more basic model variables, their role is not clear. Renee Dawis extended the model to include personality as one of several "other factors" that moderate the relationship between the three outcome variables. Alternatively, Beryl Hesketh and Barbara Griffin suggested that because of the established empirical relationship between interests and personality and between job performance and personality, individual differences in personality could belong in the structural model of TWA as one of the essential aspects requiring a fit between person and environment.

MORALE

Morale has been a recognized business concept and management concern for as far back as the construction of the pyramids. Although managers intuitively understand what morale is, there is no crisp, universally accepted definition. Morale can be understood as a state of mind—a positive outlook toward the workplace, wherein work is fun and a source of pride for the employees. Morale can be separated from the concept of employment, whereby one can focus simply on behaviors indicating a desire to be part of the team, a sociological phenomenon. Signs of low morale are negative employee attitudes, reduced energy levels, high stress levels, and an overall gloomy atmosphere devoid of a palpable sense of accomplishment.

Although managers are frequently warned to keep morale high to avoid suffering a loss of productivity, evidence suggests that high morale and high productivity have a common cause rooted in constructive management practices. Businesses with low morale

are destined to face unfavorable performance consequences, since low morale can result in errors on the job, customer dissatisfaction, and employee burnout. But low morale is a symptom, not necessarily a cause, of these negative outcomes. Research on morale has indicated that there are several organizational factors influencing morale, including the degree of mutual trust between employees and management, the degree of buy-in by employees to the company's mission, and degree of trust or belief that employees have in their coworkers.

Morale as a construct should not be confused with job satisfaction, although employee satisfaction surveys have served as a surrogate for assessing morale for some time. Employees can have a strong personal satisfaction with a job that stands apart from collective organizational morale. Questions such as "I am satisfied with my salary" address individual employee satisfaction but indicate nothing about organizational morale. A company can be made up of a loose collection of highly compensated, highly satisfied employees performing in an organizational vacuum in which morale is low or nonexistent. Standard employee survey questions that address employee morale include "I am proud to be a member of this company" or "I would recommend employment in this company to a friend." In essence, morale is reflective of the fact that employees crave social interaction with their peers, respect from their managers, and opportunities to make visible contributions.

The search for high organizational morale can focus business executives on management practices that engender both high morale and high productivity. Accordingly, there are a number of methods available to improve organizational morale. The first set of methods, as discussed below, focus on engendering mutual employee/manager trust.

Communicate Honestly. Keep the employees "in the loop" by communicating directly and honestly about business conditions. Even in bad times, reality is often more desirable than the receipt of information via the "grapevine." Asking for employee input and advice can yield creative solutions and provides employees with a much-desired sense of control in uncertain times.

Listen to Employees. Use both formal (such as surveys) and informal methods to understand employee ideas and concerns. Informal methods include suggestion boxes, establishing an ombudsman role, and

conducting “brown bag” lunches where employees and management meet to have lunch and exchange ideas. Listen attentively to ensure complete understanding and follow up on employee suggestions. Publicly make the connection between improvements in the internal organization and employee suggestions.

Focus on the Positive. Take every opportunity to communicate improvements in the company situation, such as successful responses to environmental change, product launches, marketing campaigns, capital acquisitions, and positive swings in financial status. Celebrating accomplishments provides strength when conditions get difficult. Deliver day-to-day positive reinforcement in the form of oral comments and handwritten notes.

Focus on Employee Health, Safety, and Financial Security. Support benefit offerings, such as 401(k) plans, employee assistance programs, flexible spending accounts, and college investment programs to align employee personal and professional goals. Provide creative solutions for employees who require flexible schedules, for example, to attend to child care needs, and allow personal time off in cases of short-term medical or personal emergencies. Helping employees meet their long-term goals improves morale and builds lasting adhesion to both the company and fellow employees.

Provide a Quality Work Environment. Invest in quality work processes, tools, and equipment. Keep physical space and furnishings comfortable and safe. Ensure that frontline personnel have the authority to take care of the customers with minimal management oversight. In addition to providing superior customer service, this delegation of authority will foster employee pride in themselves, their team, and the company. Encourage calculated risk-taking and entrepreneurial behavior.

The primary method to strengthen buy-in to the company’s mission is to continuously extol the virtues of the company, including its contributions to society, not only as a thriving enterprise but also as a good corporate citizen. Companies can exhibit positive civic leadership in a number of ways, including permitting time off for community service, matching employee contributions to charities, and providing free products or services to those in need. Employees want to know that their company’s values are in line with their personal values.

Finally, to foster trust and belief in coworkers, show appreciation and celebrate success to ensure that employees understand how their accomplishments contribute directly to company success. Praise all employees responsible for a given success, with special attention to the frequently forgotten units within the organization, such as facilities, the administrative staff, or customer service, without whom nothing could be accomplished. Acknowledge employee accomplishments in trade organizations. Reprint and distribute employee-authored articles. Post letters of appreciation from customers on company bulletin boards. Encourage employees to acknowledge each other in writing.

In conclusion, high employee morale is not a sufficient condition for creating high organizational productivity, but management’s efforts to foster morale can contribute to high organizational productivity. When morale is high, employees will identify and prevent potential organizational problems well beyond the ability of management to identify and build plans to address such issues. When morale is high, employees will encourage and help each other to accomplish what were once thought to be unimaginable feats.

MOTIVATION AND CAREER DEVELOPMENT

This entry considers the relationship between the internal motivation of people and their career development. The discussion centers on what has been theorized and researched connecting the internal drivers of behavior and decision making to career outcomes and career satisfaction.

Generally, *motivation* can be defined as a force or energy that exists within a person and influences

effort, directs behaviors, and ultimately affects performance and other individual outcomes. Researchers believe the importance of personal motivation in career development has grown in recent years for a variety of reasons. For example, work roles have become more flexible, less well-defined, and subject to increasing change both within organizations and across the span of a career, which often involves multiple organizations. Career transitions appear to be more frequent and involve larger qualitative differences than in years past. These more significant qualitative differences reflect a transition from one career to another, for example, a person moving from an occupation as an engineer to one as a teacher.

Self-management of one's own career development is seen as increasingly important in this more uncertain environment. Individuals are being urged to take responsibility for their own careers not only by the popular press and career counselors but also by the organizations in which they presently reside. Researchers have argued that people want to feel in control of the direction of their own careers, with a sense that they can significantly impact their own destinies. However, this desire varies across individuals, and some find the prospect of having control of their own destinies frightening in what seems to be an increasingly uncertain world. The direction and intensity of personal motivation to influence one's career development varies across individuals. Personal motivation and career self-direction affect not only career success but also other factors, such as mental health and life satisfaction.

One well-known early theory relevant to the topic of motivation and career development was presented by Donald E. Super in his classic book *The Psychology of Careers*, in which he discussed the course and cycle of an individual's working life. In the *exploration stage*, a person develops a self-concept. In the *establishment stage*, the self-concept is implemented. The *maintenance stage* involves an individual preserving or being nagged by a self-concept. The *years of decline* involve a person's adjustment to aging and a new sense of oneself.

Recent researchers have emphasized careers as involving multiple, short learning cycles over one's life span. An individual's career can be viewed as a series of ministages of exploration, trial, mastery, and exit across functions and organizations. New cycles are motivated by constant learning and mastery. Douglas T. Hall and associates have argued that a shift

has occurred from the organizational career to the "protean career." From this perspective, careers are seen as driven by the person, not the organization. In addition, careers are reinvented by the individual over time as the person and environment change. In this sense, the career of the twenty-first century is not measured by chronological age and stages in life, but by continuous learning and identity changes. Thus, during a model career in the twenty-first century, growth is motivating and involves a process of continuous learning fueled by a combination of personal characteristics, work challenges, and relationships. The following is a further description of the protean career and what motivates the individual's career development.

The *protean career* is a process managed by the individual, not the organization. It consists of all of a person's experiences gained through school, training, various organizations, and changes in occupations. The person's own career choices and search for self-fulfillment are the unifying themes in life. Success is not externally defined, but consists of the person's internal sense of success. Career development involves continuous learning and is self-directed, relational, and found in work challenges. The individual is motivated in this process to achieve the goal of psychological success (as defined below). The most important motivator of learning for the individual is the fact that the "new career contract" is not with the organization, but with oneself and one's work. Success is described in terms of one's unique vision and the fulfillment of central values in life that allow one to arrive at psychological success.

Psychological success involves the feeling of satisfaction, pride, and accomplishment that comes from achieving the most important goals in one's life. These goals are not just work related and can be varied. They could include, for example, achievement, family happiness, inner peace, fulfillment in a hobby, or other life goals. To realize the potential of the protean career, a person must develop new competencies related to managing oneself and one's career. A person must be motivated to develop self-knowledge and adaptability in a continuous learning process. This motivation profile is viewed as fitting the demands of the twenty-first century, with a shift from those with "know-how" to those with the motivation and capability to "learn how." The more an individual can learn how to adapt to changes in the work environment and to continuously grow and evolve as the

world changes, the more the person is “learning how to learn.” To achieve success, a person will need to be motivated to be adaptable as well as have a sense of identity concerning life goals. From this perspective, adaptability and identity are more important than basic skills and knowledge. The motivation and capability to learn how to learn will be essential to success in the self-directed protean career. The protean career is seen as dominating in the twenty-first century, and those motivated by continuous learning, with a clear understanding of their life goals, are viewed as well-positioned for success.

Recently, Hall and Dawn E. Chandler expanded on the concepts of the protean career and psychological success in their research on careers as a calling. A *calling* can be viewed as work that a person perceives as his or her life purpose. From this perspective, the person evaluates work from a subjective self-referent view of career meaning. The calling comes from intrinsic motivation that is not driven by instrumental goals. For this type of individual, what can be termed the *subjective career* is the most pertinent perspective from which different facets of their own career can be evaluated. Career research cannot ignore the subjective career to the extent that it has in the past. This is particularly true given today’s turbulent career environment, in which individuals are less dependent on organizational career arrangements. In this environment, an individual must have the intrinsic motivation to be an adaptable and able learner in the pursuit of his or her calling.

Hall and Chandler have observed that when an individual is motivated by a career calling, subjective measures are critical to an understanding of success. Psychological success in a career develops in cycles, as the result of setting and attaining challenging goals. A sense of psychological success is likely to be felt when the person independently sets and expends effort toward a challenging and personally meaningful goal and then attains that goal. When faced with difficult task situations, people with a sense of purpose will more likely be able to manage setbacks, because they will believe that, ultimately, they will succeed.

Hall and Chandler proposed a model of a success cycle involving a sense of purpose or calling, self-confidence, goals and effort, objective and subjective success, and identity change. For example, when people experience their career as a calling, they will have a strong focus on goals that reflect that purpose. As a result of this goal clarity, they will expend the effort

needed to succeed and carry out the calling. Objective success will lead to subjective success, a more competent self-identity, and self-confidence. The new sense of competence will reinforce one’s sense of calling. Thus, the development of the career calling is an ongoing, cyclical process involving the exploration of personal goals, trial efforts, and reflections on success.

DIMENSIONS OF MOTIVATION AND CAREERS

Manuel London and associates have researched career motivation and its dimensions for more than 20 years. They have postulated and found empirical support for three basic dimensions of career motivation: resilience, insight, and identity. *Career resilience* provides the personal drive to keep trying in the face of obstacles and career barriers. When faced with a difficult situation, career resiliency enables a person to persevere. In addition, resiliency allows the individual to adapt to changing circumstances, even when these circumstances are frustrating, discouraging, or disruptive. Career resilience is built on a belief in oneself, need for achievement, a willingness to take risks, and working either independently or cooperatively depending on what the situation requires.

Career insight means having a strong understanding of oneself and the work environment. When career insight is well developed, the person has a keen and accurate sense of his or her strengths and weaknesses and elements in the environment that support or block his or her ability to perform in that situation. Career insight is the ability to be realistic about oneself and one’s career, without delusion. Insight enables accurate assessments and perceptions, which are put to use to establish and pursue career goals. London has referred to insight as the spark that energizes people to act, with resilience keeping the spark alive.

Career identity channels a person’s energy, behavior, and performance toward a specific set of career objectives. Moreover, career identity involves the extent to which a person defines himself or herself by work. Career identity encompasses task, job, organizational, and professional involvement. Driving forces for a person with a strong career identity include the needs for achievement and advancement, recognition and accomplishment, and a desire to take a leadership role.

The three components of career motivation are complementary. Resilience, which provides the strength and courage to keep trying and moving forward even

in the face of obstacles and setbacks, is the foundation that allows meaningful career insight to develop. Insight, the energizing component developed through experiences and reflection, then allows the individual to choose and pursue a career direction that uses his or her talents to the fullest. Work life and career development will naturally involve encountering obstacles and barriers. Career barriers will cause individuals to question their career identities and rethink career insight up to that point in their career development. How constructive this process is for long-term career success depends largely on career resilience. Resilience will enable an individual to realistically assess a career barrier and determine constructive coping strategies for the situation. Resilience, then, provides the foundation for enabling useful insights into oneself and the work environment. Career resilience is the essential component of career motivation facilitating the individual's ability to not only develop career insight and identity but also cope effectively with career obstacles and barriers.

Empirical research has provided support for the three dimensions of resilience, insight, and identity as three distinct components of career motivation. Using the career resilience, insight, and identity framework, four patterns of career development have been identified: (1) healthy development, (2) redirection, (3) intervening self-doubt, and (4) breaking away from an ineffective pattern.

In addition, London noted that the concepts of career resilience, insight, and identity can be related to concepts in other career theories. For example, John L. Holland related how career decisions are affected by the ability to face barriers and the need for information, reassurance, and vocational identity. Career insight can be related to Donald Super's "vocational self-concept crystallization." Career identity can be conceptually tied to the concepts of work commitment, organizational commitment, and organizational citizenship. Also, each of the three career motivation concepts can be found in Hall's model of career identification. In the career identification model, the importance of career to the person (career identity) depends on self-knowledge of one's inclinations (career insight) and career success (which enhances self-confidence, part of career resiliency). Career resilience is also linked to the concepts of hardiness, self-efficacy, achievement motivation, and career maturity. Career resilience can also be linked to the concepts of flexibility, perseverance, and reactivity in work adjustment theory.

London and associates also developed theory on the relationship of career motivation to situational characteristics. Specifically, reinforcement contingencies are seen to develop career resilience. Reinforcement for good performance, opportunities to achieve, and an environment supportive of risk taking all contribute to the development of career resilience. Information processing contributes to the development of career insight and career identity. An environment in which a person is encouraged to set goals and in which information about career opportunities within the organization is provided contributes to career insight. An organization that provides abundant opportunities for self-development and opportunities for advancement in the organization and in which there are expert role models with whom to identify and learn from contributes to increased career identity.

CAREER SELF-MANAGEMENT

The concept of *career self-management* is closely related to the topic of personal motivation and career development. One perspective on career management has been provided by Raymond A. Noe, who noted that many human resource professionals have advocated career management to improve a person's motivation. In the literature, career management, developmental behavior, and performance are believed to be linked. The process of career management consists of career exploration, development of career goals, and using career strategies to achieve career goals. Vocational psychologists developed the *theory of exploratory behavior*, on which the concept of career exploration is based. Career exploration involves collecting information about one's values, interests, and strengths and weaknesses. The behaviors involved can include both mental and physical activities that provide information about oneself or the environment. Studies have shown that career exploration is related to developmental behavior, including participation in seminars and the acceptance of mobility opportunities.

The second aspect of career management from Noe's perspective is the development of career goals. *Goal-setting theory* has been used to provide insight into the development of career goals. Goal-setting theory postulates that goals influence behavior by focusing attention, stimulating and maintaining effort, and facilitating the development of approaches for goal attainment. Having career goals may be an important determining factor in developmental behavior

and a person's willingness to participate in developmental activities. Goals can influence the individual to engage in behaviors and activities in order to improve on skills and address weaknesses. The more focused people's career goals are, the more likely they will be to engage in behaviors to reach them and the greater their motivation to participate in developmental activities. Career goals are also believed to be positively related to a person's performance.

The third aspect of career management from Noe's perspective is the use of career strategies to achieve career goals. A *career strategy* is a behavior or activity that increases the probability of career goal attainment. Examples of career strategies include participating in a mentoring relationship or developing skills and competencies. A person's use of career strategies is likely to stimulate additional developmental behaviors. The entire career management process is likely to be influenced by a person's age, position, and the manager's support for developmental activities. These factors are also likely to influence a person's developmental behavior and performance.

Noe's empirical research provided limited support for the relationships discussed above. The research did support the idea that an individual's motivation to participate in developmental behaviors was related to environmental exploration. The relevant factors of environmental exploration include seeking career-related information from peers, managers, and other sources. In addition, management support was significantly related to developmental behavior.

Researcher Zella King has provided a thorough discussion of the nature of career self-management as well as its causes and consequences. From King's perspective, career self-management is seen as heightening a person's perception of control over his or her career and leading to career satisfaction. However, career self-management may also be associated with negative outcomes and maladjustment. From the career self-management perspective, a person is seen as using three types of self-managing behaviors as adaptive responses to career development issues: positioning, influence, and boundary management. When these three types of behaviors are used to respond to or eliminate career barriers successfully, constructive vocational adjustment occurs. The career self-management perspective builds on earlier research by John O. Crites on vocational adjustment in order to revise and update vocational adjustment theory to provide a more contemporary perspective.

Earlier vocational adjustment theory argued that people are motivated either by internal or external forces to behave in certain ways in their jobs. For example, an individual might endeavor to seek acceptance from others, attempt to achieve recognition and status, or work at being granted greater autonomy in a job. When people are stymied in their attempts to achieve outcomes they desire either by external circumstances such as frustration or internal conflicts such as competing desires and internal conflicts, they will attempt to adjust by eliminating the obstacles or reducing the tension experienced. If the individuals are effective in their responses, they will succeed at vocational readjustment and experience a feeling of success and job satisfaction. However, if responses to the difficulties are not successful in overcoming the problems they face, they will continue to experience frustration and conflict and can be considered vocationally maladjusted. From a career development perspective, the motivation to achieve vocational adjustment occurs over the entire course of a career, from the first job to retirement. Naturally, the contexts in which they occur, the nature of the challenges faced, and the responses of the individual will vary across the span of his or her working life.

Importantly, recent perspectives have emphasized that understanding career development must include consideration of an individual's personal life in addition to working life. A total picture of career self-management must include a person's life desires outside of work. A comprehensive career management perspective includes a consideration of adjustments made by an individual to deal with total life desires, including work, family, leisure, spiritual pursuits, and other areas of life important to the individual.

As noted above, King has described career self-management as a dynamic process involving the three types of co-occurring behaviors, namely, positioning, influence, and boundary management. *Positioning* involves behaviors aimed at making sure the individual has the contacts, skills, and experience to achieve his or her desired career outcomes. *Influence* involves behaviors aimed at actively trying to affect the decisions of key individuals important for the person to be able to achieve desired outcomes. *Boundary management* involves attempts to balance the demands of work and nonwork activities important in one's life. Each of these three types of behavior may be rationally and consciously planned by following a clear path, or they may be improvised as demands arise

through various situations encountered over time. In any case, positioning, influence, and boundary maintenance can be considered basic elements of career management; each one is intended either to eliminate external challenges that would otherwise prevent a person from achieving desired career outcomes or to address internal sources of conflict between roles.

The three types of career management behaviors can be viewed as driven by three determinants: self-efficacy, desire for control, and career anchors. In other words, self-efficacy, desire for control, and career anchors are the underlying reasons that explain why career management behaviors are initiated in the first place. Each concept has a prominent place as a behavioral construct in the management and psychology literature. *Self-efficacy* refers to the belief of a person that he or she can effectively perform the behaviors required in a particular situation. With respect to *desire for control*, career self-managing behaviors are seen as producing responses aimed at increasing a person's perceived control over his or her career. *Career anchors* can be viewed as higher-order goals or career orientations. They are basic organizing principles that guide an individual's career-related decisions, driving and constraining choices about how to achieve desired career outcomes.

MOTIVATION AND CAREER-ENHANCING STRATEGIES

Ghulam R. Nabi researched motivational factors to predict career-enhancing strategies. *Career-enhancing strategies* consist of behaviors that are not part of the formal job description specified by the organization. Many researchers believe that career-enhancing strategies are beneficial to an individual's career management and do contribute to positive career outcomes. They include expertise development, self-nomination, and networking. *Self-nomination* refers to, for example, promoting one's aspirations and desire for advancement as a means for attaining greater job responsibility. *Networking* refers to building a network of organizational contacts to gain information, power, and support in order to enhance one's career. The motivational attributes used to predict career-enhancing strategies include advancement motivation and work/career centrality. Research results indicate that advancement motivation is positively related to expertise development and self-nomination. These results provide support for the belief

that advancement-motivated people tend to be intrinsically motivated to channel their energy to include career-enhancing strategies. In addition, work-related centrality has been found to be positively related to expertise development and networking. People who consider work to be a central part of their lives (and are therefore presumably career oriented) were found to have higher levels of self-nomination of their aspirations and abilities to those higher up in the organizational hierarchy and also to engage in more networking. The results are consistent with prior research emphasizing that employees who tend to consider work and career the most central part of their lives are motivated to use career strategies more frequently than those for whom work/career is less central.

MOTIVATION AND MENTORING

Rachel Day and Tammy D. Allen have done research that they believe is the first to reveal connections between mentoring, career self-efficacy, career motivation, and protégé career success. These researchers used the career motivation framework (consisting of career resilience, career insight, and career identity) developed by London. Career motivation is viewed as one factor in explaining the benefits protégés realize from mentoring relationships. The results showed that protégés reported more career motivation than did nonprotégés and that career motivation mediated the relationship between career mentoring and protégé performance.

This research built on earlier research that found that employees with managers who were supportive, provided clear performance feedback, encouraged subordinates to set career goals, and exhibited other mentor-type behaviors were more likely to report high levels of career motivation than employees who did not have such managers. Building on this line of research, Day and Allen found that people who were mentored did report higher levels of career motivation than those who had not been mentored. In addition, people receiving more mentoring had greater career motivation. In this research, individuals who received more career mentoring reported greater self-efficacy. The researchers concluded that career-mentoring activities such as encouraging the protégé to take challenging assignments and providing coaching and exposure may reinforce protégé feelings that he or she is capable and competent. Furthermore, career motivation was found to be related to career success.

Specifically, career motivation was positively related to an individual's salary, subjective reports of career success, and performance.

CONCLUSION

This entry examined research relevant to intrinsic motivation and career development. Researchers believe that personal motivation as a driver of career development has become increasingly important for a variety of reasons. These include the fact that tasks, jobs, and occupations have become more flexible, less well-defined, and subject to increasing change both within organizations and across the span of a career that often involves multiple organizations. The role of internal motivation is critical in understanding individual behavior and decision making in these circumstances.

Specific research relevant to this topic includes several different research streams. One is the career stages theory of adult development. This life span approach describes how an individual's self-concept impacts vocational choices. Stages in this theory include exploration, establishment, maintenance, and disengagement. More recent research emphasizes a shift from the organizational career to the protean career. From this perspective, careers are seen as driven by the person, not the organization. In addition, protean careers are reinvented by the individual over time as the person and environment change. The motivation and capabilities to "learn how to learn" will be essential to success in the self-directed protean career. Recent conceptualizations of the protean career and psychological success have been extended to research on a career as a calling. A calling can be viewed as work that an individual perceives as his or her life purpose. From this perspective, the person evaluates work from a subjective self-referent view of career meaning.

Research on the specific dimensions of individual motivation related to career development has postulated and found empirical support for three basic dimensions. These dimensions are resiliency, insight, and identity. Career resiliency provides the personal drive to keep trying in the face of obstacles and career barriers. Career insight means having a strong understanding of oneself and the work environment. Career identity channels a person's energy, behavior, and performance toward a specific set of career objectives. Moreover, career identity involves the extent to which a person defines himself or herself according to work. The concept of career self-management is also closely

related to the topic of personal motivation and career development. The process of career management can be viewed as consisting of career exploration, development of career goals, and using career strategies to achieve career goals.

Another perspective emphasizes three types of self-managing behaviors as adaptive responses to career development issues. These three types are positioning, influence, and boundary management. When these three types of behaviors are used to respond to or eliminate thwarting conditions or career barriers successfully, constructive vocational adjustment occurs. Career-enhancing strategies belong to a related area of research. They consist of behaviors that are not part of the formal job description specified by the organization. Many researchers believe that career-enhancing strategies are beneficial to an individual's career management and do contribute to positive career outcomes. Career-enhancing strategies include expertise development, self-nomination, and networking. Mentoring and career motivation have been part of another area of investigation. Research results show that protégés reported more career motivation than did nonprotégés and that career motivation mediated the relationship between career mentoring and protégé performance. As the nature of tasks, jobs, and occupations continues to evolve and change, motivation will continue to be an important area of research for understanding successful career development.

MULTICULTURAL ORGANIZATION

A *multicultural organization* is defined as one that seeks and values all differences and develops systems and work practices that support the success and inclusion of members of every group. Multicultural organizations are characterized by equality, justice, and full participation at both the group level and the individual level. In multicultural organizations, differences of all types are not merely tolerated; they are actually sought out because their inclusion offers critical opportunities for improvement and enhanced outcomes for organizations, including increased profitability, learning, creativity, flexibility, adaptation to change, and organizational growth.

Leaders in contemporary organizations are paying attention to multiculturalism for a number of reasons. Two converging factors in particular are contributing to organizational interest in multiculturalism. First, organizations are increasingly the locations of diversity across a broad spectrum: People of different races, genders, educational levels, sexual orientations, socioeconomic status, religious affiliations, and any number of dimensions of diversity are coming together at work. To effectively manage and leverage this diverse workforce, organizations must pay attention to the environment being created for the workforce.

A second important factor is that organizations are operating in a context of constant change: Advances in technology, rapidly changing customer bases, and dramatic policy shifts and legal challenges all affect organizations. Both factors require organizational leaders to consider the importance of building multicultural organizations.

Scholars who study and write about multicultural organizations acknowledge that only a small number of organizations are truly multicultural. In contrast to multicultural organizations, most organizations fall into one of two other categories: monolithic or plural. *Monolithic organizations* are typically very homogeneous and are characterized by substantial numbers of White males, who make up the majority in the overall employee population; few women or people of color in management positions; high levels of occupational segregation; high levels of discrimination and prejudice; and an explicit valuing of one dominant group, culture, or style to the exclusion of other minority groups. The *plural organization* differs from the monolithic one in several important ways. Plural organizations are characterized by a more heterogeneous workforce, policies and practices that are more inclusive of people who are not part of the dominant group, greater integration of minority group members into informal networks, and reductions in discrimination and prejudicial attitudes. Plural and monolithic organizations share these criteria: (a) Both are characterized by skewed integration of minorities across functions, levels, and work groups; and (b) both assume that those who are different will assimilate to fit into the dominant culture.

Organizations move from being monolithic to multicultural by paying attention to change in very concrete ways and at several levels. Much of the work on multicultural organizations focuses on change in three particular ways: structural change, cultural change, and behavioral change. *Structural change* focuses on the formal systems that guide and control the work of the organization. Proponents of structural change are paying attention to recruitment, advancement, retention, career development, and attention to other policies and/or procedures, such as benefits, flexible work schedules, compressed workweeks, and job sharing and job rotation. *Cultural change* is concerned with basic assumptions, values, beliefs, and ideologies that define an organization's view of itself. Proponents of cultural change guide the organization by encouraging an environment that welcomes a wide range of work styles and behaviors and embraces diversity in

thought, practice, and action. *Behavioral change* is dedicated to altering behaviors, attitudes, and perceptions (at the individual and work group levels) that hinder the goals of diversity. Proponents of behavioral change challenge the organization to surface intentional and unintentional consequences of actions that differentially and negatively impact minority group members. Each of the three forms of change is important in moving an organization from monolithic to multicultural; using them in conjunction with one another provides a powerful mechanism for leveraging several different interventions.

Multicultural organizations use a number of different interventions to support their employees. Common interventions include managing/valuing diversity training, orientation programs for new members, targeted career development programs, mentoring programs, focus groups, task forces, performance appraisal and reward systems that consider diversity, and company-sponsored social events. There is a temptation to pick and choose from among these many different interventions at random. But multicultural organizations determine which interventions to use and when to use them through a strategic and proactive planning process, often consisting of the following five steps: (1) laying the groundwork and securing organizational leadership for intervention; (2) assessing organizational needs related to diversity; (3) developing and communicating a vision, goals, and strategic plan; (4) implementing selected interventions; and (5) monitoring and evaluating progress and results. Each step is important in preparing an organization to shoulder the complex and intensive work involved in supporting multiculturalism.

Although it is no small feat for an organization to become multicultural, it is nonetheless a worthy endeavor. In light of the rapidly changing nature of work in the twenty-first century, multicultural organizations provide a competitive edge over organizations that remain monolithic and plural in nature: the ability to provide a forum to fully support and draw from all of their human resources.

MULTINATIONAL ORGANIZATION

The growth of the *multinational organization*, which has been part of the globalization process in recent years, has had the effect of changing and internationalizing many careers. Through the development of foreign facilities and mergers with foreign companies, multinational organizations extend their business internationally and often become global in scope, at the same time retaining a "head office" focus in a home country. This country is not necessarily the United States: In 2001, only 12 of the world's 50 largest companies by foreign assets were based in the United States.

Multinational organizations have a number of competitive advantages, including the maintenance of a worldwide strategic focus, international reputation and "brand image," and the ability to locate business in whichever country local conditions (such as prevailing labor costs) provide the greatest advantage. Against this, they may lack familiarity with local politics, mores, and culture. In all countries, there is periodic concern that the effect of multinational corporations, particularly very large ones, may be to concentrate power and resources in the hands of nonaccountable foreigners, usurp the functions of government, and act in a socially irresponsible manner, particularly in the displacement of labor and its replacement by low-cost foreign alternatives.

As far as labor is concerned, multinational organizations must decide whether to appoint local people or to

expatriate employees from elsewhere, particularly the “home” country of the organization. Local employees have the advantage of familiarity with the local scene and often lower cost. Expatriates, mainly people who have already had several years’ experience in the organization, have better awareness of the strategy and global operations and culture of the organization and often have had more appropriate education and training than any locally available alternatives. If expatriates are mobile across countries within the organization, they also have the potential to cross-fertilize the organization with an understanding of its different locations.

A common pattern is to have foreign subsidiaries managed, at least initially, by experienced and knowledgeable managers from within the organization, particularly from the home country and head office, with the objective of securing close control and adherence by the subsidiary to organizational strategies and structures. These managers are frequently given “expatriate assignments” of up to five years, after which they return to their own countries. Local people are typically employed in lower-level, more routine work but may be developed to progressively fill more senior roles.

There has been much interest in, and research on, the effects of expatriate assignment on careers. On the positive side, moving to a new country, particularly a culturally dissimilar one, is likely to provide the opportunity for considerable personal growth, the development of cross-cultural skills and a global perspective, and an increase in the individual’s value, both in the employing organization and elsewhere. Against this, traveling across cultures adds additional stresses to those associated with any job change. Expatriates may lack “cultural intelligence,” or the ability to function well in unfamiliar cultural settings. Assignees are normally accompanied by their partners and children, who must make cultural and educational adjustments of their own.

There has been concern, too, about the phenomenon of “expatriate failure,” whereby the expatriate is forced to return early, leaves the organization, or fails to achieve his or her objectives. Returning assignees often find that their expectations of rapid career progression based on their newfound foreign expertise are not appreciated by the organizations. For these reasons, expatriation has failed to live up to its potential as a strategy for career development. There are also indications that expatriation failure is more common among American than among, for example,

European expatriates, perhaps because the latter have a more cosmopolitan perspective.

Research in this area typically adopts a “human resources” frame; that is, it views failures in expatriation as failures in the management of expatriates and seeks to develop improved techniques of expatriate selection, training, orientation, mentoring, and career planning, which will reduce the likelihood of failure and increase the utilization of expatriate experience in organizations. The theory and practice of international human resource management emphasizes a more strategic approach that locates expatriate assignments within a broader organizational planning frame involving the appreciation of the employee’s long-term career development. A recent trend has been for multinationals to reduce long-term expatriate assignments in favor of “global executives,” who travel frequently and exercise authority in a number of foreign locations but continue to be based in their home countries.

In research and discourse about expatriate assignment, the perspective of the individual expatriate is sometimes lost. Expatriates often travel with their own objectives in mind, such as adventure, exploration, and living in different cultures, as well as organizational objectives. They also must take responsibility for the success or failure of their assignments and for the development of their own careers. “Expatriate failure” as defined by the organization on its own terms may have a corollary in “expatriate success” as defined by the individual, in terms of personal development, cross-cultural learning, newfound career mobility, and the opportunity to move to a more congenial organization.

Too great a preoccupation with expatriate assignment may divert attention from the careers of two other key groups. One group, foreign employees of multinationals, often have to make major adjustments in their careers to the new structural and cultural dictates of the owning organization. No doubt, the spreading of foreign direct investment around the world provides new opportunities for many workers, including the opportunity to travel, but it also poses great challenges. The other group is made up of the millions of people who each year migrate from their own countries to try to find greater opportunities elsewhere, including career opportunities. Migrants are typically energetic, but even those with good qualifications and experience have been discriminated against and marginalized in the workforce and have had their careers disrupted far more often than have

corporate expatriates. This results in major human distress as well as underutilization of the diversity of precious human resources.

In coming years, the forces of globalization, multinationalism, migration, and workforce diversity can be expected to increase. International and “global” careers—which not only cross boundaries but lose their identification with any single country—will become more common. International travel will become a feature of more and more careers. Much mature thought and research is required to enable us to respond to these opportunities and challenges.

—Kerr Inkson

MULTIPLE INTELLIGENCES

What does it mean to be an intelligent person? Philosophers, psychologists, educators, and everyday people have answered this question using a wide variety of definitions for *intelligence*. This question has particular significance for someone seeking a career path in which the chance for success and satisfaction will be maximized. Naturally, everyone wants to make a “smart” career choice.

Since Alfred Binet created the first intelligence test in Paris, France in 1904, it has been assumed that human intelligence can be accurately defined as a single entity (*g*, or general intelligence) and measured by an IQ score. Our understanding of how the human brain/mind processes information and how cultures around the world function has evolved over the past 100 years. Advances in scientific and cultural knowledge have necessitated that we evolve beyond a simplistic representation of intelligence as a singular entity to account for the full potential of the human brain. Successful career planning requires a more complicated and culturally informed model of what it

means to be an intelligent person capable of solving important problems and creating products of value on the job.

In his landmark book *Frames of Mind: The Theory of Multiple Intelligences*, Howard Gardner provided extensive research to support his contention that human intelligence is multifaceted rather than singular. To qualify as an intelligence in Gardner’s *multiple intelligences* (MI) theory, each ability must satisfy a range of criteria: the potential for isolated breakdown of the skill through brain damage; the existence of savants, prodigies, and other exceptional individuals with this ability; support from psychological training studies and from psychometric studies, including correlations across tests; evolutionary plausibility; and a distinct developmental history culminating in a definable set of master performances. In addition, each intelligence must have an identifiable core operation or set of operations as well as susceptibility to coding in a symbol system (e.g., language, mathematics, picturing, or musical notes).

Gardner used these eight basic criteria to identify several different intelligences possessed by all humans as part of their cerebral endowment. Of course, given that the normal human brain consists of approximately 100 billion neurons and each individual is exposed to an infinite variety of environmental stimuli influencing the course of intellectual growth, each person possesses a unique profile of strengths and limitations.

The eight intelligences currently identified by MI theory are Linguistic, Logical-mathematical, Spatial, Kinesthetic, Musical, Naturalist, Interpersonal, and Intrapersonal. Each intelligence has its own memory system, with cerebral structures dedicated to processing its specific contents. The intelligences are broad categories of ability composed of specific sets of skills evident in daily life (e.g., musical intelligence includes instrumental skill, vocal talent, etc.). As our scientific knowledge increases, it is possible that the list of intelligences will change accordingly. In fact, at the time of this writing, Howard Gardner is reviewing the scientific evidence regarding a possible ninth intelligence, Existential. The core components of the eight intelligences are briefly summarized below, along with their career implications.

Linguistic and *Logical-mathematical* intelligences are most often associated with academic accomplishment and are the primary elements of general intelligence (*g*). The core features of Linguistic intelligence

include the ability to use words effectively for reading, writing, listening, and speaking. Linguistic skill is important for providing explanations, descriptions, and expressiveness. Gardner has described the poet as the epitome of linguistic ability. Other career fields requiring skill in this area include teaching, journalism, and psychology. Convergent aspects of Linguistic intelligence assessed by standard intelligence tests include vocabulary and reading comprehension. Activities requiring divergent thinking include storytelling, persuasive speech, and creative writing.

Logical-mathematical intelligence involves skill in calculations as well as logical reasoning and problem solving. People strong in this intelligence are usually described as being “smart” (e.g., mathematicians, philosophers, logicians, engineers). Logical-mathematical intelligence is required for multistep, complex problem solving and mental math. Most IQ tests assess a person’s ability to reason logically and problem solve quickly but do not examine divergent and reflective aspects of Logical-mathematical intelligence. Divergent aspects of this intelligence include curiosity, the identification of novel problems, or the generation of new and worthy questions.

Musical intelligence includes sensitivity to pitch, rhythm, timbre, and the emotional aspects of sound, as pertaining to the functional areas of musical appreciation, singing, and playing an instrument. A composer requires significant skill in many aspects of this intelligence, especially involving creative musical thinking. Some musical careers (e.g., instrumentalist, vocalist) may require more circumscribed abilities that emphasize technical skill rather than creative output.

Kinesthetic intelligence highlights the ability to use one’s body in highly skilled ways for both expressive (e.g., dance, acting) and goal-directed activities (e.g., athletics, working with one’s hands). Well-developed kinesthetic ability for innovative movement is required for success in professions such as choreography, acting, and directing movies or plays. Precision, control, and agility are the hallmarks of athletes such as karate masters, professional soccer players, and gymnasts. Brain surgeons and diamond cutters must have well-developed fine-motor dexterity, and modern dancers and mimes are able to express complex abstract ideas through subtle gestures and movements.

Spatial intelligence includes the ability to perceive the visual world accurately and to perform transformations and modifications on one’s initial perceptions

via mental imagery. Functional aspects of spatial intelligence include artistic design, mapmaking/reading, and working with objects. Visual artists and interior designers exemplify creative spatial thinking, and a successful architect will need both creative abilities and technical expertise. An automobile mechanic or engineer, in contrast, may rarely need creative or artistic abilities to find the solution to a malfunctioning engine.

A person strong in the *Naturalist* intelligence displays empathy, recognition, and understanding for living and natural things (e.g., plants, animals, geology). Careers requiring strong naturalist skills include farmer, scientist, naturalist, and animal behaviorist. Skilled scientists use pattern recognition to identify an individual’s species classification, create taxonomies, and understand ecological systems. Empathic understanding is a related ability that allows people to care for and manage the behavior of living entities.

Unique contributions of the MI model to intelligence theory are the personal intelligences. The *Intrapersonal* and *Interpersonal* intelligences are presented as separate yet related functions of the human brain (especially the frontal lobes). Intrapersonal ability emphasizes self-knowledge, and interpersonal involves understanding other people.

Vital functions of Intrapersonal intelligence include accurate self-appraisal, goal setting, self-monitoring/correction, and emotional self-management. Results of research have highlighted the importance of metacognition for learning in the basic academic skills of reading and mathematics. Intrapersonal intelligence is not the same as self-esteem, but it may be a strong factor in promoting self-confidence and effective stress management. Well-developed Intrapersonal intelligence may well be essential to an individual’s sense of satisfaction and success. Intrapersonal intelligence has been referred to as the “royal road to achievement, learning, and personal satisfaction” and is thus key in maximizing career success. Specific vocations that require skills in intrapersonal self-management include pilots, police officers, writers, counselors, and teachers.

Interpersonal intelligence also plays a vital function in a person’s sense of well-being. It promotes success in managing relationships with other people. Its two central skills, the ability to notice and make distinctions among other individuals and the ability to recognize the emotions, moods, perspectives, and motivations of people, are known to be critical factors in successful

employment. The ability to manage groups of people is required for managerial or leadership positions. Good teachers, counselors, salespersons, and psychologists need to understand a specific individual and then be adept at managing that relationship.

CAREER IMPLICATIONS OF MI THEORY

There are four practical implications for applying MI theory to career planning, selection, and development. First, the chances for maximum career development are increased when there is a good match between the job tasks and an individual's MI strengths. Second, the strength and development of Intrapersonal intelligence is a key factor in positive career selection and advancement. Third, career development will be enhanced when a person's significant others (parents, teachers, counselors, supervisors, peers, coworkers, etc.) are aware of the individual's particular strengths and are supportive of their development. Fourth, the potential negative impact of a person's weaknesses on career success will be minimized when particular strengths are emphasized and then employed, to bridge any significant deficits.

The challenge of matching one's MI strengths to an appropriate career path whereby the chances for success will be maximized is not always easy to accomplish. Successful completion of most real-world tasks, jobs, and careers requires competence in a combination of at least two or perhaps three or more different intelligences. There are several approaches to guide career planning using MI theory. The first approach involves a general consideration associated with one's main MI strengths, either individually or in combination. The second approach is to look more carefully at specific skills within the main MI strengths and match those to particular careers. For example, if the person's top-two main MI strengths are musical and linguistic, he or she might consider a career such as a music teacher, lyricist, or music critic. These are related but quite different career paths. If the person's specific skills are in the areas of writing and musical appreciation, this would focus career planning on musical scholarship or criticism.

Intrapersonal understanding is essential for effective personal judgment and decision making. Research has found that low self-understanding contributes to career confusion and indecision. When young people are taught to use MI language to carefully describe which of their skills will be engaged by

particular jobs, they are assisted in imagining career paths that will allow them to use and develop their MI strengths.

Skill building and career development do not occur in a vacuum. An individual needs accurate feedback from significant others to form a realistic self-understanding as well as an understanding of the world of work. For someone to achieve career advancement, he or she needs to be challenged to build the skills required for higher levels of employment. This challenge typically comes from parents in the early years, later from teachers, and as an adult from professors, mentors, or supervisors.

A person's limitations or weaknesses can inhibit career advancement. For example, a person wishing to become a nurse may have adequate interpersonal and linguistic abilities but have difficulty passing the required math courses. This person has several choices for overcoming this block. He or she might choose a different career objective not requiring advanced math, such as sales or child care. Or the individual might devote creative energy to discover how to pass math by using linguistic and interpersonal strengths to study.

A key element in the MI definition is that competence in each intelligence can be acquired via the convergent thinking associated with IQ or via divergent (creative) thinking. This shift in definition expands the core criteria for identifying who is "smart" and who is not. In addition, MI changes the basic question from "How smart are you?" to "How are you smart?" In other words, in what way is a person smart? MI theory recognizes that each person has his or her own particular MI strengths, and the task of assessment is to accurately describe those strengths so each person's potential may be developed via guidance, challenge, and support.

An additional benefit for using MI theory to enhance career selection is that it recognizes that a person can be successful through the use of creative thinking both at work and in everyday life. Successful performance in a career often requires the creative use of a combination of two or more intelligences. For example, a lawyer who is low in writing skills but strong in interpersonal thinking will emphasize his or her courtroom performance over the writing of legal briefs. Similarly, career development does not necessarily depend on high logical-mathematical skills to maximize success if the person is able to think creatively when solving important problems, creating products, or providing services.

To conclude, it must be understood that the multiple intelligences are different from learning styles or personality characteristics. MI theory describes a person's "abilities," whereas personality and style characteristics emphasize one's "preferences." These constructs may or may not be highly correlated. For example, a person can be friendly, extraverted, and sociable but have very few skills for negotiation, empathy, and collaboration. A benefit of MI theory for career planning is that it focuses individuals' thinking on matching their actual abilities, rather than merely preferences or wishful thinking, with career paths. Research has found that career seekers often gain greater clarity for selecting college majors or career goals when they are provided with information about their multiple-intelligences profiles as well their interests or preferences.

MYERS-BRIGGS TYPE INDICATOR

The *Myers-Briggs Type Indicator* (MBTI) was created by Isabel Briggs Myers and Katharine Briggs to make Carl Jung's theory of psychological types practical for everyday use. One of Myers's primary motivations in developing the MBTI was her desire to help people find work that was congruent with their individual preferences.

The most fundamental use of the MBTI in the career field is to provide an individual with insight into his or her preferences and then to recommend job families, occupations, or occupational specialties that potentially provide a good fit for those preferences. The MBTI has also been used to foster the career exploration and search process for career decision making and for career management and development activities.

THEORY

The essence of Jung's psychological type theory is that much seemingly random variation in behavior is actually quite orderly and consistent due to basic differences in the way individuals prefer to use their perceptions and judgment. *Perception* involves how people become aware. *Judgment* entails coming to conclusions about what has been perceived. Systematic differences in how perception and judgment are exercised lead to corresponding differences in behaviors, interests, values, motivations, and skills. Since the basic cognitive functions of perception and judgment enter into almost every behavior, the scope of practical applications of the MBTI is very wide. The primary uses of the MBTI include team building, management and leadership development, individual counseling, enhancing relationships, conflict resolution, understanding teaching and learning styles, and career management and development.

In addition to measuring preferences for perception and judgment, the MBTI also measures two attitudes: (1) the attitude in which preferences are expressed, and (2) the attitude preferred in dealing with the outer world. Each of the two cognitive functions and the two attitudes comprises a pair of dichotomies. Every person has a preference for one pole of each of the four dichotomies. An often-misunderstood component of the theory is that every person is assumed to use both poles of each of the four dichotomies at different times or in different situations, but to respond first, most often, and most comfortably with the preferred pole.

THE FOUR PREFERENCE DICHOTOMIES

The MBTI instrument includes the following four separate scales: Extraversion-Introversion, Sensing-Intuition, Thinking-Feeling, and Judging-Perceiving. The intent of the instrument is to reflect a habitual choice between these rival alternatives.

The Extraversion-Introversion (E-I) index is designed to reflect a person's preference for extraversion or introversion in the sense intended by Jung. Extraverts are oriented primarily toward the outer world and thus tend to focus their perceptions and judgments on people and objects. Introverts are oriented primarily toward the inner world and thus tend to focus their perceptions and judgments on ideas or sensations.

The Sensing-Intuition (S-N) index is designed to reflect a person's preference for two opposite ways of perceiving. Those who prefer Sensing (S) perceive

observable facts and present reality through one or more of the five senses. The opposite is the process of Intuition (N), through which meanings, relationships, or possibilities are perceived.

The Thinking-Feeling (T-F) index is designed to reflect a person's preference between two contrasting ways of judging. A person may rely primarily on thinking (T), to decide impersonally on the basis of logical consequences, or primarily on feeling (F), to decide on the basis of personal or social values.

The Judging-Perceiving (J-P) index is designed to describe the process a person primarily uses in relating to the outer world. A person who prefers judgment (J) uses either thinking or feeling in relating to the outer world, whereas a person who prefers perception (P) uses one of the perceptive processes, either Sensing or Intuition.

THE 16 TYPES

The four indexes are independent of one another, yielding 16 possible combinations. The combinations of the four preferences are called "types," which are denoted by the four letters of the preferences. For example, "ISTJ" refers to a person who prefers Sensing as his or her mode of perception, makes Thinking judgments about those perceptions, and uses Introversion to focus on his or her inner world and Judging for the outer world. The theory further postulates specific dynamic relationships between the preferences. For each type, one process is the leading or dominant process, and a second process serves as an auxiliary. Each type has its own pattern of dominant and auxiliary processes and attitudes (E or I) in which these are habitually used. The characteristics of each type follow from the dynamic interplay of these processes and attitudes, in which the whole becomes greater than the sum of the parts.

The 16 types are displayed in a type table, as shown in Table 1.

The MBTI differs from other personality instruments primarily in two respects. First, the theory postulates and the instrument measures dichotomous preferences. Almost all other psychological instruments assume and measure traits ordered on a continuum. Second, in MBTI theory and practice, each preference is assumed to be equally valuable, with its own characteristic strengths and potential weaknesses. In contrast, trait instruments usually characterize one end of the continuum as "negative" and the other "positive," or they describe people as having "too

ESTP	ESFP	ENFP	ENTP
ESTJ	ESFJ	ENFJ	ENTJ

much" or "too little" of the trait. The intent of the MBTI scales is, instead, to sort people into the equally valuable categories to which they naturally belong, based on their preferences. Also unlike trait instruments, measurement around the midpoint of each scale of the MBTI is more important than fine differentiations at other points along the scale. To increase measurement precision around the midpoint, item response theory is used to score the MBTI items and to assign people to one pole or the other on each of the four dichotomies. These differences are the cause of the majority of misunderstandings of the MBTI.

ASSUMPTIONS

The basic postulate underlying the use of the MBTI in the career domain is as follows: Individuals are attracted to and more satisfied with occupations in which they find (a) opportunities to express their unique type preferences, (b) tasks associated with those occupations that are interesting and challenging, and (c) rewards for doing what they like to do and what they are good at doing. Conversely, people tend to avoid or become dissatisfied with occupations that do not meet these criteria. In fact, when a person enters an occupation that is not congruent with his or her natural preferences, that person will be more likely to be dissatisfied, to leave the occupation, or to experience more job-related stress. A corollary of the basic postulate is that type preferences are also related to career variables, such as occupational values, leisure activities, job satisfaction, turnover, preferred work environments, and a host of other variables relevant to career counseling.

If the basic postulate is correct, one would expect that the distribution of types across occupations would not be the same as the distribution of the types in the general population. The most direct method for testing the postulate is to compare the distribution of the 16 types in a variety of different occupations with the distribution of the types in an appropriate base population.

Type distribution studies have been conducted on many hundreds of occupations, on 22 of the 23 job families used by the U.S. Department of Labor Occupational Information Network, which currently serves as the standard job classification system for the U.S. labor market, and on specialty choice in medical, engineering, and other professions. The primary method of testing the hypothesis is categorical analyses of contingency tables subjected to significance testing, although log-linear analyses of larger tables have also been used. For example, in a study of tax preparers, 100 percent of the sample exhibited a preference for Sensing, and two types, ISTJ and ISFJ, constituted 44.4 percent of the sample. Since this proportion represents almost 2.5 times the proportion of these two types in the base population and the occupation requires exacting and scrupulous attention to detail and a vast amount of detailed knowledge, both characteristics of Sensing types, this is a highly significant finding, both statistically and practically. Although not all results are as clear-cut as this, the evidence that the frequency of the 16 types found in different occupations supports the type proposition is abundant and compelling.

The type hypothesis has also been tested by examining the degree of overlap in a list of occupations recommended for people of opposite types. If types are not differentially attracted to occupations, then one would expect that occupations recommended for, say, an ENFP, would be similar to those recommended for people of the opposite type, ISTJ. A high-percentage overlap would mean that the same occupations were attractive to people of opposite types, a finding that would be inconsistent with type theory. In contrast, a low-percentage overlap would indicate that different types are, indeed, attracted to different occupations. Research has shown little or zero overlap in the occupational lists for seven of the eight pairs of opposite types, and the only pair of opposite types on which there was overlap had only one of the occupations in common.

Type theory also predicts that different types will have different criteria for job satisfaction. For example, those who prefer Extraversion are more satisfied with jobs in which they can interact with a wide variety of people throughout the day. Measuring specific aspects of job satisfaction is more effective than using a global criterion, and such specific aspects are related to type preferences. Furthermore, MBTI scales have been shown to predict a sizable portion of the variance in job-specific satisfaction, over and above

that contributed by situational factors, as well as intention to leave the job and actual turnover.

PRACTICE

The primary uses of the MBTI in the career domain are for career exploration, career choice, and career development. The basic assumption is that certain tasks, occupations, and work environments are more attractive to some types and not to others. It is important to note that the MBTI is not recommended for use by organizations for the purpose of employee selection or promotion. In fact, such use would violate the ethical principles of the Association for Psychological Type.

When using the MBTI for career choice, the results can help clients identify characteristics of jobs or work environments that are congruent with their preferences. For example, the Judging-Perceiving index can help clients identify the amount of structure or autonomy desired to perform a task, while the Extraversion-Introversion index is used to determine the amount of contact with others that is needed. The results can also be used to understand and resolve career dissatisfaction. For example, a manager with a preference for Intuition may balk at spending most of his or her day dealing with operational details.

Basic requirements for using the MBTI in career counseling and management include the following: (a) a database of people whose type and occupation are known, (b) a method for ranking those occupations by their attractiveness to each type, and (c) descriptions for how to use type for career search, exploration, decision making, and management. There are two large-scale databases, one maintained by the Center for Applications of Psychological Type and another by CPP, Inc., the publisher of the MBTI. The former database is available through the Atlas of Type Tables and contains over 300,000 people and hundreds of occupations. The CPP database is the foundation of the *MBTI Career Report*. This database is more recent and contains over 106,000 people from 282 specific occupations representing 22 job families. Furthermore, these people have indicated that they are satisfied with their jobs. The number of people of each type in this database ranges from 2,489 INFJs up to 13,624 ESTJs. The system used to categorize the MBTI occupational database is adapted from the O*NET occupational classification system used by the U.S. Department of Labor as the standard for U.S. occupations. Career clients can therefore easily link their results to the

national occupational database, which includes detailed job descriptions, educational requirements, and a plethora of additional information.

The method used to rank the occupations in each database is based on an index called a *self-selection ratio*. The numerator of the self-selection ratio is the percentage of people of that type in the occupation. The denominator is the percentage of people of that type in the base population. For the application of type theory to careers to be valid, it must be demonstrated that persons of a particular type are found in a much higher or much lower frequency in a given occupation than would be expected based on the frequency of that type in the base population. In contrast, if the frequency of that type in the occupation is the same or similar to the frequency of that type in the general population, one would conclude that occupational membership is determined by factors unrelated to MBTI preferences. A self-selection ratio greater than 1.00 for a given type in a given occupation therefore means that the type is overrepresented, suggesting that people of this type are attracted to this occupation more than would be expected. In contrast, a self-selection ratio less than 1.00 is evidence for underrepresentation of that type, suggesting that people of this type avoid this occupation. If type preferences had no effect on the selection of an occupation or a career field, self-selection ratios for all 16 types for all occupations would equal 1.00. Once self-selection ratios have been computed, they can be used to index the attractiveness of any given occupation for each of the 16 types. For example, in the *MBTI Career Report*, the highest self-selection ratio for a specific occupation is 7.45 for ISFPs employed as veterinary assistants. This ratio means that ISFPs who are satisfied with their jobs are found in this occupation at almost 7.5 times the frequency than would be expected given the frequency of this type in the entire sample. In contrast, for those occupations ranked as least attractive in the *MBTI Career Report*, the self-selection ratios range from zero for many types across numerous occupations (i.e., there are no such types in that occupation) up to .50 (i.e., the proportion of this type in the occupation is one-half what one would expect given the frequency of this type in the general population). Overall, the magnitude of self-selection ratios for broad job families and for attractive and unattractive occupations supports the link between type and career choice.

A number of practitioners have provided descriptions of the preferences for each type for tasks and work environments. The *MBTI Career Report* provides interpretive statements based on the client's reported type to address personal style, challenges, and strategies in the areas of career choice, career exploration, and career development. The interpretive statements in the report represent a distillation and condensation of hundreds of statistically significant research findings, including data collected from a national representative sample of the U.S. population. These data include the relationship of MBTI type with the following aspects: ideal work environment, satisfaction with 14 specific aspects of work, intention to leave one's current job, confidence in performing different kinds of work, organizational values, and on-the-job behaviors.

N

NATIONAL CAREER DEVELOPMENT ASSOCIATION

The *National Career Development Association* (NCDA) is the home for approximately 3,800 practitioners, scholars, and students devoted to promoting the career development of all people over the life span. As the third largest division of the American Counseling Association, NCDA provides service to the public and professionals involved with or interested in career development. NCDA has a long history of service to the counseling profession.

In 1913, the National Vocational Guidance Association (NVGA) was founded. The inception of NVGA stemmed from the changing economic and educational milieu and a social demand for the guidance of youth. In 1951, the association accepted divisional status in the American Personnel and Guidance Association, now called the American Counseling Association. In 1985, NVGA became the National Career Development Association (NCDA). On a global scale, NCDA promotes sharing of workforce policy and practices and welcomed its first international affiliate in 2002, the Japan Career Development Association. NCDA provides a voice for members who deliver career services to diverse groups in a variety of settings.

NCDA has been instrumental in disseminating knowledge on career theory, research, and practice. In 1921, NCDA published its first periodical, the *National Vocational Guidance Association Bulletin*. In 1952, after a few title changes, the journal was renamed the *Vocational Guidance Quarterly* and later

became the *Career Development Quarterly* (CDQ) in 1986, which remains as the official journal of NCDA today. The purpose of the CDQ is to foster career development through the design and use of career interventions and publish articles on career counseling, individual and organizational career development, work and leisure, career education, career coaching, and career management. In addition to the CDQ, the counseling profession has made great progress in defining the specialty of career counseling.

NCDA speaks for professionalism and is the recognized leader in developing standards for career counseling and development. NCDA sets ethical standards for the field, including guidelines for the provision of career services on the Internet, and provides competency and performance indicators. NCDA works with licensing and credentialing bodies to support the recognition of career counselors and career development facilitators (CDF). The CDF credential was developed to provide standards, training specifications, and credentialing for individuals who are currently providing career assistance but are not professional counselors. In cooperation with the Association for Counselor Education and Supervision (ACES), the ACES/NCDA commission on Preparing Counselors for the New Millennium was developed to stress the continued importance for career training in the counseling curriculum. Committed toward higher standards, NCDA has recognized members for their exemplary service to the profession.

Recognition for achievement and service has been a hallmark of the NCDA. Recognition awards and monetary grants are conferred annually to members, including graduate students in counseling for their

outstanding practical or theoretical contributions to the career field. Awards are presented at the annual conference, which is a global gathering that attracts over 1,000 career development professionals across many career service areas. To recognize career professionals who exhibit professional distinction, NCDA recently created three special membership categories: Fellow, Master Career Counselor (MCC), and Master Career Development Professional (MCDP). Through these efforts and many others, the NCDA continues to foster a sense of community among its members and will strive to be a leader in the field of career development for years to come.

NATIONAL LABOR RELATIONS ACT (NLRA)

The *National Labor Relations Act* (NLRA) is the basic federal law that governs unionization and collective bargaining in the United States. When it was originally enacted in 1935, the NLRA was called the Wagner Act, based on the name of its main sponsor, Senator Robert Wagner of New York. The NLRA underwent major amendments in the Taft-Hartley Act of 1947, also called the Labor-Management Relations Act. The NLRA was also amended in 1958 and in 1974.

The NLRA regulates labor relations in almost all private sector businesses in the United States that affect interstate commerce. The NLRA does not cover public employees (who are covered by state labor relations laws), agricultural employees, or employees in the

railroad and airline industries. Labor relations in the latter industries are governed by the Railway Labor Act.

BASIC PRINCIPLES OF THE NLRA

The collective bargaining system in the United States as governed by the NLRA has five basic principles: employee choice, majority rule, exclusive representation, the "appropriate bargaining unit," and labor and management determination of terms and conditions of employment. The principle of employee choice means that employees in an "appropriate bargaining unit" (to be discussed below) choose whether they wish a union to represent them for collective bargaining purposes, and if so, which union. The principle of majority rule means that the choice of whether employees choose to be represented is made by a majority of the employees in the "bargaining unit." If a majority of the employees in the bargaining unit do not select representation, the employees in the unit are not represented by a union.

If a majority of the employees in the bargaining unit choose union representation, the principle of "exclusive representation" comes into play. Under this principle, the union selected by a majority of the employees in a bargaining unit represents all the employees in the unit, regardless of whether the employees supported unionization. The employer, in turn, has a legal obligation to bargain with the union in good faith over terms and conditions of employment for the represented employees.

The fourth principle is that the selection process for unionization takes place among the employees in an "appropriate bargaining unit." An appropriate bargaining unit is a grouping of employees who work for a single employer and have a "community of (employment) interest" or common employment interests. They may be the employees who work in a company facility or the employees in an occupational group or a department or within a particular craft. Employees who have a community of interest are employees with similar supervision, pay structures, tasks, hours of work, responsibilities, and work location.

The fifth principle is union and management determination of terms and conditions of employment. The employer has an obligation to bargain in good faith with the union representing its employees, and the union has an obligation to bargain in good faith with the employer. Neither party has an obligation to agree, however. Terms and conditions of the employment are

determined by the parties' negotiations influenced or affected by the bargaining power of the parties as manifested by their use of economic weapons, such as a strike, a lockout, or employer replacement of strikers. The purpose of these economic weapons is to move the parties toward agreement, even if one party concedes. The law does require that the parties reduce an agreement to writing. An agreement in writing is generally enforced through a grievance procedure ending in binding arbitration.

BASIC RIGHTS UNDER THE NLRA

The NLRA provides employees the right to bargain collectively, to form, join, and assist unions (called labor organizations), and the right to engage in concerted activity for other mutual aid or protection. Thus the NLRA is not limited to employee attempts to unionize. The NLRA also protects the rights of employees to refrain from any activities related to collective bargaining or unionization.

The employees who may exercise rights under the NLRA are only employees who are considered "employees" for purposes of the act. Persons employed in industries not covered by the NLRA are not considered "employees" for the purposes of the NLRA. Other persons employed who are not considered employees for the purposes of the NLRA are supervisors, managerial employees, independent contractors, and persons whose jobs are related to an employer's labor relations function.

ADMINISTRATION OF THE NLRA

The National Labor Relations Board (NLRB), an administrative agency of the federal government, administers the NLRA. The NLRB consists of five members who serve staggered five-year terms. The NLRB members are nominated by the president of the United States and must be confirmed by the U.S. Senate. By the third year of a president's term, the president will have appointed a majority of the board members. There is a custom, however, that no more than three board members may be affiliated with one political party. Because of these limited terms and appointment by the president with confirmation by the Senate, the NLRB is designed to be an agency that changes its composition, and to some extent its views on labor relation issues, with the changing political consensus in the country.

The NLRB has two main functions: determining representation and preventing unfair labor practices. In its representation function, the NLRB determines whether a unit of nonunion employees wishes to be represented by a union. Upon a showing of "substantial interest," which is generally demonstrated by at least 30 percent of the employees in a bargaining unit signing union "authorization cards" designating the union as their collective bargaining representative and presenting the cards to an NLRB regional office, the board will initiate its representation procedures. After resolving any disputes regarding the bargaining unit, the typical method for determining representation is through a representation election. During the one-year period from October 2002 through September 2003, the NLRB conducted 2,797 representation elections. Employees chose representation in 1,458 elections (52.1%) and did not choose representation in 1,339 (47.9%). A total of 181,496 employees voted in these elections. Of these, 74,649 were in units that selected representation, and 106,847 were in units that did not select representation.

The second major function of the board is preventing unfair labor practices. An employer commits an unfair labor practice under the NLRA when it discriminates, interferes with, or coerces its employees who are attempting to exercise their rights under the NLRA or when the organization refuses to bargain with a union that represents its employees. A union commits an unfair labor practice when it discriminates against an employee who wishes to exercise rights to refrain from union activity or commits any one of several other types of offenses. During the period from October 2002 through September 2003, the NLRB closed 30,390 unfair labor practice cases. Of these, 23,444 were charges of unfair labor practices against employers.

CONCLUSION

Although the NLRA has been in existence for more than 70 years, labor relations in the United States and its regulation by the NLRA continues to be controversial and the cause of a wide gap in viewpoints between employers and unions. The NLRA and labor laws in the United States touch on issues of individual rights and collective rights, property rights, and human rights to organize. These are issues that lie at the very heart of the relationship between business, society, and government in the United States.

NEEDS

The term *need* describes a recurrent concern for a certain type of outcome resulting from individuals' interactions with their environments. Examples of biological needs are hunger, thirst, sex, or avoidance of bodily harm; examples of psychological needs include social contact, dominance, and curiosity. The common denominator of most biological and psychological needs is that the successful attainment of a need-specific outcome (e.g., food, water, orgasm, interpersonal closeness, high rank, new rewards) is pleasurable and satisfying. Anticipation of the pleasurable end state provides motivational needs with energy and direction. For instance, hungry individuals invest effort and energy into the procurement of food but not into the attainment of dominance or social contact. Needs also influence learning and memory by facilitating the retention of behaviors that are instrumental in need satisfaction and the recall of contexts that are associated with need satisfaction or frustration.

Research on individual differences in psychological needs (often called motives) has focused on the

needs for achievement (n Achievement), power (n Power), and affiliation (n Affiliation). These needs are also labeled implicit motives, because they operate outside of a person's conscious awareness and are assessed indirectly, through empirically derived scoring systems that are used to analyze stories individuals write in response to picture cues. The validity of picture-story measures of implicit motives has been documented by studies relating them to a large array of phenomena, ranging from psychophysiological responses, to measures of mental and physical health, and to societal and historic phenomena. Importantly, implicit motives predict career trajectories, entrepreneurial activities, and managerial success. Moreover, implicit motives do not correlate with measures of explicit or self-attributed needs assessed per questionnaire. Implicit and explicit motives are activated by different types of cues, predict different types of behavior, and interact in shaping individuals' adjustment and well-being.

THE POWER MOTIVE

The implicit power motive represents a recurring need to have impact on others or the world at large. Findings from longitudinal studies show that power-motivated individuals have more successful careers, as reflected in higher occupational levels attained. In large companies, they are also more likely than other individuals to rise to higher management levels, particularly if they have a strong prosocial power motive. There are two reasons for power-motivated individuals' greater career success: First, a successful career provides prestige and social visibility and therefore satisfies power-motivated individuals' need to have an impact on others. Second, to the extent that the work itself gives power-motivated individuals frequent opportunities to influence and direct others' work, it can provide an outlet on a daily basis for the need to have impact on others and thus promote frequent need satisfaction. Research also shows that power-motivated individuals excel at influencing and leading others. They are particularly adept at using behavioral strategies that project intelligence and competence. As a consequence, they have an easy time persuading others and rallying them to their cause. Research on U.S. presidents has shown that presidents whose inauguration speeches were particularly saturated with n Power were also judged by historians as being the most effective at leading the country.

Depending on the individual's socialization and learning history, n Power can be expressed in prosocial, controlled ways by helping, leading, or teaching others or in antisocial, uncontrolled ways by coercing, controlling, or aggressing against others. Research suggests that career and management success are frequently associated with controlled forms of power motivation (also called inhibited or socialized power motivation), which enables individuals to be socially successful by taking the long-term consequences of their behavior into account. In contrast, individuals characterized by uncontrolled power motivation are more likely to express their need for impact in impulsive acts, exploitative behavior, and alcohol abuse. Not surprisingly, individuals with this variant of power motivation are less likely to have successful careers or to be promoted to higher management positions.

THE ACHIEVEMENT MOTIVE

Individuals with a strong implicit achievement motive derive pleasure from doing well or improving on a task. In contrast to power-motivated individuals, who feel comfortable delegating work to others, achievement-motivated individuals want to have complete control of the task and master it on their terms; extrinsic demands for good performance or external interference with the way they want to complete the task can be powerful disincentives for achievement-motivated individuals. Achievement-motivated individuals achieve optimal task performance by setting medium difficulty, challenging goals and seeking frequent feedback on how well they are doing en route to goal attainment.

The implicit achievement motive is a predictor of several aspects of career success: on average, achievement-motivated individuals earn more, they make more realistic occupational choices, and they tend to be more satisfied with their job than individuals low in achievement. In large companies, achievement-motivated individuals are also more likely to rise to higher management levels, as long as they do not need to manage large numbers of people and can still make contributions on their own. In contrast to power-motivated individuals, however, they rarely make it to the top management positions, and if they do, they tend not to do well in these positions, because they no longer have direct control over the tasks and goals to be accomplished but have to delegate the actual execution of plans and tasks to others.

Implicit achievement motivation has also been linked to innovation. A strong achievement motive predisposes individuals to constantly seek new, better, and more efficient ways of achieving their goals. As a consequence, the achievement motive has been linked to increases in the U.S. patent index, to the adoption of innovative agricultural practices by farmers in developing countries, and more generally to greater curiosity. High levels of achievement motivation make individuals more interested in and capable of doing well in business, because this line of endeavor requires that one take moderate risks, have personal control over process and outcome, and find new and innovative ways of making and marketing products. It also provides the achievement-motivated person with constant feedback as costs and profits increase or decrease. For achievement-motivated individuals, money is important only to the extent that it reflects how well they are doing in a particular line of business.

THE AFFILIATION MOTIVE

People with a strong implicit affiliation motive derive satisfaction from establishing, maintaining, or restoring close, friendly relationships with others. As a consequence, they are more likely to cooperate with and help others and less likely to enjoy competing with, confronting, or directing others than individuals low in affiliation motivation. Affiliation-motivated people are also characterized by good interpersonal skills. In laboratory experiments and naturalistic studies, the affiliation motive has been found to predict good task performance and positive social interactions when affiliation incentives were present (e.g., a warm and friendly instructor or manager) but not when such incentives were absent. Affiliation-motivated individuals tend to have less success than others when they head small companies, and high-affiliation individuals are also less likely than low-affiliation individuals to be promoted to higher management levels in large companies, primarily because high-affiliation individuals tend to shrink away from conflict and hard decisions regarding personnel. High-affiliation individuals do tend to excel in integrative management positions, though, because such positions allow them to use their interpersonal skills to resolve conflicts and facilitate cooperation within and between groups.

One reason why affiliation-motivated individuals do not show much evidence of career and managerial success may be that the n Affiliation measure has a strong

fear-of-rejection component. In other words, affiliation-motivated individuals are particularly motivated to avoid rejection and try to belong to a group without necessarily aiming at building truly deep and meaningful relationships with others. Researchers have therefore developed a picture-story measure of *n* Intimacy, which, despite some overlap with *n* Affiliation, captures a positive, hopeful component of the need for close social contact. Although little research on the effects of *n* Intimacy on career success exists, some studies suggest that intimacy-motivated individuals have overall better social adjustment and mental health than individuals low in intimacy motivation.

DIFFERENCES BETWEEN IMPLICIT AND SELF-ATTRIBUTED NEEDS

A large body of research suggests that picture-story measures of implicit needs and questionnaire measures of individuals' self-attributed needs and goals do not substantially correlate. This means, for instance, that a person can be endowed with a strong implicit power motive without possessing a strong conscious need to dominate, influence, or control others. Likewise, a person can be low in implicit power motivation but endorse many items related to the pursuit of power and dominance on a questionnaire. Of course, the absence of a substantial correlation also means that some people can be high and some can be low in both types of measures.

Whereas implicit motives are hypothesized to be based on affective preferences—that is, on the capacity to experience the consummation of a motive-specific incentive as rewarding and pleasurable—explicit motives are linked to the goals and expectations that are normative for a particular group (e.g., family, peers, society) and that thus focus the individual's decisions and behaviors on what the group deems important and desirable. Explicit motives guide voluntary goal setting and thus can either channel the expression of implicit motives into certain contexts and behaviors or even override motivational impulses, which increases both the flexibility and the stability of behavior. Thus a crucial difference between implicit and explicit motives is that the former motivate and the latter channel and regulate goal-directed behavior.

Implicit and explicit motives also differ in the types of incentive cues they respond to. Implicit motives respond to task-intrinsic (or activity) incentives, that is, to the pleasure of working on a challenging task, in

the case of implicit achievement motivation, or the pleasure of having friendly conversations with others, in the case of implicit affiliation motivation. Explicit motives, in contrast, respond to social-extrinsic incentives, that is, to salient external demands and social norms. For instance, individuals' self-attributed need for achievement can become activated by an experimenter's explicit instructions to do well on a task, and individuals' self-attributed need for affiliation can become a salient guide for behavior if cued by specific demands to be friendly and socialize with others. Some research also suggests that implicit motives are more likely to respond to nonverbal incentive cues than to verbal-symbolic stimuli.

Finally, implicit and explicit motives influence different types of behavior. Implicit motives are particularly likely to show an effect on nondeclarative or operant measures of motivation (i.e., measures that tap into individuals' know-how in operating on their environment), whereas explicit motives and goals have a stronger influence on declarative measures of motivation (i.e., measures that assess individuals' self-related "knowing that" or their attitudes, judgments, choices, and decisions). For instance, individuals' implicit need for achievement has been shown to predict their performance on a speed-based achievement task (a nondeclarative criterion) but not their decision to continue on the task (a declarative criterion). Conversely, individuals' self-attributed need for achievement has been found to predict the decision to continue on the achievement task, but not their performance on the task itself.

INTERACTIONS BETWEEN IMPLICIT AND SELF-ATTRIBUTED NEEDS

There is growing evidence that despite their statistical independence, implicit and explicit needs interact in shaping individuals' well-being and life outcomes. For instance, it has been found that individuals whose explicit goal pursuits in a particular motivational domain (e.g., power) are supported by a strong underlying implicit motive disposition experience more motivational well-being upon realizing their goals than individuals whose goals are mismatched with their implicit needs. Both research and theory also suggest that the pursuit of explicit goals becomes effortful and demanding for individuals' capacity to self-regulate if the goals are not supported by strong implicit needs. Thus, for instance, a person

who is committed to the goal of becoming a manager and directing the activities of others, but whose implicit need for power is low, will experience the pursuit and realization of this goal as more difficult and challenging than a person who wants to become a manager and has a strong implicit power motive. Because research on the interactions between implicit and explicit needs has just started to gain momentum, it is currently unclear to what extent people are also objectively less successful at realizing explicit goals that are misaligned with their implicit needs and are more likely to suffer from impaired social adjustment and mental health problems. However, it has been demonstrated that individuals can maximize the fit of their explicit goals and their implicit needs if they explore a potential goal experientially (e.g., by vividly fantasizing about the pursuit and attainment of the goal) before deciding on whether to adopt the goal. This suggests that although people often consciously desire outcomes for whose attainment they do not have the necessary implicit motivational resources, they can increase the degree to which their goal choices match their implicit needs through careful exploration of the incentives and disincentives associated with the pursuit of a given goal.

NEPOTISM

Nepotism is generally defined as preference given to a relative by a person in a position of power in an organization. Nepotistic preferences are most often defined in terms of hiring decisions but may also be manifest in evaluations, pay decisions, and other personnel decisions. Anthropological theory and historical evidence suggest that hiring decisions are heavily influenced by preferences given to one's relations. When compared with a standard of merit, this form of nepotism is typically viewed as unfair and unethical and is often prohibited by organizational rules and governmental laws.

From a psychological perspective, this traditional definition of nepotism is framed first as a hiring decision on the part of a manager or supervisor and then as an acceptance or rejection decision on the part of the person presumably receiving the unfair benefit of nepotistic hiring. No published measures have been developed for nepotism; however, it may be that the usual indicators of nepotism (generations of family working in the same workplace or occupation, family ties in business and government, married people in the chain of command within an organization) are not always the result of such a top-down decision. Recent research suggests that career choices based on offspring or spousal preferences for occupations may lead to the appearance of nepotism, even though the offspring or spouse may in fact be a meritorious candidate. Moreover, the choice to enter an occupation may be opportunistic from the career choice perspective. Researchers have referred to this career choice and opportunistic nepotism as "new" nepotism.

There are also arguments that antinepotism laws may have a disproportionate negative impact on women, who are less likely to be in positions of power and therefore more likely to be excluded from jobs than their male counterparts. Research to date has not supported this argument, but the paucity of research

and theory in this area leaves this and other questions open.

NETWORKING

Networking refers to a set of behaviors used to develop and maintain relationships that can potentially provide information, influence, guidance, and support to individuals in their careers. Actively maintaining contacts inside and outside of one's organization, engaging in professional and community activities, and increasing one's organizational visibility through accepting challenging work assignments are examples of networking behaviors. Social network and careers research have emphasized the importance of engaging in networking behaviors in the attainment of valuable career outcomes such as enhanced advancement, compensation, career satisfaction, and career mobility.

Networking is believed to enhance career outcomes mainly because networking behaviors help individuals develop their social capital. Social capital refers to the resources available to individuals through their network relationships. Some of the resources embedded in one's network of relationships include information, expertise, professional and political advice, exposure, friendship, and support. Availability of such resources in turn facilitates career advancement and development primarily because these resources enable individuals to have greater access to different career opportunities both inside and outside of their current organization and to develop their ability to act on these opportunities.

Network researchers state that the accumulation of valuable social capital requires the development of networks with certain structural characteristics. Network size or the number of contacts that constitutes one's network is one of the important characteristics of an effective network. Although the development of large networks is critical for finding new job opportunities and for creating intrafirm mobility, the sheer size of a network is not sufficient to accumulate valuable resources. In addition to the size of a network, network structure and composition also need to be considered when developing effective networks.

Network structure explains how contacts in one's network are connected to each other. It is considered to be beneficial for an individual to build a low-density network connected through weak ties. Weak ties are represented by less frequent and less emotionally intense relationships than strong ties. Weak ties are thought to be advantageous because they reach outside of one's immediate social clique and therefore offer unique, nonredundant information and resources to the individual. Low-density networks are characterized by structures in which one is connected to individuals who are not connected with each other. By linking otherwise disconnected individuals, one gains important information and control benefits such as referrals on his or her behalf, timely access to diverse and unique sets of information, and greater control over the flow of information and resources due to brokering opportunities available in such a network.

Network composition refers to characteristics and types of contacts that make up one's personal network. It is advantageous to develop a diverse network composed of contacts from a variety of social contexts (e.g., work, family, and community) and contacts with different demographic and organizational characteristics (e.g., gender, organizational level, and organizational affiliation). Knowing many kinds of people from many different social contexts is believed to improve one's chance of getting a good job and to increase one's power base and advancement opportunities in an organization. Forming relationships with contacts who hold high status positions inside and outside of one's organization is found especially useful to obtain future promotions and highly prestigious jobs.

In recent years, networking as a career management tool has gained considerable research interest due to a drastic increase in the number of people experiencing more fluid careers with high cross-organizational

mobility. It is believed that successful navigation of such careers requires the development of interpersonal relationships through networking, because this helps individuals exploit career opportunities outside the current employment context and remain continuously employed. Given the importance of networking in the pursuit of newly emerging careers, researchers have started to focus more specifically on understanding the types, predictors, and outcomes of networking behaviors.

Studies examining the relationship between networking behaviors and career outcomes have found that networking is associated with salary progression, promotions, and enhanced interfirm career mobility. Recent research has become more refined in terms of identifying different types of networking behaviors and studying their effects on important career outcomes. This research identified five different types of networking behaviors—maintaining contacts, socializing, engaging in professional activities, participating in community, and increasing internal visibility—and found that only two networking behavior types, increasing internal visibility and engaging in professional activities, positively affected the number of promotions, total compensation, and the perceived career success of managerial and professional employees.

Recent research has examined several demographic, dispositional, attitudinal, and job-related factors as possible predictors of networking behaviors. This research has found that the demographic variables of gender and socioeconomic background and the personality and attitudinal characteristics of

self-esteem, extraversion, and favorable attitudes toward workplace politics are significant predictors of involvement in networking behaviors. In terms of job-related factors, one's organizational level and type of position influence whether individuals engage in networking behaviors.

Because of its highly pronounced importance in the pursuit of newly emerging fluid career forms, networking has become a mainstream topic of interest in both the popular press and scholarly writings. Empirical research has shed some light on the dimensions, predictors, and consequences of networking behaviors. However, further research is needed for developing more comprehensive theoretical models and scales of networking behaviors.

OBSOLESCENCE OF KNOWLEDGE AND SKILLS

The *obsolescence of knowledge and skills* has long been recognized as a problem affecting individual careers and organizational effectiveness. While obsolescence has been discussed from a management as well as a psychological perspective at least as far back as 1930, concern over the problem became widespread following the rapid changes that began during the post–World War II era.

The problem of obsolescence has been most often addressed with reference to professional or managerial careers in organizations. However, the problem also affects careers in which professionals are self-employed (e.g., medicine and law) as well as in other occupations that require a body of knowledge and skills. Therefore, obsolescence has an impact on knowledge workers, a widely diverse and rapidly growing population of workers who require a base of specialized and practical knowledge acquired through education and experience.

DEFINING OBSOLESCENCE

Obsolescence can be defined as the degree to which knowledge workers lack the up-to-date knowledge or skills necessary to maintain effective performance in either their current or future work roles. There are several concepts or dimensions that are part of this definition of obsolescence, and they include the following:

1. *A lack of new knowledge or skills.* Obsolescence occurs when the individual lacks new knowledge or skills. Obsolescence involves a failure on the part of the knowledge worker to keep current. However, obsolescence is a matter of degree. While knowledge workers typically need to deal with the problem of staying up to date, few are totally obsolete. Even among those who do stay current, it is practically impossible to be completely up to date.
2. *Ineffectiveness.* Obsolescence becomes a problem for the individual as well as the organization when it results in ineffectiveness. However, most types of ineffectiveness would not be attributed to obsolescence. For example, a knowledge worker who may have the most up-to-date knowledge and skills but is unwilling or unable to use them may be ineffective but not obsolescent. Such ineffectiveness may be attributable to personal (e.g., motivational) or organizational (e.g., poor supervision) factors that can inhibit performance. Only ineffectiveness that stems directly from a lack of current knowledge and skills should be attributed to obsolescence.
3. *Job and professional roles.* Obsolescence has most often been connected to the effectiveness of performance in one's current work role. Consequently, knowledge workers who lack the knowledge or skills necessary to perform their current jobs effectively are obsolescent. This has sometimes been referred to as job assignment obsolescence or simply job obsolescence.

However, other types of obsolescence relevant to specialist or professional career roles have also been identified, although with less frequency than the job assignment type. Those roles may be affected by

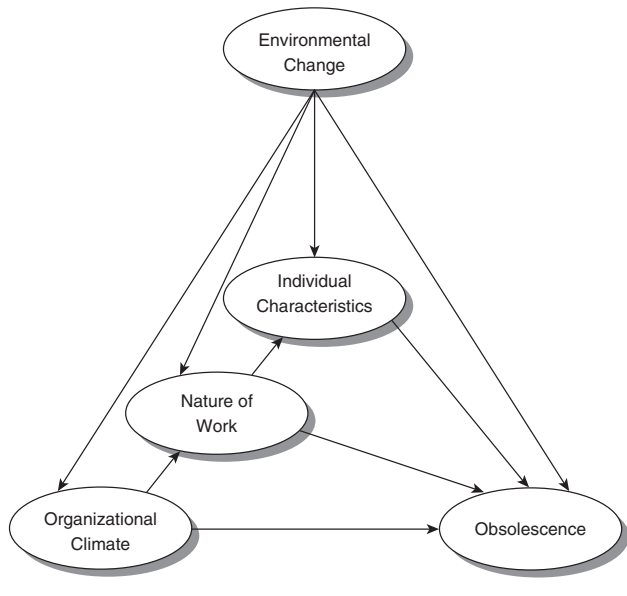

Figure 1. The Kaufman Model of Obsolescence

professional obsolescence, which occurs when individuals do not keep up with the latest developments in their disciplines. Such obsolescence potentially impairs effectiveness of performance in future work roles during the knowledge worker's career.

Although knowledge workers may be up to date in their present job assignments, they may not have kept broadly current in their professional disciplines, and so their capability to take on different or greater responsibilities becomes more limited. For example, this type of professional obsolescence became visible among many knowledge workers who were terminated in the aerospace and defense industries. They were very likely current in the specialized knowledge and skills required by the jobs in their industry. However, they may have failed to maintain the broader professional knowledge and skills that would have more easily facilitated their reemployment in a different job role related to their discipline but in another industry.

CAUSES OF OBSOLESCENCE

The complexity of obsolescence is manifested by multiple contributing factors. These can be somewhat simplified by applying a theoretical model that integrates these factors and shows some of the possible relationships among them (see model in the figure above). According to the model, obsolescence is due to environmental change, individual characteristics, the nature of the work, and organizational climate.

Environmental Change

The roots of obsolescence have been traced to the knowledge revolution, the information explosion, and the dynamic changes that have occurred in technology, organizations, occupations, and management methods. Such environmental change is the driving force toward creating a knowledge economy that produces and distributes ideas and information, requiring a workforce dominated by knowledge workers. However, this knowledge economy, in turn, has not only accelerated the rate of change but has also contributed to the rapid obsolescence of knowledge workers themselves. Therefore, environmental change can be depicted as all-pervasive, directly affecting the obsolescence of knowledge workers as well as the individual, work, and organizational factors that contribute to the problem (see figure).

Individual Characteristics

Knowledge workers differ among each other not only in their degree of obsolescence but also in many other individual or personal characteristics that may either predispose them to keep abreast with new developments or contribute to their becoming out of date. These individual characteristics are demographic as well as psychological in nature and can have a direct effect on obsolescence (see figure).

Age

It is widely assumed that obsolescence increases with age. Acceptance of this assumption has institutionalized the stereotype in many organizations that obsolescence is an inevitable consequence of aging. This can result in a self-fulfilling prophecy that as knowledge workers get older, they are more likely to be treated as obsolescent, and consequently their behavior reflects the stereotype. There is conflicting evidence regarding obsolescence and age that can generally be classified into one of three types of relationships, based largely on cross-sectional research. One relationship found that peak contributions and performance occur when knowledge workers are in their thirties and steadily decline among older groups. These results may reflect the self-fulfilling prophecy, as well as reinforce the stereotype, that older knowledge workers are more obsolescent.

The second type of relationship is a consistent upward trend in contributions and performance with

increasing age that tends to reach a peak for those over age 50. This contradicts the first relationship that obsolescence increases with age. The third general relationship found between age and contributions or performance among knowledge workers is twin peaked or bimodal. Typically, contributions and performance are highest among knowledge workers who are at an early career stage (in their thirties), after which there is a drop-off for those in mid-career followed by a resurgence among those who are over age 50 and in the later stages of their professional life. Such results indicate that there is not a simple relationship between increasing age and obsolescence. A possible reason for a peak appearing early as well as later in the career may be that there are two populations of knowledge workers: one whose contributions and performance decline with age and another that either maintains the level of contributions and performance or improves them over time. A more definitive answer to how age and obsolescence are related awaits longitudinal research.

Half-life

Related to increasing age is the half-life of a professional education. The half-life can be viewed as the time it takes after completion of formal studies for half of the knowledge acquired in one's professional studies to be no longer useful or applicable because of new developments in the field. Therefore, it is the length of time that has elapsed since a knowledge worker has completed his or her education, rather than age, that may be a crucial factor in susceptibility to obsolescence. There is evidence that the half-life has been growing ever shorter, which is in keeping with the accelerating rate of creation and application of new knowledge in a wide variety of fields, especially those affected by rapid technological change. However, the half-life of some fields has been found to be shorter than others—with four years not atypical and some even shorter. Software engineering, computer science, and fields impacted by changes in information technology typically have the shortest half-life. Therefore, knowledge workers in fields with a short half-life have the greatest need to stay up to date.

Psychological Factors

Although the half-life of a professional education may play an important role in creating a susceptibility

to obsolescence, personal characteristics that are psychological in nature may be critical. If in fact there are two populations of knowledge workers, one that becomes obsolescent and another that stays up to date despite increasing age, it would be useful to identify some of the more important psychological factors that contribute to differential development.

An important psychological characteristic that can facilitate or inhibit obsolescence among knowledge workers is their *cognitive ability*. Different types of cognitive abilities appear to be related to obsolescence, depending on the occupation. For example, limited proficiency in mathematics is associated with obsolescence among engineers, whereas more general problem-solving abilities are important for managers to stay current. Moreover, the cognitive strength that knowledge workers bring to their first jobs can help determine the degree to which they stay abreast of new knowledge during subsequent career stages. Knowledge workers who enter the workforce with weak cognitive abilities would be more obsolescence prone. However, there is evidence that some cognitive abilities improve throughout the career, largely as a result of experience.

Knowledge workers who fail to keep current in their field, even when they have the ability to do so, very likely lack *motivation*. Research supports the great importance that lack or loss of motivation plays in knowledge workers becoming obsolescent. Those with strong motivation apparently do not experience the decline found among those in their forties and tend to prolong their achievement over a broad span of their career. Motivational changes that occur during the midlife or mid-career crisis may help explain the different relationships found for age. During the midlife period, some knowledge workers may perceive that what they have been doing is no longer fulfilling or important and that they have not attained the success in their careers that they expected. Obsolescence is a likely outcome among those who have not been able to cope with their mid-career crisis adequately, whereas those who remain current may not have experienced the crisis or resolved it successfully.

Other individual characteristics, related to motivation, that can affect obsolescence have been identified. *Occupational interests* of knowledge workers are well established at the start of the career, remaining highly stable thereafter and help influence occupational choice as well as other career-related outcomes. The degree to which knowledge workers engage in activities

likely to keep them up to date with new developments is influenced by their interests.

More directly related to motivation are individual differences in *needs*. However, unlike interests, which remain relatively stable, needs can change greatly over time and contribute to motivational changes affecting obsolescence. For example, security needs of knowledge workers tend to be relatively strong at the start of their careers but then decrease in strength in the next five years, whereas their needs for growth increase significantly in intensity, regardless of career success. Knowledge workers whose careers are successful are able to satisfy their growth needs, such as achievement, esteem, and self-development, whereas the satisfaction of such needs drops among those who do not experience career success. If the frustration of growth needs continues into the mid-career stage, they may level off or diminish, whereas security needs are likely to increase. As growth needs level off or diminish in mid-career, obsolescence can become a problem among knowledge workers.

Growth needs are satisfied through the achievement of relevant *goals*. The most important goals for new knowledge workers are challenging work and opportunities for advancement. These goals can change during the career, depending on whether or not they are achieved. Also, a socialization process occurs in which the individual's goals may become more congruent with organizational goals. Knowledge workers' goals that satisfy growth needs may be classified as either (1) local—oriented to the individual's organization or (2) cosmopolitan—directed to one's profession. Obsolescence is most likely to occur among knowledge workers who lack a cosmopolitan goal orientation focused on doing work involving new ideas, acquiring new knowledge, and attaining professional recognition.

By mid-career, knowledge workers who have not kept up to date may seek to satisfy their growth needs by striving for local goals such as advancement. If they reach a stage in their careers when neither cosmopolitan nor local goals are attainable, security goals become important. At that stage, obsolescence may be irreversible. For those who keep up to date, such goal attainment requires that *energy* be expended. Therefore, a lack or loss of energy also predisposes knowledge workers to obsolescence. Moreover, individual *initiative* has been identified as a personal characteristic that contributes to the expenditure of energy to stay up to date. Initiative involves

not only starting an action but also the capacity to discover new ways of goal attainment. Therefore, knowledge workers with low initiative would be more likely to become obsolescent. Initiative may be related to career *resilience*, one component of a multidimensional career motivation construct. Resilience includes adaptability to change, willingness to take risks, and having self-confidence, all of which have been identified as individual characteristics of knowledge workers who stay up to date.

Nature of the Work

There is consistent evidence that the nature of the work carried out by knowledge workers is the most important factor contributing to obsolescence, both directly and by its effects on individual characteristics (see the figure above). There are several aspects of the work carried out by knowledge workers that can affect their obsolescence.

Although challenging work is one of the most important goals of knowledge workers, most feel that their knowledge, skills, and abilities (KSAs) are not utilized well. Poor utilization affects the development of knowledge workers and can occur early in the career.

The First Job Experience

There is consistent evidence that the nature of the work experienced by knowledge workers in their first job has long-lasting effects on their career development and can contribute directly to obsolescence. For example, the Bell System's classic long-term Management Progress Study found that, for newly hired college graduates, the work challenge during the first year had a greater effect on later career growth than the challenge of succeeding years. Work challenge included the degree to which the new managers were expected to utilize their knowledge and skills, use new methods, solve novel problems, apply their learning capacity, become involved in self-development, commit their time and energy, and demonstrate initiative. Those who had challenging work in their first job increased their motivation to achieve and their concern for accomplishment, as distinct from advancement or salary increases. Work challenge may be even more critical to knowledge workers in technology. For example, longitudinal studies of engineers in several organizations demonstrated that being initially assigned to work that demands utilization of technical

knowledge and skills results in higher levels of job performance, professional contributions, and competence in their subsequent careers. However, the greatest effect of challenging work occurred among engineers who were more capable to start with. This demonstrates how professional career development can occur when knowledge workers have the appropriate abilities and the work environment demands utilization of those abilities. The effects of work challenge may be another demonstration of the self-fulfilling prophecy. Knowledge workers who are expected to utilize their knowledge and skills in challenging work in their first job will be motivated to increase their competence early in their careers. Conversely, those whose utilization is much more restricted are at risk for becoming obsolescent.

Dimensions of Utilization

Utilization of knowledge and skills is an important aspect of work challenge and has been found to be strongly related to obsolescence. Two relatively independent dimensions of utilization have been identified, *misutilization* and *underutilization*. Misutilization occurs when light intellectual demands are combined with heavy time pressure. For example, misutilization of knowledge workers results from time pressure to carry out routine assignments that should be done by clerical personnel or technicians. In a study of engineers, the two most important causes of obsolescence were related to misutilization, namely, (1) work assignments that do not require knowledge of the latest developments and (2) the pressure of schedule demands that leave no time or energy for study. Three-fourths of the engineers who reported considerable misutilization in their work had difficulty keeping up with new developments. On the other hand, over half of those who felt that misutilization is not a problem reported having no trouble keeping up to date.

Work assignments that do not utilize professional knowledge, skills, and abilities may also result in underutilization, which is similar to misutilization insofar as they both involve light intellectual demands. However, the underutilized knowledge worker has light, rather than heavy, time demands. Underutilization apparently occurs most frequently during the first job and affects the new employee's development, because the job itself does not offer challenge. However, obsolescence may not occur as readily as it would if the professional were misutilized.

Nevertheless, either can contribute to obsolescence. Underutilized knowledge workers who do not possess the initiative to take advantage of the light time pressure at their job in order to keep abreast of new developments could also be on the path to obsolescence.

Changes in Job Assignments

Knowledge workers who have had frequent changes in job assignments during their career more easily adapt to change and adjust quickly to their new responsibilities. The challenge provided by frequent job assignment changes serves to maximize utilization of their KSAs and minimize obsolescence. There is evidence that providing different job assignments starting at the beginning of the career is highly associated with remaining professionally up to date in later years. However, not all changes in job assignments help knowledge workers keep up to date. For instance, being assigned many routine jobs does not provide challenge, and would tend to contribute to obsolescence, very likely through misutilization. In addition, job assignments should last long enough for the knowledge worker to become proficient in the specialties required to perform the job effectively.

Specialization and Diversity of Job Assignments

Knowledge workers often become proficient in narrow specializations in their job assignments. However, many wish to utilize their abilities in a broad field of interest. Knowledge workers who have a wide understanding of important new fields rather than a thorough knowledge of narrow specialties make greater contributions to both their organization and their professions. This is even more characteristic of those who are older. A diversity of specializations, rather than only one, not only enhances a knowledge worker's usefulness to the organization but also stimulates a wide range of professional contributions. On the other hand, being assigned to a narrow area over a long period of time can lead to an inability to perform other parts of the job. Knowledge workers feel that obsolescence is likely to occur when the work becomes so specialized that the broader base of knowledge is unused and forgotten. Moreover, the single most important stimulation for professional development and growth is on-the-job problem solving that requires a diversity of challenging work assignments.

Organizational Climate

Organizational climate includes attributes of the work environment determined by management and organizational practices that affect obsolescence. According to the model in the figure above, organizational climate not only has a direct effect on obsolescence, but it also affects the nature of the work, which has a major impact on obsolescence. Providing challenge through utilization of knowledge and skills is to some degree determined by the technology of the organization. But organizational climate can also stimulate or stifle utilization, which, in turn, affects obsolescence. Some aspects of organizational climate that have been identified as relevant to obsolescence include colleague interaction and communication, leadership style and expertise, and management policies, as well as their effects on organizational communication, influence, uncertainty, and rewards.

Colleague Interaction and Communication

One aspect of organizational climate is created by the colleagues of the knowledge worker. Interaction and communication with colleagues provide an important source of stimulation for keeping current. However, the impact of such communication on obsolescence will vary with the particular group of knowledge workers. For example, one study demonstrated that engineers, compared to scientists, receive much more of the information needed to stay up to date from interpersonal communication within their own organizations.

How work groups are organized can motivate knowledge workers to gain new knowledge and skills. Working with people from diverse fields can stimulate knowledge workers to learn about different specialties. Not only does diversity in the composition of work groups help stimulate professionals to keep informed of new developments, but including at least one “gatekeeper” helps in the flow of current information. Gatekeepers are generally the most competent and up-to-date knowledge workers in their group. They stay in close contact with other gatekeepers in the organization as well as in the external world and keep the organization current with new developments.

The duration of time knowledge workers have been in the same group appears to influence the stimulation provided by colleagues. For instance, interaction with colleagues and diversity of group members have been

found to be effective in stimulating competence in both job and profession only when the knowledge workers have not worked together for too long. After several years, individuals who have worked closely together no longer provide stimulation and novelty. This would suggest that job assignments as well as group composition should be changed periodically.

Leadership Style and Expertise

A participatory style of management has been widely advocated as the best way to motivate knowledge workers, since it provides them with a considerable amount of influence in decision making about their work. Although giving knowledge workers freedom to explore new ideas and to pursue their own interests is related to remaining up to date, providing them with freedom is most effective when the supervisor consults them before making important decisions affecting the work of the group. The development of subordinates can be stimulated or stifled, depending on the degree to which the supervisor understands the current knowledge and skills relevant to the work group. The technical competence of managers is more important than their human relations skills in encouraging knowledge workers to keep up to date. Respect for their supervisors' competence and judgment is the most important reason knowledge workers comply with supervisory directives. Technical expertise is the most prominent basis for supervisory influence, and it also has a very strong relationship to the knowledge contributions, satisfaction, and performance of their work group.

A climate that discourages obsolescence can be created by competent managers who embrace and utilize new methods. For example, knowledge workers whose managers encouraged them to use major technical advances tended to be more up to date in their specialties. Alternatively, those whose managers emphasized meeting schedules were more likely to be obsolescent. Since managers can determine how the work assignments are distributed, they can use the work itself to motivate subordinates to stay up to date. Just as managers can stimulate their work group members to stay up to date through challenging and diverse job assignments, they also may contribute to obsolescence by assigning work that does not properly utilize professional KSAs. The manager's style, combined with expertise, can be a powerful influence in creating a climate of utilization and challenge that

can motivate knowledge workers to keep up to date. Since managers can have a direct influence on the updating behavior of their work group members, they also play an important role in encouraging individuals to participate in continuing education activities.

Management Policies

The role of managers in motivating their work group members to stay up to date is limited by external constraints created by top management policies. For example, knowledge workers complain about management policies relevant to schedules or work assignments that resulted in underutilization or misutilization. Such policies came from top management and virtually ensured that obsolescence would be a problem among knowledge workers in their organization. Although underutilization or misutilization can be intended results of management policy decisions, such problems more likely occur as an unintended consequence of policy.

Communication within organizations is critical for many knowledge workers to stay up to date. However, a major complaint is that the lack of regular information exchange among departments as well as between different levels in the organization affects knowledge workers' ability to influence the decision-making processes. Management policies that create a climate in which knowledge workers have little or no influence on decisions that affect their work can result in underutilization, as well as greater uncertainty. Such a climate of uncertainty may involve frequent changes or cancellations in scheduled objectives, job requirements that are not clear, misinformation, and job assignments with inadequate feedback. Policies that create an organizational climate laden with uncertainty can have pervasive effects among knowledge workers. The symptoms are poor communication, limited influence, avoidance of risks, and underutilization—all of which can contribute to obsolescence.

Among the most important policies directly affecting obsolescence are those that determine whether or not professional growth and development are rewarded by the organization. There is evidence that the reward climate created by management policies can enhance or inhibit obsolescence. If knowledge workers do not see that their efforts in self-development are rewarded by the organization, the likelihood that they will become obsolescent is increased. For example, knowledge workers who feel that keeping

themselves abreast of new developments will not result in more challenging work assignments, salary increases, or promotions are also more obsolescent. On the other hand, those who perceive that their organizations reward updating with challenging work, promotions, and pay are also the most up to date. In a study of computer marketing and support professionals, participation in self-development activities was perceived as most likely to lead to worthwhile accomplishment and self-esteem as well as opportunities for promotion. Furthermore, the expectation that organizational rewards would be forthcoming for updating efforts was significantly related to current and future efforts at self-development. The organizational reward climate apparently has an important impact on the effort expended by professionals to stay up to date.

However, when organizations reward professional development, older knowledge workers may be excluded. For example, for older managers, those who possess the *most* initiative, self-assurance, and intelligence tend to be rewarded the *least*, although it was the opposite for younger managers. By discouraging development of older knowledge workers who are most capable of and still desire growth, management avoids having to make an investment that may provide a short-lived and limited rate of return to the organization. Such a management policy reinforces the self-fulfilling prophecy that obsolescence is inevitable with increasing age. However, rewarding self-development reinforces motivation toward professional growth even among older knowledge workers, who, with their experience and loyalty, can continue to contribute if they are encouraged to remain up to date.

OCCUPATIONAL CARD SORTS

The *occupational card sort* is a technique used by career counselors to assist persons who are unclear about their present or future vocational choice. It accomplishes this by (1) increasing the range and quality of information about self and about specific occupations, (2) expanding or narrowing the range of occupations being considered, and (3) encouraging further self and career exploration.

The occupational card sort is made up of a deck of cards, most often with occupational titles on one side and various types of information about the occupational titles on the reverse side. That information might include the definition of the occupation and various groupings or classifications of the occupation, such as the Holland Occupational Code, the World of Work classification, or data from the O*Net system. While occupational titles are the most common element on the front of such cards, other developers

have used skills, values, or college majors as the items to be sorted.

The typical process used for the occupational card sort is to have the client sort the cards into three piles: Might Choose, Probably Would Not Choose, or Undecided. A simple instruction would be to have clients rank their top 10 occupations from their Might Choose pile. In some uses of the deck, the counselor will use the codes on the back of the Might Choose pile to derive a summary code, for example, a Holland Occupational Code. Several studies have found this to be an adequate method for deriving such a code, though there has been controversy over whether or not the deck should be used in this fashion. Some argue that if all that is desired is a simple code, instruments developed for that purpose should be used instead, and that the best use of the card sort is to gather more in-depth information or to initiate discussion or thinking about vocational issues.

To accomplish this, many counselors have their clients further sort their cards, for example, sorting only the cards they considered for their Might Choose pile into several piles representing the various reasons why they most liked the occupations. One subpile might represent occupations chosen because they would allow the client to help others, another might be a pile of occupations they believe would allow them to have a flexible combination of work and family life, and so on. As clients discuss their reasons with the counselor, it can open up discussion about the relative importance of various choice mechanisms. It can also alert the counselor to any obvious misinformation the client might have about the world of work.

Some counselors use the cards as stimuli for discussion, having clients go into great detail about their thinking about each card. For example, a client might put the card "Teacher" in their Would Probably Not Choose pile. With prompting on the part of the counselor, clients might be able to identify several issues that are playing themselves out in their deliberations about many occupations, not just teacher.

There are many attractive features of occupational card sorts, including the active level of involvement of the client, the immediacy of the results, the low cost, and the less formal atmosphere compared to paper and pencil or computerized testing. By having to generate their own reasons for why the occupational titles ended up in one pile or another, clients are actively engaged in creating the data and are manipulating the

data in their heads, conjuring up images, and making greater distinctions and connections. The results of this process may allow the client to have a greater sense of ownership of the results and to feel a greater sense of accomplishment in the process. This is in contrast to a computer-scored inventory that does most of the processing for clients, the result of which is simply given to clients, without their having to do much reasoning. Finally, card sorts can promote a greater interaction with a counselor, which could bring about greater clarification of values and interests, gender role stereotypes, and other limiting beliefs. In fact, some of the early occupational card sorts were developed as a means of addressing gender role stereotypes, not just in the popular beliefs of clients, but in interest inventories themselves.

Occupational card sorts provide a process-oriented alternative to paper and pencil and computerized methods of assessment and exploration. As such, they can be particularly useful when working with persons who produce flat interest profiles or for whom none of the more traditional forms of career counseling seem to work. They are sometimes described as belonging to the group of more subjective, qualitative, or even projective methods of assessment, as contrasted with objective or quantitative methods.

OCCUPATIONAL CHOICE

For many individuals and for a long time, *occupational choice* has been seen as the goal of career development. Theory and practice focused on either occupational choice or career development, but more recently these have been integrated into more complex conceptions of career. Historically, occupational choice is a comparatively new phenomenon. Up until the twentieth century, most people's occupations were determined by their station (position in the society) and their family circumstances. Occupations were usually inherited and passed on through generations within families. This was so prevalent that many family names in English-speaking countries are actually occupation titles, such as Baker, Farmer, Cook, Carpenter, Potter, Taylor, Ryder, and so on. The vestiges of this form of career are evident in the development of family dynasties traditionally associated with property and agriculture but more recently with large corporations in which owners pass leadership on to their progeny across generations. However, increasing industrialization and its sociological impacts resulted in major changes in the structure of the labor market, including the decline of some traditional occupations and the establishment of new occupations associated with machine operation and increased urbanization. It was not possible to "inherit" an occupation if the occupation had not existed previously. Progressively more people had to choose occupations.

In fact, early in the twentieth century it was recognized by social reformers such as Frank Parsons that occupational choice constituted a very significant way in which individuals could actually improve their life circumstances. If people could choose rather than inherit occupations, then this was a major opportunity for them to better their lives on the basis of talent and motivation rather than just birth or station. Later in the twentieth century, others with a social reform agenda in Western societies also saw the potential of occupational choice and opportunity as crucial in the development of disadvantaged groups such as minorities, those with disabilities, women, and indigenous peoples. Indeed in the counseling literature relating to occupational choice, a major theme has become the relative priority of social change in comparison with individual fulfillment.

The paradigm for such choice was that of matching characteristics of the person with those of particular

occupations. The concept of “career” was the progressive development of a person’s working life within the occupation originally chosen after leaving school, college, or university. A rigorous example of the matching paradigm originated in the University of Minnesota and became known as the theory of work adjustment (TWA). The fundamentals of this theory were that good occupational choices would be made when there were correspondences between characteristics of individuals and those of occupations. Thus if there was a good match between the abilities of an individual and the performance demands of an occupation, then it was likely that the person would be successful in working in this occupation. The TWA called this “satisfactoriness.” If the personal preferences of an individual corresponded with the rewards offered by an occupation, then it would be likely that the person would like working in this occupation. The TWA designated this as “satisfaction.” As a result, a suitable occupational choice was understood to be one in which the person was both satisfactory in performance and satisfied in preference.

HOLLAND’S MATCHING THEORY OF OCCUPATIONAL CHOICE

The matching paradigm has had a venerable history in vocational psychology. Another theorist who prominently applied it to occupational choice was John Holland. His approach to occupational choice was both minimalist and pragmatic. Holland sought to answer the question: What is the simplest and yet most helpful way to assist individuals to make occupational choices? Holland’s approach was to make the match between individuals and occupations more systematic. This was done not by the development of normative measures of abilities, interests, and values, as the TWA researchers had done, but by simply asking people through a self-scored questionnaire what they thought their skills and preferences were. Holland’s research generated a taxonomy both of human types and occupational stereotypes. This classification has become and remains the single most influential representation of occupational interests in contemporary career development practice and has frequently been used also as a basis for organizing occupational information for those facing occupational choices.

The Holland typology or “hexagon,” as it has been designated due to the theorized set of relationships between the six types, can be summarized as follows:

1. Realistic (R): a preference for using practical skills with machines and the natural environment
2. Investigative (I): a preference for using intellectual skills for scientific and technological activities
3. Artistic (A): a preference for using creative skills for aesthetic, design, and entertainment activities
4. Social (S): a preference for using interpersonal skills for caring, supportive, teaching, and counseling activities
5. Enterprising (E): a preference for using persuasive skills for leadership, business, selling, and managing activities
6. Conventional (C): a preference for using clerical skills for office, financial, and administrative activities

The Holland approach enabled both individuals and those working in various occupations to be classified using this typology according to a three-letter code representing one of each of the six types. For example, someone after having completed a Holland theory-based questionnaire may derive a three-letter code of ISR (refer to the descriptions of Holland types). According to the Holland approach, such an individual is much more like a food technologist (also coded ISR) than a photojournalist (coded AEC). Therefore, this person would be advised to consider occupations such as food technology rather than those such as photojournalism.

This is the essence of the Holland approach. However, Holland was not naïve enough to think that “perfect matches” were easily generated by self-estimates of individuals and occupation incumbents. Obviously, other factors might influence occupational choice such as family, the labor market, and so on. Moreover, Holland recognized that individuals may match a variety of occupations rather than just one. While cognizant of such considerations, Holland maintained that his approach enabled individuals to narrow down the range of occupational alternatives from the otherwise daunting task of trying to consider literally thousands of possible occupation titles.

SUPER’S DEVELOPMENT THEORY OF CAREERS AND CHOICE

A more descriptive approach to the issue of occupational choice was adopted by Donald Super. Actually, Super is usually credited with shifting the focus of counselors and researchers alike away from

“occupations” to that of career. Super’s theory focused on describing the process of career development, and over a 40-year period, the theory evolved by incorporating ongoing thinking in other areas of psychology into his theory. Super’s initial theory sought to describe individuals’ careers in terms of stages: growth, exploration, establishment, maintenance, and decline (later renamed “disengagement”). Originally, Super’s theory considered occupational choice as a single event in this developmental paradigm. Occupational choice was seen as individuals implementing their self-concept. That is, as individuals develop through the growth and exploration stages, they develop a set of perceptions about themselves that they then seek to match with particular occupations. The closer the match, the greater the sense of personal and work satisfaction. Although broader in scope than Holland, this resembles the trait and factor approach. However, as Super elucidated the theory incorporating life span and life space concepts emphasizing the multirole nature of careers, the self-concept was later conceptualized as an internalized perspective of the person’s self along with the person’s perception of the context in which the person lives out other chosen roles in addition to worker, including parent, student, citizen, homemaker, child, and leisurite. Occupational choice for Super came to be viewed as one way in which individuals manifest their selfhood in the world. However, Super also introduced the concept of “life role salience,” indicating that work is only one of several roles that at any time in people’s lives may be most important for them.

The demands of different roles for individuals may also result in role conflict, especially in terms of time, effort, and money. However, sometimes different roles may compensate for one another. For example, individuals who want to be parents but are prevented from having children for whatever reason may assume the role of workers in a child care setting.

Thus increasingly, Super incorporated contextual factors into his theory of career development, and in doing so, occupational choice became only one of many important decisions that people may be, and usually are, called upon to make in their lives. Implementing the self-concept through occupational choice involved synthesizing all the developing characteristics, roles, evaluations, and learnings of individuals, on one hand, and compromising with the constraints of external reality, on the other. Indeed, occupational choice for Super gradually assumed a

developmental perspective. Decision making began to be understood as an ongoing process of development and change. Super introduced two ideas to account for this. As the person developed and changed, so too did the self-concept, resulting in a series of occupational choices, each one attempting by “successive approximations” to secure a better match between self and work. The other concept that Super employed was that of the “minicycle,” in which individuals make ongoing occupational choices by recycling through the stages of growth, exploration, and establishment. Thus by the time of his death in 1994, Super had embedded occupational choice in the broader conceptualization of ongoing personal change and development, a multiplicity of influences, and a multirole perspective in which life structure and career became virtually synonymous.

INTEGRATING CHOICE AND DEVELOPMENTAL PERSPECTIVES—CIRCUMSCRIPTION AND COMPROMISE

More recent formulations in vocational psychology have usually sought to synthesize the disparate perspectives of choice (as exemplified by the Holland approach) with development (as exemplified by the Super approach). One such attempt was that of Linda Gottfredson. She viewed occupational aspirations as developing through a process of circumscription (eliminating the unacceptable options) and choice through a process of compromise (relinquishing some preferences to broaden the range of available options). Like Super, Gottfredson drew attention to developmental experiences shaping individuals’ perceptions of themselves; however, Gottfredson placed more emphasis on early development. The salient aspects of childhood development for occupational choice were seen by Gottfredson as the formation of sex type, then prestige, and then interest preference perceptions of both the personal self and the environment. Thus, occupational choice was viewed as the process of matching the perceptions of the self with the corresponding perceptions of the world of occupations. Gottfredson charted a Cognitive Map of Occupations based on generally held stereotypes of occupations in terms of their sex type (how masculine or feminine they were perceived to be), prestige (what is the perceived socioeconomic status of each occupation), and field of work (classified according to the Holland categories outlined earlier). For example, most people

would agree that construction worker is perceived as a male, low-prestige, Realistic occupation, while dental hygienist is seen as a female, mid-range, Social occupation. As individuals develop their understanding of themselves and their environment, particular occupations come to be seen as congruent or incongruent with the self. Incongruent occupations, often unconsciously, are eliminated from consideration on the basis of the occupational stereotype. By the time career-related decisions are being made, individuals have circumscribed their occupational options to what Gottfredson called a “zone of acceptable alternatives.” While individuals may have ideal preferences within this range of occupations, often adventitious factors may precipitate another choice within the same range. To illustrate, consider a 17-year-old boy having narrowed the range of options by eliminating all occupations except those that are male, mid-range, and Realistic. He would likely be thinking about trade and technician-level occupations, since such occupational stereotypes correspond with such a self-concept. This person might consider electronic communication technician as his most preferred option. However, the competition for obtaining such work may result in the boy deciding to commence training and work as an electrical mechanic, because that occupation is also in his zone of acceptable alternatives and because he is offered a position by an uncle who owns an electrical manufacturing firm (a serendipitous event).

Such a scenario illustrates a number of new dimensions to our understanding of occupational choice. First, choice can be about what we do not want as much, if not more, than what we want. Second, the often unconscious influence of perceptions, images, and stereotypes, rather than standardized occupational information, is frequently influential in and determinative of occupational choice, regardless of their accuracy. Third, occupational choice is not necessarily “a perfect match” but may be simply in some way “acceptable.” Fourth, unplanned contextual factors (such as having an uncle in the industry) can be influential in the occupational choice outcome.

Gottfredson also sought to address the issue of how individuals respond when they are unable to choose and enter an acceptable occupation. Such individuals have to “compromise.” Gottfredson postulated that the most recently developed perceptions of self, being less integral to individuals’ understanding of themselves, are more likely to be relinquished as a way to broaden the zone of acceptable alternatives. Thus

individuals are more likely to broaden their interest preferences rather than their prestige preferences and more likely to lower their prestige preferences before broadening their sex type preferences. In a more recent formulation of her theory, Gottfredson indicated that while this pattern of compromise generally applies, it can be moderated by the degree of the compromise and the individuals’ level of concern. By introducing in a systematic way the notion of compromise, this approach sought to integrate developmental, psychological, and contextual processes into occupational choice.

INTEGRATING CHOICE AND DEVELOPMENT PERSPECTIVES— SOCIAL LEARNING THEORY

John Krumboltz and his associates used principles derived from learning theory as a basis for incorporating a wider range of influences than Holland’s pared-down approach. Basically there are three types of learning:

1. Classical conditioning or associative learning: two ideas or events are so frequently linked that the learner makes a connection between the two on a continuing basis.
2. Instrumental conditioning or reward and punishment: this is learning by experience that particular actions can have either positive or negative outcomes.
3. Observational learning or learning by example: by observing others and our world we learn by inference, imitation, and demonstration.

Using these principles, Krumboltz and his associates outlined a set of influences on people as they develop and make career decisions. These influences include (1) genetic endowments and special abilities; (2) environmental conditions and events, many of which are beyond the control of the individuals; and (3) learning experiences, which result in the development of task approach skills (which include personal standards, habits, ways of thinking and observing, and emotional reactions). Part of this process also is the development of individuals’ understanding of both themselves (self-observation generalizations) and their environment (worldview observation generalizations). These become outcomes that combine further with other task approach skills such as decision-making style to produce actions in the form of decisions (such

as an occupational choice) and behaviors intended to lead to or implement decisions. Increasingly, Krumboltz has come to emphasize two particular aspects of this formulation relevant to occupational choice. The first is the impact of unplanned events as influences on people's career development and occupational choice. His vision of such influences is much broader than Gottfredson's, extending beyond immediate serendipity to include the vagaries of training and employment opportunities, finances, laws, natural disasters, family circumstances, community expectations, and technological change.

The second aspect is the extension of occupational choice into the broader context of life transitions. Decisions associated with work influence and are influenced by other decisions people make about their life circumstances. Thus, for example, the fact that someone is married or gets divorced, moves interstate, wins the lottery, has a life-threatening experience, and so on cannot be dissociated from the person's work circumstances. In fact, Krumboltz very recently has gone so far as to suggest that career counselors should become life transition counselors, who develop a long-term continuing relationship with their clients as individuals course through their lives and as planned and unplanned events impact on them and precipitate the possibility or necessity for change. The analogy that Krumboltz uses for a life transition counselor is an individual's personal dentist, who is visited regularly for checkups and from whom treatment is sought when a problem arises. Such a counselor would also help in the development of habits to prevent or minimize negative unplanned events in the same way a dentist might help by providing a mouth guard for playing human contact sports.

DECISION-MAKING APPROACHES TO OCCUPATIONAL CHOICE

An alternative approach to occupational choice that overlaps some of the preceding formulations is the focus on the actual process of choice or deciding. A systematic application of this decision-making approach was that of Irving Janis and Leon Mann. Decision-making perspectives tend to be sequential in their presentation of the choice process. Janis and Mann outlined the decision sequence as follows:

1. Accepting the challenge: deciding to decide rather than procrastinate, shift responsibility, or engage in defensive avoidance
2. Searching for alternatives: using creative problem-solving techniques such as brainstorming and modification of flawed alternatives
3. Evaluating alternatives: using a balance sheet to weigh gains and losses to self and others of particular occupation options
4. Choosing and becoming committed: using strategies such as "maximizing" (finding the one best alternative) or "satisficing" (selecting an alternative that is acceptable even though it may not be the very best); developing contingency plans was also recommended in case the worst case scenario in the future were to eventuate
5. Overcoming setbacks and adhering to the decision: analyzing when plans fail or the unexpected occurs in order to learn from the experience and to discover how plans might be redeemed and adverse outcomes redressed; flexibility was advocated to be able to adapt alternatives in light of unforeseen change

Some of the themes of contemporary perspectives of occupational choice are evident in the Janis-Mann model such as incorporating others as well as self in the choice process, the use of creativity in developing choice alternatives, the uncertainty of the future, and the need for flexibility in responding to change.

SOCIOLOGICAL PERSPECTIVES ON OCCUPATIONAL CHOICE

From time to time in the career development literature, an insurgent voice of protest is raised, challenging the very concept of "occupational choice." It is objected that the idea of "choice" is a prerogative of the privileged, and that for many who are disadvantaged, there is little or no choice. This view often emphasizes sociological and labor market perspectives—social class, remote location, economic disadvantage, and employment supply and demand. One-industry towns are a classic example of this viewpoint, which could be summarized by saying that people do not choose occupations, jobs choose people. This constitutes a salutary reminder, especially to psychologists in the career development field, that many of the influences on individuals' occupational choices are not in fact psychological at all.

RECENT FORMULATIONS OF OCCUPATIONAL CHOICE

The five approaches to occupational choice outlined represent a sampling of how thinking about this

topic has been approached and has changed. A range of other more recent conceptions are also mentioned to provide an indication of some of the latest thinking about occupational choice in career development.

Social cognitive career theory expands on the learning theory approach. Learning processes are linked in this perspective with cognitive processes of self-regulation, including self-efficacy (the belief in one's own ability to effect change), outcome expectations (beliefs about the consequences of actions), and personal goals (commitments to act to effect desired outcomes). This approach emphasizes the importance of the person *and* the environment in the process of occupational choice. Individuals both shape and are shaped by their interactions with their contexts. The choice process is viewed as a feedback loop, commencing with the expression of a goal, action taken to implement this goal, performance attainment information gained as a result of the action taken, feeding back into the expression of a revised goal, and so on.

The cognitive information processing model is an emerging approach to occupational choice, expanding on earlier decision-making perspectives. Occupational choice is a specific instance of a range of decisions that individuals are called upon to make in their lives with varying levels of generality and complexity. This approach draws attention to metacognitions such as self-talk, self-awareness, and monitoring and control in the process of decision making. The choice process is conceived as a five-stage cycle in which people act in and act on their contexts. Moreover, decision making at one level of generality such as lifestyle (e.g., the desire to live in a warmer climate) is likely to influence decision making at a more specific level such as occupational choice (e.g., having to find a new job in a different location). The five-stage cycle process is (1) communication (perceiving a need or gap), (2) analysis (identifying the causes of and connections with the problem), (3) synthesis (developing potential action alternatives), (4) valuing (prioritizing alternatives), and (5) execution (developing a strategy for choice implementation). Then there is a return to the communication stage to evaluate if the need is met and so on through the cycle again.

Contextual accounts of career stress the complexity and multiplicity of possible influences in career development. However, rather than seek understanding of these in causal sequences, proponents of contextualism tend to look for the goal directedness and meaning for individuals in their present contexts. This

approach to career understands occupational choice in terms of action and construction. Action is individuals' capacities for change, intentionality, meaning, and continuity. Truth and meaning emerge from the transaction of individuals with their contexts. Construction is the person's capacity to interpret and integrate his or her experience in meaningful ways as a basis for further action such as occupational choice. Interpretation and narrative become major means to assist individuals make occupational choices within the broader context of life planning. These theorists often talk about career in terms of being constructed as a project that emphasizes intrinsic motivation, purpose, and meaningfulness. This approach incorporates emotions as motivators, regulators, and interpretive keys to meaning and significance. From this perspective, occupational choice is not about questions of "how" to choose a career but "why" a career is being constructed this way and "what" this tell, us about each individual's sense of purpose.

Recently, attempts have been made to introduce systems thinking into the career development field as a way to understand contextual diversity and the need for greater conceptual comprehensiveness. Such approaches view career in terms of a pattern of (mutually influencing) life influences in which individuals are both systems comprised of subsystems and are subsystems of more general systems (such as family, workplace, and community), which are themselves part of even more general systems such as the economy, geopolitics, and the law. Such an approach emphasizes the embeddedness of individuals in their context and the interactive potential of systems to influence one another in unplanned and disproportionate ways.

Allied to systems thinking in career development is the emergence of chaos and complexity theory applications. Such theories build on the contextual and systems accounts of career by focusing on the implications of complexity in terms of occupational choice. These theorists draw attention to the role of chance, the nonlinearity of change, and the adaptive and evolutionary propensities of the self-organizing properties of systems. In particular, the chaos and complexity approach focuses on the susceptibility of individuals as complex systems to change and the concatenating effects of such change. This can in turn result in the dramatic transformation of the system (sometimes called a phase shift). For example, some form of "conversion" or "trauma" experience can

totally alter the personality and course of individuals' lives. Occupational choice is viewed as a decision-making task undertaken in a context of perpetually incomplete knowledge and significant, though always limited, control. The susceptibility of complex systems to change renders preparing for, initiating, and dealing with change, the perpetual challenge for career decision making and development.

In attempting to understand how we make career decisions, we must at some stage confront our irrational natures. There is a plethora of research pointing to our inability to apply logic appropriately in decision-making tasks. However, much theorizing on occupational choice has taken an overly optimistic view of our rationality and what can be predicted. Such traditional thinking has started from the premise that certainty of choice is the desirable outcome and that rational deductive logic can be applied to systematically remove uncertainty until all that remains is the logical career choice. Aside from the issue of whether absolute certainty is attainable or desirable, it is unlikely that most of us make career decisions based on logic alone. Hunches, emotions, weaknesses, prejudices, unplanned events, indeed life events in general, will all conspire against the purely rational choice. Furthermore, this dynamical nature of reality and human experience reminds us that we can act purposively to fashion a job to our liking, rather than passively and supinely fitting into a rigid and predefined job.

A FINAL COMMENT

In most contemporary theoretical and research literature, the term *occupational choice* is rarely cited. Most writers refer to *career choice* and *career development*, since the idea of "career" incorporates the broader notions of not just occupation but leisure, family and community commitment, and other salient activities. Some theorists who still value simplicity continue to want to focus specifically on the mechanisms of choosing. However, the dominant perspective that is ascending is that choices relating to work have to be understood and made within the broader context of individuals' lives, in which a multiplicity of potential influences may be operative. Moreover, the notion of "occupational choice" has associated with it, from its historical origins, the idea of a front-end, single career choice for life. While some of the predictions about the need to change careers from 5 to 10 times in the future are yet to be verified, the idea of a

single "occupational choice" seems to sound curiously old fashioned. However, it is still the case that about 40 percent of most Western societies' workers have remained basically in one occupation for virtually all of their working lives, suggesting that such an idea might still be relevant. Furthermore, labor market statistics in Western economies typically reveal that the lability of employment varies considerably across occupations, again suggesting that the idea that people will alter occupations very frequently may not be universally applicable across most labor markets.

Therefore, it may be somewhat premature to jettison the concept of occupational choice entirely from the career development literature and counseling practice. For example, the word *vocational* has largely been eschewed by writers in favor of *career* in the same way that *guidance* has given way to *counseling and development* in most contemporary literature. However, the resurgent interest in the role of spirituality in career development has emphasized ideas of purpose, fulfillment, identity, and calling, to which the term *vocation* originally applied. Thus it suddenly does not seem so improbable that *vocation* will make a comeback in the career development literature. If so, then consigning occupational choice to desuetude may also be premature. Researchers, theorists, and practitioners are all taught the virtues of parsimony in explaining outcomes and behaviors. However, if science in general has taught us anything in the last hundred years, it is that reality is anything but simple. In fact, it is wonderfully and astonishingly complex. Therefore, trying to explain everybody's working life and behavior with a single paradigm and even with a single set of terms may not be achievable or even desirable. Notwithstanding whatever the half-life of some other types of work may be, for at least some occupations and those who choose them, the idea of an occupational choice remains meaningful, relevant, and applicable.

OCCUPATIONAL CLASSIFICATION SYSTEMS

Occupational classification systems are schemas for grouping jobs and job data. Government agencies often use occupational classification systems to standardize the way job data are collected and how jobs are described. For example, the U.S. Bureau of Labor Statistics (BLS) uses a standard classification structure to collect and sort national job data, such as wages, employment projections, and occupational outlook information. The census also uses this system to collect and present its data on jobs spanning geographic regions and industries in the United States. Because of the standardized nature of many classification systems, they may be used to compare job information across organizations and government agencies.

Occupational classification systems are developed in a variety of ways. One commonly used qualitative development method is known as the top-down approach. Such systems are often hierarchical and are developed by experts who have knowledge of the occupation or job information. The information is grouped into a structure of more generalized occupational groups, using characteristics such as work function, job title, or skill level. Occupational classification systems can have two or more hierarchical levels in which to group jobs. Because the developers usually tailor classification systems for a specific purpose, there is no consistency in the number of hierarchical levels or number of job titles included.

A second empirical approach involves applying statistical techniques such as cluster analysis or factor analysis to the knowledge, skill, and ability data associated with various jobs. The job analysts name the resulting clusters that become the hierarchical levels within the structure. These classification groupings are based on data rather than subjective opinion, which can be advantageous for purposes such as validation and research. However, classification systems developed using only statistical methods can be difficult to interpret and may lack the face validity necessary to be widely accepted.

In response, a third approach combines the qualitative and quantitative approaches described above. For example, experts design and develop a structure of occupations using the top-down approach, based on some need or organizational objective. Once the hierarchical structure has been established, statistical analyses are used to verify, modify, or provide validation support for the rationally derived hierarchical classification schema.

DEFINITIONS

In the above overview, terms such as *occupation*, *job*, and *occupational category* were used in the explanation of occupational classification systems. Although some people tend to view the terms *job* and *occupation* as synonymous, they are not. Therefore, to clarify and eliminate potential confusion, definitions are provided below.

Position

A position is a group of specific tasks performed by a single worker.

Job

Michael T. Brannick and Edward L. Levine described a job as work performed in association with others performing similar work, for similar goals, and in roles defined by mutually agreeable titles. In keeping with the above examples, an example of a job is “heart surgeon.”

Occupation

An occupation is a collection of similar jobs. Thus, it can be considered “broader” than a job. An example of an occupation is “surgeon.”

Occupational Category (or Occupational Family)

An occupational category is a collection of occupations. Thus, it can be considered “broader” than an occupation. An example of an occupational category is “health care practitioners.”

In the sections that follow, occupational classification systems are described in terms of some of their commonly known uses. In addition, five examples of both domestic and international occupational classification systems are discussed. Finally, advantages and disadvantages of classification systems are described, and suggestions for improvement are provided.

USES OF OCCUPATIONAL CLASSIFICATION SYSTEMS

According to Human Resources Development Canada, occupational classification systems serve three main functions. The first function is the collection of occupational statistics. Economists and statisticians use these systems when collecting census and other data such as data on worker mobility, technological change, and occupational employment statistics.

Second, occupational classification systems are often used to analyze changes or patterns in the labor force. Government agencies and organizations use these systems to understand changes in workforce demographics and other important labor market trends. This information is sometimes used to guide policy and develop systems for training, recruiting, and job matching. In addition, the information may be used to draw comparisons across work that, on the surface, may appear quite different.

A third function of occupational classification systems is both for career exploration and planning. It is important for job seekers, employment counselors, and employers to understand the requirements and descriptions of jobs and occupations so they may assist people in finding professions that match their skills and interests. Career guidance counselors use these systems to educate students or workers considering a career move or job transition. By matching job seekers’ interests and level of knowledge and skill in job-related activities with those of various occupations, they can make an informed choice about a new career to pursue.

EXAMPLES OF U.S.-BASED CLASSIFICATION SYSTEMS

The Standard Occupational Classification (SOC)

As described in the U.S. Department of Commerce’s *SOC Manual*, the SOC is a system for classifying all occupations in the economy, including private, public, and military occupations. This classification system replaces all occupational classification systems previously used by federal statistical agencies. It is used by these agencies to collect occupational data and provide a means to compare occupational data across agencies. The SOC was developed, as stated in the agency’s user guide, to “cover all occupations in which work is performed for pay or profit, reflecting the current occupational structure in the United States.”

The SOC was originally released in 1977 by the U.S. Department of Commerce to provide a way to cross-reference and aggregate data collected by other social and economic statistic reporting programs. As many programs in the U.S. government began to collect statistical data, a need grew for a unified occupational classification system for the federal government. With the help of various government organizations, a system was developed for statistical reporting purposes. Its classifications are based on the type of work performed and, in some cases, the level of skill and education requirements.

The current SOC contains four levels of aggregation within its hierarchy. The first and most general category is known as the major group level. There are 23 major groups in the SOC. Within the major group level are 96 minor groups, which are less general than the major groups. The third level in the hierarchy is the broad occupation. There are 449 broad occupations. The fourth and most specific level is the detailed occupation. There are 821 detailed occupational titles at this final level of the SOC. It is at this level of detail that brief occupational descriptions are provided and jobs are typically grouped. The table below provides an example of the four-tiered hierarchical structure of the SOC.

THE OCCUPATIONAL INFORMATION NETWORK (O*NET)-SOC SYSTEM

The O*NET-SOC is the result of a merger between the O*NET occupational system and the SOC.

Table 1. Example of the SOC Four-Tiered Hierarchical Classification Structure, Including Codes and Titles**Major Group**

21-0000 Community and Social Services Occupations

Minor Group

21-1000 Counselors, Social Workers, and Other Community and Social Service Specialists

Broad Occupation

21-1010 Counselors

Detailed Occupation

21-1011 Substance Abuse and Behavioral Disorder Counselors

21-1012 Educational, Vocational, and School Counselors

21-1013 Marriage and Family Therapists

21-1014 Mental Health Counselors

21-1015 Rehabilitation Counselors

21-1019 Counselors, All Other (“residual category”)

SOURCE: Sample taken from the *SOC Manual* (Bureau of Labor Statistics, 1999).

O*NET was once based on an older coding and classification system known as the Occupational Employment Statistics (OES). Shortly after the final revision of the SOC, the Office of Management and Budget mandated that all federal reporting agencies adopt the SOC as the standard classification and coding system. The National O*NET Center then transitioned its OES-based codes and titles to an SOC-based system, utilizing SOC occupational codes and titles. In addition to incorporating the four levels of the SOC, O*NET added a fifth level of occupational detail to accommodate for occupations in O*NET’s original list that did not “fit” well into the SOC’s structure.

In addition to being a classification structure, O*NET also provides descriptive data on over 900 occupations. Because of the cross-occupational nature of O*NET’s descriptive information such as knowledge, skills, abilities, work activities, and work context, direct comparisons between occupations can be made. This system of occupations provides users with valuable data and online tools for use in vocational guidance and career exploration activities. The O*NET-SOC classification system is by far one of the most comprehensive classification structures in the world. The O*NET-SOC provides an excellent system for

grouping occupations, jobs, or job data for government or an organization’s data collection effort.

The Monster Occupational Classification (MOC)

While the SOC, O*NET-SOC, and other classification systems discussed herein have been developed by both government and quasigovernmental agencies, private organizations have also developed occupational classification systems to meet their needs. As an example, consider the organization Monster.com, a popular online job-posting Web site. In recent years, Monster decided to incorporate an occupational classification system into its résumé database. After extensive research both domestically and abroad, the SOC was chosen to be the framework for a system that would serve to organize, by job title, over 40 million résumés. Unfortunately, the SOC was insufficient to classify all new job seekers’ résumés and those already in Monster’s archival database, so tailoring it became essential. For example, the SOC has limited detail in occupational areas such as computers, information technology, and finance. Monster, with the help of occupational classification experts, expanded these and other areas to meet its needs while at the

same time maintaining the SOC-based coding structure. Monster initially named it the SOC+, but they customized it to become more Monster specific. Soon after, it came to be called the MOC (i.e., the Monster Occupational Classification).

EXAMPLES OF INTERNATIONAL CLASSIFICATION SYSTEMS

The International Standard Classification of Occupations (ISCO-88)

The ISCO-88 is a system currently being revised and maintained by the European Union and has been adopted by many countries in Europe. According to the National Research Council, the ISCO-88 has three primary objectives: (1) to facilitate international discussion regarding occupations through its usage; (2) to provide international occupational data for research, decision making, and other activities; and (3) to serve as a model, not a replacement, for countries developing their own occupational classification systems. The hierarchical system contains 10, 28, 116, and 390 titles at various levels, and occupations are clustered according to duties performed. The information reported about each occupation includes a brief paragraph of duties performed and a listing of its general education requirements.

The National Occupation Classification (NOC)

The NOC is Canada's occupational system that provides a hierarchy based on skill level, skill type, education requirements, and industry type for each occupation. The hierarchy contains 26, 47, 139, and 514 titles at various levels and contains tasks reported for each job. Information such as education, training, experience, and licensing information are provided for each occupation.

ADVANTAGES AND DISADVANTAGES OF CLASSIFICATION SYSTEMS

Advantages

Using occupational classification systems provides several advantages to organizations or agencies. First, occupational classification systems provide an excellent framework to organize jobs and work activities. Organizations may group many jobs into one category,

thus streamlining various human resources functions such as training course design and assessment tool development. Second, because classification systems tend to be hierarchical in nature, jobs or occupations can be grouped at whatever level necessary to fulfill the objectives of the classification effort and thus the organization's goal. Third, a standardized occupational system may be used for occupational or cross-job comparisons and allows different systems to "talk" to each other.

Disadvantages

Some examples of the disadvantages of occupational classification systems are presented here. First, occupational classification systems tend to be inflexible. They are often difficult to adapt to adjustments in work structure. If necessary updates to the system are not made in a timely manner, the system will become obsolete. Second, an occupational structure may lack face validity and coverage. Many occupational classification systems currently in use are not easily understood by the average person. Making correct classifications and using the coding system properly are often reserved for experts, such as job analysts or industrial psychologists.

Another disadvantage is that occupational classification systems can be inefficient practical tools. It is often time consuming and difficult to peruse an entire four-tiered classification structure to group all jobs within a single organization into the most appropriate categories. Finally, the level of generality and/or specificity of the occupations listed as part of a hierarchy are often inconsistent, thus making the task of classifying jobs more difficult. When developing a classification system, occupations at their respective hierarchical levels should be as close to the same level of generality or specificity as possible to increase the ease of grouping jobs.

SUMMARY

Occupational classification systems are developed for a variety of purposes. Often, they are developed by government agencies to carry out objectives such as (1) to assist economists and statisticians in their data collection efforts, (2) to analyze changes or patterns in the labor force and provide labor market information, and (3) to assist individuals in career exploration, career planning, and job seeking. Although all of the

occupational classification systems discussed have been useful, the flexibility, face validity and coverage, efficiency, level of generality, and questionable validity continue to present challenges for their developers and users. As a result, organizations such as the National O*NET Center and Monster.com attempted to overcome these challenges by developing classification systems that are dynamic and adaptable, to accommodate frequent changes in jobs and technology. However, there is still clearly a need for further research and practice to uncover newer, streamlined, and valid procedures for developing and using occupational classification systems in a variety of settings.

OCCUPATIONAL COMMITMENT

The term *career* has been defined by several prominent behavioral scientists as a pattern of work-related experiences, including attitudes and behaviors, that span a person's life. Such a definition encompasses

different work referents, including job involvement, organizational commitment, *occupational commitment*, and work/nonwork roles. Adopting this definition suggests that a person can change jobs, organizations, and occupations, as well as retire and then even "unretire," all as a part of his or her career.

In their study of different work commitment measures, Gary Blau, Allison Paul, and Natalie St. John found that the *career* commitment measures could be combined into a more parsimonious measure of *occupational* commitment. Other research shows that just as organizational commitment has three components, so too does occupational commitment, namely affective commitment, normative commitment, and continuance commitment. Affective commitment is one's emotional attachment to his or her occupation, normative commitment is a person's sense of obligation to remain in the occupation, and continuance commitment involves the individual's assessment of the costs associated with leaving one's occupation.

In a quantitative review of the research on occupational commitment, Kibeom Lee, Julie Carswell, and Natalie Allen noted that most prior research had defined occupational commitment as the psychological link between an individual and his or her occupation that was based on an *affective* reaction to that occupation. This definition clearly emphasizes the affective component, that is, individuals with higher occupational commitment strongly identify with and have positive feelings about their occupation. Although empirical work has found support for the affective, normative, and continuance components of occupational commitment, such research has been less successful in demonstrating differences in the relationships of these separate occupational commitment components to other variables, which would provide stronger evidence for the uniqueness of each component. Recent research, however, has found support for the distinction between the three components of occupational commitment, demonstrating that affective commitment had a stronger negative relationship to occupational withdrawal cognitions and had stronger positive relationships to forms of professional participation. Moreover, normative and continuance commitment combined to explain withdrawal cognitions, such that there was a negative relationship between normative commitment and withdrawal cognitions only when continuance commitment was low.

Research supports the view of John Meyer and Natalie Allen that continuance *organizational* commitment

develops as employees recognize that they have accumulated investments or costs that would be lost if they left their organization, or that the availability of comparable alternatives is limited. Applying this notion to *occupational* commitment suggests the usefulness of the concept of career (or occupational) entrenchment. Career entrenchment focuses on the perceived costs associated with leaving one's occupation and the perceived lack of occupational alternatives. Research suggests that occupational entrenchment consists of three dimensions: occupational investment, emotional costs, and limited occupational alternatives.

Occupational investment represents the accumulated investments or costs (e.g., time, money, training) in one's occupation that would be lost if one changed occupations. Often, professionally trained employees need to have either advanced schooling or some form of certification to enter their occupation and then must maintain their competence through attending continuing education programs and/or participation in associations. *Emotional costs* refer to the anticipated emotional price associated with pursuing a new occupation. For example, the loss of coworker friendships and severance of professional ties can exact an emotional toll on a person changing his or her occupation. Based on investment model research, coworker friendships, a network of contacts, time, money, and training *each* represents investments or accumulated costs in one's occupation. Limited occupational alternatives tap the perceived lack of available options for pursuing a new occupation. Individual efforts to maintain occupational investments and minimize emotional costs will divert an individual from scanning the environment for viable occupational alternatives.

Gary Blau has suggested that emotional costs and occupational investments might be better represented together as *accumulated occupational costs*, and he found support for four components of occupational commitment: affective, normative, accumulated costs, and limited alternatives. The components of accumulated costs and limited alternatives represent two distinct aspects of continuance commitment. By subsuming occupational entrenchment within occupational commitment, researchers now can focus on a common integrative construct, that is, occupational rather than career commitment.

Occupational commitment is an important construct for future study because organizations will continue to restructure and revise the psychological contract of mutual employee-organization expectations,

employees will make multiple job changes during the course of their work lives, and the contingent workforce will continue to grow. Collectively this suggests that employee commitment may be shifting in many industries from organizations to occupations. As such, understanding the meaning, antecedents, and consequences of occupational commitment will only become more important for both academics and human resource practitioners to understand.

—Gary Blau

OCCUPATIONAL INFORMATION NETWORK (O*NET)

Commissioned by the U.S. Department of Labor's Employment and Training Administration, the *Occupational Information Network* (O*NET) aspires to be America's most comprehensive and widely applicable career development resource. A replacement for the *Dictionary of Occupational Titles*, O*NET's primary feature is its detailed, research-based descriptions of nearly 1,000 occupations. Available as a database, an interactive Web site, and a

reference text, O*NET provides a range of informational resources intended for use by laypersons and by all professionals who play a role in workforce development. To serve such a wide audience, O*NET describes all occupations using plain-language terms organized by a general model of workforce development concepts.

Developed from extensive surveys of workers and expert job analysts, O*NET profiles 974 occupations using over 275 different characteristic descriptors. All of this information maps onto six broad categories. An occupation's *worker characteristics* include the interests, values, and abilities of the typical worker, while *worker requirements* refer to job-performance-related skill and knowledge areas. *Occupational requirements* are nonspecific aspects of the job or work environment, such as frequency of team-based work, while *occupation-specific information* would include descriptors like "obtaining evidence from suspects." Finally, *occupational characteristics* include compensation and job outlook trends, and *experience requirements* describe the education and training necessary for employment in a given occupation.

It is difficult to overstate the volume of information provided by O*NET. Consider the occupation of mechanical engineer. A computer printout of O*NET's most detailed mechanical engineer profile contains 19 pages of bullet-point style information. The precision of this descriptive information is considerable. For example, not only does the mechanical engineer profile specify that knowledge of chemistry and the ability to read technical drawings are both relevant to the job, but it also quantifies the relative job-relatedness of these and many other characteristics on a 100-point scale. This kind of detailed information is directly accessible from the O*NET Web site, and the O*NET developers' guiding assumption is that these profiles could be used by a college student exploring possible careers, a recruiter evaluating job candidates, a department chair setting curriculum standards, or a scholar researching trends in the labor force.

In addition to the occupational profiles themselves, O*NET has inspired numerous supplementary tools and applications. The O*NET Web site assists general audiences in identifying career options through an interactive self-assessment exercise and a searchable database of all occupational profiles. For career counselors, O*NET provides free measures of abilities, values, and interests—the results of which connect directly to O*NET occupational summaries.

Researchers can download the entire O*NET database and accompanying technical reports. Finally, within certain guidelines, program developers have been encouraged to adapt O*NET resources to their specific needs. To this date, such developments have included a Spanish-language version of the database, a new occupations guide for the Armed Services Vocational Assessment Battery (ASVAB), and a career guidance training program for paraprofessional counselors in Wisconsin.

In summary, no other career development resource approaches the breadth and depth of information, or the scope of potential applications, associated with O*NET.

OCCUPATIONAL OUTLOOK HANDBOOK

Career researchers and counselors emphasize the value of accurate information in the career planning process, and the *Occupational Outlook Handbook (OOH)* is the most widely used source of occupational information in existence. Drawing on an ongoing U.S. Department of Labor data collection project, the *OOH* is a print and Internet reference designed to provide essential information to individuals exploring their career possibilities. The *Handbook* covers around 270 occupations—accounting for nearly 90 percent of the U.S. labor force—and allots about two to three double-columned pages of text to each entry. In doing so, the *OOH* attempts to present the concise balance of occupational breadth and depth that readers need to develop an initial understanding of occupational paths worthy of further consideration.

Despite differing focus areas, most models of career development view effective career decision making as an integration of self-knowledge and occupational knowledge. Self-knowledge includes information obtained via interest inventories, aptitude tests, and other assessment techniques, while occupational knowledge implies a realistic, fact-based understanding of the world of work. As a person acquires self-knowledge, this usually stimulates a search for corresponding occupational knowledge: Which occupations will allow me to work with my hands, interact with people, make at least \$50,000 per year, or operate my own business? The *Occupational Outlook Handbook* is an encyclopedia of answers to such questions.

All *Occupational Outlook Handbook* entries are organized according to a common set of category headings. A Significant Points section presents a few of each occupation's most important characteristics or trends. Nature of the Work describes common job duties and day-to-day work activities. Working Conditions addresses the work environment, including hours, extent of travel, psychological stressors, and physical demands. An Employment section lists the total number of jobs that the occupation contributes to the labor market, as well as a breakdown of job numbers by various industries. Training, Qualifications, and Advancement delineates the experiences and credentials required to enter and progress within the occupation. Job Outlook projects the number of openings expected over a 10-year period given trends in job turnover and new growth, while Earnings presents salary averages and ranges. Finally, each entry offers a short list of Related Occupations, as well as a few Sources of Additional Information, such as professional association Web sites.

The Internet has transformed the *Occupational Outlook Handbook*. Though it continues to be published as a text, the *OOH* is also now available as a free online search engine, allowing people to locate information under various topic areas or by occupational keyword. Upon locating occupations of interest, Web users can download entire *OOH* entries or find answers to specific questions via an interactive menu of the aforementioned category headings (e.g., Earnings). The popularity of this new resource is evident in the 5.5 million hits it receives each month. With this advance in technology, a broader audience is utilizing the *OOH* in their career decision making.

OCCUPATIONAL PRESTIGE

The inclusion of *prestige* as part of interest assessment is not a new phenomenon but has gained increasing attention over the past few years. As a construct, prestige encompasses level of aspiration, level of training, preference for public recognition and esteem, desire for high income, occupational level, responsibility, and socioeconomic status. Prestige may also reflect an individual's preference for a blue-collar versus professional lifestyle. Although prestige has been incorporated within several earlier models of occupational perceptions, it generally has not been incorporated within interest assessments.

Prestige has also played an important role in models of career development and occupational selection. Sex typing, that is, the societal view that certain careers are masculine or feminine, and prestige, together with interests, have been proposed to form a basis of occupational choice, with each being viewed as independent. However, research has demonstrated that such independence is not appropriate, supporting the collective examination of interests with prestige. When scales measuring prestige or status have been incorporated within interest assessments, these scales were supplementary rather than primary, and the link between prestige and occupational preference was not explicit. Research, however, has consistently indicated that people do rely on prestige in their evaluation of different occupations. Furthermore, prestige has also been shown to have more importance to individuals than the sex typing of occupations during career choice dilemmas.

One reason for the lack of incorporation of prestige within interest assessments (despite its theoretical and empirical history) is that prestige is often viewed as a part of values, and many researchers have sought to

distinguish values from interests. Interest assessments are generally thought to be measuring aspects of a person's identity, where interests refer to the relative liking and disliking of things. Values, however, refer to the relative importance of things to a person, with scales of this type being found within separate instruments. Yet the distinction between interests and values may be more a function of the scales designed to measure these constructs rather than any actual differences.

The predominant model of interest and vocational preference is Holland's Hexagon, where six personality types, that is, Realistic, Investigative, Artistic, Social, Enterprising, and Conventional (RIASEC), are arranged in the shape of a hexagon. The different types provide information about the characteristics of individuals along with related occupations based on their type. Holland's typology provides a convenient and meaningful way to present individual differences in interests. Although the field has focused much attention on the hexagon itself, research has distinguished two key features of Holland's model: the circular ordering of the RIASEC scales and the two dimensions, or perpendicular x - and y -axes, that underlie Holland's model. These dimensions account for the distribution of the types in a circular arrangement. The two dimensions are most often represented by data-ideas and people-things, and each type is an abstraction of the data formed by the underlying two dimensions. Occupations have also been mapped on this two-dimensional plane.

Through more fully assessing the content domain of interests, research has demonstrated the presence of an additional dimension to the two traditionally utilized, data-ideas and people-things. The addition of this dimension adds the relative prestige of occupations and is perpendicular to the plane formed by the two dimensions that underlie Holland's types. The presence of this prestige dimension in interests has been found in occupational preference ratings but also in activity preferences.

Employing a three-dimensional model that has the data-ideas and people-things dimensions (x - and y -axes) combined with high-low prestige (z -axis) allows for more thorough assessment of interests. The three-dimensional model allows occupational preferences to be mapped on the three-dimensional coordinates (x -, y -, and z -axes) of a structure, for example, a sphere, thereby combining the RIASEC-type-based occupations with relative prestige ratings of occupations. Several structures that model interest data

utilizing the above three dimensions have been researched. These are the cylinder, cone, and sphere. For the cylindrical structure, prestige needs do not affect interest preferences, that is, the same types lying on the x , y plane would be valid for high, moderate, and low prestige (the z axis). For the conical structure, prestige needs affect interest preferences only at one end of prestige, for example, high reliance on prestige at high levels, but increasingly equal prestige preference from the mid to opposite end of the cone. For the spherical structure, prestige needs differentially affect interest preferences at both ends of prestige, for example, the RIASEC types lie at the equator, that is, the plane defined by the x - and y - axes, with prestige (the z -axis) running from the north to south poles of the sphere.

Because it has been found that individuals with high or low needs for prestige generally do not differ as much in their occupational preferences relative to those with moderate needs for prestige, that is, individuals at either pole of the prestige dimension are less differentiated in their interest preferences relative to those at the equator, a sphere is the only structure that appears to account for the differential reliance on prestige during the evaluation of occupations. However, more research pursuing the integration of prestige with basic interests is needed.

As mentioned above, prestige is not a new construct. What is relatively new, however, is the incorporation of prestige within a model of interest and occupational preferences that explicitly measures and utilizes prestige to describe individual differences across three dimensions and translating this information into occupational preference in a manner that is utilizable to career counselors and their clients.

OCCUPATIONAL PROFESSIONALIZATION

For more than a century, people who study work, occupations, and society more generally have been interested in what distinguishes a profession from an occupation and how an occupation becomes a profession. Over time, theorists have provided different answers to these questions and proposed different processes of *occupational professionalization*. What underlies all of the theories is the fundamental assumption that professions such as medicine and the law are different from other occupations and that professional status is something desirable and something to be aspired to. This entry reviews five main approaches to the study of professions: functionalist, taxonomic, professionalization, power, and systems. The approaches are presented in chronological order, tracing the historical development of ideas. The entry also discusses more recent trends in research on professions and professionalization and concludes with thoughts about why modern occupations continue to strive for professional status.

THEORETICAL APPROACHES TO THE STUDY OF PROFESSIONS AND PROFESSIONALIZATION

The Functionalist Approach

During the late nineteenth century, Émile Durkheim, often cited as one of the fathers of sociology, was interested in the function or purpose of a division of labor in society. He argued that the functional division of labor binds people to one another in a new way and creates a new sense of "solidarity" among people who differ from each other but who are mutually dependent. Durkheim was also greatly concerned with what he perceived as a growing sense of isolation and disconnectedness between individuals in an industrial society. He defined a profession as an

occupational group whose members share a body of knowledge and a moral commitment. Professions were important to him because he believed that they provided support for members and linked them to the broader society thereby reducing the experience of isolation and disconnectedness. This functionalist approach does not address the negative or *dysfunctional* effects professions have on subordinate occupations and the people who seek out professional advice and services. Nor does it describe the process by which an occupation becomes a profession (i.e., occupational professionalization).

The Taxonomic Approach

Research more narrowly focused on the topic of professions emerged in the 1920s and 1930s. Around this time, researchers such as Sir Alexander M. Carr-Saunders and Paul A. Wilson were concerned with differentiating between occupations and professions. To that end, they identified criteria that marked professions. Examples of such criteria include service orientation, technical knowledge, and specialized training. This approach to studying the professions, referred to here as a taxonomic or classification approach, may be overly concerned with what some see as the futile task of determining what is and is not a profession while, like the functionalist approach, being short on ideas regarding the causes and consequences of professions.

The Professionalization Approach

The professionalization approach evolved from the taxonomic approach described above and dominated the American and British literature on professions through the mid-1960s. It focused on the organization of professions and their stepwise progression from occupational group or craft guild to full profession. Theorists in this group, especially Harold L. Wilensky, were among the first to identify an orderly process whereby an occupational group becomes a profession. In other words, they specified a process of *occupational professionalization* that included creating training schools and professional associations, initiating licensure requirements, and establishing a code of ethics. According to this approach, professional status depends on whether an occupational group has gone through all the necessary steps. This approach to understanding professionalization has been criticized

for being unidirectional and more concerned with organizational structure than work. Furthermore, some have argued that the stepwise approach conceptualizes professions as homogeneous and the professionalization process as constant both across professions and over time.

The Power Approach

Research during the 1960s and 1970s moved away from the process-oriented, stepwise professionalization approach and led to the emergence of power theories to explain professional status. These theories focused on the way a few well-established professions (e.g., medicine and the law) dominated and subordinated other occupational groups that did similar work—often to the detriment of the people who sought professional assistance. For example, Eliot Freidson asserted that the dominance of medicine over other occupations such as nursing was potentially harmful to patients and that people in need of health care would be better served by a less hierarchical organization of health occupations. Power theories also tended to describe professions as monopolistic and self-serving. From this perspective, one way to identify a profession is to look at the amount of power an occupational group possesses. Critics of this approach have described it as simply another version of the taxonomic approach that focuses on power, as opposed to organizational structure, as the defining characteristic of professions. Some have suggested that it does not sufficiently forward our understanding of how an occupation achieves professional status.

Andrew Abbott and the Systems Approach

In his effort to understand the nature of expert knowledge and the people and groups that produce, practice, and control it, Andrew Abbott came to understand professions and the process whereby an occupation becomes a profession differently from the way his scholarly predecessors understood them. His predecessors researched individual professions and saw them as evolving independently of one another. They focused on how professions were organized and how much power they had. Abbott, on the other hand, saw professions not as individual and independent entities but as members of an interdependent system

where a shift in one impacts the work and boundaries of others. He focused on the work of professionals and the way they compete for jurisdiction over certain types of work. Jurisdiction can be described as the power or right of an occupational group to produce knowledge and claim expertise in a certain area. This focus on work and jurisdiction signified a fundamental departure from the way professions had been studied in the past.

In addition, Abbott's concept of professionalization was different from earlier accounts, namely the stepwise professionalization approach. Abbott rejected the idea of unidirectional movement from an occupation toward full professional status. For him, going through a series of steps did not necessarily make an occupational group a profession. Rather, an occupational group became a profession as a result of gaining jurisdiction over certain types of work (e.g., childbirth or mental health). Jurisdiction was achieved via competition and settlement with competing occupational groups. For example, the turn of the twentieth century revealed midwives in stiff competition with physicians for jurisdiction over childbirth in the United States. Physicians, with their scientific knowledge, arguably won the dispute for control over childbirth. However, midwives (both lay and nurse-midwives) continued to attend a small percentage of births in the United States and have been mounting an organized effort since the 1970s to regain legitimacy and jurisdiction over at least some, namely "normal" or "low-risk," births. According to Abbott, such disputes result in the continuous construction and reconstruction of jurisdictional boundaries over time.

Four concepts are central to Abbott's systems theory: work, jurisdiction, competition, and system. When more than one profession tries to claim expertise with respect to a certain type of work, jurisdictional disputes arise and must be settled. Rarely can jurisdiction be equally shared. Thus professions compete to have their work acknowledged as legitimate and their knowledge recognized as dominant. A shift in one profession's jurisdictional boundaries affects others, and as this process unfolds over time, the entire system of professions is impacted. Such is the nature of this amoebalike system of interlocking professions—constantly shifting, swelling, and contracting. Much of the recent literature on professions and professionalization tests, extends, or illustrates shortcomings in Abbott's work.

RECENT DEVELOPMENTS IN PROFESSIONS RESEARCH

Since Abbott published *The System of Professions* in 1988, no researcher has undertaken so systematic and comprehensive a project aimed at introducing a new and groundbreaking theory of professions. At the same time, the professions literature has not stagnated. Theoretical and empirical research on professions has continued to flourish by (1) testing and augmenting existing theories and (2) describing the changing environment in which professions negotiate jurisdiction and the new professionalization strategies such changes have inspired. New and interesting areas of inquiry in the study of professions and professionalization include intraprofessional relations, workplace size and degree of bureaucratization, gender, and unconventional professionalization strategies.

INTRAPROFESSIONAL RELATIONS

Sydney A. Halpern was interested in why some professions are better than others at subordinating competing groups. Using comparative and historical methods to analyze data gathered from medical publications and professional association meetings, she explored the degree to which American medicine has had control over adjacent occupational groups such as radiologic technology, physical therapy, laboratory technology, and nurse anesthesia over time. She tested the professionalization, power, and systems theories and found that none fully explain American medicine's pattern of domination. Rather, she suggested that *intraprofessional* relations (e.g., between two medical specialties like radiology and internal medicine) significantly affect *interprofessional* boundary negotiation (e.g., between radiology and X-ray technology). She found that a subsection of a profession (e.g., radiology), not the profession as a whole (e.g., medicine), embarks on an effort to challenge a competing group (e.g., X-ray technology). Her data revealed that for a subsection to be successful in its efforts to subordinate a competing occupation, it must have support from other subsections of the profession. In light of her findings, Halpern suggested that Abbott's theory should be extended to explain not only interprofessional relations but intraprofessional relations as well.

WORKPLACE SIZE AND DEGREE OF BUREAUCRATIZATION

Cecilia Benoit criticized researchers' tendency to universalize findings from studies of American and British professions and professional boundaries to other countries. She reviewed historical data on midwifery in Sweden, the Netherlands, and Canada and found that the concepts of medicalization of birth and deprofessionalization (i.e., loss of professional status) of midwives as a result of the rise and dominance of obstetrics are not as relevant in Sweden, the Netherlands, and some Canadian provinces as they are in the United States and Britain. Rather, in the countries she studied, birth continues to be understood as a natural process, and midwives have attained a level of professional status not seen in the United States and Britain. Most important, she argued that workplace size and degree of bureaucratization are important factors for whether an occupational group becomes a profession. She asserted that midwives in Sweden, the Netherlands, and Canada may have achieved professional status, at least in part, because they work in small, relatively nonbureaucratic settings.

GENDER PERSPECTIVE

Kristin Barker built on Abbott's systems theory and presented evidence of a gendered system of professions. She focused on the dispute between the American Medical Women's Association and the American Medical Association regarding the 1920 Act for the Promotion of the Welfare and Hygiene of Maternity and Infancy, popularly known as the Sheppard-Towner Act. She analyzed discourse on Sheppard-Towner between 1921 and 1929 as recorded in the *Medical Women's Journal* and the *Journal of the American Medical Association*. She found that shared gender both divided and united women in their efforts to gain jurisdiction over pregnancy and birth. Intraprofessional (i.e., within the medical profession) and interprofessional (e.g., among medicine, nursing, and social work) collaboration helped women gain initial jurisdiction. However, the interprofessional coalition did not include midwives and, in the end, served to undermine midwifery's historic claim to jurisdiction over childbirth. Due to these and other circumstances, women, regardless of professional status and affiliation, lost the battle over childbirth to the

predominantly male medical profession. Barker urged fellow researchers to pay careful attention to the gendered nature of jurisdictional disputes, both intra- and interprofessionally.

Tracey L. Adams also contributed to the literature on the gendered nature of professions and professionalization processes. She presented a case study of dental hygiene in Ontario to explain how some female-dominated occupations attempt to gain professional status. Her data consisted of articles published in Canadian dentistry journals between 1945 and 2000, government documents, legislation, research reports, dental hygienists' MA and PhD theses, and interview transcripts. Adams found that ideas about (1) women having equal access to historically male-dominated work and (2) women being inherently more caring and better communicators play a significant role in the relatively successful professionalization of dental hygienists in Ontario. She raised questions about whether claims to jurisdiction and professional status based on feminine gender will prove successful in the future as dentistry, among other professions, becomes increasingly populated by women.

UNCONVENTIONAL PROFESSIONALIZATION STRATEGIES

As described above, dental hygienists in Ontario used feminine gender as a strategy for gaining professional status and autonomy from historically male-dominated dentistry. This strategy, mobilizing gender-specific arguments when making claims to professional status, is not new. Women physicians in the United States during the late nineteenth and early twentieth centuries used this strategy to enhance their status within medicine. They argued that women have a special capacity for caring and healing and are uniquely suited, perhaps even better suited than men, for medical practice. Although this is not a new strategy, it is still considered unconventional—mainly because prior research on professions rarely addressed gender and, therefore, gendered professionalization strategies have only recently been described.

Martin Laffin and Tom Entwistle wrote about another unconventional professionalization strategy. They began by describing typical professionalization projects and went on to suggest that new conditions (e.g., changes in how policy is made and globalization) are forcing occupational groups and existing professions to experiment with new approaches. They

identified three major shifts in occupations' approaches to professionalization: (1) from exclusive jurisdiction to interdisciplinarity and overlapping jurisdictions, (2) from an "insider" approach to affecting policy to public advocacy, and (3) from stand-alone professions to interprofessional collaboration and the formation of "strategic alliances." They argued that such changes in professionalization strategies force us to reconsider what it means to be a professional and what it looks like when occupational groups undertake professionalization projects.

CONCLUSION

This entry has described five approaches to understanding professions and the process of professionalization: functionalist, taxonomic, professionalization, power, and systems. Each approach contributes to our understanding of what a profession is and the process by which an occupation becomes a profession. Recent research points to a number of areas ripe for further inquiry such as intraprofessional relations, workplace size and bureaucratization, gender, and emerging professionalization strategies. Regardless of focus or temporal location, all of these studies share an underlying assumption. They assume that professions are different from and more desirable than "ordinary" occupations. This leads to the question: Why is professional status desirable or, in other words, why do occupations aspire to professional status? First, at the level of the individual, professionals may make more money, exhibit more autonomy, and experience higher status and more control over their work than people who do similar work in nonprofessional adjacent occupations. Second, there is some evidence that professionalizing improves services and the quality of work done by members of the occupational group. Thus a commitment to quality service may serve as motivation. Third, professions and professional organizations exercise a considerable amount of power in the public and legal spheres. Together, these benefits of professional status may contribute to improved quality of life for members of professions, to continued interest by occupational groups in professionalization, and to continued relevance of occupational professionalization as an area of academic inquiry.

OCCUPATIONAL STEREOTYPES

Occupational stereotypes are a reflection of our tendency to use heuristics in our thinking about the world in the place of data. The result in this domain can be, and often is, prejudice and unequal opportunities for those demographic groups who become labeled. Classes of occupations can also suffer from generalizations made about them. However, occupational stereotypes can also be beneficial in understanding the complexities of modern working life.

The capacity to organize systematically their knowledge of themselves and their world is one of the outstanding characteristics of human beings. However, the processes of discovering, observing, educating, concluding, and remembering are all selective and interpretive in nature. Our environment and our experience of it are multilayered and complex, and so we select aspects of both and form them into patterns by thought processes such as induction, deduction, and abduction. This is how we understand our experience of the world, and this becomes the basis of human knowledge. This knowledge is either

learned directly by individuals or taught to them indirectly by others.

The necessity of this selection and interpretation process is that of simplification. Humans focus on some aspects of their experience and environment and neglect others. Those aspects that they select they interpret as a way to make the experience meaningful. Thus knowledge is an individually or communally constructed sampling of reality. From such sampling or knowledge, individuals develop expectations and form behavioral responses. Sometimes individuals may have limited direct experience of some aspects of the world, and those aspects of the world may be mediated by the selective exposure to and dogmatic interpretation by authority figures in those individuals' lives. This may result in stereotyped thinking, characterized often by oversimplification, prejudice, projection of individuals' own inadequacies onto others, and ignorant or willful misinterpretation of the character and behavior of others. Racism is a typical example of stereotyping in which whole communities or nations are reduced in the minds of others to a few basic (almost always very negative) characteristics in order to justify some form of violence or exploitation. This is an example of the very negative side of stereotypic thinking. However, insofar as stereotyping represents a summary of our experience of reality, as a form of knowledge, it also has a positive dimension.

OCCUPATIONAL STEREOTYPES IN THE CAREER DEVELOPMENT FIELD

Perhaps not unexpectedly, occupational stereotypes in the career development literature have been understood, investigated, and utilized in both positive and negative ways. Negatively occupational stereotypes have been viewed as individual and community cognitive errors in thinking. Such stereotypes are seen as derived from incomplete or false information, from biased values, and from feelings of threat associated with change or a challenge to existing power groups. An example from the career development field that has received a lot of attention has been to investigate and challenge the stereotype that all girls are poor at math. The resultant occupational stereotype is that females should avoid mathematically based occupations, including most sciences (other than biology). Research sought to expose that there is no obvious genetic basis for females being worse than males at math and that the limitations of females doing well at

math were environmental, such as adults telling them that girls either do not need a career or should take humanities rather than science subjects, since this seemed to fit a stereotype of the artistic and nurturant woman rather than the logical and mathematical scientist. Research also indicated that females were often treated differently in educational contexts, resulting in limiting their exposure to math-based courses and resources for developing basic arithmetic skills.

Various interventions were subsequently developed to challenge these gender and occupational stereotypes, including more gender-fair occupational information, counseling to encourage exploration of nontraditional careers, changes to legislation to facilitate female participation in such careers, the development of mathematical self-efficacy scales to assist females to redress some of the social conditioning telling them they would not have mathematical skills, and parental education about the possibilities for female participation in math-based studies and careers.

Significant research has been conducted on the impact of gender and ethnic occupational stereotypes. Generally, there is widespread evidence of the existence of such stereotypes that appear to be robust over time. They have been shown to have impacts on (among other things) hiring decisions, vocational assistance and expectations, mother-child interactions, self-efficacy, and event-related brain potentials (electrical brain activity).

Positively, occupational stereotypes have been viewed as reflections of individuals' knowledge of the world of work. Such knowledge reflects their experience of work and may become the basis for both improved self-awareness in relation to work as well as a foundation on which to build occupational exploration and job search strategies.

OCCUPATIONAL STEREOTYPES AS PROBLEMS

In the field of social psychology, there is a vast literature on prejudice into which cognitive mechanisms such as stereotyping are to be found. Some of this overlaps the career development field insofar as work often constitutes a major way in which disadvantaged and minority groups are able to redress their social and financial disadvantage. The focus of most of this work is on people's overgeneralized, only partially true, often misleading, and almost always oversimplified

ideas and perceptions about such groups. Such ideas and perceptions are frequently the result of lack of knowledge and personal contact with other groups or a "clash of cultures" in which stereotyped thinking becomes a perceptual filter through which the actions of other groups are interpreted.

Relevant to work, such stereotyping adversely impacts the selection of candidates for work. At both the legislative and educational levels, endeavors have been made to reduce the inequity of such thinking and action along the lines of gender, age, disability, culture, religion, and ethnic origins. For example, those with cerebral palsy are frequently perceived to have major cognitive deficits, when in fact the condition is predominantly a motor dysfunction, and as a consequence are excluded from some occupations for inappropriate reasons. Notwithstanding the obvious importance of this whole area of theory, research, and practice, in career development the focus of attention relating to "occupational stereotypes" has been much more specific.

OCCUPATIONAL STEREOTYPES AS POSSIBILITIES

John Holland was the vocational psychologist who decided to make occupational stereotypes one of the main bases for his theory of career development and its practical applications. Holland began with the acknowledgment that most people view the world of work in terms of occupational stereotypes. However, rather than see these occupational stereotypes as problems, confusions, and barriers to career development, he saw them as providing opportunities to develop and assess individuals' understandings of both themselves and occupations. In fact, Holland saw such occupational stereotypes as often accurate and distilled pieces of knowledge that individuals gained through their experience of the world. Where this experience was limited with respect to a particular occupation, then individuals' stereotypes of these occupations were indications of people's projections of themselves. This too was valuable data for counselors to utilize in career counseling for occupational choice. In some ways this perspective prefigures modern constructivist counseling approaches, most notably that of Mark Savickas, which emphasizes perception as construction and construction as a key to meaning and change.

Initially, Holland used occupational titles as a way to categorize and assess individuals' preferred ways of

interacting with their environment, which he thought of as personality. Holland's research led him to conclude that both individuals and occupations could be classified according to six general types. Briefly these six types are as follows:

1. Realistic (R): a focus on manual, mechanical, outdoor, practical, building, and agricultural activities
2. Investigative (I): a focus on intellectual, scientific, analytical, conceptual, and mathematics activities
3. Artistic (A): a focus on creative, idealistic, aesthetic, performance, introspective, and emotionally expressive activities
4. Social (S): a focus on supportive, teaching, religious, sociable, cooperative, and caring activities
5. Enterprising (E): a focus on business, sales, media, leadership, and extroverted activities
6. Conventional (C): a focus on office, clerical, money handling, methodical, and conforming (to rules) activities

In theory each person's and each occupation's type was the ordered combination of all six categories. However, for most practical purposes, the subtype—the highest three assessed type scores—were employed for both individuals and particular occupations. For example, architect's subtype is Artistic Investigative Realistic (AIR), which makes sense in that the job involves creative design (Artistic), knowledge of materials and calculations (Investigative), and an appreciation of the realities of building and construction (Realistic). Initially, Holland sought empirically to confirm occupational stereotypes by establishing which type and subtype combination were most dominant for workers in each occupation. Subsequently, he elaborated this to include also a consideration of the kinds of tasks that people in the occupation performed.

This classification has found widespread acceptance, application, and both empirical and counselor support over the last 30 years up to the present. It constitutes the basis for many of the most popular classifications of vocational interests and occupational information databases in both English-speaking and non-English-speaking countries. This classification also formed the foundation for Holland's own person-occupation matching theory of occupational choice and for the development of a number of inventories assessing both individuals and work environments.

As Holland's thinking developed and changed over time, he increasingly wrote about "work environments" rather than "occupations" or "occupational stereotypes." A work environment was created by particular types of individuals congregating and fashioning a physical and social context reflective of their preferred ways of interacting with each other and the rest of the world.

The Holland taxonomy does have some limitations characteristic of all stereotypes. Holland himself has noted that work environments are rarely homogeneous. As a consequence, a single occupation such as "counselor," while having a dominant subtype SAE, also has been found through research to have other subtypes such as SEA, SCE, ASI SAI, SEC, and SAC. Holland attributes such variation to characteristics of the work environment that are predominantly not psychological in nature, such as the size and complexity of the organizational context, the relative power and independence of workers in a particular occupation, and the perceptions and expectations of others in the work environment. This in turn points to recent perspectives of understanding both individuals and their work in terms of complex, multivariate contextual as well as psychological influences. Holland's approach was based on simplicity, practicability, and research data, and it exemplifies such virtues. However, the tradeoff with simplicity is the risk of oversimplification, an issue with which the field of career development as a whole is continuing to come to terms.

The other main area of criticism of the Holland taxonomy also illustrates the issue of generality versus specificity. These criticisms are leveled at the actual content of the classification at the type level. For example, it has been noted that the Realistic category as represented by numbers in the workforce is about eight times the size of the Artistic category. This does seem disproportionate and has led some writers to suggest that this reflects a bias that requires redressing by further differentiating the Realistic category. Another example is criticism of the actual type names, which some counseling clients find misleading (such as private investigator is not I but E) and less than flattering (not many people like being labeled "conventional," which connotes being boring and predictable). However, notwithstanding such limitations, Holland's taxonomy has been found to be useful by counselors, researchers, test constructors, and career development theorists (see the following) alike.

THE COGNITIVE MAP OF OCCUPATIONS

Linda Gottfredson took Holland's notion of occupational stereotypes and applied it to sociological as well as psychological aspects of career development and choice. Gottfredson noted that most people's knowledge of occupations is social rather than vocational. Thus, for example, comparatively few people in the general population can enunciate the duties of a petroleum engineer. However, most can agree on whether it is most typically seen as a male or female type of occupation and whether it is a high, average, or low-level social status occupation. Gottfredson's theory indicated that as individuals develop from childhood, so too do they develop increasingly differentiated images of themselves (self-concept) and occupations (images or stereotypes). According to the theory, this development has a set sequence: sex types, prestige (and ability) level, and field of work (classified according to Holland's taxonomy).

Research has confirmed by and large that the general population shows high levels of agreement about most occupations according to masculinity-femininity, prestige range, and dominant field of work (interest/activity). Gottfredson used such data to develop the Cognitive Map of Occupations to illustrate this consensus. Moreover, these (social) images of occupations have a major impact on the development of occupational aspirations. Individuals' developing understanding of themselves in gender terms, for example, is matched by a sex type perspective about the world of work. These two images are matched in a process that eliminates occupations whose images are viewed either consciously or unconsciously as incompatible with the developing self-concept. Thus a female child will typically not see occupations that involve highly masculine-oriented activities such as mining, boxing, and construction work as appropriate. Once eliminated, such occupational options (based on their occupational images) are not reconsidered by the developing person.

This same process, called "circumscription" by Gottfredson, then occurs in sequence for prestige/ability level and field of work. Individuals thereby limit the range of acceptable alternatives to those whose images (or stereotypes) are a reasonable match with their own self-concept based on sex type, prestige level, and field of work. According to Gottfredson, people are often unaware of this process occurring. One of the roles of career counselors may be to make the circumscription process more "visible" to their clients so that they, the clients, can then consider both the

accuracy and appropriateness of such a development of occupational aspirations. This may lead them to challenge their occupational stereotypes by choosing a non-traditional career, and they may require some ongoing counselor support to "swim against the (traditional) social tide." Making the process explicit may also help people to "compromise" when they cannot find an appropriate occupational image and/or fail to be able to implement it successfully. This compromise process is seen as a reversal of the circumscription process. Individuals are more likely to relinquish field-of-work preferences before they relinquish prestige preferences before they relinquish sex type preferences. Images of occupations remain the basis for this compromise process. More recently, Gottfredson has introduced the idea of degrees of compromise as a way to illustrate the relationship between the three developmental dimensions of self and occupational images and to account for the discrepancies between her original formulation and subsequent research findings.

SOME CONCLUSIONS

Stereotypical thinking is simply a function of the often unacknowledged reality that humans are always limited in their knowledge. Such an acknowledgment is often only grudging in much of the career development theory literature. As a consequence, these formulations typically overemphasize the rational in career decision making. If career development theorists and counselors commence with the assumption that there are major limitations on our rationality, then more can be done to utilize and if necessary redress the implications and effects of stereotypical thinking. Occupational stereotypes may serve as limited but useful summaries of how individuals view their world, thereby giving insight into their perceiving and meaning making. Occupational stereotypes may produce deleterious effects if they unnecessarily limit individuals either in terms of personal cognitive constraints or in terms of external contextual barriers, from being able to consider and choose from the potentially widest range of options available. Either way, the worst thing that can be done is to ignore the reality of occupational stereotypes as a fundamental way humans formulate their understanding of themselves, their world, and their careers.

ON-THE-JOB TRAINING

On-the-job training, often referred to as OJT, occurs whenever more experienced employees teach less experienced employees how to do one or more of the tasks of a job. It is practical, hands on, and found in all organizations at almost every level. On-the-job training is the single most commonly used training method in organizations today.

The most common applications of OJT are in training new workers in manual tasks. Typically, new employees are assigned to work alongside more senior employees, who show the novices how to do required tasks and oversee their work. All employees undergo some OJT, typically in cases where how-to knowledge is company specific and only one or two employees are learning at a time (e.g., administrative tasks such as time accounting or business-expense claims). Coaching and mentoring, especially at managerial levels, are also forms of OJT.

According to some studies, employees who receive more hours of OJT programs may start at lower wage levels; all studies report higher wage and productivity growth rates in firms with extensive OJT programs. The more educated the employees, the higher the rates of return for OJT; in fact, the return rate is more than 80 percent for college-educated employees. Studies have also shown that much OJT learning is portable across employers and even across industries. With

today's boundaryless career model, OJT learning seems a wise investment.

Historically, all training was OJT. Children learned from their parents and extended family members. Medieval guilds established formal apprenticeship programs that many craft unions still use today, albeit with formalized courses of instruction and skill testing to determine task mastery. For example, the United Association's five-year program to train plumbers and pipefitters includes 1,700 to 2,000 hours of OJT each year.

OJT is highly cost effective, particularly in small companies where few employees require training at any given time. Companies normally spend three to six times as much on OJT as they do on formal training. The return on organizational investment is higher, since OJT includes no external trainer costs and materials fees. In addition, fewer employees are unproductive during OJT than during formal training, so productivity drops less—a particularly important benefit in smaller companies.

Learning is focused and usually faster, since both the trainer and the trainee generally engage in actual production during the training period. The training utilizes the actual equipment and materials from the live job, so no adaptation or retraining is required following the training period. Furthermore, no latency period follows OJT that allows the new skills to be forgotten. Hence, OJT is an excellent way for established employees to enhance their skills and learn new ones. OJT uncovers learning and ability problems quickly and allows them to be addressed within the departmental unit. In addition, since the trainer is usually a peer or supervisor, OJT can help build relationships with new employees.

Although OJT is very effective, it is not perfect. Most OJT trainers have received little or no instruction in teaching methods. Trainers are usually chosen because they are good at their jobs, rather than because they can explain those jobs. They may not be productive when their training styles do not match the learning styles of their trainees.

Because on-the-job training rarely has specific goals other than a simple how-to, learning goals and training plans with predetermined content are usually absent. The training process may be haphazard, and trainees often learn by rote, with little understanding of why tasks are performed. Hence, OJT is highly unsuitable for training in theoretical situations.

The implementation problems of OJT can be largely overcome through careful planning. Job instruction training, or JIT, was developed to teach manufacturing during World War II; it is still acknowledged as

the best approach today. JIT has four overall stages: prepare, present, try out, and follow up.

The prepare stage is actually the most complex and difficult, and it is the one most commonly left out. The job supervisor needs to break down all the steps of the job, seeing the job through the eyes of a total novice. From the steps comes an instruction plan that can be tailored to individual trainees. The final part of this stage—putting the trainee at ease—is critical to provide motivation and set the stage for success.

The present stage has four steps: tell, show, demonstrate, and explain. First, the trainer gives the trainee an overview of the task while pointing out the equipment, materials, and so on that are involved, following the main steps listed in the training document prepared in Stage 1. The trainer runs through the job once to communicate the overview and convey the gist of the job, showing the sequence of steps and their rhythm. Next, the trainer demonstrates each step in detail, actually doing the steps of the task and explaining each step, one at a time, while the trainee watches. The steps may not be demonstrated in the sequence of actual operation; often it is better to demonstrate simple tasks first to build confidence. Showing finished products at each appropriate step helps the learner understand what is required. While demonstrating, the trainer explains why each step is done in the way it is done.

The third or try-out stage involves direct trainee participation. First, the trainee talks through what has been learned, then instructs the supervisor on the steps of the job. Once the trainee and supervisor are comfortable that the trainee is ready, the trainee does the job steps under supervision. The trainer provides both positive and corrective feedback. Finally, the trainee practices, with clearly defined targets for performance measurement.

During the Stage 4 follow-up, the trainer monitors progress, offering feedback and pointers where needed and when asked. This ongoing involvement gradually tapers off as the trainee masters the tasks.

In office environments, OJT has advanced dramatically in the last few years with computer-based training (CBT). Many office workers learn most new skills at their desks with vendor-supplied, self-paced training materials. These materials can be as simple as texts and associated data files (enabling users to learn new computer applications quickly) or as elaborate as multimedia simulations with audio, video, and even virtual reality components. As expected, the training complexity tends to increase with the sophistication of the job to be learned.

Corporate intranets are the latest delivery mechanism for OJT. Such nets enable nearly all employees

to participate in general educational programs (e.g., ethics, diversity, and sexual harassment) that require feedback and/or assessment; these nets also deliver training on companywide systems. This simple, user-controlled distribution system, coupled with a tracking mechanism to ensure training delivery and mastery, delivers considerable bottom line benefit.

On-the-job training has been and continues to be the most widely used job-training method. Computer delivery of OJT incorporates many of the JIT steps; it offers the potential to improve OJT and increase its already proven benefits. As careers become even less structured, employers' training requirements increase, and technology supports more interactive and realistic user interfaces, OJT will become even more pervasive and more effective.

ORGANIZATIONAL CAREER MANAGEMENT

This comprehensive view of *organizational career management* systems discusses the portfolio of career planning and management practices available to organizations and explores ways by which organizations can use career systems to meet their needs. It focuses on organizational career management: what it is, why it is needed, and what it does. Special attention is given to career management practices and how they form an integrative system for people development within organizations.

What is a career? A career can be seen as the pattern of work-related experience that spans the course of a person's life, an evolving sequence of a person's

work experience over time, the sequence of employment-related positions, roles, activities, and experiences encountered by a person, or as a process of development along a path of experience and roles in one or more organizations. Careers take place in specified social environments, and particularly in organizations. A “normal” or typical professional career usually follows a sequence of developmental phases, each of which is delineated by a distinct shift in the individual’s sense of self, but each is shaped and influenced by the organization in which the person works.

A career belongs to the individual, but in much, if not most, employment settings, the career is planned and managed for the individual by the organization. The organizational structure identifies an internal road map, clarifying positions and the interrelationships between these positions, as well as the relevant competencies necessary to fill them. Furthermore, organizational career management includes mechanisms that enable people to navigate this road map. This is how organizations take a leading role and have control over career planning and management.

The organizational system of career management relates to several levels, as depicted in Yehuda Baruch’s CAST model. The three P’s—philosophy (strategy), policy, and practice—are parallel to the three A’s of individuals—aspirations, attitudes, and actions. The need for matching individual and organizational needs has been emphasized by many scholars. Peter Herriot and Carol Pemberton’s model associates the business environment with the organization in terms of strategy, structure, and processes. Even more important, their model compares and contrasts the organizational and individual needs and expectations.

Moving from the strategic level to the practical level—the actual human resource management (HRM) activities that form the career management system—the next section of the entry outlines a comprehensive portfolio of HRM practices, which can be conducted by organizations to plan and manage employees’ careers. Evidence is presented regarding the extent to which these practices are actually applied in organizational settings. Based on both data and conceptualization, six dimensions are utilized to demonstrate the nature and role of these practices. Finally, a framework that integrates the various practices into a comprehensive system is offered.

The interpretation of the utilization of these practices needs to be taken in the context of dynamism of the social system. Contemporary work has focused on the changing meaning of careers. There is a clear shift

from long-term relationships to transactional “short-termism,” with major changes in the nature of the psychological contract between employers and employees.

THE UTILIZATION OF CAREER PRACTICES

The importance and prominence of organizational career planning and management (CPM) as part of HRM have been widely recognized. Organizational career systems comprise a three-level framework of strategy, policy, and practice. At the practical level, one may find a number of activities and practices that aim to help organizations manage the careers of employees, in particular managerial and professional careers. An appropriate system should aim to ensure a fit between individual needs and aspirations and organizational requirements.

The list of practices discussed in this entry evolved from several earlier studies of CPM practices. Table summarizes findings from these studies, all of which examined the use of CPM practices in organizations as reported by human resource directors. The next section describes these practices, with a specific consideration of their relevance and viability in the context of the twenty-first century. This is followed by a discussion of how the practices can be integrated into a single comprehensive system.

Before embarking on the task of describing the various practices, let us identify their target population. Each person, be they the porter or the CEO, has a career, a personal and occupational journey. Each organization is a career system, the landscape for people’s journeys. Nevertheless, many individuals develop their career outside the boundaries of large organizations. Self-employed people who run small businesses, freelancers, and the unemployed all have their career external to an organizational framework. However, most working people are engaged in organizations, usually as employees. Career management practices are carried out by organizations, usually via the HRM unit, to answer employees’ needs and match them with the organization’s needs.

A PORTFOLIO OF CAREER MANAGEMENT PRACTICES

Posting (Advertising) Internal Job Openings

Whenever a position needs to be staffed, the organization can look to fill the vacancy with candidates either inside the organization (internal candidates) or

Table 2. Empirical Studies Examining the Use of Career Practices

Career Practices	A 1 – “not applied at all” to 7 – “applied extensively”		B1 % of use by the organizations	B2 % of use	C % of use
	Mean	sd	%	%	%

outside the organization (external candidates). The choice depends on the level and type of the position and the norms of the organization's career management practices. A model developed by Jeffrey Sonnenfeld and Maury Peiperl identifies such a typology of external versus internal recruitment. Many organizations employ a policy that requires internal job posting before any external search is conducted. Extensive use of job posting within the company indicates to the employee that the organization focuses on the internal labor market, preferring internal promotion to recruiting managers from outside.

Formal Education as Part of Career Development

With this practice, the organization selects people of managerial or technical potential and sends them to a program of formal study as part of their development path. The education can include a first degree in engineering, an MBA, other academic studies, or professional and vocational qualification training. Once the organization has identified a training or education gap in the near or far future, these programs can rectify the problem with this long-term approach.

Lateral Moves to Create Cross-functional Experience

Lateral moves to create cross-functional experience are on the increase and may be seen as elementary career planning and management practices that most organizations with HRM systems need to apply. The flattening of organizations means fewer hierarchy levels and thus fewer opportunities for upward mobility. Because people no longer move up the ladder so fast, organizations need to clearly indicate that a route with slower upward mobility reflects career success rather than failure, a shift from past norms.

Retirement Preparation Programs

This practice is directed at a target population of employees approaching retirement and about to leave the organization. In these programs, the employee is prepared to face retirement in several ways. Much attention is devoted to financial considerations such as understanding the pension conditions and learning tax regulations. However, the more effective programs also take into account the psychological issues surrounding an individual's need to readjust to life without work. With the advent of heavy redundancies (reductions in force or layoffs), fewer people are leaving the workplace at the legal retirement age. As a result, traditional preretirement programs might become quite rare in the future. Progressive organizations may opt to transform the preretirement program into a preredundancy program.

Booklets and/or Pamphlets on Career Issues

Booklets, pamphlets, or leaflets on career issues represent a formal presentation by an organization regarding all kinds of career-related information. Such information is directed at all employees but is important especially for newcomers, either recently recruited to the organization or recently promoted to the managerial ranks.

Dual Ladder

The dual ladder provides an organizational hierarchy for nonmanagerial staff, such as professional or technical employees, that is parallel to the managerial hierarchy. The major role of such a ladder is to enable upward mobility and recognition for those employees who cannot or do not wish to pursue a managerial role in the organization.

Induction or Socialization

The process of introducing people to their new organization is the first CPM practice that the employee experiences. This is a process whereby all newcomers learn the behaviors and attitudes necessary for assuming roles in the organization. Part of this process is formal, led by organizational officials, whereas other aspects are learned in an informal manner.

Assessment and Development Centers

Assessment centers have been found as a reliable and valid tool for career development. Assessment centers were first used as a selection device for managerial recruitment. Later they were also used for identifying managerial potential and for developmental purposes.

Mentoring

The principal aim of mentoring is to bring together a person with managerial potential and an experienced manager who is not necessarily the direct manager. Such a senior manager can provide advice and tutoring, serving as a kind of "uncle" or "godfather" in the workplace. Thus mentoring is directed mostly at managerial personnel and is used frequently for graduate recruitment programs. The potential of this practice has been suggested in many studies. Mentoring might also be dysfunctional, due, for example, to a negative relationship between mentor and protégé, a possible collision of interests between the individual's mentor and his or her direct manager, and the challenges of managing a cross-gender relationship.

Career Workshops

Career workshops are short-term workshops focusing on specific aspects of career management that aim to provide managers with relevant knowledge, skills, and experience. These can be specific to providing certain skills, to help the individual learn about organizational processes and changes, or to improve self-career management (e.g., workshops to introduce career concepts such as career resilience or intelligent careers).

PERFORMANCE APPRAISAL AS A BASIS FOR CAREER PLANNING

Performance appraisal (PA) systems operate in most organizations. There is, however, a need for a close

connection between the PA system and career development. PA is perhaps the most fundamental system and can be utilized by human resources in a very similar way to that by which accounting reports (such as profit and loss statements or balance sheets) provide information regarding financial and accounting systems. Valid and reliable PA systems provide answers to acute questions such as who should be promoted, who should be made redundant in case of a downsizing, and who should receive training and development. The most recent development in PA is 360-degree feedback that includes self-appraisal, peer appraisal, upward appraisal, committee appraisal, or a combination of several sources in addition to that given by the direct manager. Although the literature supports the use of 360-degree feedback, this practice is very demanding in terms of the time that needs to be invested and the analysis that needs to be conducted.

CAREER COUNSELING

Career counseling involves two-way communication between the employer and the employee, and two main sources are available for conducting the counseling. The first is the direct manager (or another higher manager) who has a good knowledge of the employee's attitudes, behaviors, skills, and so on, and the second is a human resource manager. Depending on the complexity and the financial resources of the organization, external counseling can additionally be provided.

SUCCESSION PLANNING

Succession planning (also labeled *management inventory*) can be valuable for long-term planning. It determines the possible replacement of every manager within the organization and evaluates the potential for promotion of each manager. It is primarily directed toward the managerial workforce. It will be different, but not less important, in a flattened organization where lateral movements predominate.

PROGRAMS FOR SPECIAL POPULATIONS OF EMPLOYEES

With an increasing level of employee diversity, new work arrangements, and globalization, career practices need to address the needs of specific populations, such as ethnic minorities, women, physically disabled, and dual-career couples. In the banner of equal opportunities and with increased litigation brought against companies, organizations realize the need to go beyond

paying lip service to equality and to make sure that all members are given a fair option for promotion.

NEW CAREER PLANNING MANAGEMENT PRACTICES

Building Psychological Contracts

The concept that a psychological contract exists between the employee and the workplace was discussed earlier and is a crucial aspect of the employment relationship. Recent research has examined the negative impact of breaking these psychological contracts. The cycle of career planning and development for each person joining the workforce starts with the establishment of a mutual agreement, a psychological contract, that sets the stage for future relationships.

Secondments

A secondment is a temporary assignment to another area within the organization and sometimes even to another associated organization (such as a customer or supplier). A person from the managerial or professional echelons of one organization is transferred for a specific time (usually from one to three years) to another organization. Experience is shared in a way that benefits both the organization and the individual.

CPM PRACTICES THAT REQUIRE REASSESSMENT FOR THE FUTURE

Written Personal Career Planning for Employees

Written career planning documents imply a commitment on the organization's part. Long-term commitment (e.g., lifetime employment) has already become virtually an extinct feature of organizational life. Written personal career plans are problematic also in the sense of creating employee expectations that may not be capable of being fulfilled in the organization.

Common Career Paths

A career path is the most preferred and recommended route for the career advancement of a manager in an organization. Such career paths can lead people through various departments and units within the organization, as in the case of future top-level managers in multinational companies who take a managerial role in an overseas subsidiary. With traditional hierarchical structures flattening and diminishing

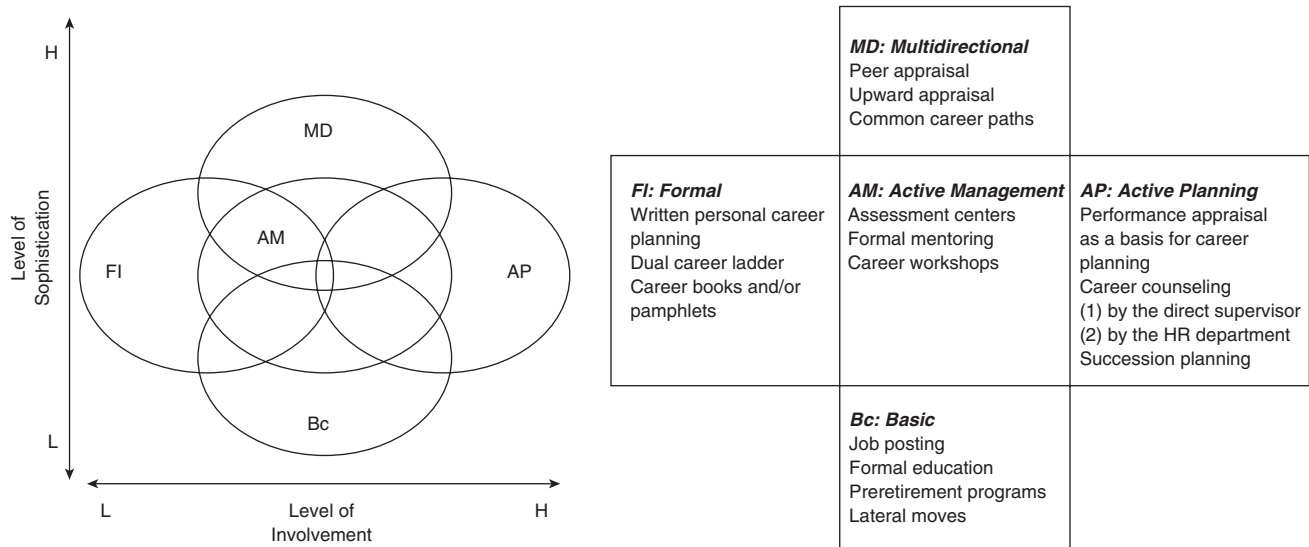

Figure 2. Baruch and Peiperl's Two-Dimensional Model of Career Management Practices

and with the creation of boundaryless and virtual organizations, future development in career paths seems likely to decline. It is now the norm, rather than the exception, for organizations to have no fixed career paths and for individuals in them to see no further than one or two years ahead.

Integrating a Set of Practices Into a System

The practices presented above have a significant problem if they are presented as distinct, almost stand-alone practices. However, both managerial logic and practical experience point out that there should be a system designed to manage careers, and this system applies the various practices according to need. However, a question remains: What are the relationships between these practices? Two answers are provided here in the form of descriptive and normative models.

A DESCRIPTIVE MODEL FOR CAREER PLANNING MANAGEMENT PRACTICES

The first answer is based on a descriptive model, that is, what happens in real organizations. The results of an empirical study in the United Kingdom (shown in the figure above) reveal five clusters of CPM practices. It is a model based on field-research data gathered from almost 200 organizations and was constructed using a statistical procedure known as factor

analysis. The classification of CPM practices is configured along two dimensions: (1) the degree of sophistication embodied in the practice and (2) the level of organizational involvement required by the practice. The five clusters are described below:

Basic

Job posting, formal education as part of career development, preretirement programs, and lateral moves to create cross-functional experience appear in this category. These may be seen as elementary CPM practices that most organizations with HRM systems need to apply. Evidence indicates that they are applied in most of the organizations studied. Although currently widespread, they may best fit the traditional, bureaucratic organization model. Contemporary organizations, for example, may be reluctant to invest in education, see no need for preretirement programs, and due to the frequency of organizational changes, abandon long-term planning.

Active Planning

This category includes performance appraisal as a basis for career planning, career counseling by the direct supervisor, career counseling by the human resources department, and succession planning. These practices share both an active involvement on the part of the organization in individuals' career development over time as well as the organization's need to fill jobs

in the future. This manifests a forward-looking, initiative-taking HRM system.

Active Management

Assessment centers, formal mentoring, and career workshops are the three practices in this group. They clearly all have an informational element, which characterizes either the process of gathering information for the organization or the use of information for developing individuals. The bidirectional nature of this information transfer (between the organization and the employee) is characteristic of organizations that take the time to put these elements in place.

Formal

Written personal career planning for employees, dual career ladders, and books and/or pamphlets on career issues are the three practices in this group. These represent elements of career management whereby the organization provides the employee with a formal system of information and presentation of opportunities. However, this represents a downward direction of information transfer (from organization to employee) rather than bidirectional.

Multidirectional

Peer appraisal, upward (subordinate) appraisal, and common career paths comprise this category. The inclusion of common career paths in this category is a bit surprising, because they are logically associated with formal career structures. The remaining two practices could be characterized as increasing options by expanding the directions through which people can receive feedback and develop within the organization. These are more advanced practices, which many organizations will need in the future.

Analyses regarding these five clusters revealed that they were associated with different aspects of an organization's culture. For example, practices in the active planning category tended to be provided in open and proactive cultures, the basic practices in team-oriented cultures, and the multidimensional practices in open cultures and in organizations that used an internal labor market to fill positions. Not surprisingly, formal practices were more likely to be provided in large organizations than in small organizations.

The practical implications for HRM suggested by this descriptive model are as follows:

- For the basic: Offer basic career system elements, satisfy employees' expectations, and provide a relevant infrastructure
- For the formal: Support the internal labor market, provide stability, and clarify options for career development within the firm
- For the active management: Maximize the firm's knowledge of employees and maximize the employee's knowledge of the firm, including the options within the firm
- For active planning: Make performance-career links explicit, offer personal and emotional support, provide for succession
- For the multidirectional: Maximize performance feedback, promote an open culture, but beware of risks in small or "closed" organizations.

A NORMATIVE MODEL FOR CAREER PLANNING MANAGEMENT PRACTICES

Whereas a descriptive model identifies clusters of practices that are currently used in organizations, a normative model identifies what should be used. A subsequent study expanded the number of dimensions for evaluating the relevance of a career practice from two to six and was based on the perceptions of leading career scholars who were asked to identify how the various CPM practices can be characterized by these six dimensions. The six dimensions are as follows:

1. Involvement: From a very low to a very high level of organizational involvement needed while dealing with the specific career practice
2. Sophistication and complexity: From a very simplistic to a highly sophisticated and complex practice
3. Strategic orientation: From a very practical "tactical" practice to a very strategic practice
4. Developmental focused: From a low to a high relevance for developing individuals
5. Organizational decision-making focused: From a low to a high relevance of the practice to aid organizational decision making
6. Innovative: From a very traditional or conventional practice to an innovative and unorthodox practice.

Based on a Delphi approach, Baruch's 2003 normative model emerged, based on the views of 16 leading scholars from the Careers Division of the Academy of Management. Table 3 presents the evaluation of the practices along the dimensions.

Table 3. Ratings by Scholars of 22 Career Planning Management Practices on Six Dimensions

<i>Dimensions on Which the Career Planning Management Practices Were Rated</i>	<i>Organizational Involvement</i>		<i>Strategic Orientation</i>		<i>Innovative Orientation</i>		<i>Developmental Focus</i>		<i>Organizational Decision-Making-Oriented</i>		<i>Sophistication and Complexity</i>

Integration

Career practices should not be discussed in isolation, as if they are a set of unrelated or disassociated practices. Careers in organizations are meant to be planned and managed in a joint manner. A system should be designed to answer the needs and requirements of both the individual and the organization. Professional, effective HRM will make sure that the career system operates in a well-integrated, comprehensive way.

Applying a twofold level of integration is necessary to achieve a fit and optimal utilization of career practices. These levels are “internal” integration among the various practices and “external” integration between the bundle of practices (that is, the career system) and the organizational culture and strategy. Both internal and external integration should be driven by the organization’s strategy, because it determines major business decisions. For example, the decision whether to go international or stay within national borders has implications for career practices, because such a strategy necessitates policies and practices regarding expatriation and repatriation.

Internal integration relates to the match between the various career practices, a fit that is in dire need. For example, an effective performance appraisal system should be associated with other CPM practices. Inputs from certain practices (e.g., mentoring) will influence the use of others (e.g., workshops, secondments). For external integration, career systems that best fit the organization depend on the operational strategy of the whole enterprise. The career system should be developed in line with business objectives and needs. The culture of the organization will help in shaping the career practices and their use, but in a complementary way, career management practices can help in the reshaping of organizational culture.

FUTURE DIRECTIONS

With the boundaryless organization came the boundaryless career, and with them came new psychological contracts. These had a profound effect on the management of careers. Much of the burden of career planning and career management has shifted from the organization to the individual, as individuals are expected to shape their own future. The involvement of the organization will vary too, according to the target population (e.g., their educational level, professionalism, and proactivity). Thus there is apparently a lesser need for a system of “command and control”

from the organization and a greater need for a support system in which human resources is the enabler of successful individual careers rather than the manager of them. This will be reflected in CPM systems in organizations of the future. The future will bring more managerial complexity, resulting in more sophistication required from career systems.

ORGANIZATIONAL CITIZENSHIP BEHAVIOR

Organizational citizenship behavior (OCB) is an action taken by an individual that is discretionary and not formally recognized or rewarded by an organization but in total promotes the organization’s effective

functioning. Simply put, it is behavior that goes above and beyond the requirements of the job yet is not necessarily compensated by the traditional organizational reward system. Individual instances of OCB do not, in themselves, enhance effectiveness, but aggregated over time and across persons, citizenship behaviors increase organizational effectiveness and efficiency. Examples of OCBs include helping a coworker with a work-related problem and promoting a positive work environment. Related concepts include extra-role behavior, prosocial organizational behavior, organization spontaneity, and contextual performance.

A number of reasons have been offered to support the underlying assumption that citizenship behaviors promote organizational effectiveness. OCB is believed to serve as an effective means of coordinating activities between team members and across work groups, increase coworker and managerial productivity, and enhance stability of organizational performance. Moreover, citizenship behaviors have implications for individual careers, as they have been found to have a positive influence on managers' evaluations of performance. Research suggests that OCBs influence performance evaluations over and above objective measures. Supervisors perceive citizenship behaviors as contributing to the value of an employee's performance and consider them when making reward allocation decisions. In addition, citizenship behaviors are positively related to employee retention.

Organizational citizenship behavior was originally conceptualized as an alternative explanation for the satisfaction-causes-performance hypothesis. It was developed in response to studies that found only modest relationships between employee attitudes and traditional measures of work performance. Research indicates that employee attitudes, such as job satisfaction, are expressed through extra-role behaviors for which employees have volition and discretion. In essence, employees respond to supportive treatment from their organizations with organizational citizenship behaviors.

Theorists have relied primarily on the social exchange framework to support the proposition that employee attitudes influence organizational citizenship behavior. Social exchange theory suggests that people seek to reciprocate those who benefit them. Therefore, to the extent that job satisfaction results from organizational efforts, employees will respond by performing citizenship behaviors. Although less applied, researchers also note a second justification. According to the social psychology literature, prosocial

behaviors are likely to be performed by individuals experiencing a positive mood state. Therefore, to the extent that job satisfaction results in a positive mood state, satisfied employees are likely to display organizational citizenship behaviors.

Organizational citizenship behavior research has considered both overall measures of the construct and various dimensions of it. Although there has been a general lack of consensus about the dimensionality, the five most commonly examined dimensions are altruism, conscientiousness, sportsmanship, courtesy, and civic virtue. Altruism consists of discretionary behaviors that aim at helping certain people in an organization with a relevant task or problem. An example of altruistic behavior includes employees helping coworkers finish an important project, even though the helpers are not responsible for its completion. Conscientiousness, which was originally termed *general compliance*, involves employees going beyond the minimum requirements of the job. For example, an employee who forgoes a vacation day to work on a project that would not otherwise meet the completion deadline would be displaying conscientiousness. Sportsmanship refers to one's willingness to tolerate personal inconveniences and impositions without protest or fuss, thus conserving energy for job tasks. Courtesy includes proactive gestures such as consulting with others before taking action and passing along information. Civic virtue refers to the involvement that an employee shows in the political life of the organization such as attending meetings and discussing organizational issues on personal time.

Since its conception, studies have gone beyond the examination of satisfaction to identify other predictors of organizational citizenship behavior. A number of attitudinal, dispositional, and individual difference measures have been examined. Although job satisfaction has been the most robust correlate, additional attitudinal predictors include perceptions of fairness, perceptions of leader support, and organizational commitment. In addition, various task (e.g., task feedback, intrinsically satisfying tasks) and leadership behaviors (e.g., contingent reward behavior, supportive leader behavior) have been consistently linked to OCB.

The limited research examining consequences of OCB have focused on organizational as well as individual outcomes. As noted previously, this research has found that citizenship behaviors have a positive impact on several important personnel decisions made by managers. In particular, citizenship behaviors have shown an influence on performance evaluations and

managers' reward allocation decisions (e.g., salary, reward, and promotion recommendations). In addition, the limited amount of research examining organizational outcomes has shown strong support that citizenship behaviors increase work group and business unit performance.

Due to the implications for both organizations and individuals, organizational citizenship behavior has received a great deal of research attention in the last 20 years. Research continues to be refined in terms of the factors that influence performance of such behaviors and the ensuing outcomes. Recently, research has been refined to differentiate between targets of organizational citizenship behaviors. This research has examined those behaviors intended to benefit the organization as well as those that are intended to benefit specific individuals within the organization, such as coworkers.

ORGANIZATIONAL COMMITMENT

Organizational psychologists—researchers and practitioners alike—have long been interested in understanding how people react, psychologically, to the various aspects of their workplace and in understanding

the consequences of these psychological reactions. Given that most people are likely to spend at least some of their working careers as members of one or more organizations, it is perhaps not surprising that a great deal of this interest focuses on employees' commitment to the organizations for which they work. Indeed, of the several "work attitude" variables studied by organizational psychologists, only job satisfaction has received more research attention than *organizational commitment* (OC). As with the study of job satisfaction, much of this research deals with the conceptualization and measurement of OC. In addition, considerable attention has been given to understanding the conditions under which OC develops and its consequences.

CONCEPTUALIZING ORGANIZATIONAL COMMITMENT

The early OC literature produced various, and quite distinct, definitions of the concept. At a general level, however, most scholars would agree that organizational commitment refers to a psychological state that characterizes an employee's relationship with the organization for which he or she works. This psychological state has important implications for whether the employee will choose to maintain a particular course of action, in this case, remaining with the organization. Thus regardless of their specific conceptual definition of OC, most researchers expect that strongly committed employees have a greater intention to stay with the organization than those with weak commitment.

Beyond this, however, there are different views about the *nature* of the psychological state that binds an employee to the organization. Indeed, just as the word *commitment* is used somewhat differently in everyday language, early researchers in the field provided differing conceptualizations of OC and developed different measures of the construct. In all cases, however, commitment was described in one-dimensional terms. For some early researchers, OC was an emotional attachment to the organization much like love or affection. Others focused on identification with the organization and what it represented. Some researchers viewed OC in terms of a reluctance to endure sacrifices, or incur costs, that voluntarily leaving the organization would entail. Still others described commitment in terms of a moral obligation to remain with the organization.

From these different views has emerged wide acceptance of OC as a construct that has not one, but

multiple, dimensions. Although specific details vary, the basic premise of most of these multidimensional models is that a given employee's commitment to the organization has more than one psychological base or component and that each of these should be measured separately in order to give a full picture of the employee's commitment to the organization. Of these various multidimensional models, the three-component model (TCM) proposed in the 1990s has received the most empirical attention. Although it is through this lens that the research on the development and consequences of OC is viewed here, it is important to note that research from various traditions has contributed to this body of knowledge.

As its name implies, the TCM proposes that OC has three distinct components. Each develops via somewhat different processes and represents a distinct psychological tie that binds the employee to the organization. *Affective commitment* refers to the employee's emotional attachment to the organization, characterized by an enjoyment of the organization and a desire to continue membership in it. Employees with strong affective commitment remain with the organization because they *want to* do so. In contrast, *continuance commitment* refers to the extent to which the employee perceives that leaving the organization would be costly. The focus is not on emotional attachment to the organization but rather on what employees would lose if they left. Employees with strong continuance commitment remain because they feel that they *have to* do so. *Normative commitment* refers to the employee's feelings of obligation to the organization and the belief that staying with it is the "right thing" to do. Employees with strong normative commitment remain because they feel that they *ought to* do so.

It is important to note that affective, continuance, and normative commitments do not represent a typology of commitment. That is, a given employee's commitment is not characterized in terms of one of the three components but rather as a "commitment profile" made up of all three. Furthermore, the model proposes that the three components have interactive effects on employee behavior.

MEASURING ORGANIZATIONAL COMMITMENT

Researchers and practitioners usually assess OC directly, using multiple-item scales, or questionnaires, administered to the employees themselves. Typically,

employees respond to these questionnaires anonymously in order to ensure that they feel as free as possible to provide candid responses. As with any such measures, it is critical that items reflect the underlying construct in question. Especially in early OC research, this was accomplished with varying degrees of success. Particularly noteworthy, however, is the 15-item Organizational Commitment Questionnaire (OCQ). Developed in the 1970s to assess identification with, involvement in, and emotional attachment to the organization, the OCQ represents a valid and reliable measure of desire-based, or affective, commitment to the organization. It has been used in hundreds of studies over the years, and this research has contributed greatly to what we know about the development and consequences of the affective component of OC.

In order to extend this research, and to assess propositions based on the multidimensional view of OC referred to above, TCM researchers used the construct approach to develop separate measures of each of the three proposed OC components. Since then, the affective, continuance, and normative commitment scales (ACS, CCS, NCS, respectively) have been used extensively in research conducted in dozens of organizational and cultural contexts and with members of various occupations. Both the original and alternate versions of the scales have been subjected to considerable psychometric scrutiny. Overall, the evidence shows that the measures are reliable, correlate with other variables in general accordance with TCM propositions, and, based on factor analytic evidence, appear to represent distinct factors.

DEVELOPMENT OF ORGANIZATIONAL COMMITMENT

Although OC might be expected to develop on the basis of both "person" and "work experience" factors, the evidence suggests that the latter plays the more important role. Some demographic and other individual difference variables (e.g., age, locus of control) are modestly related to OC, but it is what people experience in their jobs and at their organizations that seems to have particular influence on OC development.

With respect to affective commitment, meta-analytic evidence (that is, a quantitative review of a body of empirical research) suggests several work experiences that seem especially important. Perhaps not surprisingly, affective commitment is particularly strong among employees who feel that they have been

treated by their organizations in a supportive manner. Such perceptions can, of course, arise from numerous policies, practices, and everyday events; of key importance here is that employees feel that the organization is on their side. Also important, and perhaps indicative of organizational support, are various types of workplace justice: interactional, procedural, and distributive forms of justice have all been shown to be positively related to affective commitment. Affective commitment is also stronger among employees who experience minimal role ambiguity and role conflict at work and whose managers and/or leaders adopt transformational leadership styles. Finally, although this has not been examined meta-analytically, there is evidence that affective commitment is stronger among employees whose work experiences enhance, rather than degrade, their feelings of competence.

The TCM proposes that normative commitment—the “ought to” component—will develop on the basis of both cultural and organizational experiences that highlight the mutual obligation between employees and the organization and/or make the reciprocity norm salient to employees. These theoretical propositions have received relatively little empirical attention. Meta-analytic results show that some of the same variables (e.g., organizational support, role ambiguity, justice) that seem to influence affective commitment are related to normative commitment, albeit relations are weaker. Possibly the relations between some of these experiences and normative commitment are explained by employee interpretations focusing on the feelings of indebtedness and obligation that underlie normative commitment. Furthermore, there is some evidence that the impact of work experiences on normative commitment depends on employees’ cultural values (e.g., individualism vs. collectivism).

Consistent with theory, continuance commitment is more strongly related than are the other two components to two sets of variables: perceived alternatives and perceived investments. Specifically, continuance commitment is stronger among employees who believe that they would have few, rather than several, viable sources of employment if they left the organization. This makes sense, since for such employees the costs associated with leaving their current organization would be quite high. In addition, continuance commitment is stronger among employees who believe that they have made significant investments developing their skills and acquiring education that would not transfer readily to other organizations.

Compared to those with easily transferable skills/education, such employees would incur greater costs if they left the organization.

CONSEQUENCES OF ORGANIZATIONAL COMMITMENT

As mentioned earlier, examining OC consequences in terms of the commitment profile (or interactions between components) is most consistent with theory. Some researchers have taken this approach, but most studies have involved the examination of potential OC consequences on a component-by-component rather than profile basis. In such research, the emphasis has been on employee retention, work performance, and employee well-being.

The links between OC and employee retention are clear and consistent. Meta-analytic research shows that affective, normative, and continuance commitments are all negatively related to employee intention to leave the organization voluntarily. This research also shows that both affective commitment and normative commitment, but not continuance commitment, predict actual turnover.

For many organizations, of course, how employees *behave* at work is as much, or greater, a concern as whether they stay. In this regard, the distinction between the three components of commitment becomes particularly important. Beyond their demonstrated link with turnover intention, affective, continuance, and normative commitments are considered, and have been shown, to have somewhat different implications for employee behavior.

Meta-analytic research confirms that affective commitment is linked to several key performance indicators. Employees with stronger affective commitment are less likely to be absent from work than those with weaker affective commitment, and interestingly this effect is stronger for absence under the employee’s control than for involuntary absence (e.g., illness, emergencies). Affective commitment also predicts job performance. Across a wide variety of jobs, both self-report ratings and supervisory ratings of in-role (or required) work performance are higher among those with stronger affective commitment. Employees with strong affective commitment are also more likely to go the “extra mile” at work, engaging in more organizational citizenship behavior (OCB) than those with weak affective commitment. OCB includes various behaviors (e.g., exerting greater effort, courteousness,

helping coworkers, championing the organization) that help create a more productive and more positive workplace. As such, it is important for both the organization and its employees.

Normative commitment is unrelated to employee absence. Its relations with other performance indicators, however, are positive, though effects are more modest than for affective commitment. Interestingly, meta-analytic evidence shows that relations between normative commitment and both in-role performance and OCB are stronger in studies conducted outside North America, suggesting that cultural factors might play an important role in the behavioral expression of this component of commitment. Finally, although this has not yet been tested, it has been argued that normative commitment might influence the “tone” with which the employees carry out their work, particularly if they also have weak-to-moderate levels of affective commitment. Specifically, a strong sense of feeling of obligation to stay, in the absence of strong desire to stay, might occasionally create feelings of resentment, prompting such employees to carry out their duties in a competent but more grudging manner.

Like normative commitment, continuance commitment is unrelated to employee absence. In contrast to affective and normative commitment, however, it is also unrelated to organizational citizenship behavior; those with strong continuance commitment are neither more nor less likely to go the extra mile. Most noteworthy, however, is the strong negative relation—reported in meta-analytic research—between continuance commitment and in-role job performance. The fact that employees with strong (vs. weak) continuance commitment perform more poorly has a critically important implication for those organizations that develop retention strategies around what employees will lose if they resign. Such organizations might well increase retention but do so at the cost of employee performance. This will be especially so if employees are given little reason to develop affective commitment to the organization and, as a consequence, feel “trapped” within it.

Finally, researchers are beginning to examine whether OC has implications for employee well-being. Presumably, most people prefer to feel positively, rather than negatively, toward the environment in which they work. Some have argued, however, that strong affective OC could interfere with well-being by causing employees to focus undue attention on work. Thus far, there is little evidence of this latter view.

Indeed, meta-analytic research suggests that strong affective commitment is related to reduced stress/exhaustion and greater quality of life beyond the workplace. In contrast, however, continuance commitment is related to poorer quality of life and greater stress levels.

EMERGING ISSUES IN ORGANIZATIONAL COMMITMENT RESEARCH

Organizational commitment has received a considerable amount of research attention over the past 30 years. Because it has important consequences for organizations and their employees, this attention would appear to be well placed. Nonetheless, there remain many challenging issues that researchers and practitioners continue to examine.

As mentioned earlier, the examination of consequences in terms of the commitment profile represents an important research direction. Preliminary research suggests that different profiles are associated with different consequence patterns, but more of such work is needed. In a related vein, although commitment research began with a focus on the organization, more recent theorizing incorporates the idea that employees feel multidimensional commitment to numerous work-related domains, or foci, nested within the organization (e.g., department, work unit, supervisor) and beyond it (e.g., career, occupation, union). Although complex, a comprehensive understanding of commitment in the workplace will only come through considering, in concert, the various components of commitment that employees feel toward these various interrelated foci.

Other challenges are driven by the changing nature of the workplace. For example, as outsourced work becomes more common, it will be important to determine how employees develop psychological attachments to their two focal organizations (employment agency, current workplace) and how these attachments interact in influencing work behavior and other employee outcomes such as well-being. In addition, we need to learn more about the effects of other alternate work arrangements (e.g., part-time employment, temporary/contract-based work) on the development and consequences of OC. Within the workplace, employees and managers are placing greater emphasis on the interplay (or “balance”) between work and nonwork/family considerations. Thus, it will be important to examine how policies and practices

related to these issues influence the development of OC. Finally, likely driven by the increasing cultural diversity in the workforce, the challenges of globalization, and the growing researcher base worldwide, greater attention is being focused on the role that cultural factors may play in shaping the structure, development, and consequences of organizational commitment.

ORGANIZATIONAL ENTRY

Organizational entry is a multistage process whereby a new employee is brought into an organization. This process, which can be examined both from an individual and an organizational perspective, generally includes such steps as the initial attraction and recruitment of a job candidate, the assessment and possible selection of that job candidate, and then the orientation and socialization of the new hire into the organization. Past research has found that the organizational entry process is linked with a number of individual and organizational outcomes. When handled successfully, the organizational entry process can help produce new hires who have positive work attitudes, an increased commitment to the organization, lower absenteeism and turnover, and improved performance. In contrast, when organizational entry is not handled well, the new employee can have less positive work attitudes, reduced commitment, higher absenteeism and turnover, and lowered performance. Thus organizations tend to pay significant attention and devote considerable resources to ensure that the organizational entry process is a favorable experience for the new hire and that organizational performance goals for human resources are consequently achieved.

STAGES OF ORGANIZATIONAL ENTRY

John Wanous, who has written extensively on the organizational entry process, identifies four distinct stages through which the individual and the organization proceed in the hiring of a new employee. The first stage is known as *recruitment* and involves various activities to achieve mutual attraction between the prospective job candidate and the hiring company. At this stage, the goal for the job candidate is to become known to the hiring organization through whatever mechanisms are most appropriate. These mechanisms can include attending job fairs, responding to employment advertisements, posting one's résumé on an Internet job site, or networking with family and friends. For the hiring company, recruitment involves becoming known and reaching out to prospective employees. These steps could include presence at or the hosting of job fairs, the placement of employment advertisements in newspapers or on the corporate Web site, and the use of professional recruiters and employment agencies. The ultimate goal of the recruitment stage of

organizational entry is to create a pool of job candidates who are attracted to the organization and who, at the same time, are attractive to the organization.

Wanous's second stage of organizational entry is the *selection* of the new hire, or the process of mutual choice. In this step, the job candidate and the organization make critical assessments of one another. These assessments are designed to test for a match or fit between the abilities, personality, and interests of the person seeking the job with the requirements, culture, and environment of the hiring organization. The idea of matching the person with the organization is more generally known as P-E (person-environment) fit or as P-O (person-organization) fit. Research on the importance of "fit" has consistently shown that it has significant performance implications. The achievement of P-E fit has been shown to produce employees who are more satisfied with their career choices and jobs, have higher performance levels, have more favorable work attitudes, show reduced stress and burnout, and have greater job stability in terms of tenure. There are a number of individual and organizational approaches to assessment and selection, including a personal interview, a site visitation, personality and ability tests, and anticipatory socialization activities such as internships and cooperative education assignments.

Once a selection has been made, the organizational entry process moves to the third stage, which Wanous refers to as *orientation*. At this point, the goal is to facilitate the initial adjustment of the new employee to the organization. Orientation can include formal activities such as training sessions as well as informal events such as a luncheon with departmental management. The intent of the orientation process is to help the newcomer through the stresses and uncertainties of organizational entry while also ensuring that the newcomer understands the organization's mission, goals, procedures, and corporate culture. Normally, the orientation of a new employee takes place within the first three months of employment but in many cases occurs during the very first week.

The final stage of organizational entry is new employee *socialization*, or in Wanous's terms, the process of mutual adjustment. In this step, the goal of the organization is to fully "integrate" the newcomer into the company. By its very nature, socialization is the organizational entry stage that typically takes the longest amount of time to complete, mainly because it involves attempts to change individual attitudes and behaviors to meet organizational expectations and

values. Indeed, one of the primary goals of socialization is to exert control over the new employee such that the newcomer is willing to subjugate his or her own individualism to the collective values, norms, and culture of the organization. The positive side of this indoctrination process is that it creates a pool of employees who adhere to the company's expectations and who act in accordance with the wishes of the management of the organization. Of course, the negative side of socialization is that new employees become too conformist and potentially lose individual creativity or, more seriously, blindly follow the company's direction even when that direction is unethical or illegal.

Mechanisms to allow full socialization and new employee assimilation to occur can include formal training, job rotations, mentoring and other supportive alliances, participation in task forces and work groups, and performance feedback and coaching by immediate supervisors. Formal socialization usually lasts as long as five years and unfolds in stages as the employee achieves greater acceptance by the organization.

OUTCOMES OF ORGANIZATIONAL ENTRY

The potential consequences of the organizational entry process can be examined both from an individual and an organizational perspective. For the individual job seeker, recruitment and selection are the initial stages where one must first display the abilities and personality traits that are attractive to the hiring organization and then convince the organization that they are the best person for the job. The individual can either be successful at these activities, by generating interest and a job offer, or unsuccessful, where little interest is generated or where no job offer is extended. If successful, the newcomer must prepare for the stages of orientation and socialization. If not successful, the individual would need to seek out other employers or change his or her approaches to seeking a job.

For the hiring organization, the first stages of recruitment and selection represent the attempts to find and hire individuals who will fit or match the job requirements and the internal environment within the company. When a strong match is achieved, the organization will be hiring new employees who are expected to have positive work attitudes and a strong commitment to the organization. Thus organizations are well advised to use realistic recruitment practices so that the newcomer is not disillusioned or overwhelmed during the early part of the work career. By

giving a job candidate a realistic and balanced preview of what the job entails, hiring organizations have a better chance at producing a more satisfied and committed workforce.

The orientation and socialization stages of organizational entry are critical early periods of an individual's career development. For the newcomer, the expected outcome of these stages is a greater degree of understanding of the organization, its structure, mission, and operating procedures, and the important people and relationships that exist within the company. This greater knowledge and awareness of the company should produce employees with more positive work attitudes and a higher degree of commitment to the hiring organization, which improves overall morale and reduces new employee turnover and absenteeism.

ORGANIZATIONAL IMAGE

Organizational image (OI) can be defined as a construction of the public impressions of an organization created to appeal to an external audience while simultaneously interpreted by the organization's members. Construed external images, projected images, and desired future images can be developed and transmitted by mass media, public relations consultants, and savvy marketers. Typically, these image consultants attempt to manipulate the public's perceptions of a given corporation to help its top management achieve the firm's strategic goals. One key goal, attracting and retaining high-quality talent, is requisite for continued

organizational effectiveness and survival. Related perceptual concepts include corporate reputation, organizational identity, and brand image.

The importance of organizational image in career-related research has typically focused on investigating the relationship of organizational image within recruitment efforts. The logic that potential recruits will be attracted to an organization based on positive perceptions of its image is consistent with much of the staffing literature. Before potential recruits consider job-specific factors (e.g., starting salary, promotional opportunities) in job search efforts, they are believed to be attracted to certain employers based on their organizational images. Most of this research has studied novice job seekers or soon-to-graduate college students, while less is known about OI's impact on seasoned job seekers, blue-collar workers, and current employees.

Organizational image has been identified as one of the key factors that can affect the likelihood of potential applicants choosing one employer over another. Companies that are considered good employers often seek a strong, positive image in the marketplace. Successful employers consciously manage outsider perceptions and employee experiences to impact the firm's image. Top management seeks those coveted "Employer of Choice" awards and "Best Company to Work For" rankings because they can contribute to a competitive advantage in attracting and retaining talented employees, loyal customers, and satisfied shareholders. Research indicates that a positive OI can significantly increase organizational attractiveness and job pursuit intentions.

Organizational scholars have explained the formation of OI from several information processing perspectives. Early career pursuit begins with incomplete knowledge and a broad search for cues and clues. Individual image formation typically follows a phased sequence from exposure to stimuli to an attention phase to a comprehension stage, then acceptance, and finally retention. Social identity theory has also been used to explain how an employing organization can provide a key determinant of an employee's self-concept and self-image. Seeking career opportunities with a specific employer is also an overt expression of a person's value orientation, career expectations, and identity. Inferences and symbolic meanings can dominate individual decisions during an information shortage. Job seekers and employees create and adjust an employer's attractiveness beyond measures of

objective (i.e., job/organizational) attributes to include trait inferences, symbolic meanings, and internal/external communication programs.

The construction and maintenance of positive organizational images are crucial to the attraction and retention of human resources in today's workplaces. The power of a positive image simplifies individual career decision making by reducing the uncertainty of the potential employment outcomes in the eyes of the job seeker and employee. Images are adjusted and modified on an ongoing basis by organizational stakeholders both within and outside the firm. Employers that fail to develop and maintain satisfying images risk recruiting shortfalls and employee defections.

Researchers have found that the dimensionality of OI is as varied as the multiple audiences or stakeholders holding mental referents of the organization. Perceptions that an employer practices good corporate citizenship, follows progressive labor practices, and shows a proenvironment sensitivity would generally contribute to the formation of a positive organizational image. Beyond the social desirability bias of these employment-related perceptions is the need for thematic and symbolic consistency across the messages communicated to insiders and outsiders alike.

Other organizational image typologies seek to analyze and understand the construction, maintenance, and modification of employer images over time. One particular decision-making perspective has identified four key image types, which are organizational self-image (the common belief and value structure shared within the organization), trajectory image (future image goals on the organization's agenda), action image (specific planning tied to each goal identified in the prior stage), and projected image (the resulting image from action image implementation). Another analytical approach identifies three main image forms: construed external image (employees' perceptions of how outsiders perceive their organization), projected image (an organizationally constructed image to be communicated to various stakeholders), and desired future image (a visionary perception of the organization).

Strategic dilemmas like that facing Wal-Mart's management team as it tries to repair its tattered organizational image as valued community partner and potential employer could be addressed by applying these analytical perspectives. Only by thoroughly understanding how its current image has been impacted can it hope to reconstruct a positive

employer image for careers in retailing. Failure to manage its organizational images proactively has reduced its ability to recruit talent or to stem defections and lawsuits from career employees.

The construction and maintenance of organizational images has been found critical to attracting, developing, and retaining an employer's talent pool. Individual career attachment decisions (e.g., seeking alternative employment, pursuing promotional opportunities) have been tied to public perceptions of a given organization. OI is best viewed as a dynamic and continually evolving representation of an employer in the eyes of a diverse public.

Image audits can provide one tool for understanding how a company's Web site design communicates its attractiveness as an employer or how the stigma of bankruptcy might affect employee retention. Difficult-to-staff occupations such as public sector nursing or the military could benefit from a more conscious management of their employer images using such assessment methods. Employers trying to attract more racially and gender diverse applicants should assess any mediating effects that their OI can have within these groups.

Research attention on OI is just starting to converge across the fields of organizational communication, marketing, public relations, and organizational behavior. Corporate leadership's responsibility is to harness this complex knowledge base to help achieve its strategic goals and agendas with employees and customers alike.

ORGANIZATIONAL JUSTICE

Organizational justice refers to judgments of the moral rightness or social appropriateness of events in the work environment. As studied by management scholars, this organizational justice or fairness (these terms tend to be used interchangeably) is treated as a subjective judgment made by an individual or group of individuals. Organizational justice research emphasizes the description of events that lead workers to perceive fair or unfair treatment. It also focuses on the consequences of these perceptions.

Evidence indicates that employees prefer to work in a just environment. Indeed, when fairness is lacking individuals tend to be less productive, have poorer attitudes, and less well-being than when fairness exists. In other words, injustice harms both employee and employer alike. For this reason, considerable attention has been devoted to understanding the causes of injustice and suggesting ways of alleviating the resulting problems. In this regard, researchers have identified at least three classes of organizational events that can give rise to justice (or injustice) perceptions. These are outcomes received (distributive justice), the allocation process (procedural justice), and interpersonal treatment (interactional justice).

Distributive justice refers to the perceived fairness of outcomes. This is an evaluation by an individual or group of what has been received. Notice that “fairness” is distinct from “favorability.” The former refers to a moral evaluation or a judgment of normative appropriateness. The latter refers to the hedonic value of an outcome. An unqualified job applicant, for example, might be disappointed at not receiving a desirable position, but could still acknowledge the fairness of the rejection. That having been said, there is an egocentric correlation between favorability and fairness, such that we rate outcomes as more fair when they are beneficial to us and less fair when they are not.

Judgments of outcome fairness are often made by comparing the results of an actual allocation to an ideal distribution prescribed by some allocation rule. Three such rules have been especially influential: equality (to each the same), equity (to each in accordance with contributions), and need. Notice that the application of each of these rules requires that we possess some knowledge about what others have received. Consequently, we need some “referent other” to which we can compare ourselves. As our standard

changes, so do our justice judgments, and this is so even if our outcomes remain constant. Other things being equal, women who are underpaid relative to men in the same position, report higher pay satisfaction when they compare themselves to other (underpaid) women, and lower pay satisfaction when they compare themselves to their better compensated male peers.

Procedural justice refers to perceived fairness of the allocation process. Whereas distributive justice is about *ends*, procedural justice is about the *means* by which these ends are assigned. When compared to distributive justice, procedural fairness tends to have a larger impact on evaluations of decision-makers (e.g., supervisory trust) and social institutions (e.g., organizational commitment). Distributive justice, on the other hand, tends to have a larger impact on evaluations of particular outcomes (e.g., job satisfaction). Six characteristics of fair procedures have been suggested. Procedures are fair when they are applied consistently, bias free, correctable, accurate, representative of all stakeholders, and consistent with ethical standards. Procedural justice has been found to be important in the design of effective human resource policies, such as those for selection, performance evaluation, and grievance resolution.

Interactional justice refers to the perceived fairness of the interpersonal treatment one receives. Interactional justice is highly correlated with procedural justice, though most contemporary scholars prefer to distinguish them on the grounds that procedures refer to formal aspects of the process, whereas interpersonal interactions refer to social aspects. In addition, the two types of justice seem to show distinct patterns of associations with other variables.

Two types of interactional justice have been identified. *Informational justice* refers to the thoroughness and openness with which decision makers explain and describe events. Providing an adequate explanation for a layoff would be an example of informational justice. *Interpersonal justice* refers to the dignity and respect with which one is treated. Politeness is an example of interpersonal justice. Informational fairness and interpersonal fairness tend to be correlated. For this reason, some scholars are inclined to collapse them together as interactional justice. Nevertheless, the recent years have seen a move for treating them as distinct, and the evidence to date is very promising.

While most research to date has examined the main effect relationships between the different types of

justice and work-relevant criteria, another line of inquiry suggests that the three types also interact. It has been found that distributive justice is more strongly related to work attitudes and behaviors when procedural justice is low. To describe the same effect in a different way, if either distributive justice or procedural justice were high, then employees tended to show relatively positive work attitudes and relatively more productive work behaviors. However, if *both* distributive and procedural justice were low, then worker reactions became more negative. A two-way interaction of the same form has also been documented between distributive justice and interactional justice.

Findings such as these have prompted scholars to investigate the possibility of a three-way interaction among all of the different types of fairness. Though more work is needed, efforts to date have yielded some success stories. One study found that employees were most apt to engage in counterproductive work behaviors when all three types of fairness were low. Other work has found that this same interaction predicts the filing of grievance claims and reactions to affirmative action programs.

Due to the implications for both individuals and organizations, organizational justice has in recent years surfaced as an important and fruitful area of study. Organizational justice investigations focus on the events leading up to a fairness evaluation, the outcomes resulting once a fairness perception has been formed, and the contexts in which these perceptions are formed. Although focus more distantly has been on distributive justice, and more recently on procedural justice, research as of late finds interactional justice to be a promising avenue for future research.

ORGANIZATIONAL POLITICS

The mention of *organizational politics* is frequently met with harsh words and disparaging glances. Society, as a whole, has grown to view anything political with chagrin. Much of this disdain comes from the awareness that politicking, when successful, is associated with manipulation, and in some cases, verbal or physical intimidation. Moreover, the general public has been inundated with stories of abuses of political authority including misappropriation of funds and dubious financial transactions of government and industry officials. These personal transgressions have done little to remove the dark cloud that has developed over anything construed as *political*.

Unfortunately, politics pervades virtually every work environment and no public/private enterprise, service/manufacturing industry, or blue-collar/white-collar occupation is immune from its influence. Simply put, as long as there are employees with diverse personalities, needs, and wants, workplace politics are to be expected. Politicking is viewed unfavorably because it often blurs the relationship between what one contributes at work and what one receives in return. Instead of raises and promotions coming to those who work the hardest and contribute the most to company profitability, rewards are given to those who are most successful at manipulating the reward allocations of decision makers.

WHAT ARE POLITICAL BEHAVIORS?

Politicking represents deliberate, self-serving behaviors (although frequently indirect) that are often inconsistent with the goals of the organization. Behaviors can be very subtle or extremely caustic, and

Table 4. Attributes and Examples of Political Behavior

<i>Attribute:</i>	<i>Example:</i>
1. Purposeful effort to maximize returns.	“There are three of us up for the next promotion and I better make sure that I get it.”
2. Behavior is self-serving, although benefits do not always go directly to the politician, per se.	“I’m going to do whatever I can to see that my subordinate, Smith, is promoted to sales manager instead of Johnson’s subordinate.”
3. Goals are often inconsistent with the objectives of the organization.	“I could care less about the company share price; I just need to find a way to make vice-president by the end of the year.”
4. Specific tactics can be very innocuous or extremely destructive.	“I could either tell the boss how much effort I put into my report, or I could destroy Garrett’s report that I found on the copy machine.”
5. Influence attempts can be directed upward, downward, horizontally, or externally—often simultaneously.	“If I want this promotion, I better get my subordinates to tell upper management that I am a good manager, sabotage the efforts of my peers, start having lunch with those choosing the next director of promotions, and getting my best customers to call my supervisor.”
6. Often undertaken to secure outcomes unable to be achieved under more accepted means.	“Johnson has outsold me every quarter for the last 10 years, but I’ve been here longer. I need to make management understand that longevity is more important than performance.”
7. Most likely to be used when environments possess limited resources.	“I’ve heard that there is only enough money in the budget for one new computer. I need to convince management that my computer is outdated although it really isn’t compared to others.”
8. Politicking is not a tactic used for poor performers exclusively.	I’m the best performer in my department, but I keep getting passed over for promotions. It’s clear that I need to advertise my successes since it is apparent that nobody will notice otherwise.”

directed toward multiple constituents both internal and external to the organization. The only requirement for politicking to surface is for the work environment to possess finite resources or a limit on available rewards. Resources can take the form of equipment, personnel, mentors, and/or social support. Rewards include status enhancements, promotions, pay increases, and development opportunities.

In general, individuals see politicking as a means to secure desired outcomes perceived as unattainable under more organizationally legitimate means. The table above outlines the major attributes of politicking at work along with examples of each.

Despite disparaging opinions, employees would likely agree that much would go undone and many successes unrealized if politicking were eliminated from the corporate landscape. For example, trade associations hire lobbyists largely due to their ability to sway the opinions of important legislators. In this instance, politicking occurs, but the self-serving benefit is more indirect.

It is apparent that politics has a rightful place in organizations. Unfortunately, there is little consensus

in terms of the exact location of this “rightful place.” What is known, however, is that politicking is viewed favorably when it leads to personally beneficial outcomes such as greater than anticipated raises, promotions, and favorable treatment from supervisors.

ADVERSE CONSEQUENCES OF WORKPLACE POLITICS

Reactions to workplace political activity can range from mild amusement to devastation. On the one end of the spectrum, many organizations have the “chronic politicians” who spends considerably more time trying to manage their image than actually working. These individuals are viewed as largely transparent, with their obvious motives and their tactics caricatures of the quintessential “slick snake oil salesman.” That is, these individuals come across with an obvious personal agenda, their style is too smooth, and they are too ready with a canned response or elusive statement when confronted. In short, these individuals offer little in the way of contribution but much in the way of comic relief or irritation.

The negative effects of perceived politics typically occur over an extended period of time, because one does not just experience a single event; there are typically multiple events. Thus, on the other end of the continuum, politics can have debilitating effects on both job and health factors. For example, one's perceived contributions and probability of appropriate rewards are likely curtailed if politicking causes a disruption of work activities. In this regard, effort dedicated to providing a positive contribution is replaced with in-fighting, turf wars, and one-upsmanship.

Politics can lead to a variety of physical and psychological health ailments, which include substance abuse, high blood pressure, general anxiety, sleep disturbances, and depression. Furthermore, a failure to attend to conflict generated by politics at work has the potential to have indirect crossover effects on family relations. Specifically, because individuals often have difficulty leaving their problems at the office, strain at work can amplify the incidence of domestic conflict at home. Finally, the consequences of strain-induced politics can be even more devastating. A regrettable consequence of anxiety-provoking politics is an associated increase in mental health ailments, which include, but are not limited to, dejection, hopelessness, and in the most extreme case, self-destructive behavior.

THE FUTURE OF POLITICKING

There is little reason to believe that active politicking will fade away in the future. With outsourcing, globalization, and major restructurings affecting the way jobs are designed and redesigned, organizations are going to have fewer assets to allocate. As such, competition for resources will be intense and potentially tumultuous as "doing more with less" becomes more than business jargon. For example, instead of all employees receiving technology upgrades every two years, 25 percent of the workforce may take delivery of new equipment every three years. Workers may see their jobs moved permanently overseas. To make sure that one receives the resources to be successful at work (or to secure the signal of status that comes with such commitments), performance (i.e., working hard) and nonperformance-based influence strategies (i.e., working at influencing others) are likely to be incorporated into one's daily routine.

Deliberate workforce modifications, which have made climbing the corporate ladder a far more daunting task, further increase the possibility of politicking.

Because layers have been eliminated in many organizations, there are fewer rungs (entry-level → managerial → executive) to navigate, suggesting that promotions will occur less frequently. Instead of occurring every year or so, employees can expect the time between promotions to be extended (i.e., greater than three years). Because rewards are available so infrequently, the stakes become greater when a promotion is anticipated. Failure to successfully influence may result in a failure to secure the promotion.

Restructurings serve as a catalyst for politicking in other ways, as well. Because levels of evaluators are being eliminated, employees cannot rely on supervisors' direct observation of performance to ensure that efforts are viewed favorably. Bosses are no longer able to appraise performance by direct observation because there are simply fewer bosses wandering around to witness employee work contributions. As a result of fewer interactions, subordinates may go out of their way to advertise their successes, minimize the contribution of their colleagues, or both.

Finally, layoffs increase the likelihood of politicking because the consequences of not fully participating in influence attempts at work are great. Very rarely do downsized individuals find jobs with equivalent work attributes in terms of pay, status, and potential for promotion. In environments expected to experience a layoff, some individuals may choose positive behaviors, while others may opt for tactics viewed by many as disreputable in order to ensure survival.

STRATEGIES TO MANAGE POLITICS AT WORK

"An eye for an eye," "Fight fire with fire," "tit for tat," "Do unto others as you would have them do unto you." Matching the tactics of workplace politicians seems like a logical response when one feels aggrieved. For example, if a coworker sabotages one's work efforts, it may sound appealing to respond in a comparably hostile way. Despite the allure, there is a downside to using tactics that are largely reactive and reciprocal. Grudges develop, anxiety increases, and time dedicated to work is now dedicated to planning for the next attack. Most important, reactive strategies never directly address the underlying issues that create the need for politicking.

Organizational politics are harmful because they create uncertainty, insecurity, and confusion. Individuals are unsure of where they stand with management, what represents acceptable performance,

and how they can expect their career to progress in political settings. Instead of putting out fires by matching political behaviors with aggressors, reducing uncertainty is a more useful and health-promotive option. There are a number of proactive strategies to understand office politics and reduce ambiguity in the workplace, each of which is briefly discussed below.

Seek and Maintain Mentoring Relationships

A mentor can be extremely helpful not only in terms of career development but warding off the adverse effects of politics (in fact, these objectives are largely interrelated). For example, a mentor can help establish links between performance and rewards (i.e., “If you sell 100 cars this year, your bonus will be . . .”), keep the employee on track in terms of progress and promotions (i.e., “In five years, I expect you to be sales manager”), offer support (i.e., “Let me talk to your manager and see if I can get you some resources), and shield the employee from the potentially debilitating effects of unnecessary politicking (i.e., “Concentrate on your job and I’ll take care of the rest”). Because mentors often develop a sense of identity with their protégé, they are generally sensitive to external factors that may serve to derail scheduled progress. Mentoring programs are effective because communication is more frequent and thorough, and discussions are allowed to extend to interpersonal aspects of work that are critical to success (e.g., “Watch out for Johnson. He’ll do anything to get the next promotion”). If the organization does not have a formal mentoring program, informal programs are often equally effective. In sum, having the support of someone influential is often needed to maximize career success. Having a senior member of the organization help mitigate the potentially debilitating effects of politics, especially early in one’s career, can go a long way in this regard.

Develop Short- and Long-Term Performance and Career Goals With Superiors

If mentoring is unavailable, goal setting can serve to minimize much of the uncertainty that encapsulates political environments. If done correctly, consensus is reached in terms of performance expectancies, methods and timetable for achievement, and rewards for

accomplishment. More structure equals less ambiguity, and by sticking to agreed-upon guidelines for behavior, the uncertainty caused by workplace politics is likely curtailed. As noted, the time managers are able to spend directly planning and observing employee work activities will become more limited. Thus the responsibility to remain on track is likely to fall on the shoulders of the subordinate.

Remain Active in the Interpersonal Context at Work

Often, individuals are blindsided by politics because much of the manipulation occurs outside the boundaries of formal work activity. Lunches, company parties, work breaks, and other social gatherings provide employees the opportunity to get away from work while still tolerating discussions about work. Remaining active in the social environment is particularly important for individuals who are likely isolated from their colleagues for reasons otherwise unrelated to the job, such as gender, age, and race. It is clear that understanding the reasons and tactics of those opting for politically motivated influence can minimize uncertainty. Remaining active may allow one to be part of the conversation and develop a greater appreciation for the causes and consequences of politicking.

Work on Interpersonal Skills

It has been suggested in the popular press that emotional intelligence (i.e., social skill) is a key predictor of career success. Individuals with high levels of social skill are able to empathize with others, listen carefully, read communication cues and patterns, and develop social networks. These attributes are particularly relevant in terms of minimizing politically derived ambiguity because socially skilled individuals are (1) able to pick up on the subtle cues that identify causes of behavior, (2) competent in accurately assessing the emotionality of the politician, and (3) skilled in soliciting the advice and support of others in their extensive social network. In terms of specific application, a socially skilled employee may be in a position to recognize when politicking occurs, can understand it, and may help coworkers who are less socially skilled to understand it as well. Understanding helps remove ambiguity and uncertainty. Furthermore, the socially skilled individual need not

rely on manipulation to receive support and recognition, hence eliminating the need for politicking.

Adopt an Opportunity Instead of a Threat Mentality

Politics exist and will continue to exist in the foreseeable future. In general, it is comfortable and socially acceptable to focus on the negative attributes of organizational politics (e.g., wasting time, confounding the relationship between performance and rewards, creating emotional and job-related strain). Society is enamored with conflict, personality clashes, and encounters that lead individuals to be at odds with one another. Take, for example, the countless number of newspaper articles and television talk shows that focus on the less attractive elements of family and social interactions.

In contrast, some level of organizational politicking can be beneficial. In a complex way, politics breathes life into the organization by increasing competition and requiring employees to participate more fully in the social environment at work. Most employees would classify an organization completely devoid of politics as boring, a figment of top management's imagination, or dead. Politicking, despite all of its drawbacks, gets individuals interested in the inner workings of the organization.

Furthermore, politics signal that the organization has deficiencies or areas for improvement. For example, the goal of the organization may be to promote group achievement. Selection instruments may have instead focused disproportionately on the best way to maximize individual rewards. Understanding the impetus for politicking and designing effective programs to address these motivations can go a long way to enhance organizational effectiveness. In this case, designing a more appropriate selection tool that focuses on maximizing group rewards not only enhances organizational effectiveness but also makes one valuable to the organization. This leads to the last strategy.

Take an Active Role in Your Career

Politicking requires individuals to take an active role in career development and become more accountable for securing desired outcomes. One way to survive most political wranglings is to add value and become irreplaceable. This may take the form of

technical skills (e.g., "You're the only one who understands the new computer program"), securing an important client (e.g., "The Cortez account is worth \$5 million, and if I go, it goes with me"), designing a new process that improves organizational effectiveness (e.g., "Jose designed the new selection process"), or possessing the interpersonal abilities that are desired by decision makers (e.g., "When we need a loan, we send our best negotiator, Brown"). Developing these competencies cannot occur overnight. Thought, planning, and adopting long-term developmental strategies are required, which inherently assumes a proactive approach to career development.

CONCLUSION

Organizational politics exist in virtually every work environment. They are self-serving behaviors (frequently indirect) that are often inconsistent with the goals of the organization. They are behaviors that can be very subtle or extremely caustic and may be directed toward multiple constituents internal and external to the organization. Politics can have debilitating effects on both job and health factors. However, even though politics comes with adverse consequences, political behaviors can have a rightful purpose in organizations. We have offered a number of strategies to reduce uncertainty in the workplace, because this is a primary factor leading to the negative effects of politics. By doing so, individuals can reduce the negative effects of politics and take control of their careers.

ORGANIZATIONAL SOCIALIZATION

Organizational socialization describes how people learn to fit into a new organization or job. It is a process by which an individual learns appropriate attitudes, behaviors, and knowledge associated with a particular role in an organization. The general theory asserts that people who are well socialized into an organization are more likely to stay and develop their careers with that organization. This is a critical process for individuals pursuing successful careers and for organizations building effective workforces. Every year in the United States, around 3 million people graduate from high school and 2 million people earn college degrees. Most will begin looking for jobs and organizations that will provide satisfying careers. However, for many new and established employees, the fit between themselves and their organizations is better described as a misfit. About 2 million

people voluntarily quit their jobs in the United States every month. This figure does not include retirements, deaths, or disability reasons for quitting, and most of these people will try again to look for new jobs and satisfying careers.

Building a competent workforce, one where people believe they fit in well with their organizations, is often viewed as a competitive edge in today's business. For organizations, a competent and committed workforce minimizes costly turnover and selection expenses. Moreover, individual employee attributes associated with successful organizational socialization can accumulate across the organization to positively affect organizational performance and effectiveness. Organizational socialization is a primary process to facilitate work adjustment for new employees or for employees taking on new roles.

For individuals, a good fit within the organization can lead to several positive benefits. People who are well socialized are more committed to their organizations, more satisfied with their jobs, and earn more than people who don't learn to fit in with their organizations. Furthermore, people who are well socialized are less likely to quit their jobs and more likely to build successful careers within the organization. The extent to which both organizational and individual socialization processes support a good person-organization fit will define the extent to which that individual has been successfully socialized.

WHO IS SOCIALIZED IN ORGANIZATIONS?

Typically, organizational socialization concerns how new hires adjust to a new job and organization, and these people are generally described as organizational newcomers. However, the process by which an individual learns appropriate attitudes and behaviors applies to anyone who faces a new job. Thus many employees who have been promoted or transferred within their current organization will also need to adjust to their new roles. Organizational newcomers generally have more to learn than job changers, because they need to adjust to both a specific job and an organizational culture, so most of the research on organizational socialization focuses on organizational newcomers.

When an individual begins a job at a new organization, that person may already have some expectations of what the job and organization will be like. Some of these expectations may be realistic (e.g., "I will work

from 9:00 to 5:00”), whereas other expectations may be unrealistic (e.g., “Top managers will adopt all my suggestions”). Furthermore, as the individual begins work, early experiences will meet some expectations (e.g., “I expected to work in teams and I was assigned to a team”), but other expectations will not be met (e.g., “I did not expect some of my team members to be difficult to work with”). Many newcomers experience reality shock when their expectations are unmet, regardless of how unrealistic those expectations may be. Newcomers who experience these surprises would try to make sense of them. Based on their own predispositions and past experiences, and based on how others within and outside the organization interpret these surprises, the sense-making process can help a newcomer resolve unmet expectations. Individuals whose sense making complements the organization are more likely to stay with that organization (e.g., “Top management did not adopt my suggestion because they saw problems I didn’t foresee”). Individuals whose sense making attaches negative attributes to the organization are more likely to quit their jobs (e.g., “Top management did not adopt my suggestion because they are closed minded and stupid”).

Although most of the research in organizational socialization examines organizational newcomers, many established employees also undergo socialization processes as their jobs change. Obviously, employees who are transferred to new locations or to new business units need to learn how to fit in with their new job demands. Global organizations are constantly moving their personnel around in order to maximize the capacity of their human resources. Less obvious are the socialization needs of employees who might stay in their positions but experience organizational changes around them. Employees with new managers might have to adjust to a different vision for the business unit. New technologies may render old ways obsolete and demand adjustments from established employees. Finally, organizational mergers and acquisitions may force new values and work processes on established employees, requiring them to adjust and fit in with the new order. Thus organizational socialization is a relevant issue for any individual faced with substantial job or organizational changes.

HOW THE ORGANIZATIONAL SOCIALIZATION PROCESS UNFOLDS

The organizational socialization process unfolds within human resource management processes.

Recruitment and selection systems identify candidates who are considered for employment and those who are eventually hired. These processes are often designed to hire a particular type of person who will fit into the organization. Furthermore, recruitment and selection activities are often first-contact experiences for the newcomer and organization; they help shape initial expectations each has about the other.

There are several stage models of organizational socialization; each describes evolving experiences of newcomers as they adjust to a new job/organization. Most of these models describe three basic stages, beginning with anticipatory socialization, entry-encounter experiences, and ending with change and mutual acceptance. The anticipatory socialization stage describes how early job/organization expectations are shaped as a person selects and prepares for a particular career. Career choices are often based on rough ideas or expectations of what that career will be like. For example, a person’s family, teachers, and friends might share their experiences and influence an individual to choose a career in business. Preparation for this career might include a university’s masters of business administration program. Faculty and fellow students can further shape this person’s initial job expectations even before the person has applied for a job. Furthermore, managers and recruiters can help a job candidate form specific expectations about an organization and the candidate’s role within that organization. The extent to which these expectations are met on the job will define the amount of adjustment required to successfully fit into the organization.

The second stage of socialization typically includes early learning and adjustments after organizational entry. The newcomer learns how to do the job as well as how to fit into the organization’s culture. This learning stage includes the sense-making process that helps the newcomer reconcile unmet expectations and surprises. Organizations can conduct formal orientation and training programs to help newcomers learn how work is conducted in the organization. In addition, informal learning occurs on the job as the newcomer observes and solicits information from superiors, peers, and subordinates. These informal lessons may reinforce formal organizational procedures (e.g., a secretary reminds you to be on time for your department meeting) or they may introduce informally acceptable behaviors that are not sanctioned by the organization (e.g., a coworker tells you that it’s OK to call in sick if you need a personal day off).

The final stage of socialization generally recognizes successful adjustment as an organizational newcomer is transformed into an organizational insider. Insiders have learned the ropes to fit in and can serve as valuable resources of information for future newcomers. Organizations may hold initiation ceremonies or rites of passage to signify that a newcomer is no longer a rookie or recruit but a full-fledged member of the organization. Although most of the research on organizational socialization centers on newcomers, some studies recognize that insiders can learn more about their own roles as they socialize newcomers or as newcomers precipitate shifts in role expectations for insiders.

Research in organizational socialization has failed to support any particular stage model. Although stage approaches provide rich descriptions of the transformation from organizational newcomer to insider status, they ignore many organizational factors and situational contexts that may unintentionally influence the socialization process, and they ignore personal characteristics of individuals who are adjusting to a new job and work environment. Thus, stage models can help describe what newcomers experience, but they do not offer any specific interventions to help newcomers to be successfully socialized into their organizations.

Following the development of socialization stage models, six classes of organizational socialization tactics have been proposed as ways for organizations to socialize their newcomers. These strategies are described as continuums of organizational intervention, with one end of the continuum describing an institutionalized approach and the other end describing an individualized approach. First, the formal-informal continuum describes how formal and structured socialization tactics can range, from formal orientation programs to informal spontaneous conversations with organizational insiders. Second, the collective-individual continuum concerns the number of people who are socialized together, ranging from massive training and induction programs for large groups to individually tailored strategies for one person. Third, the sequential-random continuum describes the extent to which discrete, identifiable stages of socialization exist versus socialization that proceeds within a general newcomer stage. For example, a police recruit may undergo a sequential pattern of academy training, field training, and patrol assignment with a senior partner, whereas a secretary may not have a set of

socialization experiences to complete. Fourth, the fixed-variable continuum describes the extent to which the socialization process unfolds over a specified time frame. For example, after six months of police academy training, a ceremony is held for rookies as a rite of passage—recognition that they have become police officers. Conversely, a secretary may not have a specific time frame to become recognized as a full member of the organization. Fifth, the serial-disjunctive continuum describes whether there are role models for newcomers to imitate. Serial tactics have existing role models performing the same job as the newcomer (e.g., rookie officer can model senior officer), whereas disjunctive tactics do not have any role models (e.g., unique job is created to manage new technology). Sixth, the investiture-divestiture continuum describes the extent to which a newcomer's individuality and identity are accepted by the organization. Investiture strategies welcome individual characteristics and embrace this diversity into the organization. Conversely, divestiture strategies mold the newcomer to behave like all other organizational members with little tolerance for unique behaviors (e.g., military recruits trained to dress and act alike).

The socialization tactics provide an organizational perspective on newcomer socialization. Different tactics will process people into different types of organizational members. Organizations that use more institutionalized tactics—by processing newcomers together in groups, establishing a fixed sequence of career progression, exposing newcomers to insider models for the new role, and pressuring newcomers to change their self-definition—are thought to yield more compliant employees who understand and accept organizational values. In contrast, individualized tactics—which involve individual processing, more variable career progression, few existing role models, and greater acceptance of the self—are predicted to yield more innovative employees who are less accepting of the status quo.

Although the organizational perspective helps us understand processes for work adjustment, it neglects socialization factors that are not organizationally designed or controlled. In particular, newcomers processed by institutional tactics must at some point be integrated into an organization's social network. They will come into contact with supervisors, coworkers, and staff who will comprise a more local socialization context. Socialization will continue in ways that may be either consistent or inconsistent

with formal tactics. How well are the effects of formal tactics likely to hold up under this resocialization effort? As newcomers adjust to their jobs, they may be less responsive to institutional socialization tactics and more responsive to other aspects of the workplace. Moreover, the organizational perspective often treats newcomers as a passive employee open to socialization tactics. An individual's personality and career expectations might be powerful drivers in seeking information and engaging in proactive socialization experiences to fit in more effectively than other newcomers.

In contrast to the organizational perspective, other researchers have focused on the individual perspective, examining information seeking by newcomers as they attempt to comprehend the organization and its defining characteristics. This research has examined what newcomers attempt to learn (content) and how they attempt to learn it (process). In addition, some research has sought to go beyond information acquisition per se to understand how informal, insider processes influence newcomer socialization. For example, much of the information-seeking research has focused on active newcomer efforts to ask questions and inquire of insiders. However, active efforts by supervisors and coworkers to socialize newcomers are relatively more important to adjustment than newcomer proaction. Positive work relationships with supervisors and peers reduce negative effects of unmet expectations on job satisfaction and other traditional indicators of socialization effectiveness.

The research literature on information seeking and successful socialization is mixed. Some studies support a positive link with findings that show that information seeking reduces uncertainty about the newcomer's job/organization, which in turn, helps build the newcomer's competence and self-efficacy. Conversely, other studies found negative links between information seeking and newcomer socialization when there are social costs if a newcomer is constantly asking questions or if feedback is not positive. Thus information seeking may backfire on newcomers who ask too many questions, because insiders may perceive them as incompetent, intrusive, or meddlesome. Finally, there may be no link between information seeking and socialization if the information is not related to adjustment and/or the newcomer cannot use the information to facilitate his or her work adjustment.

The organizational socialization process is complex because it involves actions taken by both the

newcomer and the organization, and lessons learned may be intentional or unintentional. Newcomers will go through a socialization process, regardless of what the organization may do or not do; thus good human resource management would prescribe some planning to guide employee adjustment to the job and organization. Transparent human resource practices that support the organization's mission and values are more likely to help employees make sense of their roles in the organization than management practices that conflict with or confuse employees. For example, mentors can provide an informal, personal socialization process when senior members tutor junior members and groom them for successful careers within the organization. Although this mentoring may be informal, managers and supervisors who are likely to be mentors can be trained to provide positive socialization experiences for their newcomers.

The socialization process is not entirely controlled by the organization; nor is it entirely controlled by the individual. The mix of formal organizational interventions (e.g., orientation program) and informal interventions (e.g., a mentor) may not provide compatible lessons, thus rendering the sense-making process complex. Furthermore, an individual's acquisition of knowledge does not always occur at a conscious level. A newcomer's learning may be implicit knowledge gained from observations and experiences but without a concerted, conscious awareness that one has learned anything. The first day on a new job is often one of information overload for the newcomer. Explicit lessons (e.g., a supervisor explains the workload to a newcomer) and implicit lessons (e.g., a newcomer feels uncomfortable around a particular supervisor) merge to help the newcomer determine if he or she fits with the organization. The tacit knowledge gained from implicit learning serves as a base for a newcomer's sense of intuition. This intuition could influence subsequent attitudes and behavior. Thus a newcomer may not be able to articulate why he or she feels uncomfortable about a supervisor, but that feeling may signal potential problems as the socialization process unfolds.

WHAT IS SPECIFICALLY LEARNED IN ORGANIZATIONAL SOCIALIZATION?

There are several models of socialization content describing *what* a newcomer learns during the adjustment process. One of the earliest models describes

three dimensions for learning: functional, hierarchical, and inclusionary. The functional dimension focuses on the content of a person's job functions. Obviously, in order to be successful in a job, one needs to know how to perform it. Knowledge in one's function (e.g., accounting knowledge for accountants) is essential to career success. The hierarchical dimension focuses on the rank of a person's position. Different attitudes and behaviors are usually associated with different positions related to status and power. Thus executives might be expected to hold a set of values and behaviors that differ from technical staff, secretarial staff, and production crews. Finally, the inclusionary dimension focuses on the extent to which one is included in work operations. Regardless of rank or function, a person with critical knowledge, political connections, or negotiation skills can be instrumental or central for others to get their work accomplished effectively. People who know their job, know their rank within the organization, and know how to help others are well socialized. They may be so successful that they are prime candidates for promotion. If this occurs, then the learning cycle repeats as the newly promoted individual learns a new function, new rank, and new inclusionary knowledge and behaviors. Although this three-dimensional model can be useful in describing different content areas for newcomers to learn, it has not received much empirical research support.

More recently, socialization researchers developed six content areas for organizational socialization and developed scales to research learning in these areas: performance proficiency, language, people, politics, organizational goals and values, and history. Performance proficiency involves learning to perform a job successfully. Language involves learning special acronyms and terminology used by the organization. The people dimension includes learning to get along with other organizational members. Politics involves learning formal and informal power structures. Organizational goals and values involve understanding the organization's culture. Finally, history involves learning about the organization's past as well as the specific history associated with the newcomer's business unit. Organizational newcomers generally scored lower on these dimensions than organizational insiders. Furthermore, people who are better socialized tend to be more satisfied with their jobs, are more involved in their careers, and earn more income than people who are less well socialized. Perhaps most interesting is the finding that people who don't

perceive themselves to fit with the organization's goals and values are most likely to quit their jobs and change organizations. Regardless of *how* people learn in these content areas, mastery was associated with greater socialization and greater socialization was associated with positive job and career outcomes.

Other content areas have been discussed that involve personal learning (e.g., learning more about one's own desires and needs), role management (e.g., learning how to manage work and personal lives), and specific organizational interventions (e.g., training received). Within global organizations, new socialization content areas include cultural issues as expatriates and host-country nationals learn to bridge cultural differences and work in multinational environments. These content areas vary widely in terms of their application to most newcomers and illustrate how lessons learned during the socialization process can affect personal values and sense of identity that go beyond organizational control.

PRACTICAL IMPLICATIONS

Organizational socialization occurs whether the individual or organization manages it or not. Organizations can facilitate this process by building a strong organizational culture that provides consistent lessons to newcomers using both formal and informal methods. A strong culture describes clear values and expectations shared by most organizational members. This base of common knowledge, attitudes, and behaviors will maximize the likelihood that a newcomer will receive similar instruction from most organizational members. Thus, coworkers can reinforce what was learned in a formal training program by serving as good role models for the newcomer. If an organization does not have a strong positive culture, or if the culture is not endorsed by top management, the potential for conflicting lessons increases and the confusing experiences make adjustment more difficult for a newcomer. In this case, organizations should carefully manage the socialization process by designing appropriate orientation/training programs for newcomers, matching newcomers with appropriate role models and mentors, and monitoring the socialization process to correct misunderstandings or to help newcomers make sense of their early experiences. However, no amount of organizational intervention can socialize newcomers to be radically different from current insiders unless factors supporting new organizational roles and values are promoted to all employees.

In addition to culture-related socialization interventions, organizations can help their employees adjust to their jobs by providing adequate training and resources to help employees maximize their job performance. Company manuals can help newcomers learn important acronyms and jargon that distinguish organizational members. Employee handbooks can shape newcomer expectations and identify behaviors and customs of insiders that the organization would like to promote. Finally, performance feedback can give newcomers a sense of how the organization perceives the person-organization fit and provide guidance to improve the fit, if warranted.

Individuals should also be proactive managers of the socialization process. By astute observations, selective information seeking, and positive responses to organizational demands, individuals can better determine if the type of person desired by the organization is the type of person the newcomer wants to be. Newcomers should adhere to the organization's dress code and be sensitive to behaviors that are judged to be acceptable or unacceptable by management. Newcomers should also learn organizational jargon and acronyms quickly in order to avoid calling attention to themselves as "outsiders," naïve to insider language. Finally, newcomers with exceptional job performance may be identified as having high potential in the organization with great value for long-term career success.

Both short- and long-term career goals can help determine whether the person-organization fit is good enough for the newcomer. Individuals should also recognize the need for resocialization when jobs, assignments, and work groups change. An individual might perceive a great fit with the organization when the person is a professional, but the fit might be disastrous when the person is promoted to management. Building a wide and strong social network within the organization can help the individual anticipate realistic expectations for future organizational roles. Extending the network outside the organization can help an individual learn whether a different organization, new job, or even new career would provide a better fit to that person.

FUTURE RESEARCH DIRECTIONS

We have seen an evolution in socialization theory and research from descriptive stage models to a focus on variations in process and outcomes attributable to the organization (tactics), to current attention on the

individual being proactive, seeking information, and learning specific content areas for work adjustment. With relatively few exceptions, there has been little integration across theoretical perspectives. Clearly more research is needed to better understand how organizational interventions and newcomer sense making interact to shape lessons learned and the fit between newcomer and organization.

Theorists in organizational socialization caution that efforts to mold people into organizational members with rigid roles and values may result in an overconforming workforce that may lack the capacity to be innovative or creative. Thus the maximum benefits from organizational socialization might be best realized from adjustment processes that give newcomers a good sense of identity with the organization, without overly restricting a newcomer's individuality. Future research can explore a continuum of socialization adjustment and perhaps identify a tipping point where too much socialization can be detrimental to organizational adaptability and innovation.

New developments in network theory may be applied to organizational socialization research. A newcomer's social networks significantly influence organizational socialization. Specifically, information networks affect the newcomer's learning, while friendship networks affect the newcomer's assimilation. Together these networks help a newcomer learn how to fit in well with other organizational members and with the organization as a whole. Future research can focus on newcomers' networks by examining types of network links that would aid or hinder their work adjustment. In addition, future research can expand beyond the newcomer's network to study how multiple networks of a work group can build a particular type of organizational climate that would be passed on to the newcomer. Within a dynamic framework, these networks can be explored to examine the socialization process as it unfolds, to determine critical transitions or experiences that influence socialization. Furthermore, not only can the dynamic perspective examine how the newcomer changes, but it can also examine how newcomers might change an existing organizational climate of established insiders. A particularly strong or powerful newcomer has the potential to resocialize insiders to a new way of work.

Finally, future research can explore the link between organizational socialization and personal adjustment. Most of the research has examined organizational socialization from the organization's perspective and

what the organization can gain from well-socialized employees. Little research has examined how organizational socialization affects an individual's personal mental health. In an extreme example, organizations that mold employees to adopt a strong set of values may create a cult of people engaged in behaviors that may harm the individual. Military organizations socialize soldiers to protect their own and kill the enemy. Unethical organizations socialize managers to promote unsafe products or report false earnings. These tactics may have short-term benefits to the organization, but the long-term effects on the organization and the individual may be devastating.

Future research in organizational socialization will be challenging. Ideally, research should examine how organizational interventions and individual actions and reactions interact to determine the person-organization fit. Corrective measures taken by one or both parties who perceive a misfit should be explored. Actions taken to correct misperceptions could save a valued employee from leaving the organization. Conversely, if a true misfit is identified, a separation of the individual from the organization is likely to benefit both parties, and early recognition of a misfit could minimize negative consequences. Well-designed longitudinal studies can track the socialization process as it unfolds, shedding more light on the dynamics of organizational socialization.

Organizations interested in attracting and retaining the best people should manage the socialization process in order to maximize a workforce that is committed to providing value to that organization. Individuals interested in building a satisfying career should manage the socialization process in order to effectively determine if the present organization fits well with that individual's needs and desires. Together the intended and unintended actions of the individual and the organization will determine what is learned, how it is learned, and whether the fit between the individual and organization provides rewards for both.

ORGANIZATIONAL STAFFING

Organizational staffing is concerned with having the right people at the right place and time to achieve organizational outcomes. Staffing is a complex, multifaceted process that affects all areas of the organization but is particularly important with regard to organizational effectiveness. As such, the organization strives to attract, motivate, and retain a workforce with the appropriate characteristics to achieve the organization's mission, strategy, goals, and objectives. Viewing staffing as a continuous process rather than a discrete event (e.g., hiring a particular individual) is an essential component of virtually all contemporary staffing models and conceptualizations. Staffing

includes recruitment, selection, employment, and retention and is strongly affected by numerous laws and external conditions that bear directly on organizational employment processes.

Staffing strategy flows from the organization's mission, strategic plan, goals, and objectives that, in turn, influence human resource planning efforts. Human resource plans are developed for the organization as a whole and, in larger organizations, for each business unit. From the staffing perspective, the human resource plan examines an organization's demand for labor and the current labor supply to determine whether any gaps exist. Plans are devised to address the gaps and achieve the desired staffing levels. At the department level, such action plans identify the number of hires and the positions that will be filled within a specific timeframe. Plans must also address economic conditions, the labor market, and skill and technology changes as part of ongoing environmental scanning. Finally, the plan should address issues of diversity and affirmative action.

HUMAN RESOURCE PLANNING AND JOB ANALYSIS

Human resource planning helps to identify gaps in supply and demand, but what specifically needs to be known in order to recruit, select, and employ new personnel? All staffing systems are essentially matching processes that evaluate the fit between individual and organizational characteristics. Traditionally, the fit between the individual and a particular position was examined, but increasingly the overall fit with the organization is most important. The individual factors of most concern are knowledge, skills, abilities, and other characteristics (KSAO). In light of organizational matching just noted, personality characteristics are an important consideration as well. The way in which organizations assess individuals to determine the suitability of the fit will be examined below in connection with recruitment and selection processes.

Organizations assess jobs and job families through systematic study called job analysis, a process that describes and records job behaviors and activities. Job analysis is generally considered the backbone of an effective human resource management system, and it is particularly important in staffing functions of recruitment and selection, as well as assessing the level of job performance. Job analysis involves the collection of information about jobs in the organization

(not the persons holding the jobs). As such, the analysis focuses on duties, responsibilities, knowledge, skills, and other characteristics required to perform the job. Information can be collected via observation, interviews with job incumbents and supervisors, questionnaires, professional and trade associations, other employers, and published works such as O*NET commissioned by the Department of Labor.

Job analysis information is used as a basis for job descriptions and job specifications. These written documents summarize the information collected during the analysis phase. Job descriptions include the job title, duties, responsibilities, task activities with relative importance of each, job context and working conditions, and the date of the analysis. The date is important, since jobs evolve and shift over time as organizational conditions and technologies change and as new jobs are developed. Job specifications also include the job title, employee qualifications (experience, education, specialized certificates or licenses, etc.), job summary, KSAOs, and date of the analysis. Up-to-date job analysis information (including job descriptions and job specifications) is essential for human resource planning and the range of organizational staffing processes.

Recruitment

When human resource planning indicates that additional employees need to be hired, the organization engages in recruitment activities. The initial goal of recruitment efforts is attracting a pool of potentially qualified applicants to the organization. This pool is then screened until an appropriate number of candidates are offered employment. Recruitment activities include assessment of immediate and long-term employment needs, monitoring the labor market conditions, designing recruitment materials and methods, generating pools of qualified candidates, monitoring the effectiveness of different sources and methods of recruiting, follow-up with candidates regarding hiring decisions, and evaluation of the overall recruitment efforts. Legal issues like the definition of an applicant, company disclaimers, the nature of job advertisements, and misrepresentation of employment opportunities also come into play.

There are a number of strategic choices that organizations make regarding the recruitment process. Does the company want to develop employees by promoting from within, or are needed employees brought

in from outside of the company (i.e., internal vs. external recruiting)? Does the human resources department handle recruitment activities, or is an outside recruitment agency retained for this purpose? What role does technology play? How much discretion do business units and managers have in recruiting employees? How is the recruitment budget developed? Is the recruitment budget administered in a centralized or decentralized fashion? How does the company incorporate diversity issues in the recruitment process? Who is responsible for the success of recruitment activities?

Organizations also make strategic decisions about the appropriate methods for recruiting. Available technology has a significant influence on this process. Web-based recruiting is currently enjoying widespread use, and in fact prospective employees may be encouraged or dissuaded from applying based on a review of the company's Web site.

Once the organization sorts out its recruitment strategy and plan, recruitment is generally conceptualized as sources of recruits and methods utilized to attract recruits. Recruits can be found inside and outside of the organization. Internal candidates, who are already employed by the organization, might be considered for promotion, transfer to another unit or location, job rotation, or other assignment. Often internal job openings reflect a career or mobility path where the open position is the typical next step for the employee. Internal methods include job postings, skill inventories, nominations, and succession plans. Consider job postings. A position can be posted on a bulletin board, in the company newsletter, on the Internet, or on the organization's intranet. Hiring managers need to follow company policy on where to post, the duration of the posting, and the closing date for applications to ensure that interested candidates are aware of the opening. Postings have several benefits such as improved morale, retaining valued employees who may be seeking additional challenges and rewards, and reduced costs when compared with external methods. However, issues can arise when multiple, equally qualified internal candidates apply for a posted job and only one can be selected or when the "heir apparent" is passed over for another candidate. Plans should be made for dealing with such situations.

The organization may need to augment the pool of qualified applicants by looking outside the company. Recruits from the outside may bring new ideas and increase diversity. External sources of employees

include referral programs, walk-ins, employment agencies, temporary help agencies, trade associations and unions, schools (high schools, colleges, and universities), and foreign nationals. External methods include advertisements in the media (print, TV, radio, Web), employment agencies, open houses/job fairs, executive search firms, direct mail, and so on. The mix of methods will depend on the recruitment budget and previous success with each method.

The way that an organization portrays itself (e.g., company Web site and newspaper advertisements) and the jobs for which it is hiring (e.g., full time, part time, permanent, temporary) are critical aspects of the recruitment process. Providing "realistic job previews" that give recruits an accurate and balanced perspective (including negative information) regarding the job and the company is widely recognized as an effective practice in retaining employees once hired. Research supports the notion that realistic previews can reduce employee turnover and, in addition, can increase employee job satisfaction and organizational commitment. There are several possible explanations for the effectiveness of realistic previews: realistic information may inoculate the recruit against unrealistically high expectations when newly hired, the match between the individual and the job may be enhanced by giving realistic information, and the organizational commitment of the new hire is increased because of lack of external coercion or pressure.

Whether or not a recruit is eventually offered employment, the quality of the experience is an important determinant of the feelings and perceptions that recruits have of the process and attributions (positive or negative) they make about the organization. Managing this process so that the majority of individuals have a positive experience is essential, since they will convey such opinions to others and possibly be a consumer of the company's goods and services. Organizations should strive to convey a positive image of the recruitment process.

SELECTION

Selecting employees from a recruitment pool requires information about how well the prospects will perform the job and fit with the organization's culture. All selection systems are probabilistic, meaning that selection mistakes will occur despite the best efforts to minimize such hires. As such, the complexity and sophistication of selection systems vary

greatly. Having explicit policies and procedures along with accurate record-keeping are required in case selection processes face legal challenges. Most organizations use multiple selection devices or procedures to evaluate applicants in a thorough fashion. The employment interview is widely used often in conjunction with application blanks and résumés, references, tests, work samples, and, increasingly, physical ability and drug tests.

The employment interview, a conversation with the purpose of gathering information about an applicant's suitability for hire, does suffer from a number of shortcomings. Research has criticized interviews as unreliable, subject to a number of judgmental errors. The first impression that is formed of an applicant by an interviewer, almost instantaneously, whether positive or negative, is resistant to change even when disconfirming evidence is available. Another error, among many others, is the contrast effect, comparing interviewees with one another. An average applicant may appear very strong when compared to a weak candidate interviewed previously. Training interviewers and using structured interviews (asking the same questions in the same order for all applicants) can help to reduce some of the problems noted in the research.

In addition to the interview, tests are widely used in organizational selection systems. Tests can be thought of as behavioral samples that predict other things, like expected performance levels if hired for the job. The use of tests has increased the focus on important variables in the selection system, such as consistency of measurement (reliability) and whether a selection device measures what it is supposed to measure (validity). Validation of selection devices, showing that such measures are related to job performance, has become an important legal issue when an individual or group claims that the test was not an accurate measure of job performance.

Information gathered during the selection process is evaluated with reference to fit and expected job performance. Two major strategies for combining the results of multiple selection procedures are compensatory and multiple hurdles. In the compensatory approach, a low score on one measure can be offset by a high score on another, yielding an overall score for the candidate. By contrast, in the multiple hurdle approach, the candidate must achieve a minimum or cut-off score on each device (or hurdle) or be eliminated from the candidate pool. Selection models have become quantitative and sophisticated, requiring a

thorough grounding in statistical models for construction and interpretation.

How useful is a selection system? A major aspect of usefulness is the proportion of applicants who perform successfully after being hired. To the extent that success in hiring can be tied to the use of specific selection procedures, there is a gain in the success rate that can be attributed to the use of the procedure(s). Other variables also come into play. The so-called utility of a selection system is influenced by several factors: the number of people hired divided by the total number of applicants (selection ratio), the rate of success of applicants without using the selection device (base rate of success), and how well the test is related to job performance (validity of selection devices). The utility of the system increases when there are many applicants for a few positions, when the base rate is moderate (i.e., 50%), and when the validity of the selection procedure is high. The cost of the selection system is also an issue; adding a new selection procedure must be judged by time, expense, and contribution to predicting success on the job.

RETENTION MANAGEMENT

Retention management is often conceptualized as a process that begins with organizational entry of newcomers through organizational exits, including such events as retirement and reductions in force (downsizing). The focus thus far has been on acquiring employees to enhance organizational effectiveness. New employees have been recruited and selected. The new hires are on the payroll, they have been through the employee orientation program, some have been given training while others will be trained subsequently, and employees will go through a performance appraisal process to see how well they are doing. How long will our new hires remain with the organization? The answer is that we do not know. Organizations are focusing considerable attention on retention management because of the replacement costs and the overall investment in human resources.

The term *turnover* is used when an employee leaves the organization. Perhaps the employee has found a more attractive job at another organization (voluntary turnover), or on the other hand, the employee was performing poorly and was terminated (involuntary turnover). Notice that the former action was initiated by the employee, while the latter was initiated by the organization. Sometimes an organization

will attempt to dissuade an employee from leaving by matching or exceeding the terms of employment offered elsewhere. Similarly, the organization might attempt to provide assistance when the employee is not performing commensurate with expectations. It should be noted, however, that not all turnover is undesirable from the organization's perspective. The classification of turnover has become very complicated as retention has increased in importance. Understanding the causes of turnover (using exit interviews and research) as part of a retention management system is critically important.

There are also situations where large numbers of employees may be at risk. Many organizations have and continue to restructure to increase efficiency, deal with global competitiveness, and achieve profitability. Such reductions in force or downsizing efforts lead to job losses and layoffs. The employees who remain, the "survivors," are also affected by the layoffs. Having a plan with a fair process for implementation has been shown to be very important in downsizing.

LEGAL ISSUES

As noted previously, there are legal requirements that affect every aspect of organizational staffing. Organizations need to be aware of legal obligations and requirements or face the possibility of expensive litigation. Staffing, in a legal sense, deals with the employment relationship. There are laws regulating virtually every aspect of the relationship. Central to this are laws on equal employment opportunity and affirmative action (EEO/AA). These laws include, among others, Title VII of the Civil Rights Act (1964, 1991), the Age Discrimination in Employment Act (1967), Americans with Disabilities Act (1990), the Rehabilitation Act (1973), and Executive Order 11246 (1965). Enforcement of the Civil Rights Act, Age Discrimination in Employment, and Americans with Disabilities falls under the jurisdiction of the Equal Employment Opportunity Commission (EEOC). The *Uniform Guidelines on Employee Selection Procedures* have been adopted by the EEOC, the Civil Service Commission, the Department of Labor, and the Department of Justice. The *Guidelines* provide structure in determining nondiscriminatory testing and selection procedures for employers, labor organizations, employment agencies, and licensing and certification boards. In addition to compliance with the laws noted above, organizations need to develop and

implement equal employment opportunity programs indicative of the organizational commitment to EEO.

Volumes would be needed to review and summarize all of the legal issues in organizational staffing. Those responsible for staffing systems need to be fully conversant with the legal requirements to ensure compliance.

ORIENTATION

In common usage, to orient oneself is to locate oneself in respect to points of reference. In an organizational setting, *orientation* is the process of assisting individuals in locating themselves with respect to the organization's culture, values, vision, mission, goals, structure, and procedures. While typical notions of orientation begin with the new member's entrance into the organizational system, organizations may also consider the orientation process to impact persons outside their system. In some regards, this broader definition of orientation relates to branding, corporate goodwill, and reputation. For the purposes of career development, most employers begin to focus attention on the orientation process somewhere between the recruiting stage and the onboarding stage (when a new employee begins employment). However, many organizations fail to recognize that the process can and should continue past this single moment in time.

It is helpful to think of the orientation process as the organization's formal effort to compete with other potential perspectives. Because the candidate or employee is part of other systems—families,

friendships, and so on—they have access to other, possibly competing, views of the organization that recruits and ultimately employs them. Thus any activity that supports the organization's ability to shape the individual's view of the organization should properly be seen as an orientation effort.

Identifying appropriate goals for each stage of the orientation process and addressing those goals through the appropriate mechanisms are keys to a successful employee orientation process. In each stage, organizations must balance short- and long-term goals.

At the *pre-entry stage*, the principal short-term goal is to generate and encourage positive attitudes toward the organization. This step includes the provision of information sufficient to transform a potential candidate into an actual candidate or to convince a candidate to accept an offer to join the organization. The longer-term goal is to create a commitment to the organization and its objectives. At this stage, of course, the goal is simply to lay the groundwork for that commitment. Because of the demand for highly individualized information and the need to begin the attitudinal transformation of the candidate, personal interactions and other interactive tools tend to be highly successful. However, the expense of these mechanisms means that most organizations must find ways to offer as much interaction as possible to most individuals while focusing in-person efforts on those opportunities with the highest likely return on investment. Organizational Web sites and intranets are the most popular alternative to in-person activities, as they have the potential to provide the wide range of information needed to address concerns and answer questions. A well-crafted Web site or intranet is also a potent transmitter of positive cultural messages.

The *entry stage*, which typically encompasses the first four to six months of employment, is where most organizations focus the bulk of their orientation resources in terms of time, money, and energy. Nearly all organizations hold some sort of local, on-site or in-office orientation for new employees. Most employee orientation programs have several content elements in common: organizational policies and practices, basic logistics of the work, such as parking, security, expected hours, and so on; organizational structure and key individuals in the organization; and the organization's history, culture, values, strategies, vision, goals. Many orientation programs also include introductions to or elementary development of key job skills. That is

not to say, however, that all new employee orientation programs *should* include all these elements. The appropriate goals at this stage vary greatly along several dimensions, including the nature of the business or industry, the type of role to be filled by the new employee, the complexity of skills involved in the job being filled, and the subsequent orientation activities planned for the new employee. For example, the orientation goals of a telemarketing company that has traditionally high turnover and fairly straightforward job descriptions should be quite different from those of a consultancy, which might also have high turnover but which expects a much greater range of skills of its employees. In each case, the company will want to continue its positive cultural message, emphasizing those attributes that make it an attractive employer. But while the telemarketer may choose to emphasize employees' opportunities for commissions, the consultancy may choose to emphasize employees' opportunity to move rapidly toward partnership.

In order to emphasize the company's commitment to its new employees, most employers elect a person-to-person approach for employee orientation, using some combination of human resource personnel, professional trainers, and other staff to personally deliver the message. On the other hand, many companies' orientation programs include long informational sessions that are frequently tedious for the new employee and whose content they do not retain. A far better mechanism for this kind of information is some sort of reference material, to which the employee can turn when questions arise. Good examples are manuals and a company intranet. In practice, it is often to other staff that the new employee turns, so many companies adopt the practice of assigning a mentor or "learning buddy," to make sure the new employee has someone specific to turn to with questions.

Finally, each organization must determine those points throughout an employee's career at which they are in need of further orientation. Each time an employee enters a new career stage, the organization has a new opportunity to orient or reorient them within the system. Examples include annual performance appraisal cycles, promotions, taking on a new role, and taking on management responsibilities. At each of these moments, the organization should help the employee understand how they fit into in the system from their new vantage point. Organizations that fail to recognize the need for further orientation, or that miss the opportunities to provide that positive

orientation, risk losing influence over employees' views to competing perspectives, thus increasing the likelihood of employee turnover. The variety of mechanisms for addressing those goals is as broad as the variation between organizations.

OUTPLACEMENT

Outplacement refers to company-supported initiatives that help terminated employees cope with their termination and find reemployment. These initiatives are often conducted by outplacement firms hired by organizations undergoing downsizings or staff reductions, although some companies provide outplacement assistance internally. Outplacement has become a common business practice, with millions of employees receiving outplacement over the last few decades. The outplacement provided to employees is often part of their severance packages.

The outplacement process typically entails several stages. In the first stage, outplacement counselors attempt to help individuals cope with the shock, anxiety, and stress associated with their recent job loss, often by employing active listening techniques and stress reduction exercises. During the second stage, outplacement specialists help displaced employees evaluate their career interests, skills, and goals. A variety of career-related tests are often utilized at this stage along with in-depth conversations about career plans and strategies for career development. In the final stage, outplacement specialists help clients develop effective job search activities, such as résumé writing, networking, and interviewing. Finally, many outplacement firms and sponsoring organizations follow up with terminated employees to inquire about

their job search and to assess their satisfaction with outplacement services.

Although limited in quantity, research has begun to examine the scientific basis for various components often used in outplacement. For instance, one line of experimental research has demonstrated that job search programs that provide job search assistance and social support result in higher earnings and foster easier job acquisition than those that do not provide such assistance and support.

TYPES OF OUTPLACEMENT

The type of outplacement assistance offered to employees varies widely. For instance, basic assistance programs may consist of single, half-day workshops that focus exclusively on résumé writing and job search activities. In contrast, more in-depth programs might consist of elaborate testing and evaluation, unlimited one-on-one counseling, comprehensive job search support, and unlimited use of facilities and technologies at the outplacement firm. Although there has been little research testing the effectiveness of various outplacement programs, James Westaby's research, utilizing a large sample of displaced managers and executives, has found some evidence to support the use of comprehensive programs in comparison to less comprehensive programs. After controlling for past salary, severance, and demographic variables, this longitudinal study found that displaced managers and executives participating in comprehensive programs with high levels of outplacement support had a greater likelihood of reemployment and received higher salaries in new jobs than individuals participating in programs with lower levels of outplacement support. Results also indicated that the participants in comprehensive programs also took more time to find reemployment. Thus while comprehensive outplacement may result in longer time to reemployment, the outcomes for displaced workers are advantageous. More research is needed to examine the reliability of these findings across various outplacement firms, as well as the degree to which other factors, such as the quality and experience of staff in the outplacement firm, influence outcomes for displaced workers.

KNOWLEDGE AND SKILLS OF OUTPLACEMENT SPECIALISTS

Outplacement specialists often need to have multidisciplinary knowledge and skills to deal with the

complex set of issues involved in the outplacement process. For instance, specialists often need to have knowledge, skills, and abilities related to individual counseling, career development, social and organizational psychology, job search technologies, financial planning, human resource management, labor law, and labor markets. Outplacement counselors also need to be cognizant of a variety of issues facing their clients such as potential financial strain, psychological pathology, coping patterns, social support, family interactions, job search motivation, expectations about the outplacement process, and self-efficacy toward acquiring quality reemployment. In addition to helping displaced workers develop and implement concrete job search plans of action, outplacement counselors are often well served by continually showing support, encouragement, and empathy to displaced workers. In addition to building trust between the counselor and displaced employee, this helps repair self-esteem for many individuals experiencing shock as a result of losing their jobs.

ORGANIZATIONAL ISSUES

From a macro perspective, many organizations engage in staff reductions and downsizings to cut costs or to survive difficult business conditions. To assist in staff reduction processes, many companies partner with outplacement firms because of their expertise in managing the complex set of issues associated with such transitional periods. For instance, not only do outplacement firms have systems in place to help displaced workers find reemployment as quickly as possible, but they also provide recommendations to management about how to handle related issues, such as dealing with communications and severance payments to departing employees. Many companies also report additional benefits of using outplacement assistance, such as boosting the morale of employees surviving the workforce reduction, reducing costs of unemployment insurance, lowering the incidence of wrongful discharge litigation by mitigating perceptions on unfair treatment, helping preserve a positive reputation in the community, reducing stress on managers responsible for implementing organizational changes, and feeling as though they acted in a socially responsible manner. However, despite these potential advantages, providing outplacement to displaced workers entails financial costs. The fees for providing outplacement services to displaced employees can range from 10 to 20 percent of

an employee's compensation. However, the costs would be reduced for less in-depth outplacement options, such as group workshops. More research is needed to evaluate the return on investment associated with the use of outplacement not only from business perspectives but also from sociological and psychological perspectives.

Outplacement activities are designed to help terminated employees find reemployment in a timely manner while buffering the repercussions of job loss. The type of outplacement provided to displaced employees varies widely across companies, depending on the type of individuals being displaced and the budget available for outplacement. Several studies have shown a number of beneficial outcomes of outplacement services for terminated employees, both subjective and objective, although future research is needed to further explore the validity and utility of outplacement for serving the diverse needs of displaced employees and their sponsoring organizations.

OUTSOURCING AND OFFSHORING

Outsourcing affects hundreds of thousands of employees around the world every year and generates over \$100 billion in outsourcing contracts in the United States alone. In simple terms, outsourcing is the contracting out of noncore organizational activity to an outside vendor. Outsourcing occurs both domestically

and globally. *Offshoring* is the term used to describe the process whereby jobs are contracted out globally, usually to countries with talented but comparatively less expensive human resources. Current estimates indicate that over 80 percent and perhaps 90 percent of larger companies outsource at least part of their businesses. Although outsourcing initially targeted only transactional-type jobs like housekeeping and catering, it has moved to high-skill technical jobs such as information technology and human resource management. Activities that are often outsourced include information systems/technology, real estate and physical plant logistics, human resources, customer service, finance, marketing, and sales.

Offshoring, because it involves the transfer of jobs from one country to another, is politically controversial. Companies feel pressured to use this kind of outsourcing to maintain price competitiveness but often downplay the use of these practices. In 2004, Foresster Research projected that by 2015, 3.4 billion U.S. office-based jobs will go offshore. This is 10 times the number experienced in 2003. The main countries that have benefited from this practice have been Mexico, China, India, and other Asian countries.

Supporters of this practice suggest that these job losses will be replaced by higher-level technical and analytical jobs in other sectors spurred by the increased demand and purchasing power of the recipient countries. Until these new jobs are created, there are fears of unemployment in the countries where companies use this outsourcing practice. Questions of ethics and quality of the services provided are an area of debate.

It has been proposed that firms outsource to realize strategic advantages from cost savings, increased focus on core competencies, and increased strategic flexibility. Other common reasons include cost reduction, control and cash infusion from sale of assets, and personnel reductions. Outsource service providers through economies of scale and scope and technical expertise can provide services at a lower cost with skilled employees and up-to-date resources. Outsourcing strategy decisions are based on two management theories: the resource-based view of the firm (RBV) and transaction cost economics (TCE).

The use of the resource-based view (RBV) of the firm has directed most corporations to focus on core competencies. Companies now realize that it is most profitable to focus resources on those things they do uniquely well. The underlying assumption of the

model is that resources are both unevenly distributed among competitors and are not perfectly mobile. Therefore, the greatest profits and competitive advantage come from focusing on an organization's inimitable resources.

The choices that companies make on what functions or job types to outsource have been guided by transaction cost economics. TCE theory helps the organization determine which of their supportive, noncore functions they should buy and which they should produce or make in-house. The theory focuses on transactions rather than commodities or technology, stating that it is transactions that mainly determine the efficiency of one mode of exchange over another. The make or buy decision is made using TCE to evaluate the governance structures of firms and markets and to determine which is best suited to economize on transaction costs. The efficiency is determined by comparing costs of planning, adapting, and monitoring task completion under each governance structure. Contributors to these costs include uncertainty, frequency with which the transactions occur, and the degree to which specific investments are required to realize least cost supply. Simply stated, it answers the question: Should the firm make or buy the product or service?

Recently, external market conditions have encouraged outsourcing of various functions. The increased focus on competition and dependency on technology are just a few of the issues directing organizations to get expert help from outsourcing providers. Globalization, for example, requires expertise in national cultures and international business practices. Mergers and acquisitions present unique human resource questions that can be better answered by experts with previous experience.

There are several types of outsourcing. At one extreme there is pure labor contracting, where the contractor provides only employees and the host company provides everything else, including process, systems, technology, materials, facilities, and management. The other extreme is where the contractor provides everything from labor to equipment and the host's sole but critical responsibility is limited to managing the relationship with the service provider. Some newer companies, often called virtual companies, outsource many of their services from the beginning; outsourcing is part of their original business plan. Other companies move to outsourcing for the above-mentioned reasons.

Outsourcing can be introduced to a company in three different ways. In the most severe case, the employees of the company pursuing outsourcing are

terminated and their tasks are taken over by the company that specializes in that particular service. In this scenario, contract workers do the work formerly done by organization members. In other instances, what was previously a division or department of a larger company becomes a stand-alone operation. This is often set up as an arm's-length management organization (ALMO). In a third case, employees and their tasks are taken over by an outside specialist (i.e., the services continue to be provided by those employees who have done the work in the past, but the original company is no longer responsible for their hiring and direct supervision). The results of outsourcing, especially the effects on the employees, can differ based on the type of outsourcing and the outsourcing process.

Most of the published outsourcing results focus on the financial issues. In general, the results are seen as positive, with reductions in cost and increases in capacity and quality of services. There are some outsourcing failures that are often blamed on unrealistic expectations, poor communication, lack of trust between contractor and host, and general mismanagement of the outsourcing relationship. The literature reports outsourcing failures at around 25 percent to 30 percent.

Possibly the greatest failure but least researched aspect of outsourcing is in human issues. In terms of the individual employees, outsourcing may be viewed as positive or negative in relationship to their careers. If the employee provides a technical skill, which is seen as only peripheral or supportive to the existing business, being transferred to a service provider that specializes in the employee's skill will present promotional opportunities not available from the original employer. These outsourcing providers are growing at a rapid pace and will provide job opportunities for many. On the other hand, if the transferred job is in an area such as housekeeping, where the contracting firm has a flat organizational structure with little opportunity for advancement, then the individual's future career prospects might be dim.

When firms outsource some employees, the outsourced employees are not the only ones that are affected. Often trust in and loyalty to the organization

diminishes as the "survivors" (those remaining at the organization) see how the outsourced employees have been treated. In many cases, the outsourced employees are still on site, so other employees are constantly reminded of their plight. Once outsourcing starts at an organization, it is not unusual for the most talented employees to leave, seeking to find jobs before they themselves are outsourced. Commitment levels of the outsourced and the remaining employees may fall, negatively affecting organizational performance. Human resource issues must be addressed in order to prevent the negative response by the employees.

Employee careers and development can be affected by outsourcing in another direct way through the outsourcing of some or all of the human resources department activities. Some organizations see outsourcing human resources areas as a way to develop expert tools such as specific types of training. Other organizations, such as Southwest Airlines see human resources outsourcing as abdicating the role of the employer to lead their people.

P

PART-TIME EMPLOYMENT

Part-time employment is a formalized work arrangement where an employee works fewer hours than what an employer judges to be customary for a full-time employee. For legal and comparative purposes, the U.S. Department of Labor defines part-time employees as those working 1-34 hours during a typical work week and full-time employees as those working 35 or more hours during a typical work week. In 2004, the Bureau of Labor Statistics reported that part-time employment status was held by about 17 percent of the U.S. labor force. This percentage is likely to increase and is particularly strong in the service and retail employment sectors. In addition, universities report that increasing numbers of their students now hold part-time positions while attending school.

Part-time work is also evident in many other countries, although the number of hours used to define part-time status is variable. European countries demonstrate a part-time employment rate of around 16%, comparable to the U.S. rate, but it has increased more rapidly as some nations have encouraged part-time work as a means of alleviating unemployment.

Historically speaking, the majority of part-time workers in industrialized countries have been female (e.g., 65 percent in the United States, 90 percent in Germany and France, 80 percent in the United Kingdom and Japan). Domestic responsibilities (e.g., housework, child care, elder care) are cited as explanations for these gender differences. Younger people, aged 16 to 19, also account for about 13 percent of U.S. part-timers, many of whom are students at the

high school or university level. Few differences in part-time versus full-time employment have been observed around racial lines. In the future, retirees are anticipated to increasingly work part time. A return to employment is predicted for several reasons. Among these reasons are better health (and longer life expectancy) of older persons, the expected financial needs of many retirees, and possible revision of governmental policies to no longer tie hours of work through earnings tests to government retirement programs (e.g., Social Security benefits).

CHANGES IN EMPLOYMENT RELATIONSHIPS

Part-time work is one of many new “nonstandard” forms of employment relationships. The conditions under which employees and employers agree to partner are no longer characterized by time and location or by implications regarding job security or advancement. Accordingly, new models of human resource staffing and individual employee career development are evolving, and these models entail part-time employment.

Motives for part-time employment from an employer’s point of view include insufficient justification for hiring full-time employees because of seasonal variation in demand (peak workload time frames such as harvest or holidays), needs for employee staffing (coverage) that are shorter than customary employment periods (i.e., less than eight hours), and insufficient demand for employee skills to justify full-time employment. Employers usually further benefit from such arrangements by paying lower wages and by not having

to provide employee benefits available to full-time employees. In addition, employers may benefit by securing a trial employment of a potential full-time employee. In short, employers accrue higher levels of staffing flexibility and lower human resource costs when employing part-time employees.

Motives for part-time employment from an employee's point of view include a desire to work fewer hours than a full-time employee (e.g., job sharing) for personal reasons (e.g., to care for children or elders, to attend school or training, health or medical limitations) or a perceived need to supplement one's personal or family income (i.e., moonlighting). Over 7 million Americans, for example, hold two jobs, at least one of which is almost necessarily a part-time job. Others are motivated to accept part-time work until full-time work with a current part-time employer (or another full-time opportunity with another employer) becomes available. Unfortunately, this latter category, termed *involuntary part-time employment*, characterizes about a fourth of all part-timers.

In addition to the voluntary versus involuntary subcategories of part-time work, other distinctions can also be made. For example, part-time work may entail on-call, seasonal, or year-round employment, may be permanent or temporary, may be a primary or a secondary job, and may or may not be arranged through a third party (i.e., contract employment). Moreover, there are difficulties in defining part-time work, because the comparative standard regarding what constitutes full-time work is also a changing phenomenon. The historical "40 hours over five days" is a moving benchmark in several ways. Many Americans routinely work more than 40 hours a week. Work schedules are increasingly based on business availability to customers around the world 24 hours a day, 7 days a week. Accordingly, many new work scheduling patterns have evolved, making the definition of full-time work a more and more arbitrary reference point (e.g., many nurses now work three 12-hour shifts per week, and this is considered full time).

A case example of this phenomenon can be seen in the increasing number of part-time professionals. These jobs are typically permanent, year-round positions that an organization has elected to fill with an employee seeking a job with reduced hours. Professions that have demonstrated a willingness to engage part-timers with some frequency include law, medicine, accounting, and computer programming. However, defining a part-time professional becomes problematic, because full-time professional work usually

exceeds 40 hours per week, leaving the appropriate hours of reduction for part-time status open to debate. In this case, full- and part-time distinctions become social contractions more than distinctions based on time worked.

SIMILARITIES AND DIFFERENCES BETWEEN FULL-TIME AND PART-TIME WORKERS

Both academic scholars and practitioners have long speculated that part-time and full-time employees are "different." One reason for this speculation is based on the idea that because part-timers spend less time at work, they are regarded and/or perceive themselves to be only partially included in the workplace. Another reason is that part-time work status alters these employees' frames of reference such that they identify more with other part-timers than full-time employees. More recently, it has been suggested that part-time employees formulate a different psychological contract than full-time employees do with their employers. None of these explanations, however, has yet to achieve widespread consensus.

Empirical studies seeking to determine whether part-time employees are materially different from full-timers with respect to work-related attitudes and behaviors have yielded inconsistent results. However, this body of research was recently examined using meta-analytic procedures (i.e., techniques that assess the combined findings of multiple studies) and revealed the following: First, there is little difference between part-timers and full-timers with respect to their level of job satisfaction (including satisfaction with specific facets of work), organizational commitment, and intentions to quit. Second, full-timers do manifest higher levels of job involvement than part-timers. Third, and perhaps most important, these conclusions did not appear to be affected by the type of job (professional vs. nonprofessional) or employee gender, and only a very small difference was detected based on voluntary versus nonvoluntary part-time status. Employees working part time on a voluntary basis reported higher job satisfaction than part-timers working part time on an involuntary basis.

As this latter finding suggests, what may be more critical to understanding whether part-time workers and full-time workers are different is whether an employee's part- or full-time work status reflects employee decision making or whether work status is organizationally imposed. The term *decision* can even be misleading if the employee freely decides to work

part time but would prefer not to work at all. And few studies have posed questions about preferences for part-time work among those choosing to work full time. In other words, the motives for accepting part-time (and full-time) work may be more complex than the simple voluntary/involuntary dichotomy suggests.

The quality of the part-time job may also have a bearing on part-time employee attitudes and behaviors as well as the employee's career stage. When the least intrinsically rewarding or challenging work assignments are relegated to part-time employees, it is unrealistic to expect such job holders to demonstrate equally favorable attitudes and behaviors as their full-time counterparts. Moreover, individuals seeking postretirement employment may approach a part-time job with a very different mind-set than a nonretired individual (e.g., opportunities for advancement may not be a relevant component of this individual's job satisfaction).

Based on scientific research, managers have a limited basis upon which to argue that part-time employees are less desirable than full-time employees. Only the job involvement of part-timers has consistently been shown to be lower than that of their full-time counterparts. However, additional research on this topic (e.g., motivation, organizational citizenship behavior, perceptions of organizational support) is needed to further substantiate this conclusion, as part-time and full-time work status remains confounded with other characteristics of work previously noted (e.g., temporary work status).

CAREER DEVELOPMENT ISSUES

Part-time work is likely to increase in the coming years as a result of two converging trends: (1) the ever-increasing rates of women's labor force participation and (2) a shift in employee career patterning away from traditional, organizationally based careers emphasizing vertical progression to protean career models. As already acknowledged, women are more likely than men to be engaged in part-time work in order to accommodate domestic responsibilities. The increased labor force participation rate of women desiring employment has thus fueled the increase in the number of part-time workers. In addition, the growing ranks of women in managerial and professional jobs have independently contributed to the increase in part-time employees by their encouragement of employers to adopt more family-friendly work-life policies that include part-time work options, along with on-site day care, telecommuting, extended family leave, and so on.

Variability in career patterns continues to increase, and these changes have made the choice to work part-time far more socially acceptable for both men and women. As employers have moved away from life-long employment models and, consequently, responsibility for their employees' career development, employees themselves have concomitantly taken on the responsibility for their career management. The term *protean career*, which asserts that individuals can and should self-direct their careers, is used to capture this change in orientation. Women and men who assume responsibility for their own career management have recognized that there is no longer a single "best" career model and that part-time work can be part of a protean career. "Cutting back," "stepping off the career track," or "following a different career trajectory" by working part-time allows for retraining, changes in career interests, opportunities to pursue personal goals such as travel, volunteer work, taking care of relatives, and so on. Indeed, career experts assert that periodic departure and reentry into the workforce may become much more commonplace.

In the near term, however, moving to part-time work is not without disadvantages. Requests to move from full- to part-time status are frequently denied, and the request itself can derail career prospects. Firms are most likely to approve requests from high-performing and difficult-to-replace employees. Women are more likely to be approved than men, especially for child care reasons as opposed to other personal reasons (e.g., to write a novel). Part-time workers are often provided less challenging assignments and experience fewer opportunities to network, which can initiate a spiral of perceptions that such employees are less valuable to the company.

Despite these disadvantages, nonstandard work options like part-time work are likely to continue to grow. Evidence is already beginning to accumulate to suggest that definitions of career success are rapidly changing away from definitions that are rooted in measures linked to organizational success, to definitions emphasizing the successful integration of personal and work-related goals. Human resource professionals, especially in the service, retail, and leisure and hospitality sectors, who recognize this shift may gain competitive advantage for their firms by demonstrating more employment scheduling flexibility to attract and retain the best employees. Indeed, securing a cadre of loyal, hard-working, part-time employees may be just the solution to employment situations characterized by low-skill jobs, limited opportunities for advancement,

and where, accordingly, employee turnover has traditionally been high and costly. Such a scenario would be win-win for employees and employers alike.

PAY COMPRESSION

Pay compression is present when individuals with more years of experience receive pay rates nearly equal to (compression) or less than (inversion) individuals with

fewer years of experience. Pay compression most commonly occurs when demands from the external labor market push the starting salaries of organizational newcomers to pay levels that are similar to those of existing employees. In other words, as job tenure with the organization increases, wage growth is stifled and the value of additional years of tenure declines over time. As a result, there is a narrowing of the pay differentials between employees with differing levels of experience. Pay compression typically results when the salaries or wages of organizational members do not grow at the same pace as external market wage rates and more recently hired employees are paid at rates similar to longer tenured employees. On an individual employee level, the degree of compression an individual experiences is determined by the relationship between an individual's seniority, their salary level, and the salary of individuals with less experience. Therefore, an individual employee's relative position within a pay structure is the key determinant of their experienced level of pay compression.

A unique instance of compressed pay levels occurs when organizations are operating in markets in which there is high demand for skilled employees and these organizations are forced to raise the pay rates of newcomers in order to attract them. When companies are designing a pay system, they may simultaneously use both external market surveys, in which supply and demand pressures are used to establish pay rates, along with internal job evaluation systems, in which the worth of a given position is determined in relation to organizational strategy and design. Research has found that pay compression may be an outcome when organizations focus more heavily on these external market pressures, via an external equity strategy, than on internal job evaluations or job equity analyses, both internal equity strategies, when determining wage rates. The greater demand for qualified employees makes employers willing to pay more for skilled workers, thus directing their efforts toward an external equity strategy. To attract the best employees, companies may ignore internal pay equity and pay the market value for workers instead. However, such actions produce pay compression by narrowing the pay ratios between newcomers to the organization and current members.

In recent years, the problem of pay compression has been particularly prevalent in high-growth industries and in occupations where market forces push starting salaries for new hires to increasingly higher levels in an attempt to stay competitive in the recruitment of new

employees. As a result, wages increase faster in the external labor market than in the internal company structure. For example, recent studies have found that internal pay rates grow, on average, 3.4 to 3.7 percent per year. However, in the external labor market, wages might increase in the range of 10 to 15 percent per year. Accommodation of these external pay rates when recruiting and selecting organizational newcomers will then narrow the pay gap between employees of differing levels of organizational experience.

Currently, pay compression is argued to be endemic across pay systems inside a vast majority of private, public, and not-for-profit organizations and across all major industry types. Some have argued that changes in the economy, the use of outsourcing, and general economic and managerial control policies are leading this new wave of pay (both wage and salary) compression well beyond what has traditionally been experienced. As pay rates become more restricted inside organizations, for whatever reason, these pay rates do not tend to recover at the pace of those newly hired by organizations. It could be argued that organizations are not only ignoring the experience and loyalty factors of their workforces but are failing to respect the external wage and salary market unless new talent is needed from outside the organization.

It is important to realize the negative ramifications that can be associated with pay compression. Multiple streams of research have shown that the amount of pay an employee receives strongly influences key attitudes and behaviors such as job performance, organizational commitment, job satisfaction, and intentions to leave an organization. The level of pay also impacts an individual's feelings of self-worth and the perception of their value to the organization. In addition, organizations and managers should be aware that individuals are not only concerned with the absolute amount of money they make but also how that level of pay compares to that of other individuals in the organization. Employees frequently compare their pay against that of their coworkers in an attempt to determine their personal value and status in the organization.

Variations in pay rates among employees are justifiable and, therefore, deserved if the relative worth and contribution of those employees differ. Under such conditions, pay differentials are viewed as equitable and fair. However, problems arise when the pay differentials between individuals are not as wide as employees believe they should or could be. In conditions of pay compression, individuals of differing levels of experience

are receiving similar pay rates. As a result, a perception of unfairness, or inequity, can be created as the more experienced employee does not feel that their pay level is reflective of their performance, loyalty, and commitment to the organization. Less tenured employees are receiving similar pay as longer tenured employees because the external labor market created an opportunity for them to demand a higher starting salary, not because their relative contributions are similar.

Because pay compression occurs across groups of differing experience, it will likely be viewed as unfair and be detrimental to employee performance and organizational outcomes. Limited variance in pay levels between individuals in a relative group, such as those with similar levels of experience, is desirable. However, to guard against perceptions of unfairness, differentials must be present across individuals of differing levels of experience. When pay compression occurs, these differentials are eroded. As a result, those longer-tenured employees will likely feel that their pay is unfair and begin to look outside the organization for opportunities to resolve this inequity. In addition, their commitment to the organization will suffer and their performance levels may fall. These individuals may perceive that their value to the organization is unrecognized, and as a result, their self-esteem, satisfaction, attachment, and motivation can suffer. Such negative outcomes suggest that organizations must be aware of the potential danger of allowing external market strategies to overtake internal equity and stimulate pay compression within their pay structures. Each new generation of employees seemingly demands greater attention to fairness of rewards in the workplace. Understanding this reality will position the issue of pay compression as increasingly salient to organizations in the future.

PAY-FOR-PERFORMANCE REWARD SYSTEMS

Pay-for-performance reward systems are one of the major types of variable-based pay plans. In compensation terms, the guaranteed salary a person receives in each paycheck is referred to as base pay. Variable pay is a monetary component that is offered in addition to base pay. Thus, variable pay plans, including pay-for-performance, involve money that is at risk of being lost. What distinguishes pay-for-performance reward systems is that the variable pay component is awarded on the basis of individual or group behavior or productivity. Such systems are seen as encouraging the retention of high-performing individuals, although skill-based pay or competency-based pay systems are seen as more consistent with high commitment workforces.

Pay-for-performance, then, is a type of variable pay that is based on behavior, productivity, or the attainment of some other goal of importance to the organization. Pay may be allocated, and also measured, at the individual, group, or organizational level. The award is an additional at-risk (i.e., unlike base salary it is not guaranteed) component that is added to base pay but does not become a part of the calculation of base pay in the future. The questions with pay-for-performance include (1) how to measure work and (2) how to convert this assessment into monetary payouts.

The four basic steps in setting up a pay-for-performance plan include the following:

1. Introduction phase: Plan the switch from the old to the new compensation plan
2. Design phase: Determine basic design, including consideration of various legal issues
3. Formula phase: Determine basic measures and formula for converting performance to money
4. Implementation phase: Introduce and communicate plan to employees

INDIVIDUAL LEVEL PAY-FOR-PERFORMANCE

Pay-for-performance may be measured and awards made at the individual level. In some ways, this may be thought of as being similar to the older concepts of piece rate, that is, a portion of individual pay is based upon the quantity or quality of individual performance. Performance may be evaluated at the individual level using objective measures of performance, performance appraisals, 360 evaluations, or evaluations of progress toward goals. A matrix is then set up in order to convert performance into pay increments; this matrix may consider simultaneously a number of performance and profitability indicators.

ORGANIZATIONAL LEVEL PAY-FOR-PERFORMANCE

Pay-for-performance may also be calculated at the team, group, or organizational level and may be based upon metrics, including cost, quality, delivery, waste, production, downtime, and safety. Organizational level schemes often involve participative management and a suggestion system. Some common organizational level pay-for-performance methods include profit sharing, gain sharing, and goal sharing. The actual payout is based on a combination of performance and overall profitability. Employee involvement and trust are key components to a successful organizational-level pay-for-performance plan.

PAY-FOR-PERFORMANCE DISTINGUISHED FROM MERIT PAY

Both pay-for-performance and merit pay involve rewards for individual performance or productivity. The fundamental difference is in the nature of the payouts. With merit pay, the associated wage increase is added to the base salary. Thus, in future years, the base salary is increased by the merit pay award from previous years. With pay-for-performance, the additional pay must be earned or is at risk every year.

PAY-FOR-PERFORMANCE DISTINGUISHED FROM SKILL- AND COMPETENCY-BASED PAY

Skill- and competency-based pay can be considered types of pay-for-performance but are usually distinguished. Whereas pay-for-performance rewards

performance or productivity, skill-based pay provides monetary incentives for acquiring various skills, knowledge, or abilities. Competency-based plans provide rewards for the acquisition of various behavioral competencies; skill- and competency-based plans are often differentiated based upon the level of worker, lower (skill) or higher (competency). The skills or competencies need not be directly related to the current job being performed but may be related to organizational needs, roles, or more general skills.

Skill- and competency-based pay plans may include a component that is added to base pay or may involve an annual payout. The incentive to acquire skills is consistent with various plans for high commitment workforces and with individual career development.

LINKS TO CAREER DEVELOPMENT

Pay-for-performance plans at the individual level may be seen as more consistent with protean career principles than with career development within a high commitment workforce. Because the emphasis in a pay-for-performance plan is on productivity and performance, individuals may be unwilling to take time out for personal development unless they see such efforts as consistent with long-term personal goals.

Skill-based and competency-based plans are very consistent with internal career development programs and with the concept of a high-commitment workforce. Both reward directly individual investments in training and development.

Organizational level pay-for-performance plans may require an investment in development, especially among lower level employees. Such plans require greater employee commitment and an understanding on the part of employees of quantitative variables and quality-improvement methodologies. Retention rates tend to be higher among high-ability or high-performing employees under a pay-for-performance plan. Turnover rates will be higher among low-ability employees. Thus, pay-for-performance can be seen as encouraging career development among highly talented employees, as the plans are an inducement to such employees to stay with the organization. On the other hand, they may have no or a negative effect on career development among low- and mid-range employees.

EVALUATION OF PAY-FOR-PERFORMANCE

Pay-for-performance involves the use of a variable or an at-risk pay component based upon either individual

or group performance. As might be expected, these plans tend to lead to greater satisfaction and acceptance when performance and productivity are high, and tend to be seen more negatively during bleak economic times. In addition, the acceptance of such plans will depend on the fairness of the performance measurement systems. Skill- and competency-based methods are probably more consistent with a high commitment workforce, and an associated emphasis on career development, than are pay-for-performance plans. A recent study found that despite the increased costs of pay-for-performance reward systems, they did result in substantial positive utility.

PERFORMANCE APPRAISAL AND FEEDBACK

The purposes of a *performance appraisal* fall within two broad categories, namely administrative and developmental. The former provides a basis for decisions regarding promoting, demoting, transferring, compensating, laying off, or terminating an employee.

Because most Western countries have laws that affect these decisions, organizational decision makers must take these into account when making an administrative decision that affects an employee's status in the organization. The second purpose of a performance appraisal is concerned with ways of inculcating in an employee the desire for continuous improvement.

PERFORMANCE CRITERIA

For a performance appraisal to increase a person's performance, five steps must be taken.

Step 1. Determination of the Metrics

Step 1 requires determination of the metrics or criteria on which a person will be evaluated. An axiom in psychology is "that which gets measured gets done." If people are unsure of what is expected of them, they are unlikely to meet those expectations. Performance criteria, the metrics that influence administrative decisions, may include bottom-line cost-related outcomes such as revenue generated, costs reduced, or voluntary employee turnover within one's team. The advantage of bottom-line measures is the relevance to the organization as well as their interobserver reliability; that is, two or more appraisers are highly likely to make the same appraisal, independently, regarding an employee's performance when bottom-line measures are used. The disadvantages of these measures are fivefold. First, they are often excessive in that they are affected by situational factors beyond a person's control (e.g., the economy). Second, they are usually deficient in that they do not take into account factors for which a person should be held accountable (e.g., team playing skills). Third, they can encourage a "results at all costs" mind-set, which in turn can lead to ethical, if not legal, issues. Fourth, outcome measures may be available for a team, but often they are nonexistent for assessing an individual's performance. Fifth, even when such measures do exist, they only yield information on the "score" and do not provide information on what an employee should start doing, stop doing, or be doing differently. Information on the latter is critical for coaching others as well as oneself for inculcating a desire for continuous improvement.

A second performance criterion that can be used for making performance appraisals is an assessment of a person's traits such as creativity and initiative. The advantage of trait measures is that they are usually applicable to all employees in all jobs. Both the CEO and the hourly employee must be "conscientious." A downside of using traits as a performance criterion is that they are ill defined. Consequently, they invite acrimony between the person who receives the appraisal and the person who conducts it. Moreover, the likelihood that two or more appraisers will make the same appraisal decision independently

is low. Hence the courts too take a dim view of trait appraisals. The solution is to define these traits behaviorally. This is accomplished through a job analysis.

To attain an organization's goals requires a strategy. To implement the strategy requires employee knowledge of the behaviors necessary to implement the strategy. This is accomplished through a job analysis. A metaphor for a job analysis is a "recipe" for success. The job analysis specifies in writing what the person must do (behaviors) to implement the strategy effectively. People who are aware of the aims and objectives of a job (e.g., program coordinator), who frequently observe incumbents performing the job, and who can discern competent from incompetent behavior are asked to identify behaviors that are critical to the implementation of the organization's strategy. Behavioral observation scales (BOS) and behavioral expectation scales are both based on a job analysis called the critical incident technique. Studies have shown that how one is appraised on BOS correlates significantly with bottom-line measures. Moreover, BOS have been shown to be content valid in that they contain a representative sample of the behaviors critical for an employee to demonstrate on the job in order to be seen as effective. Finally, these behavioral criteria facilitate performance feedback, identification of training needs, and the setting of specific high goals. In short, behavioral criteria developed from a job analysis ensure that people are coaching others as well as themselves on "the right things."

Step 2. 360-degree Feedback

Once the appraisal instrument is developed, the second step is to determine who should use it. Traditionally, the answer has been the employee's supervisor. Supervisors, however, are often unable to gain a complete picture of an employee. In recognition of this fact, many organizations get a comprehensive assessment of an employee by soliciting feedback from peers, subordinates, and the employees themselves in addition to the supervisor. Hence the term *360-degree feedback*. Through this 360-degree vantage point, an employee's strengths and developmental needs are identified. This approach is especially applicable for autonomous teams. Peers, for example, are usually in a far better position to provide accurate assessments of team members than is one single individual, namely a supervisor. The role of the boss is primarily to be an information gatherer, who assesses

the information and coaches an employee on an ongoing basis with regard to goal setting and goal attainment. The emphasis on coaching reflects the growing shift in emphasis by organizational decision makers to a performance management system rather than the traditional performance appraisal that typically occurs only one to four times a year.

Step 3: Goal Setting

Feedback is only useful to the extent that a person acts on it. For behavior to improve, the person must use the feedback to set specific high goals. Goal setting is the third step in the performance appraisal process. A study of highly educated engineers and scientists shows that the higher the goal, the higher the person's performance. Similar findings have been found in performance appraisal studies involving unionized employees. Nevertheless, the advantages of goal setting, namely increasing a person's focus, effort, and persistence, can be a two-edged sword. Once a goal is set, people may direct their attention to one area of their job (e.g., revenue) at the expense of another aspect that is also important to the implementation of an organization's strategy (e.g., team playing). A "balanced score card" ensures the proper weighting of the goals and the metrics for assessing goal attainment. Because so many faculty members in top tier universities place so much emphasis on research, many of these universities have subsequently implemented a 40/40/20 scorecard whereby 40 percent of a faculty member's assessment is based on teaching, 40 percent is based on research, and 20 percent is based on a person's contribution to the university as a whole (e.g., service on committees).

Step 4: Ensuring Objectivity

Appraisals often reflect the biases of the appraiser rather than the performance of the person being appraised. For example, the extent to which the employee is similar to the person or persons who are doing the appraisal can ensure a favorable appraisal. Gender proportion in a group can affect a person's evaluation even when there is no actual difference in the performance of women and men. Increasing the representation of women in the group increases the likelihood of a positive appraisal of a female employee. Training can minimize observer biases. When appraisers are given several hours of instruction where they view people on videotape, receive feedback

on their evaluation, are informed of the judgmental error, and discuss ways to minimize errors in the future, objectivity increases significantly. This training is the fourth step to take for ensuring an effective appraisal process.

Step 5: Coaching

The fifth step involves ongoing coaching of employees. Day-to-day coaching has a more beneficial effect on a person's performance than a quarterly, biannual, or annual performance appraisal. To the extent that the goals that are set are challenging, an employee is likely to encounter difficulties in attaining them. Waiting until the end of an appraisal period to offer an employee advice is nonsensical. Ongoing coaching should focus on outcome expectancies and the employee's self-efficacy. The role of the coach is to help people see the relationship between what they do and the outcome they can expect. "When you approach a customer this way, here is the outcome you can expect; when you approach the customer that way, here is a very different outcome you can expect." Self-efficacy refers to task-specific confidence ("I can do this"). The role of a coach is to instill optimism, to build resiliency following failure. Ways to accomplish this include (1) giving the person assignments, sequencing the tasks in such a way that they all but guarantee early wins. With a succession of wins, a can-do mind-set forms; (2) finding a model with whom the person identifies who has either attained similar goals or is in the process of doing so; and (3) identifying a significant other. A significant other is a person to whom the person listens. There is a strong tendency for us to behave in accordance with the expectations of those who are significant to us. Persuasion by a significant other that a goal is indeed attainable will increase a person's effort and persistence.

CONCLUSION

Performance appraisals are among the most important systems/processes in an organization. Performance appraisals are the basis for determining whether an organization's selection/staffing system is effective. In the process of ongoing appraisals, decision makers discover whether the person has the desire but lacks the requisite knowledge and skills to attain one or more goals. Hence performance appraisal is a basis for determining who should be trained as well as what should be trained. Ongoing coaching ensures that the

person is motivated to apply newly acquired knowledge and skills to attain the specific high goals that were set. With goal attainment, an employee's confidence is increased and even higher goals are set. This performance cycle leads to a high-performing individual in a high-performing organization.

PERSON-ENVIRONMENT FIT (P-E FIT)

The person-environment interactional and transactional models assume that human behavior tends to be influenced by many determinants both in the person and in the situation. The models emphasize the effects of person-situation interactions on personality, satisfaction, and well-being and suggest that behavior involves a continuous interaction between individuals and situations. As noted by Walter Mischel, we can't

take a person out of personality, but, at the same time, we cannot ignore the fact that environments and social cultures, like people, have personalities and influence behavior and well-being.

THE INTERACTIONAL PERSPECTIVE: A DEFINITION

Norman S. Endler and David Magnusson have defined interactional psychology as the scientific investigation of a complex interplay of situations and persons in determining behavior. They further suggest that there are four basic elements of the person-situation interactional model. The first basic element suggests that behavior is a function of a continuous process of multidirectional interaction between the individual and the situations he or she encounters. Second, the individual is an intentional, active agent in this interactional process. Third, on the person side of the interaction, cognitive and motivational factors are essential determinants of behavior. Fourth, on the situation side, the psychological meaning of situations and cultures for the individual is an important determining factor. The interactional perspective may also be expressed as $B = f(P, E)$, where B stands for behavior, f for function, P for person, and E for the environment or situation. Thus, in many respects the interactional perspective may be viewed as a synthesis of person and environment in which the interaction of the two is the main source of behavior. In attempts to assess and understand behavior, the various theories of person-environment psychology discussed below have in general mirrored the interactional perspective. However, as we shall see, within this perspective the theoretical frameworks have emphasized different concepts and variables.

PERSON-ENVIRONMENT FIT PSYCHOLOGY: MODELS AND PERSPECTIVES

John L. Holland's theory is based on the notion that behavior is a function of personality and social environment. The theory suggests that behavior is a function of the complementary match or congruence between the individual's personality style and the psychological environment. Holland suggests that individuals enter environments because of their personalities and remain in those environments because of the reinforcements and satisfactions obtained through the interactions in that environment. In

general, research testing the theory clearly indicates that individuals tend to choose and enter college majors and occupational environments consistent with their personality types. In addition, evidence suggests that to some extent person-environment congruence is related to measures of job satisfaction and stability, job involvement, work quality, productivity, and well-being but not necessarily to measures of decision making, sociability, and problem-solving ability.

Rudolf H. Moos's social ecological perspective is based on the general principle that the way one perceives the environment tends to influence the way one will behave in that environment. Thus, Moos focuses on the social climate (the personality of the environment) by suggesting that environments, like people, have unique personalities. Just as some people are more supportive and nurturant than others, so are some environments more supportive and nurturant than others. In terms of research, the evidence indicates that people tend to be more satisfied and comfortable, less depressed and irritable, and more likely to report beneficial effects on their self-esteem in environments that they perceive emphasize the human relationship dimensions. The human relationship dimensions assess the degree to which people are involved in the setting, the degree to which they support and help one another, and the extent to which they express themselves freely and openly. In essence, people report being more satisfied and more productive in environments that they perceive to be relationship oriented.

The theory of work adjustment (TWA) views work as an interactive and reciprocal process between the individual and the work environment and grew out of research begun in 1959 that investigated the work adjustment of vocational rehabilitation clients. Based on results from their initial studies, Rene V. Dawis and Lloyd H. Lofquist developed a theory that has as its primary focus the proposition that tenure (length of stay on a job) will be predicted by a combination of satisfaction (workers' self-reported job satisfaction) and satisfactoriness (e.g., supervisors' ratings of employees as performing satisfactorily). Also important is how the two interact (greater job satisfaction would lead to higher ratings of satisfactoriness, and higher ratings of satisfactoriness would lead to a great job satisfaction). Thus, the theory focused on the interaction of the person and the work environment. Research evidence from a variety of settings supports the importance of fit between the person and the

environment for achieving both satisfaction and satisfactoriness. In addition, there is a growing body of research evidence supporting their proposition that as a worker remains longer on a particular job, the worker will change in ways that are more correspondent (congruent) with the work environment.

Robert W. Lent, Steve D. Brown, and Gail Hackett recently developed a comprehensive model of career development that addresses interest development, vocational choice, and vocational performance. Central to their theory are three variables from general social cognitive theory: self efficacy ("Can I do this?"), outcome expectations ("If I do this, what will happen?"), and personal goals. Personal goals assist in organizing and sustaining behavior, although environmental events and personal history certainly help shape behavior. The model also includes Albert Bandura's triadic reciprocity that indicates bidirectional causal relationships between personal attributes, external environmental factors, and overt behavior. The research evidence indicates that self-efficacy can be improved with self-regulatory scales training programs that provide both ways of obtaining better performance outcomes and drawing more appropriate conclusions from those performances. Stated differently, when self-efficacy is improved, job performance improves. For example, training programs have been found to increase the interest and performance in math and science for young women.

Lawrence A. Pervin's model notes that person-environment interaction, and thereby questions of congruence or fit, involve relations between multiple personal goals and multiple environmental demands or opportunities for goal attainment. The questions of congruence or fit must be considered in terms of person systems, environment systems, and the relations between person-environment systems. What is important to note is that multiple goals (the person) are involved with multiple affordances (the environment and action possibilities), and the environment provides for action possibilities that are congruent for some goals but not with others. Goal hierarchies and plans are central to Pervin's concept of the person. For Pervin, behavior is motivated, and the concept of goals is suggested as a useful motivational concept.

Brian R. Little's social ecological perspective demonstrates the importance of completing personal projects in explaining and predicting human well-being and adaptation. More specifically, traits and personal contexts facilitate the pursuit of personal

projects and a sense of adaptation and well-being. To the extent that people are engaged in personal projects that are meaningful, well-structured, supported by others, efficacious, and not too stressful, their well-being is enhanced and the person-environment process is rewarding.

Kenneth H. Craik suggests that understanding individual environment transactions involves the interplay between traits, goals, and behavior settings. On the person side are goals and personality traits. The environment is defined in terms of behavior settings that are implicated in the actions of people as they pursue major life goals. Behavior settings link people and environments according to behavioral rules and individual pursuits. Personality traits may be viewed as facilitating or thwarting the pursuit of life goals in a behavior setting context. According to Craik, traits, goals, and behavior settings may be analyzed in terms of the ongoing person-environment process.

Benjamin Schneider, D. Brent Smith, and Harold W. Goldstein suggest that people make the environment and that good *person-environment fit* (the individual has the characteristics that are similar to the characteristics of the persons in the environment or the organization) may result in positive outcomes for the individual over the short term, namely in terms of adjustment, satisfaction, and commitment. These authors suggest, however, that over the long term, this cycle may yield homogeneity in thinking, decision making, and action and, in this context, discuss some aspects of the dark side of person-environment fit.

Robert Hogan and Brent W. Roberts suggest that people choose activities and interactions that are consistent with their identities and avoid interactions that are inconsistent with their identities or their motives, goals, and values. These authors note that people's past choices of situations tend to predict their future involvement in various environments. Substantial evidence indicates that preferences for environments effectively predict occupational membership, occupational tenure, and occupational change. These preferences tend to be stable over time because people tend to choose environments depending on their motives and goals.

Jack L. Nasar's theoretical framework conceptualizes the person in terms of personality predispositions and how our perceptions of physical environments facilitate an evaluative image that influences meaning and behavior. The evaluative images that are formed based on these perceptions influence subsequent

meaning of behavior. Stated differently, how we perceive the environment (pleasing, arousing, exciting, and relaxing) influences our view of that environment and subsequent behavior. Once again, the concept of congruence is relevant.

IMPLICATIONS

There are a number of conceptual and methodological issues regarding person-environment psychology and the research that has examined this process. For example, studies of person-environment congruence frequently implement a point-in-time view of congruence or fit. The primary approach has been to describe the person and the environment and explore their independent and interaction effects. In essence, the research generally is conducted in one point in time. However, a number of theoretical frameworks note that people tend to seek out complementary or congruent environments and that environments attract, retain, and influence these individuals. Bandura, for example, suggests that humans act on the environment; they create, uphold, and transform their environment in an interplay between personal agency and environmental influences. According to Bandura, people are producers of their life circumstances and not just products of them. Thus, these assumptions further suggest the need for research designs that run across time. Very few studies have empirically investigated the person-environment hypothesis from a longitudinal perspective. This very clearly needs to be added to the research agenda.

In addition, major methodological issues continue to revolve around ways of measuring people's personality, interests, and environment, and congruence itself. From all indications, people are the strength. The person concept has been operationalized using a variety of traditional inventories of personality, interest, competencies, and values that have proven reliability and validity. For example, theories conceptualize and define the person in terms of motives, values, projects, pursuits, traits, and major life goals. The measurement quality of the instruments used is such that we can be reasonably certain that we have obtained a good estimate of the person side of the equation. However, actually measuring the environment or the situation has been far more elusive. There is no question that we need better (more reliable and valid) assessments of the environment. Stated differently, we are still in the early stages of our understanding of the

characteristics of the situation or environment that affect behavior. Different from personality, we have no well-accepted taxonomies we can use to describe the significant dimensions of situational or environmental variability.

In spite of limitations, it seems that the above theories and models represent a cluster of attitudes, implicit if not explicit, concerning the relationship between the individual and the environment. Each theory does have its assumptions, even though at times they are not clearly stated. Each theory has stimulated some meaningful research that has implications for performance, satisfaction, and well-being. Many of the investigations have procedural difficulties, but the fact remains that, to a varying degree, the effectiveness of each theory has been empirically examined. In any event, these approaches hopefully will continue to lay the groundwork for more sophisticated theories, research, and practice.

PERSONAL GLOBE INVENTORY

The *Personal Globe Inventory* (PGI) is a new interest inventory based on a spherical model of interests that measures activity preferences, activity competence beliefs, and occupational preferences. The PGI is unique in that it explicitly incorporates prestige as a prominent factor in interest assessment. Through the use of innovative features in profile interpretation, the PGI offers individualized profiles, thus providing an assessment that may be applicable to many users at various points in their career development.

The globe model is an extension of John Holland's six-type model. He proposed that interests can be characterized by six personality types (i.e., Realistic, Investigative, Artistic, Social, Enterprising, and Conventional) and that these six RIASEC types are arranged in a hexagon. The development of the spherical structure of interests evolved out of a series of studies conducted by Terence Tracey and James Rounds. Their exploratory research demonstrated that an eight-type model of interests fits their data well or better than Holland's six-type model, pointing to the arbitrary nature of Holland's RIASEC types. In addition to validating the presence of the two dimensions typically found in interest data, Dale Prediger's People/Things and Data/Ideas, they found a third dimension of prestige, a salient but often overlooked variable in vocational interest assessments.

Best conceptualized as an occupational interest globe with the dimension of prestige represented along

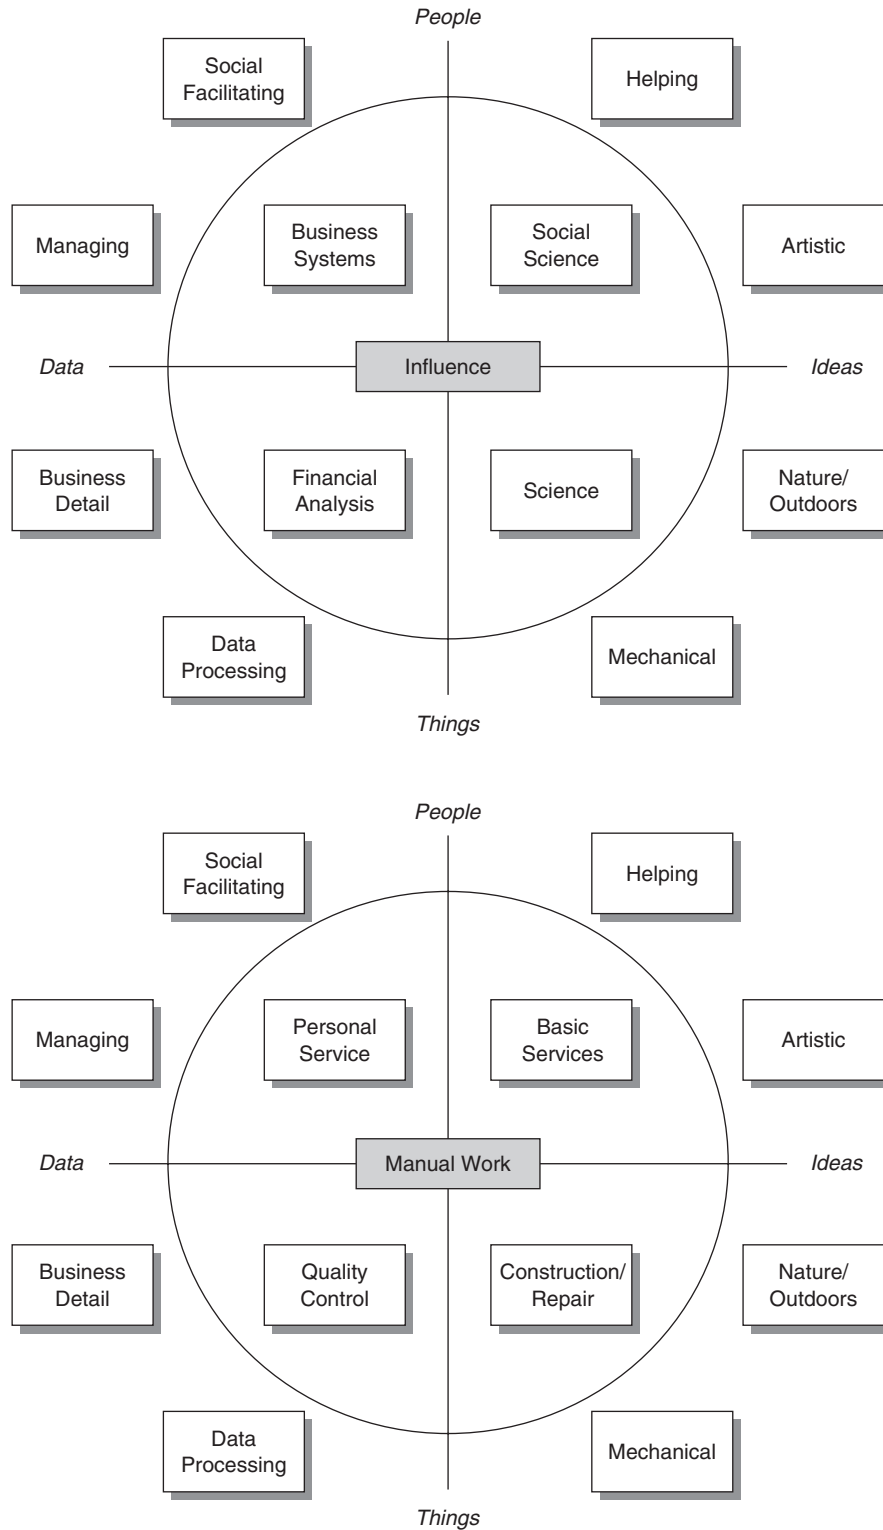

Figure 1.

the north pole–south pole axis and differentiating interest areas, the PGI is depicted in Figure 1. With the addition of the dimension of prestige, the PGI

yields scores from 18 spherical scales that represent three dimensions of People/Things, Data/Ideas, and Prestige. In addition, the PGI also yields information

provided by many other interest inventories scores including eight basic interest scales (e.g., social facilitating, helping, artistic, nature/outdoors, mechanical, data processing, business detail, and managing), six RIASEC scales, and Prediger's two dimensions. Research on the psychometric properties of the PGI supports its reliability and validity across gender, educational level, and ethnicity.

The PGI offers several innovative approaches to interest profile interpretations. PGI profiles are depicted by a circular graph with a single vector score. The direction of the vector on the circle enables a simple interpretation of an individual's major area of interest; the magnitude, or length, represents the strength or differentiation of that interest area with high vector lengths indicating well-differentiated interests. Another unique feature of the PGI is that it has the capacity to provide individually adapted output presentations based on the user's profile information so that only salient features for that particular user are graphically displayed. The flexibility of the instrument makes it applicable for a broad range of persons.

The incorporation of prestige in the PGI has implications for career development practice and research. In clinical application, the inclusion of a dimension of prestige enables assessments across a wide range of both low and high prestige areas, making it applicable for a broad group of users whose interests may reflect different preferences along the prestige continuum. In research, the inclusion of prestige with basic interest circles could allow for a more thorough investigation of salient vocational psychology hypotheses in which prestige may play a central role, like the person-environment congruence hypothesis.

PERSONALITY AND CAREERS

Personality refers to characteristics that make individuals unique, including their prototypical thoughts, emotions, interests, habits, and behaviors. Psychological in nature, personality is relatively stable over time. Personality plays a significant role in determining how a person behaves in various situations. Many dimensions of personality have been linked to *career* development. Almost every element of a person's career is in part determined by his or her personality. Such fundamental career decisions as occupational choice, early career socialization, job performance, career satisfaction, and career changes are affected by personality.

Personality can influence our behavior in different ways. Human personality plays a direct role in determining our behaviors; our dispositions or personality traits directly influence our actions. For example, extroverted people would be expected to behave in an outgoing and sociable fashion in most situations encountered throughout life. Personality reflects peoples' natural tendencies to behave in certain ways; people are remarkably consistent in their behaviors over time in part because of the direct effect of personality.

However, personality is not always an important influence on peoples' behavior; its significance varies from situation to situation. A "strong" situation has relatively clear expectations for appropriate behavior; in a strong situation, the situational expectations are stronger than personality in influencing behavior. For example, a boisterous and gregarious personality might choose to behave in a more calm and sedate fashion when meeting with the boss because this type of behavior is expected by one's immediate supervisor. In this example, the situation (meeting with the boss) dominates the personality (boisterous). Situations without such clear-cut behavioral expectations are termed *weak* situations, and in these instances, personality becomes a primary determinant of behavior.

Another perspective is based on the concept of interactional psychology; this approach maintains that behavior is jointly determined by personality and situation. People and situations interact to create patterns of behavior; people influence situations and situations also influence people. In particular, the interactional approach notes that personality plays an important role in determining the types of situations

people choose to enter. For example, an introverted person might choose jobs that do not require much contact with others. People engage in a complex process where they select, interpret, and change situations; thus they can also shape situations to suit their personality. For example, people can change their work methods, procedures, and task assignments in order to create a more hospitable situation at work. Both the dispositional and interactional approaches are relevant for understanding the relationship between personality and career development.

THE CONCEPT OF FIT

The idea of examining the fit between person and environment to gain insights into human behavior has resulted in an increased understanding of many work-related issues, including career development. The extent to which there is a correspondence or congruence between person and situation is related to such outcomes as job performance, satisfaction, job tenure, and turnover. A subset of this research has focused on the fit or match between person and occupation. The premise of this approach is that positive outcomes occur when the characteristics of people are similar to those of their occupation. The fit between a person's interests and occupational types has been especially useful in understanding careers.

VOCATIONAL INVENTORIES

Several inventories assist in vocational guidance by assessing peoples' interests and considering how those interests fit with various occupations. An early approach was the Strong Interest Inventory, which compares peoples' interests with the interests of people already working in a particular occupation. A recent version of the Strong Interest Inventory includes broad personal style scales that reflect preferences in living and working that are quite similar to personality traits. A related approach, the Kuder Preference Record, evaluates peoples' likes and dislikes and compares them to the content, tasks, and working conditions of various occupations. These inventories are both based on trait theories, whereby a match between individual traits and occupational features is desirable. Personality is recognized as a key influence on career choice, success, and satisfaction under both approaches.

HOLLAND'S THEORY OF VOCATIONAL CHOICE

John Holland's theory is a prime example of person-occupation fit research; it is based on examining the congruence or match between the career interests of people and occupational environments. People search for vocations that match their interests; such a fit results in vocational stability, satisfaction, and high achievement. Poor fit results in the opposite patterns. Holland believes that these vocational interests are a fundamental component of one's personality.

Holland's theory classifies people and jobs into six personality types, labeled Realistic, Investigative, Artistic, Social, Enterprising, and Conventional (RIASEC). Realistic types value practical things, see themselves as practical and mechanical, and like to work with animals, tools, or machines. Investigative types value science, see themselves as intellectual and precise, and like to study and solve math or science problems. Artistic types value the creative arts, see themselves as expressive and original, and like to perform creative activities like drama or music. Social types value helping people and solving social problems, see themselves as helpful and trustworthy, and like to do things focused on others, like teaching or nursing. Enterprising types value success in politics, leadership, and business, see themselves as ambitious and social, and like to lead and persuade people. Conventional types value success in business, see themselves as orderly and good at following plans, and like to work with numbers, records, or machines in a set way.

Holland's theory classified environments into the same six categories: Realistic, Investigative, Artistic, Social, Enterprising, and Conventional. Because people tend to seek out problems and work situations that are congruent with their interests and personalities, each environment is primarily populated with people having the matching personality type; for example, Investigative types dominate the investigative environment.

When there is a fit between person and environment, workers are more likely to be successful and satisfied. Practically, this theory suggests that people should choose occupations whose environmental type is similar to their personality type. In addition to predicting the value of an exact match of personality type to environment, Holland's theory also suggests other specific environments that are compatible with each personality type. Realistic people would be compatible with the investigative and conventional environments,

Investigative people would be compatible with the realistic and artistic environments, Artistic people with investigative and social environments, Social people with artistic and enterprising environments, Enterprising people with social and conventional environments, and Conventional people with enterprising and realistic environments. Because most people are a combination of the various personality types, they should consider occupations compatible with more than one category.

THEORY OF WORK ADJUSTMENT

Another example of using the concept of fit to understand vocational issues, the Minnesota Theory of Work Adjustment also considers the correspondence between people and environments. This theory considers the process through which people acquire and maintain correspondence with their environments. The level of fit between person and environments is hypothesized to fluctuate over time as both person and environment changes; thus people may change either themselves or their environments to get and maintain correspondence. This theory is consistent with the interactional approach described earlier; people and environments act on and react to each other. For example, dissatisfied workers may not just accept the dissatisfying working conditions; rather, they take action to improve conditions.

The Theory of Work Adjustment considers two types of correspondence between person and environment. Satisfactoriness results from a fit between peoples' abilities and the requirements of a particular job. Satisfaction comes from a match between peoples' needs and desires and the rewards obtainable from a particular job. As people spend more time on a job, both satisfactoriness and satisfaction will increase. However, over time, both factors depend on individual and environmental factors.

Four relatively stable personality styles describe the way in which people interact with and change the work environment. Celerity denotes the speed with which people initiate interactions with the work environment; people who are uncomfortable with a lack of correspondence are likely to be high in celerity. These people might be expected to change jobs or initiate changes to themselves or the environment because of the discomfort. Pace reflects the effort exerted in obtaining correspondence; some people may be willing to go to great lengths to better meet the demands of a job, while others may be willing to live with low

levels of correspondence. Rhythm is the pattern of effort expended in achieving correspondence; some people strive for steady correspondence, while others do so only occasionally. Endurance reflects the persistence of individuals in responding to and interacting with the environment.

BROAD AND NARROW PERSONALITY FACTORS AND CAREERS

There are many words and phrases that have been studied as elements of personality. Early work in the personality field identified nearly 18,000 words from the dictionary as being potentially useful in distinguishing people from one another. Later work determined that over 3,500 of these labels actually were stable personality traits. The overwhelming number of potentially informative personality traits has caused personality psychologists to seek ways to simplify the study of personality. Various taxonomies or ordered sets of traits into particular categories have been offered to achieve this objective. The goal of such a classification system is to reduce the thousands of personality traits into a smaller, more manageable set.

An individual personality trait is a narrow and precise approach to categorizing one of the unique features of a human being. It is focused on a single element of personality. However, logically one would expect that various sets of narrow personality traits would be related; for example, someone who is generally dependable might also tend to be very organized. A broad trait is multidimensional and is comprised of a set of more narrow traits. Broadly defined traits offer a more wide-ranging coverage of human personality. Thus a narrow trait can be thought of as one end of a continuum representing unidimensionality, while broad traits can be thought of as the other end of the continuum and represent multidimensionality.

THE FIVE-FACTOR MODEL OF PERSONALITY

The five-factor model (also known as the Big Five) is a popular broad conceptualization of personality. The Big Five taxonomy has gained widespread acceptance among personality theorists and organizational psychologists alike. Proponents of the five-factor model believe that personality can be described by focusing on five broad dimensions: neuroticism, extroversion, openness to experience, agreeableness, and

conscientiousness. Neuroticism refers to emotional instability as opposed to adjustment. People high on neuroticism are characterized by anxiety, vulnerability, and self-consciousness; those low on neuroticism are emotionally stable and calm, even tempered, and unemotional. Extraversion reflects the social component of personality. People high on extraversion are gregarious, outgoing, and talkative; people who are low on extraversion tend to be reserved, passive, and quiet. Openness to experience relates to curiosity and the tendency to seek out and appreciate new experiences and ideas, reflected in imagination, innovation, and broad-mindedness. People who are low in openness to experience are conventional, down-to-earth, and prefer routine. Agreeableness is defined by peoples' interpersonal orientation; those high on agreeableness are cooperative, trusting, and friendly, while those low on agreeableness are described as ruthless, irritable, and antagonistic. Conscientiousness reflects intrinsic motivation. People high in conscientiousness are responsible, persevering, and achievement oriented; people who are low in conscientiousness are irresponsible, disorganized, and negligent.

These dimensions of personality are consistently related to a number of work-related behaviors that influence careers. People who are low on neuroticism (that is, who are emotionally stable) exhibit "getting along" behaviors at work and demonstrate high levels of job performance across occupations, especially in jobs requiring teamwork. Furthermore, people who are low in the neurotic personality are less likely to assertively hunt for other jobs. Extraversion is related to "getting ahead" behaviors, predicting job performance in jobs with a large social component such as sales and management; it is also related to success in training. Openness to experience is related to "receptivity to change" and creative ability; it is most consistently related to training success. Agreeableness is also related to "getting along" behaviors at work; it predicts performance in jobs with a large customer service component or a significant teamwork component. Conscientiousness is related to "getting things done" at work; among the Big Five factors, conscientiousness is the best predictor of job performance across all jobs and occupations. It is difficult to think of a situation where conscientiousness would not be desirable or positively associated with job performance or any other element of careers. Conscientiousness is positively associated with frequency of job-searching behavior and negatively associated with early attrition. Organizational citizenship behavior—a desirable

occupational behavior involving going above and beyond the call of duty by performing extra roles at work—is related to the conscientious personality

There is some overlap between the Big Five factors and Holland's RIASEC types. For example, the Big Five factor of openness to experience is strongly related to Holland's Investigative and Artistic types. However, empirical evidence suggests that the Big Five are not subsumed by RIASEC and vice versa. Because RIASEC types and Big Five factors are somewhat unique and empirically distinct from one another, some recommend the use of both approaches for vocational counseling. There is also evidence to suggest that we can better predict job performance by simultaneously considering the Big Five factors and Holland's RIASEC environments. For example, conscientiousness might be a better predictor of job performance in the social and investigative environments than in the other four environments.

The Big Five factors have been found to be related to a number of affective (defined as emotion, feelings, and attitudes) career outcomes. For example, neurotic personalities tend to be less satisfied with their jobs, feel greater occupational stress, and report greater indecision concerning career-related decisions. Neuroticism is also related to work/family conflict. Extraversion tends to be associated with job satisfaction; people who are highly extraverted tend to report higher levels of job satisfaction than people low on extraversion. Extraverted personalities prefer managerial careers, whereas introverts prefer more technically oriented careers. People with a personality characterized as high on agreeableness prefer to work in supportive and team-oriented organizational cultures. Highly conscientious people tend to prefer detail-oriented cultures that are focused on outcomes. Among unemployed individuals, conscientious personalities tend to be more active in seeking jobs and have a positive sense of self-worth in spite of their employment status.

The Big Five factors have been studied extensively in relation to career success, defined in terms of the positive psychological and work-related outcomes accumulated as a result of one's work experiences. Intrinsic career success refers to satisfaction with one's career, while extrinsic career success is reflected in salary and promotion, two observable rewards from the job. Various Big Five factors are related to both intrinsic and extrinsic career success, even when controlling for the effects of other relevant factors (such as general mental ability and firm size). In

particular, conscientiousness is positively related to both intrinsic and extrinsic career success. That is, people who report having a highly conscientious personality tend to be happier with their careers, have higher incomes, and have been promoted more frequently than those who report being lower on this Big Five factor. Another Big Five factor, neuroticism, appears to be negatively related to intrinsic and extrinsic career success. Extraversion is associated with higher salary levels, and agreeableness is negatively related to career satisfaction.

The Big Five factors are broad in nature; that is, they are at a higher level of abstraction than more specific personality traits. The Big Five are not considered a comprehensive list of traits or a replacement for other personality theories or systems but as a framework for interpreting them. As we have seen, the broad factors described by the five-factor model have been helpful in understanding relationships between personality and careers; however, the existence of the Big Five factors does not preclude studying and learning about how more specific and narrow personality factors relate to career development. One way of thinking about this is to reflect on the level of analysis between personality and outcome; the broad Big Five factors are excellent predictors of general and wide-ranging outcomes (that is, outcomes at the same level of analysis), while more narrow personality traits might be useful in predicting and understanding a more specific set of career-related outcomes.

CORE SELF-EVALUATIONS

A broad dispositional concept referring to the extent to which people hold a positive self-concept, core self-evaluations are related to several career processes and outcomes. Core self-evaluations are basic evaluations that individuals hold about themselves, and they are indicated by four specific traits: self-esteem, generalized self-efficacy, locus of control, and emotional stability (low neuroticism). Core self-evaluations are related to job satisfaction, task motivation, and job performance.

Like the Big Five factors, core self-evaluations represent a broad trait comprised of more specific and narrow traits. Self-esteem refers to the overall value that people place on themselves, and it includes self-acceptance, self-liking, and self-respect. Generalized self-efficacy is the extent to which people believe that they have the ability to perform well on various tasks and across a variety of situations. It reflects the extent

to which people believe that they can cope, perform, and be successful. The extent to which people believe that they personally control their lives (rather than fate, luck, or chance) is referred to as locus of control. This trait is reviewed more fully in the next section. Emotional stability is one of the Big Five traits, and it represents emotional adjustment and manifests itself in positive tendencies such as feeling confident and secure. To the extent that people believe themselves to be described by these four traits, they would be viewed as having positive core self-evaluations. People who view themselves as relatively low on these traits would have lower core self-evaluations.

NARROW PERSONALITY TRAITS AND CAREERS

There are literally thousands of individual personality characteristics that can be used to describe humans, and many of them are potentially useful for better understanding careers. A select set of narrow personality traits that are particularly useful for understanding careers are discussed in this section.

Proactive Personality

Consistent with the interactional perspective, people can intentionally change their current circumstances, such as by making career changes. People can be classified across a reactive/proactive continuum to describe their proclivity to make such changes. Proactive personalities are people who take action to influence their environments; they identify opportunities and take action. Proactive personalities take initiative and persevere until they bring about meaningful change. Less proactive people exhibit the opposite patterns; they prefer to passively adapt to circumstances rather than change them. Proactive personality is associated with many work-related phenomena, including individual and team-based job performance, entrepreneurship, and leadership.

Proactive personality is associated with objective (salary and promotions) and subjective (career satisfaction) career success. Compared to less proactive people, proactive personalities earn a greater income, have achieved more promotions, and are generally more satisfied with their careers. The reason for this is that proactive people select, create, and influence the situations in which they work, increasing the chances for both high performance and happiness with the work. Examples of such behaviors include engaging

in career management activities such as job search behaviors, obtaining mentors, and conducting career planning.

A theme of current writings on careers in the twenty-first century is that careers have become boundaryless, requiring people to take responsibilities for their own careers in order to ensure that they are able to contribute to their employing organizations. Proactive personality is consistent with the idea of boundaryless careers, because proactive individuals actively manage their careers. Proactive personalities demonstrate career initiative. They plan for the development of their careers, develop skill sets to continue to be valuable human assets, and consult with more senior personnel about career-related issues. They also demonstrate greater levels of innovation at work, successfully implementing new ideas for achieving objectives. All of these activities point toward greater levels of career success.

Proactive personality also is related to successful job search behaviors in terms of exerting effort toward finding a job, invitations for second interviews, and the number of job offers received. Proactive personalities believe in their ability to accomplish things, which increases the chances of a successful job search. Socialization behaviors—which set the stage for successful careers—also are in part a function of proactive personality. Proactive people take the initiative in learning the behaviors and attitudes necessary for becoming effective at new jobs and workplaces. People who actively facilitate their socialization show greater task mastery, role clarity, and social integration. Thus proactive socialization leads to valuable outcomes for both person and organization.

Locus of Control

The extent to which people believe that they control the events surrounding them is referred to as *locus of control*. People with an internal locus of control believe that their behaviors are guided by their personal decisions and that the outcomes following their actions depend upon what they do. At the other end of the spectrum is an external locus of control, whereby people believe that fate, luck, and other outside forces guide their behaviors, and that events outside of their control influence the outcomes of actions. This concept was briefly mentioned earlier as a subcomponent of the broad trait of core self-evaluations. However, because this personality variable has been extensively

studied in the context of careers, it merits separate attention as an important narrow personality trait.

Generally speaking, an internal locus of control is viewed as more desirable in the world of work. An internal locus of control is associated with greater career decision-making skills and greater confidence in career decision making. Career aspiration is also associated with locus of control; internals prefer more intellectually demanding careers. There is some evidence that internal locus of control is associated with job satisfaction. People with an internal locus of control are more likely to mentor others in the workplace and to initiate mentoring relationships. On the other hand, people with an external locus of control are more likely to withdraw psychologically from their jobs and ultimately leave them.

Dispositional Affect

The moods, feelings, and emotions of workers play a significant role in a number of career-related attitudes and behaviors. Affect can be considered as a disposition, or a generalized trait or tendency to react to stimuli in a certain way. Affective disposition is comprised of two facets: positive affect and negative affect. Positive affect is characterized by high energy, enthusiasm, and pleasurable engagement; it is reflected in a happy, cheerful, and pleasant demeanor. Negative affect is characterized by distress, anxiety, and hostility; it is reflected in a generally grouchy, unhappy, and unpleasant demeanor.

Positive and negative affect are linked to job satisfaction. People with positive affect tend to be more satisfied with their jobs; the greater the level of positive affect, the more satisfied we would expect people to be. The opposite is also true: Negative affect is inversely linked to job satisfaction; the greater the level of negative affect, the less satisfied we would expect people to be. Negative affect is also linked with greater levels of work/family conflict and with occupational strain. Positive affect also influences the performance of extra-role behaviors and spontaneity. People with positive affect should be more willing to help coworkers, make constructive suggestions, and engage in self-development activities.

CONCLUSION

Personality, or the characteristics that make people unique, is an important determinant of human behavior

in general and careers in particular. Human personality affects much of who we are and what we do, both directly and indirectly, through its impact on the situations we choose to enter. A critical element is the concept of fit between person and situation or environment; personality plays an important role in determining whether a person will be comfortable in a particular situation. Various vocational inventories (e.g., the Strong Interest Inventory and the Kuder Preference Record) assess this by gauging how personality types will fit with various occupations. Holland's theory of vocational choice is also predicated on the fit or congruence between a person's personality type and occupational environments.

Thus, personality can play a significant role in helping people determine occupations that may or may not be a good match for them. It has long been acknowledged that good things can come from introspection and that it is important to "know thyself." One outcome of such self-knowledge is a better understanding of which occupations and career paths would better match your interests and personality. Being honest with ourselves about who we are and our strengths and weaknesses can help us choose situations that we will be comfortable in, as well as make us aware of situations that we might want to avoid.

Both broad and narrow personality traits are relevant for understanding careers better. Broad traits are multidimensional and wide-ranging in their coverage of human personality; narrow traits are unidimensional and specific. Among broad traits, the Five-Factor Model is a popular and generally well-accepted framework for categorizing personality traits. The Big Five factors are associated with a number of important career-related factors, including occupational choice, work adjustment, job performance, job satisfaction, and career success. Another broad trait, core self-evaluations, also is relevant for understanding careers; early evidence suggests that it is associated with job satisfaction, task motivation, and job performance.

Narrow or unidimensional personality traits can also provide insight into careers. While there are thousands of different narrow personality traits, some seem particularly relevant for the career domain. Proactive personality, or the tendency to take initiative and identify opportunities for change, is associated with both objective and subjective career success. Locus of control, or the extent to which people believe that they control the events of their lives, is associated with career choice, mentoring, and withdrawal.

Dispositional affect or consistent moods and emotions is related to job satisfaction, work/family conflict, and occupational strain.

A conclusion that one could draw from considering the various approaches to personality discussed here is that "personality matters." Our personality fundamentally shapes who we are, how other people view us, and the situations that we choose to enter. By better understanding who we are and identifying the various elements of our own personality, we can make better decisions about careers.

—J. Michael Crant

PERSONNEL SELECTION

Personnel selection is the systematic process of making decisions about which individuals to employ to fill open positions within an organization. The main goal of selection is to identify and employ those individuals who have the necessary knowledge, skills, and abilities (KSAs) to successfully complete the work of the organization. The volume and quality of this work directly affects organizational success. The individuals selected may be new entrants to the organization identified through an external recruitment process. Alternatively, those selected may be internal applicants—current employees who move to new positions within the organization and who are identified through the internal recruitment process. Internal applicants may be interested in advancing their career through a promotion or may want to change career paths.

The usefulness of selection depends on the (1) number and quality of individuals in the applicant pool, (2) identification of specific KSAs necessary to perform the job, (3) appropriate job-related content of selection instruments, and (4) psychometric properties of those instruments.

NUMBER AND QUALITY OF APPLICANT POOL

Selection begins when the company requires additional employees or a different type of employee to meet production or service demands or when a current employee leaves the organization, resulting in a job opening. Some organizations have a formal human resource planning (HRP) process in which forecasts are made about the number and types of employees

needed to achieve future organizational goals. Based on these forecasts, the company engages in recruitment activities designed to attract applicants for employment. New employees are selected from the resulting applicant pool.

The organization is in a good position if the pool contains more applicants than there are open positions and if the large majority of individuals in this pool have the minimum KSAs for success on the job. In such situations, selection identifies those individuals who have the highest level of the KSAs required and who, as a result, would be expected to perform at a high level on the job. If the applicant pool is relatively small or has relatively few qualified applicants, selection may not yield an adequate number of high-performing individuals.

IDENTIFICATION OF KNOWLEDGE, SKILLS, AND ABILITIES

The development of a selection program begins with a job analysis to detail the nature of the work the job incumbent will be doing. Job analysis information is commonly obtained from interviews, observation, archival records, reference books, or surveys completed by job incumbents and supervisors. A job description is developed from this information and describes the tasks, duties, responsibilities, and accompanying KSAs a job incumbent will need. Additional descriptive information may be included about the working conditions of the job, such as physical requirements, noise levels, and hazards.

The job analysis information is used to determine the appropriate KSAs required to perform essential job duties: Knowledge is the body of information necessary for performance (e.g., knowledge of career development theories), skill is competency in performing a specific job task (e.g., use of Excel), and ability is a general, job-related proficiency (e.g., ability to read at Grade Level 8).

CONTENT OF SELECTION INSTRUMENTS

The KSAs determine the format and content of selection instruments. Using the previous examples, applicants could be given a written theory test, asked to prepare an Excel spreadsheet, and then given a verbal test of reading comprehension. Research studies have found that selection has the best results if (1) instruments have a defined scoring system and

(2) scores are used as the primary data on which applicants are judged for their potential for future work performance. The value of the selection instrument is directly related to the extent to which the content of the questions or activities making up the instrument reflects job activities.

Application Form

Almost all selection programs start with the use of an application form. This brief document requests descriptive information about topics such as education, previous work experience, awards, and contact information. The form is limited, providing space for only general, brief statements. Studies have determined that approximately one-third of applicants provide inaccurate information to at least some of the questions on these forms.

A training and experience form is a type of application form that does provide useful information. This form contains questions that directly reflect job tasks and includes a scoring system measuring the extent of the knowledge of the task operations. For a college instructor position, a training and experience form could provide descriptions of five tasks. One task might be the following: "Develops course lesson plans covering class topics, methods of presentation of each topic, and learning objectives." The applicant is asked to indicate if he or she has ever performed or been trained in the performance of this task. If the answer is yes, the applicant is asked to provide a brief description of what was done during this work or training experience. Trained judges may be used to grade responses.

Interview

Applicants generally react more favorably to job interviews than to other types of selection measures. Unstructured interviews are those for which there is no set of specified questions or defined scoring system. The interviewer asks whatever questions are thought to be appropriate and evaluates the applicant on his or her judgment of the applicant's general performance in the interview. Structured interviews developed from job analysis information have proven to be more valuable in selection. These interviews are composed of job-related questions used with all interviewees, along with a defined scoring system for evaluating responses.

The behavioral description interview is one of the most widely used types of structured interviews. Applicants are asked to describe specific examples of how they acted in past situations similar to those they will encounter on the job if hired. The underlying philosophy is that past behavior is the best predictor of future behavior.

Cognitive Ability Tests

In a research study of 19 selection measures, cognitive ability tests (also referred to as general intelligence tests) had the highest predictive validity for job performance. These tests measure several mental abilities that are part of the tasks of almost every job. Abilities measured include verbal comprehension, numerical fluency, general reasoning, memory span, and logical evaluation. Research has consistently found that cognitive ability tests can be used for all jobs, and that they increase in value as the job of interest increases in complexity. These tests also are among the lowest cost selection measures. The strong relationship between job performance and scores on general mental ability tests may exist because these tests are also a strong predictor of job-related learning and problem solving. Those individuals who have greater mental ability are likely to learn more quickly than others and also may be able to better solve problems that occur when a job operation is in error or when a new demand is placed on the job incumbent. Both job learning and job problem solving translate into better job performance. Caution is recommended when using these tests; adverse impact against legally protected (e.g., racial, ethnic) groups has resulted from their use.

Work Samples

Work samples require the applicant to perform one or more of the job tasks. A secretary could be asked to take a word processing test. Other jobs that frequently use work samples are skilled craft positions, construction, computer programming, and food service. Designed correctly, work samples closely approximate the actual job. The organization has a much better idea of the quality of work to expect from an employee based on the applicant's performance on this measure. Work samples are usually better at predicting future job performance than other selection instruments but are costly to develop and use and

require that the applicant already be trained to perform the job.

Assessment Centers

Assessment centers are job simulations commonly used for selection of managers or professionals, often for advancement within the organization. In an assessment center, a group of job candidates participates in a series of activities. Representative activities include the Leaderless Group Discussion and the In-Basket exercise. In the former, groups of six applicants are given an organizational problem and asked to interact in order to provide a solution to the problem. Raters observe the job candidates throughout the process and rate each candidate on his or her behaviors during the exercise. The In-Basket presents the candidate with a series of office memos. The individual is required to provide detailed responses and recommendations for each memo. Responses are scored by a trained evaluator. Often assessment centers last for multiple days and are quite expensive to develop and operate. Organizations have used these devices for measuring the strengths and weaknesses of employees in order to identify training needs.

Personality and Integrity Tests

Personality and integrity tests are self-report questionnaires in which the respondent provides information about his or her feelings or behaviors. Psychologists have agreed that the optimal personality test is one that measures the Big Five personality dimensions: extroversion, agreeableness, conscientiousness, emotional stability, and openness to experience. These personality dimensions have been theoretically linked to many different jobs and found to be statistically related to performance in various jobs. This latter is especially true for conscientiousness and extroversion. Literally hundreds of personality tests have been used for selection; however, tests of the Big Five are among a very small group of such tests that have demonstrated value in selection.

Integrity tests are intended to identify those applicants who have a high probability of engaging in acts such as stealing, embezzlement, sabotage, or violence. Integrity tests have steadily evolved in recent years and currently have demonstrated the ability to predict those behaviors. Most of these tests ask the same types of questions as do personality tests. They are

scored in relationship to behaviors that are indicative of a general set of counterproductive actions that may be taken by employees. Responses that reflect or are related to these counterproductive actions are scored as signifying low integrity.

PSYCHOMETRIC PROPERTIES OF SELECTION INSTRUMENTS

Selection measures must demonstrate the test construction properties of reliability and validity in order to demonstrate their usefulness. Reliability refers to the consistency, dependability, and stability of the scores generated by the selection instrument. Selection methods that are reliable will yield the same results if administered at two different times or if used by different raters. Reliability is a necessary but not sufficient condition to ensure that the selection measures are useful.

Validity refers to the extent to which the selection measures actually do assess the knowledge, skills, and abilities required for successful job performance. Validity provides evidence that the measure can predict future job performance. In the context of selection, when KSAs have been identified for a particular job, the HR specialist has formulated testable hypotheses about the worker characteristics required for job performance. Validity refers to the process of determining if those worker characteristics are indeed related to job performance.

There are two major forms of validity. Content validity involves systematically using subject matter experts (e.g., practitioners and academics in the field of work) and job analysis information to develop the items to include in the selection measure. Accountants would be most knowledgeable about the questions to ask on an accounting test or the questions to ask in an interview for accounting jobs.

Empirical validity is the statistical demonstration that there is a significant correlation between the scores on the selection instrument and the scores on measures of job performance. Predictive and concurrent validity are types of empirical validity. In both types, scores are collected for a group of individuals on both the selection instrument and the job performance measure. Statistical analysis is then performed to determine if the correlation between these two scores is high enough to be greater than chance. If the correlation is statistically significant, there is evidence that applicants with higher scores on the selection measure will perform well on the job.

Legal Issues

Selection measures have been involved in a number of discrimination cases brought against organizations. A charge of discrimination may be filed when an individual(s) claims that he or she has been denied employment and can link that denial to one or more of the demographic characteristics identified in the equal rights federal legislation. The demographic characteristics often cited in selection discrimination cases are race, gender, religion, age, disability, and ethnic origin.

There are two forms of discrimination that may be charged by the plaintiff: disparate treatment and disparate impact. Disparate treatment occurs when membership in one of the previously noted demographic classes is used as the basis for the selection decision. If an employer decides that females should not be promoted into a particular job, disparate treatment has occurred. In this case, gender has been used illegally as the basis for the employment decision.

Disparate impact occurs when a protected group of people are treated differently from the majority. On a selection test, lower scores might be found for one demographic group than for others. A selection measure could be a weight-lifting requirement for a firefighter or a high school diploma requirement for a secretary. Both of these selection measures are likely to result in lower scores for specific demographic groups, thereby making individuals from that demographic group less likely to be hired than individuals from another group. Females, in general, are less likely to be able to meet a stringent weight-lifting requirement. Minority groups, such as African Americans or Hispanics, are less likely to meet the high school diploma requirement.

In either type of discrimination charge, the organization can only defend its selection program by clearly demonstrating that the scores produced by the selection instrument being questioned are related to job performance for individuals in the demographic group charging discrimination. The methods of determining validity discussed previously would be used to demonstrate the relationship between instrument scores and job performance scores.

Technological Development

Among the most important current selection issues is how to successfully employ technology. Many organizations have embraced the use of selection

testing using the Internet and other electronic instruments. Uses include having applicants complete application and training and experience forms online and the administration of interviews, cognitive ability tests, and personality surveys. The major issues being raised include the following: (1) Are electronically administered tests equivalent to traditional tests? (2) How can the use of reference materials be prevented? and (3) How can the identity of the applicant be definitely established? The limited research to date comparing electronic and traditional testing has looked at testing times, applicant reactions, design of tests, and proctoring of tests. This research is inconclusive on most of these issues although some studies report more positive applicant reactions for electronic tests. Additional research is needed to provide more definitive information about the reliability and validity of electronically administered tests.

Value of Selection

Research over the past 85 years has provided a great deal of information regarding the monetary value to the organization of using valid selection measures. Such measures lead to increased learning of job-related skills and increased output on the part of the employees. Overall, the monetary gain from using valid selection methods is typically large, with the gain being directly proportional to the increase in validity of the better methods versus previously used methods. The more valid selection measures have greater return.

PHASED RETIREMENT

Phased (or gradual) retirement normally means that an older worker remains with his or her employer while gradually reducing effort and hours worked. The reduced work time is viewed as a step toward full retirement and can take the form of fewer hours per day, week, month, or year. The term *phased retirement* is sometimes used more broadly to include reduced work time associated with a change in employers, a move to self-employment, or even a reduction in the intensity of work without a change in hours. Here, however, the focus is on the narrower definition: reduced work time without a change of employers.

In terms of careers and career development, phased retirement obviously belongs to the final stages of a career. It enables workers to gradually reduce work activity while continuing to exercise skills developed at earlier points in the career. Workers can enjoy both the activities and social relationships that are central to a career while developing and pursuing other interests.

There are several potential benefits from phased retirement. Older workers can use phased retirement to make a smooth transition toward a less stressful schedule, a schedule that is perhaps less stressful than either full time work or full retirement, or a schedule that allows for maintenance of social networks, earnings, and a sense of efficacy but that also accommodates a possible age-related reduction in stamina or capacities. From an employer's perspective, phased retirement can retain experienced employees with specialized knowledge of their job and of the larger organization. Finally, from the perspective of the

larger society, phased retirement could extend the work life and thereby reduce pressure on private and public pensions (e.g., Social Security).

The idea of phased retirement is not new. It has been the subject of expert discussion for decades. Nor is it simply an academic idea; there is a long history of private sector employers permitting older workers to reduce their hours as they approach full retirement. Books written in the 1950s about employment of older workers often included discussions of companies with functioning phased retirement plans.

Given that the idea has been around for decades and that older employees often express interest in phased retirement, it is somewhat surprising that phased retirement is evidently quite rare. According to the Health and Retirement Survey, in 1996 more than half of the employed respondents age 55 to 65 preferred to gradually reduce their hours of work as they aged. Yet studies from the 1970s that followed a cohort of older workers as they moved to complete withdrawal from the labor market indicate that less than 10 percent took phased retirement; most people simply moved from full-time work to full-time retirement, and those who become part-timers frequently change employers. More recent data collected by the Health and Retirement Survey indicate no substantial change in these numbers.

EMPLOYERS AND PHASED RETIREMENT

Employers play a major role in determining who has an opportunity for phased retirement. A recent survey asked 950 establishments whether there were conditions under which they would be willing to permit an older full-time white-collar worker to take phased retirement. Interestingly, most of the establishments indicated that something could be worked out. They usually had in mind an informal arrangement that would depend on the establishment's need for a part-time worker. Of those who were open to phased retirement, only about one-third had formal policies regarding phased retirement, and even those policies often make phased retirement a matter of employer discretion.

One particularly interesting form of phased retirement is called "retire-rehire." In this case, full-time workers officially retire from their firm and then return as part-time workers. There are situations where the time interval between retirement and rehire is a matter of days. The survey of 950 establishments

found that the great majority of employers who permit some form of phased retirement would allow it both before and after official retirement. A small minority of the establishments—only 7 percent—would prefer that the shift to part time always occur after official retirement.

Since phased retirements are often handled informally, one might expect them to also be offered selectively. The survey of 950 establishments confirms this. Within the same establishment, some older white-collar workers are more likely than others to have an opportunity for phased retirement. Opportunities for phased retirement tend to rise with age and job tenure. Moreover, employers were more likely to accommodate wishes for phased retirement from high-performing workers. In terms of worker performance, workers who require little supervision and who “make an extra effort to get the job done” are particularly likely to have opportunities for phased retirement.

That result holds, however, on average. Not all employers behave this way. As indicated by a well-executed recent study, there can be circumstances where employers use phased retirement to encourage retirement of low performers. In 1996, the University of North Carolina instituted a formal systemwide program of phased retirement for tenured faculty. The study used information on recent pay increases as a measure of performance. It found that the low performers—those with smaller recent pay increases—tended to enter phased retirement. The employees covered by the University of North Carolina program are, however, rather unusual employees. Since it is extremely difficult for universities to discharge or even reassign tenured faculty, and since mandatory retirement is illegal in the United States, a formal phased retirement program may be one of the few tools that universities have for inducing faculty to leave full-time positions. Thus, as noted by the authors, other employers may not use phased retirement the same way that universities do.

WHY DON'T WE SEE MORE PHASED RETIREMENTS?

A prominent explanation for the small number of phased retirements focuses on defined benefit pensions. Defined benefit pensions base benefits on a formula; as such they are distinct from defined contribution pensions, which base benefits on the amount of

money in a personal account at the time of retirement. Several authors have argued that in contrast to workers covered by defined contribution pensions (or no pension), workers with defined benefit pensions confront formidable obstacles to phased retirement.

There are two reasons why defined benefit pensions may impede phased retirement. First, under defined benefit pensions, a retired person's pension benefit will sometimes depend on earnings in years just before retirement. In that case, an older person who chooses to work half time at half pay prior to retirement could lose as much as half of all future pension benefits. Indeed, one author calculates that in such a system, a 10 percent decrease in annual earnings can translate into a lifetime wealth loss of 150 percent of annual earnings. No rational worker would choose part-time employment under such a pension. The same problem does not arise with defined contribution pensions, since benefits are based on the amount of money in a personal account. In this case, a person who works half time in the final years before retirement makes lower contributions to the personal account and thereby receives lower benefits. But the decrease is small and nothing close to a lifetime wealth loss of 150 percent of annual earnings.

Second, regulations in the federal tax code can make it quite difficult for an active employee to receive pension benefits from a defined benefit plan that is operated by a current employer. Specifically, an active employee cannot receive benefits before the plan's normal retirement age. To see the problem, consider a 63-year-old employee who takes phased retirement, receives reduced earnings, and wishes to supplement those earnings with pension benefits. If the employee's pension is a defined benefit plan with a normal retirement age of 65, then that will not be possible. If, on the other hand, the pension is a defined contribution plan, the employer can establish policies so that an active employee can draw pension benefits. The major federal limitation on such payments from a defined contribution plan is that the employee must be over age 59½.

Interestingly, in the above-noted survey of 950 employers, pensions did not play a major role in phased retirement policy. The results indicated that while defined benefit pensions are associated with reduced opportunities for phased retirement in simple cross-tabulations, when other determinants of phased retirement (e.g., industry, organizational size, and presence of a union) are controlled for, pension effects

largely disappear. As such, the hypothesis that pensions play a crucial role in shaping opportunities for phased retirement should be viewed with skepticism.

An arguably more important determinant of an employer's phased retirement policy is whether the employer permits employees to have flexible hours. If an establishment has part-time jobs, permits job sharing, and has a policy of flexible starting times, then the employer is much more likely to say that phased retirement can be accommodated. When employers say that they are open to phased retirement, in most cases they are also willing to accommodate hour reductions for younger workers. Alternatively stated, when employers say that they prohibit phased retirement, they are not usually singling out older workers; they would deny a similar reduction in hours to a young worker.

Given that most employers indicate that they would be open to working out phased retirement, why is phased retirement so rare? Of course, part of the answer may be that some workers are just not interested in phased retirement. For example, there is evidence that women are more interested in phased retirement than men, and that—at least for women—interest in phased retirement is greater if one's spouse is not retired.

But given the previously noted survey data indicating that many older employees would like to reduce their working hours as they approach retirement, it is difficult to claim that the small number of phased retirements is due to lack of interest. While strong conclusions are not possible, there is reason to think that the terms of the employer's offer of phased retirement may not be especially attractive to many older workers. The employer's offer may require a shift to a new job in the establishment as well as a change in health insurance. Health insurance may be especially important; many employers offer health insurance to full-time workers but not to part-time workers. Older workers may reflect on such an offer and decide that they would rather not take phased retirement but would rather either remain full-time workers or become full-time retirees.

PHASED RETIREMENT AND GOVERNMENT POLICY

In part because it may reduce the incidence of early retirements, many national governments have sought to encourage phased retirement. The United States has not been a leader in this area. In the United States, the primary focus has been on promoting work at older ages. In particular, changes in the Social Security

program such as the elimination of the earnings test or the gradual increase in the normal retirement age encourage all forms of work, including phased retirement. There have, however, been legislative proposals for changes in the rules regulating how defined benefit pension plans handle phased retirement. For example, the Phased Retirement Liberalization Act was introduced in Congress in 2000. It would have permitted active employees to receive benefits from a defined benefit pension plan prior to the plan's normal retirement age. This legislation was controversial and did not become law.

European countries, including France, Germany, Sweden, Finland, and the Netherlands, have been more active than the United States in implementing government policies aimed at expanding opportunities for phased retirement. For example, Germany and the Netherlands grant older workers a limited legal right to a part-time job with their full-time employer, that is, if full-time older workers ask for part-time work, there are conditions under which their employer is obligated to provide it. To date little is known about the impact of such policies.

One country with notable success in encouraging phased retirement is Sweden. From 1976 to the late 1990s, Sweden had a partial pension program whereby older people who shifted to part-time work received a payment from the government equal to about half of the associated lost earnings. Before 1994 this benefit was available after age 60, and from 1994 on it was available to people after age 61. One estimate is that in some years as much as 27 percent of the eligible workers took advantage of the program. In most cases, workers stayed in the same job with the same employer. Due in part to the restructuring of the Swedish public pension system, this government-financed program was phased out in 2001.

All indications are that with the aging of the baby boom generation, more older people will be available for work. Moreover, changes in both Social Security and private pensions (in particular, the rise of defined contribution pensions) are increasing financial incentives for work. It is then likely that in coming years increasing numbers of older people will want to work, and many of them will want part-time work. Phased retirement could be a very good way to accommodate that desire.

POSITIVE ORGANIZATIONAL SCHOLARSHIP

Positive organizational scholarship (POS) focuses on the generative (that is, life-building, capability-enhancing, capacity-creating) dynamics in organizations that contribute to human strengths and virtues, resilience and healing, vitality and thriving, and the cultivation of extraordinary states in individuals, groups, and organizations. POS is premised on the belief that enabling human excellence in organizations unlocks latent potential and reveals hidden possibilities in people and systems that can benefit both human and organizational welfare. POS does not adopt one particular theory or framework but instead

draws from the full spectrum of organizational theories.

The term *positive organizational scholarship* describes what this perspective is about: positive, because it emphasizes elevating, affirmative, and generative states and dynamics; organizational, because it highlights how these generative dynamics unfold within and across organizations; and scholarship, because it emphasizes theoretically informed accounts, backed by data and analysis, that suggest implications for organizational functioning, practice, and teaching. When applied to career development, POS uncovers new ways of thinking about antecedents and outcomes of career development and suggests new research questions about the career development process.

ORIGINS OF POS

Although the POS perspective is relatively new, its core ideas were seeded by the ideas of earlier scholars. POS origins developed in parallel, though a few years behind, the Positive Psychology movement, initiated in 1998 by Martin Seligman and colleagues. Positive Psychology aims to shift the focus in psychology from dysfunctional mental illness to mental health, calling for an increased focus on the building of human strength (as opposed to shoring up human weakness), a focus on creating good lives for healthy people (as opposed to healing people who are psychologically distressed), and building the best in people (as opposed to repairing the worst). POS is a cousin to the Positive Psychology movement—POS broadens the focus by examining these thriving and generative dynamics within organizations and by emphasizing the role of embedded contexts (extraorganizational, organizational, and intraorganizational) in explaining generative dynamics and positive states of individuals, groups, and organizations.

Positive organizational scholarship also provides a theoretical grounding for an organizational development and change paradigm called Appreciative Inquiry, introduced by David Cooperrider in 1986, which has become a widely adopted change practice used in organizations globally. The core premise of Appreciative Inquiry is that change involves search and discovery processes that value, prize, and honor the life, or what is called the "positive core," in an organization.

POS is an interdisciplinary perspective, drawing not only from psychology and organizational theory but

also from sociology, anthropology, and social work. Different aspects of POS focus at different levels of analysis and on different aspects of positive dynamics. For instance, one subset of POS, called positive organizational behavior, focuses on positive individual-level states (e.g., confidence, hope, optimism, resiliency) and their development. More macrolevel POS perspectives view positive dynamics through the lens of institutional theories, network models, and resource-based views of the firm; here the focus is on the creation, diffusion, and legitimation of POS practices in business units and organizations as well as the development of generative capacities such as resilience and capability building. For instance, network researchers have demonstrated how positive energy networks in organizations (e.g., ties with other people with whom one subjectively experiences a heightened sense of energy) explain individual and project performance over and above information networks. Institutional perspectives highlight the changing context of positive organizational practices and the struggle of reproducing such practices within and across organizations as well as the generation of alternate forms of practices. Finally, other scholars focusing on intangible organizational assets draw attention to how a positive organizational identity may build social and reputation capital for the firm and its members.

CORE ASSUMPTIONS OF POS

Several key assumptions underlie the POS perspective. First, an assumption in POS is that the factors that bring about a problem state (organizational stress, for example) are not necessarily the same factors that cause an extraordinary or positively deviant state (organizational thriving, for example). Just getting rid of the conditions that cause stress will not be sufficient for creating thriving at work. Thus, to theorize what promotes and enables positive deviance (above normal, extraordinary states that are good, honorable, or virtuous) may require new or slightly altered theoretical lenses and explanations than what currently exists in organizational studies.

Second, a POS perspective draws attention to a broader repertoire of human and collective states that organizations impact but which organizational scholars study only sporadically. In effect, POS enlarges the domain of outcomes that are examined. The POS focus on the positive and affirmative means asking questions about what individual and organizational

conditions (and their interactions) account for valued human conditions such as resilience, vitality, thriving, fulfillment, transcendence, courage, flourishing, integrity, wisdom, as well as other individual and collective virtues and strengths. POS reemphasizes the importance of outcomes such as well-being, citizenship, and health not only as means to the desired end of strong economic performance but also as ends worthy of explanation on their own.

Third, a POS perspective assumes that organizational scholars benefit from considering how, why, and when various positive states shape individual, group, and collective behavior. For example, there is a growing body of research on three possible engines of life-giving dynamics in organizations: positive emotion (e.g., joy, happiness, contentment), positive meaning (e.g., seeing one's job as a calling, perceiving one's organization as virtuous, assessing one's career as valuable), and positive connections (e.g., connections with others that are trusting, mutual, respectful, and enabling). While these topics have each been considered in isolation within various research domains in organizational studies, a POS lens encourages consideration of how they interrelate as core engines of generative and life-giving dynamics in individuals, groups, and organizations.

Fourth, POS assumes that it is important to focus on positive states and positive dynamics as a corrective to the hard-wired human tendency to attend to the negative more than the positive. Psychologists have conducted exhaustive literature reviews of psychological research and concluded that, when it comes to perceptions, the bad trumps the good. For example, we are more deeply affected by losing \$50 than by gaining \$50. The effects of negative events take longer to dissipate than the effects of positive events. However, work by Barbara Fredrickson and Marcial Losada suggests a way to counterbalance this basic human tendency. They found that a 3:1 mathematical ratio of positive to negative behaviors, communications, or emotions activates the broadening and building dynamics that enhance the capacities of individuals, dyads, and teams to act. Thus, given the human tendency to weight the negative more heavily, a POS perspective offers a counterweight, alerting our attention to the importance of amplifying the positive.

DOMAINS OF POS INQUIRY

Currently, there are several identifiable domains of inquiry that are taking shape under the broad umbrella

of positive organizational scholarship. One domain involves virtuous processes, strengths, and positive organizing; it includes work on individual and organizational virtues, integrity, compassion, resilience, wisdom, human strengths, and positive identity. A second domain involves the study of upward spirals and patterns of positive change; it includes work on appreciative inquiry, positive deviance, positive emotions, knowledge creation, and positive leader development. A third domain focuses on positive meanings and positive connections; it includes work on the dynamics of vitality and energy in organizations, relationships, cooperation, and creativity. Another domain focuses more on the institutional and structural aspects of POS; it includes work on developing and reproducing organizational designs that enable positive dynamics and outcomes. All these domains of POS inquiry are a blend of new and old theoretical perspectives that find a fuller integration under the POS umbrella.

POS INVITES EXPLORING NEW FRONTIERS FOR CAREER DEVELOPMENT

Positive organizational scholarship opens up possibilities for career research by posing innovative questions that redirect and motivate studies; these are complementary to existing thinking about careers but do stretch the reach of both POS and careers research into several new directions. First, POS invites career researchers to consider the antecedents and dynamics of positively deviant career-relevant outcomes. For example, we might ask, Under what conditions do individuals' careers flourish or enable people to live within an optimal range of human functioning? For example, some researchers have asked, What enables people to view their jobs and careers as callings? Alternatively, What are the contexts that enable people to have moments or episodes of career thriving, where thriving is defined as the experience of increased vitality and learning? Or, as other researchers have asked, When and how do work and family roles enrich rather than deplete the individuals and their organizations?

Second, POS may help career researchers see a complementary perspective to traditional research questions in career research. Traditional research on career problems (whether early career setbacks, mid-career plateauing, or retirement adjustments) has focused on understanding how people cope and rebound to where they were before the setback or adjust

to the new work situation. A POS lens shifts the focus slightly, redirecting attention to looking at how people can be resilient and grow in response to career setbacks, discovering perhaps new or unexplored career possibilities. For example, a large body of research on organizational downsizing documents how difficult it is for victims (or those laid off) to find new jobs at their previous level/compensation. However, rather than simply restoring people to their pre-downsizing levels, POS opens up the possibility that there may be many positively deviant workers who are energized by the opportunity to break out of old patterns and do something really different and meaningful. A POS lens would suggest more work on these positive rebounds and creative career redirections.

A third way in which a POS perspective might help reframe careers research is that POS invites consideration of different mechanisms to explain career-relevant processes and outcomes. For example, POS researchers might inquire as to when and how positive emotions, positive connections, and positive meaning, both in isolation and in interaction, contribute to desirable career-relevant outcomes. For example, how do organizations enrich and enable positive meanings about different roles and different careers, and what effect do these positive career-relevant meanings have for the individuals and for the organization? How do occupational, professional, and organizational contexts contribute to inspiration, hope, and a sense of possibility for different career development end states and career development pathways? How do different organizational features (e.g., culture, design, strategy, leaders) amplify and/or buffer the psychological conditions that propel individuals to deeply satisfying, authentic, and capability-building careers?

A fourth way that POS might offer new insights in career research is in the reframing of mentoring. Traditional research on mentoring has focused on how mentors contribute to the mentee's capabilities, job performance, and career trajectory. The focus is on how mentors help protégés. POS suggests a slight reframing of mentoring research to focus more attention on the effects of mentoring on the mentor. For example, recent research has suggested that the givers of social support actually receive more benefits than the receivers. Other research confirms the health-promoting, stress-relieving benefits of coaching for mentors. Thus, a POS lens would suggest focusing on the effects of mentoring on the mentor rather than on just the mentee.

Finally, a POS perspective introduces new topics for consideration that do not fit neatly into current career development topic categories. For example, it encourages consideration of how career behaviors and pathways cultivate different human strengths and virtues. It invites consideration of how organizations cultivate positive identities and shape conditions in which individuals can grow toward a “best self.” It considers how individuals can grow and develop not only in response to threats, challenges, and hardships but also to positive jolts that highlight the best in people and systems. It asks how career patterns contribute to the creation and sustenance of organization-level virtues or strengths such as wisdom, integrity, compassion, or justice. Overall, a POS perspective on career development and management invites an enriched and integrated approach to understanding ways in which career options can ultimately better both people and organizations.

CONCLUSION

The POS approach is an emergent and growing perspective on individuals, groups, and organizations that can shift our view of career development in organizations. POS offers a fresh view of individuals and organizations as sites or moments of vitality or flourishing and life-giving dynamics. Through the POS lens, then, the career choices of individuals and the recruitment efforts of organizations are redirected toward building human capital that enables those conditions and encourages the best of the human condition. A POS perspective focuses on how organizations can be sites of human and collective strength and capability building and thus, in employment interviews and in career planning, the focus is on building the best self (instead of countering the worst) and developing capabilities, rather than simply compensating for shortcomings.

PROACTIVITY

Proactivity refers to the idea that individuals initiate action and make constructive changes in their environment. As careers have become more fluid and self-structured, the concept of proactivity has become increasingly relevant to career development. In the past several years, researchers have defined the concept in terms of dispositional tendencies to act proactively, cognitive processes that lead to initiating action, and the behavioral manifestations of proactive people.

PROACTIVE PERSONALITY

One approach is to view proactivity as an individual disposition and examine individual differences in the extent to which people engage in proactive behaviors. Proactive personality has been defined as a stable disposition to take initiative in a broad range of situations and environments. The role of proactive personality in shaping one’s work environment is consistent with the

interactional perspective in which situations are viewed as much of a function of people as vice versa. People high on proactive personality can thus be characterized as people who are relatively unconstrained by situational forces, identify opportunities and act on them, and persevere until they bring about meaningful change. Proactive personality has been shown to be distinct from other personality traits such as extraversion, agreeableness, and conscientiousness. Proactive personality has been related to a number of employee outcomes, including job performance, leadership effectiveness, participation at work, tolerance for stress, entrepreneurship, and career success.

Concerning career development, a proactive personality is particularly important as the responsibility for managing one's career falls increasingly on employees. Highly proactive individuals create situations that enhance their likelihood of success and maximize their own job and career satisfaction. Empirical research has shown that individuals rated high on the proactive personality trait had achieved higher salaries, more promotions over their lifetime, and were more satisfied with their careers. In a large sample of managerial and technical workers, proactive personality had a positive effect on all three career outcomes after controlling for a number of demographic, human capital, motivation, and industry variables.

PERSONAL INITIATIVE

A second line of research on proactivity examines the underlying processes motivating a person to take initiative. According to this perspective, personal initiative is a behavioral syndrome in which individuals take an active and self-starting approach to work that is (1) consistent with the organization's mission, (2) has a long-term focus, (3) is goal directed and action oriented, and (4) is persistent in the face of barriers. Personal initiative is based on action theory, which states that individuals, to a certain extent, always plan actions, and actions are guided by goals. A long-term goal orientation is the essential element of personal initiative. Accordingly, an action-oriented person will develop a fuller set of goals that go beyond what is formally required in the job, are long-term focused, and are quickly translated into actions. In the implementation of one's goals, initiative implies that one will deal with obstacles actively and persistently. Personal initiative has been shown to be correlated, yet distinct, from the personality traits of need for

achievement and an action orientation and from problem-focused coping strategies.

With respect to career development, it has been found that individuals high on personal initiative were more likely to have developed and executed long-range career plans and had higher intentions of being self-employed. Among those who were unemployed, those high on personal initiative were more likely to be employed a year later than those low on personal initiative. These findings indicate that one's level of personal initiative impacts career planning, career choices, and job search success. It is important for career development policies and programs to consider conditions that lead to higher or lower initiative among its employees. For example, control over work conditions and task complexity increase personal initiative by empowering employees and encouraging them to develop their knowledge and skills. Career development programs need to consider the theoretical underpinnings of the personal initiative concept to teach employees to be goal directed and action oriented in developing and executing their career plans. Both the organization and the employee will reap benefits from such an approach to career development.

PROACTIVE CAREER BEHAVIORS

A final stream of research on proactivity has focused more on what proactive people do. Proactive behaviors have been defined as those that show initiative in improving circumstances or creating new ones and those that involve challenging the status quo rather than passively adapting to present conditions. For example, research has found that individuals high on proactive personality were more likely to engage in innovative behaviors, had more knowledge of organizational politics (i.e., knew who the influential people were in the organization), and took more initiative in planning their career strategies and updating their skills.

Efforts have also been made to develop typologies of proactive career behavior. Applying the extensive research on proactive behaviors during organizational socialization to the boundaryless career concept, researchers have identified four proactive career behaviors. First, career planning refers to setting goals, exploring career options, and formulating plans. Second, skill development refers to mastering important competencies for one's occupation. This includes building one's reputation through work experiences and increasing relevant knowledge, skills, and abilities.

Career planning and skill development help employees develop and implement career goals consistent with the concept of personal initiative. Third, consultative behaviors include information seeking, advice giving and help giving and receiving. Through consultation, individuals establish relationships with supervisors and colleagues that can benefit their careers. Fourth, networking behaviors build interpersonal relationships that can be used as learning systems. Networking behaviors help one navigate organizational politics and provide access to resources and information, both of which benefit one's career. Career development programs need to encourage all employees, especially those low on proactive personality, to engage in the proactive behaviors identified above.

IMPLICATIONS

A greater understanding could be achieved by integrating the three perspectives on proactivity to provide practical advice to career strategists. Individuals, especially those low on proactive personality, may need to incorporate proactive career behaviors and the concepts of personal initiative in managing their own careers. At the same time, organizations can offer employees opportunities and learning experiences that encourage the kinds of goal-directed behaviors consistent with action-oriented personal initiative.

PROCEDURAL JUSTICE

Researchers from a variety of disciplines within psychology have come to the conclusion that people care a great deal about fairness. One stream of this research, organizational justice, focuses on issues of justice in the workplace. Whereas most justice researchers agree that organizational justice is a multidimensional construct, this entry focuses on one particularly important dimension of justice called *procedural justice*.

DEFINITION

Procedural justice is generally defined as the perceived fairness of the procedures used to make decisions. In organizations, these decisions often involve allocating resources such as promotions or raises. While people are certainly concerned with the fairness and favorability of their outcomes, the procedures used to arrive at these decisions can also influence peoples' reactions.

AN OVERVIEW OF PROCEDURAL JUSTICE

John Thibaut and Laurens Walker first demonstrated the importance that people place on procedural justice. These researchers examined process control, which refers to the opportunity to voice one's opinion, and decision control, or the ability to influence the outcome via one's voice, in the context of legal negotiations. They found that people were willing to give up decision control as long as they were still allowed to voice their opinions about the process used to negotiate a decision. The process control idea has been extended into organizational settings, where employees see procedures as fair when the procedures are correctable, ethical, unbiased, based on accurate information, used consistently, and consider stakeholders' opinions. So why do people care about procedural justice? One theory, the instrumental model, states that people care about procedural justice because fair procedures should lead to fair and favorable outcomes over time. The relational model has a different take on this, arguing that people care about procedural justice because fair procedures signify that one is valued by the group. The relational model also has implications for the self, as fair treatment can affect one's identity by verifying that one is a valued group member.

Perceptions of procedural justice affect a number of important attitudes and behaviors, such as job satisfaction, organizational commitment, trust, perceived organizational support, self-esteem, and identity. Procedural justice also influences performance, withdrawal, turnover, discrimination-claiming behavior, and organizational retaliatory behaviors such as employee theft. Organizations should be concerned with the fairness of their procedures, which can also have significant implications for career development. Before describing the implications of procedural justice for career development, this entry briefly discusses career management systems in today's workforce. It then presents three major decisions or processes involved in career development—(1) choosing a career, job, or organization, (2) advancing within an organization, and (3) changing careers or organizations—and highlights the important role that procedural justice plays for both the individual's career development and the organization's success.

CAREER MANAGEMENT SYSTEMS

A great deal has been written about the changing nature of work and the move from traditional employment, where employees spent their entire careers with one organization, to a more dynamic career path. This shift to a protean career, a career that changes frequently due to changes in the employee's interests or work environment, requires that employees take responsibility for their own career development. This is important, as most employees today do not stay with the same organization for the duration of their time in the workforce. This new relationship between employees and employers creates a definite need for organizations to invest in a career management system. These systems vary a great deal in terms of their focus and goals. For instance, some systems may focus more on helping employees understand their career values, interests, and abilities, whereas other systems may center on short- and long-term goal setting. Other organizations may create a system with clearly established career paths within the organization, whereas another system may be less formalized. Regardless of the system's structure, career management is a shared responsibility among different partners and therefore becomes largely affected by interactions among those partners. The employee, manager, and organization share responsibility for supporting career management, although each partner

has different role responsibilities. Employees should perform well, discuss career-related issues with their managers, identify areas that need improvement, and establish career goals. The manager's role requires effective coaching, counseling, communication, and use of the organization's resources. Finally, the organization is responsible for creating a culture and systems that support career management.

CHOOSING A CAREER, JOB, OR ORGANIZATION

As individuals enter or reenter the workplace, their employment choices should ideally support their career goals. While a number of factors affect these decisions, the impression that an organization gives to potential employees will influence the likelihood that these individuals will pursue a career with that organization. Thus organizations should ensure that their recruiting policies and practices are procedurally fair with regard to relevant guidelines such as the EEOC, contractual policies, and labor practices. However, it is also important to consider potential employees' perceptions of the organization's recruiting procedures. If an individual does pursue a job within that organization, procedural fairness during the selection process is also critical. Potential applicants' perceptions of the organization go beyond recruitment and selection procedures, however. For example, an organization that values development and operates a solid career management system may attract better candidates and ultimately cultivate greater social capital. This should serve to enhance employees' perceptions of procedural fairness with regard to their career development and related issues. Furthermore, once new employees begin their employment, it is crucial that the organization provide beneficial training and development opportunities, because this will enhance new employees' perceptions of procedural fairness. These early experiences influence subsequent attitudes and behavior, and it is difficult for the organization to change employees' negative impressions once they are set.

ADVANCING WITHIN AN ORGANIZATION

In organizations that have career management systems with clearly established career paths, the organization should do its best to communicate the purpose of the system and how it operates, as this will enhance perceptions of procedural fairness. Employees should

know what competencies are important for success in the various positions and the developmental activities needed to develop these competencies. If an organization establishes formal procedures for determining when developmental activities occur and who participates, these procedures should be applied consistently, ethically, and without bias. Employees should be allowed to appeal the decisions, and the information used to make these decisions should be as transparent as possible. Organizations should consider allowing employees to participate in designing the procedures used to make these decisions, because this will likely enhance their perceptions of outcome fairness. All of these activities have been shown to promote perceptions of procedural fairness. These issues also have implications for talent retention, because employees who perceive the career management system as procedurally unfair may leave the organization prematurely. This can have serious consequences for the organization, particularly if the organization is concerned with succession planning.

Following from the protean career, effective development now focuses less on formalized training and more on building relationships and gaining experience. Thus, organizations should consider what they can do to enhance these outcomes. For example, employees may benefit from job rotation, either within a work team or across areas of the organization. Creating opportunities for employees to network with others in the organization or industry may also be beneficial to both the employee and the organization. Organizations should also reward employees for participating in these activities, as this sends a strong message that employees' learning and development are valued. Thus, organizations should ensure that their culture and systems support career management. However, managers also play an important role here. For instance, they need to coach employees through the development process and demonstrate supportive communication. It is important to keep in mind that the interactions between employees and managers, as well as with the organization, can affect perceptions of procedural fairness. Thus, managers need to clarify performance expectations, provide adequate feedback, and treat employees with respect during these interactions.

Because so much hinges on the developmental opportunities an organization provides, organizations should take care to implement these opportunities in a procedurally fair manner. For instance, information regarding developmental opportunities and possible

career moves should be made available to all employees to enhance perceptions of procedural justice. Special consideration should be given to employees whose skills may quickly become obsolete. The organization should ensure that these employees have access to developmental activities that will update these skills or teach skills that will be needed in the future. This is especially important if the organization anticipates laying off employees. When an organization makes a good faith effort to develop and prepare its employees for future work, even if these employees will eventually leave the organization for one reason or another, several positive things can happen. For example, employees who are laid off will react more favorably to their negative outcome, be less likely to pursue discrimination-claiming litigation against the organization, and be more likely to speak favorably of the organization. This also enhances the reputation of the organization as a positive place to work, which can serve as a powerful recruiting tool.

Once the organization is ready to make promotional decisions, issues of procedural justice will again arise. The organization should ensure that these procedures are fair before implementing them to make promotional decisions. However, employees' perceptions of these procedures must also be managed. Again, this can be done by allowing employees to voice their opinions about how promotional decisions should be made. Procedural justice may be especially important when these types of decisions are made because the organization cannot promote a large number of employees, particularly in organizations with a flat hierarchical structure. Thus, there will generally be many employees who are not promoted at any given time. If not promoted, employees who view the procedures used to make these decisions as fair will most likely perceive their unfavorable outcome as fairer than they would had the procedures been unjust.

CHANGING CAREERS OR ORGANIZATIONS

Many researchers have stated that the nature of employment between an employee and an employer is dramatically different from the past. Employees used to expect that they would be employed by the same organization for the duration of their careers and that they would eventually be promoted up the hierarchy. However, this employment arrangement has become outdated, as organizations must be flexible and responsive to customer demands and other environmental

changes. Employees need to understand this and take responsibility for their career development, focusing on their lifelong career goals and learning objectives. For example, employees need to ensure that they are performing as effectively as possible and regularly communicating with their manager concerning career development goals and progress. Employees must also know where they want their careers to go and be able to identify areas where they require development, although this can be difficult to do. On the other hand, this change also shifts a different kind of responsibility onto organizations. Because most employees spend several years with any given company, organizations should ensure that they provide the best developmental opportunities, given the organization's constraints and environment. In other words, organizations need to provide helpful learning and development opportunities, which should benefit both the individual and the organization. To many employees, the fairness of these programs and opportunities is absolutely critical.

Because of this shift in the nature of employment, employees need to know that their organization will provide strong developmental opportunities. Moreover, when organizations provide developmental opportunities and information about career prospects, employees should show stronger career motivation. This in turn benefits employees because they gain insight into their own strengths, areas needing development, and career interests. Developmental opportunities also engage employees in learning activities, ensure that their skills do not become outdated, and provide strategies for handling stressful working conditions. Organizations benefit because employees' career motivation is enhanced, which could encourage innovation, organizational commitment, flexibility, and pride in one's work. Organizational justice plays a major role in organizations of the twenty-first century, and its role in career development will continue to grow as employees recognize the increasing importance of career management to their working lives.

PROTEAN CAREER

The *protean career* is a name given to describe a career that is driven by the individual and not by the organization. The concept of the protean career dates to 1976, when in the book *Careers in Organizations*, Douglas T. Hall noted an emerging type of career form that was less dependent upon the organization in terms of defining success or achieving certain outcomes.

The most central characteristic of the protean career is that it is a reflection and manifestation of the individual career actor. An individual with a protean career—or one who is protean—is thought to put self-fulfillment and psychological success above concerns and norms that would have their source outside of the individual. Psychological success is considered to be subjective success on the person's "own terms" in contrast to "objective" success that might be measured or defined externally (e.g., by salary or promotions). While a protean career might be identified externally as a definable career pattern, the literature and this entry are primarily concerned with how the career is enacted, managed, defined, and evaluated from the individual's subjective perspective.

Two broad dimensions of the protean career are (1) a values-driven career orientation and (2) self-directed career management. Having a values-driven career orientation means that the career actor is defining career values on his or her own terms and assessing career success according to those terms. Self-directed career management occurs when a career actor actively manages his or her own career development according to personal values.

Because of the emphasis upon following one's own career path, authors in the field have often associated the protean career with careers and lifestyles that are independent of a heavy commitment to or reliance upon an employing organization, or upon traditional status symbols such as income. Although protean career actors have been assumed to be more interested in learning and in achieving life balance and self-fulfillment, strictly speaking a person could independently (in a protean fashion) select traditional career contexts and value some of the symbols of success they portend, including income and advancement.

HISTORICAL AND CULTURAL CONTEXT OF THE PROTEAN CAREER

In understanding the original and evolving definition of the protean career, it is important to realize that it emerged at a time when organizations and their influence upon careers were relatively dominant as compared to today's standards. Indeed, while individually driven careers have certainly always existed, thinking about career development as decisively independent of the organization was a novel approach in 1976.

Interest in the protean career concept grew in part due to the tumultuous organizational and business environment of the late twentieth and early twenty-first centuries. Because of downsizing, rapidly changing economic conditions, globalization, advances in technology (that allowed things such as telecommuting), increased emphasis upon contingent workers, and changing societal values around the importance of work and nonwork priorities, careers in fact became more individualized proactively or reactively on a wide scale.

A major shift relevant to the protean career involved a change in the "psychological contract" between employers and employees—simply put, what they expect of one another. A shift was seen from the traditional and "relational" contract that stressed loyalty on both sides of the contract to a "transactional" contract in which employers do not guarantee

employment but provide opportunities, and employees do not promise loyalty but do commit to high performance. Some have opined that these broad trends are exaggerated; others suggest that emerging contracts mix aspects of both the traditional and relational perspectives. What is indisputable is that the psychological contract is perceived to have shifted in a way that encourages individual management of a career.

Research has shown that it takes many organizations and employees several years to recognize and cope with the changing psychological contract and to make associated changes in career development efforts. Such organizations start with stages characterized by trauma before they are later able to adapt to the new contract. A minority of organizations are able to leverage a learning culture into a less dramatic transition based upon continuous employee and organizational learning.

The rapid emergence of the "boundaryless" career concept in the 1990s may have benefited from as well as benefited the complementary protean career concept. While the boundaryless career crosses many different "boundaries" that are more negotiable than before, its primary characteristic is that it plays out across multiple *organizational* boundaries. The implication is that a protean career approach is more obvious and functional in such a setting. Many authors have treated the protean and boundaryless careers as almost synonymous with one another, and in fact the chief scholar behind the boundaryless career concept, Michael A. Arthur, has collaborated on several works with Hall intertwining the two concepts. But as the two theories mature into constructs, their distinctive nature and myriad combinations in theory and practice are becoming evident.

Some scholars have seen the protean career in a Western or Anglo-Saxon context partly because of its origin and development primarily in U.S. business schools and because of its obvious preoccupation with the individual. While research in several Western cultures has shown the protean career construct to be a reliable and robust predictor of career outcomes, it is underresearched in non-Western and collectivistic cultures and should not be used to draw conclusions in such contexts until further research is done.

INDIVIDUAL DIFFERENCES AND THE PROTEAN CAREER

Because research constructs for measuring protean career attitudes and approaches have only recently

been developed, the empirical validation of protean career measures falls short of the theoretical maturity of the concept at this juncture. Some research has indicated that protean career attitudes are linked to a constellation of other career attitudes that might be considered “agentic” in nature. For example, strong correlations have been found between the protean career and a proactive personality, career self-efficacy, and a boundaryless mind-set. Furthermore, the protean career has been correlated with a “mastery” or learning orientation toward goals. This is in contrast with a performance orientation, which would entail a concern with success as defined by others rather than by oneself.

To this point, research has not definitively shown whether protean career identity and attitudes are associated with one’s age or gender. In terms of age, some have pointed out how acting in a protean fashion may be more challenging as one ages, especially if one has become accustomed to the traditional psychological contract wherein the organization assumes most of the responsibility for career development. But some studies have actually found a moderate positive relationship between aging and protean attitudes, whereas other research suggests that a protean orientation to the career is consistent across age groups.

CAREER DEVELOPMENT AND THE PROTEAN CAREER

Rationale for Developing a Protean Career Approach

Addressing career development begs the question of “why?” Why develop people to be more protean? It has been assumed in the literature that the organizational environment is less predictable, much more fluid, and less forgiving than in the past. Within such an environment it is further assumed that a more self-directed approach to the career is advantageous for purposes of adaptability and for enhancing the likelihood of subjective career success. Other presumed benefits of a protean approach to the career are that it will enable career actors to adjust to change better, which will benefit organizations as well as employees. Limited research has suggested that protean career actors do in fact adapt more quickly to organizational change and unemployment.

Jon P. Briscoe and Hall have argued that for a protean career approach to reap its ultimate benefit for the

career actor, both a values-driven career orientation and self-directed career management are necessary. They argue that one who is high only in a values-driven orientation will be rigid and one who is high only in self-directed career management will be able to drive and react to career changes but not ultimately be grounded. Obviously, being low in both is problematic, but individuals who are high in both protean dimensions are expected to be more transformative in terms of their career and potentially able to offer more transformational skills to their organizations as well.

As the “new” career has gained recognition in academic and practitioner circles alike, some organizations have viewed protean and boundaryless career forms with suspicion. In such organizations, the suspicion seems to be that protean or boundaryless employees may be less loyal and committed. Interestingly, several emerging studies suggest that this is not necessarily true. Some studies have suggested that protean employees become committed to their organization affectively (“I want to remain in the organization”) and normatively (“I should remain in the organization) for the same reasons as other employees. There is some evidence that protean employees are less likely to remain in the organization simply for economic advantages. Research suggests that employees prefer cultures that allow for innovation, independence, and value expression.

SKILLS RELATED TO THE PROTEAN CAREER

Hall has proposed two broad skills or “metacompetencies” that relate to the protean career—identity (self-awareness) and adaptability. He refers to these as metacompetencies in that they allow the career actor to “learn how to learn.” Identity awareness and understanding are seen as key to the values-driven nature of the career and to having a secure personal base in which to ground oneself and from which to experiment based upon changing external conditions. Adaptability involves the ability to change career and work behaviors in a way that allows one to succeed in a variety of potential contexts without the constant need for externally driven career development.

With both identity and adaptability skills, ongoing reflection is seen as a requisite “fuel” that challenges and develops the individual’s identity, values, assumptions, and skills across the course of his or her career. Thus reflection itself might be considered a requisite skill in the protean career.

IMPLICATIONS FOR CAREER DEVELOPMENT

Broadly speaking, career development practices that help individuals increase their identity awareness, adaptability, and reflection skills will enhance their protean attitudes and identity. A large barrier to self-development with respect to the protean career is the inability to go beyond adaptation to career challenges and step back to reflect upon identity, career assumptions, and working definitions of success. Research has suggested that such "double-loop" reflection on both identity and adaptability is relatively uncommon and thus represents a prime target for the focus of career development. Because double-loop learning is apparently not natural for many people, especially in areas that are taken for granted such as identity and values, this is an area that might require outside intervention to stimulate many individuals to address it.

The current dynamic organizational environment is rich in its ability to provide a variety of experiences from which the individual could "learn to learn" and in the process enhance the metacompetencies of identity and adaptability. In this sense, development opportunities abound. For individuals this implies trying to target and obtain experiences that enhance identity, adaptability, and reflection skills. The implications for organizations wishing to assist in career development is similar, except that it is expedient to ensure that the individual is a strong, independent influence upon the process.

Philip H. Mirvis and Hall have conceived of the protean career as a series of learning cycles. Through such a lens, the learning cycle becomes the key frame through which individuals and those interested in their development can attempt to leverage advances in career insights and skills.

Beyond skills in reflection and developmental experiences themselves, relationships are a major vehicle for the career development of the protean career actor. As outlined by Kathy Kram, relationships can provide learning to the career actor as well as emotional and developmental support. Such benefits allow for growth and reflection in both adaptability and identity. A paradox in the new career environment, however, is that although some of one's most developmentally oriented relationships are at work, these relationships are vulnerable to the volatile forces of business. Thus it behooves the career actor to develop a rich network of relationships beyond his or her contemporary work environment.

As of this writing, the protean career concept is mature theoretically but in its adolescence empirically. It

has received wide acceptance as a template for understanding the "new" career. Its limitation empirically may be in part due to the fact that suitable research constructs have until recently lagged behind theory. In addition, the protean concept has been used at times prescriptively in addition to descriptively. This may have slowed efforts to understand it through a more rigorous perspective. Nevertheless, recent research findings indicate that the protean career can be measured in a reliable way, and further that it seems to impact career performance in the directions it has been postulated to. The next logical step is for practitioners and academics to better understand how such an approach might be best developed and whether it will be efficacious across cultures.

PSYCHOLOGICAL CONTRACT

The term *psychological contract* has been around since the 1960s and was first used to capture the

relationship between a work group of employees and a plant foreperson in terms of what the two parties exchanged in their relationship (acceptable wages and job security in return for higher productivity and lower grievances). This initial definition of the psychological contract is similar to what is currently known as normative contracts. A number of other definitions of the psychological contract subsequently appeared, giving rise to different views on what the psychological contract was capturing. For example, the psychological contract was defined as mutual expectations, an implicit contract, and a set of unwritten expectations between an individual employee and the organization. While the early work on the psychological contract was characterized by disagreement, since the late 1980s there seems to be broad consensus that the psychological contract captures an individual's perception of the mutual obligations that exist between that individual and another party.

In the context of the employment relationship, psychological contracts encompass what employees believe their employer has promised to provide in return for certain employee contributions. Whether the employer fulfills these obligations is contingent upon the employee fulfilling its obligations to the employer. For example, an employee may believe that the employer has promised to provide long-term job security, career development, interesting work, and competitive rewards in return for employee loyalty, flexibility, and meeting the formal requirements of the job (in-role performance) as well as going beyond the formal requirements of the job (extra-role performance). Consequently, the degree to which an employee receives career development, competitive rewards, and so on is dependent upon the extent to which the employee performs at the required level, is flexible, and so on. The terms of the psychological contract may be unspoken and unwritten, and there may not be agreement between the employer and employee regarding the obligations each has to the other.

A distinguishing feature of the psychological contract is its focus on contingent obligations whereby one party (the employee) must fulfill its obligations in order to receive promised benefits from the employer. As such, providing a safe work environment or treating employees fairly in terms of the procedures adopted to make decisions or interpersonally through the enactment of those procedures would fall outside the realm of the psychological contract; in most cases, these obligations are deemed universal, that is, the

employee should not need to fulfill any obligations in order to be treated fairly or to have a safe working environment.

TYPES OF EMPLOYMENT CONTRACTS

Psychological contracts sit alongside other types of contracts such as social, legal, normative, and implied contracts. However, the distinctive focus of the psychological contract on an individual's perception of mutual obligations differentiates it from social contracts that reflect culturally shared beliefs regarding the appropriateness of behavior within a given society. Legal contracts require objective evidence that contractual obligations exist—an acknowledgment by the parties to the contract or a judicial determination that an offer was made and accepted. In contrast to the objective standard required of legal contracts, the psychological contract is subjective; it resides in the eye of the beholder in terms of the perceived obligations that exist between the parties. The employee and employer may not objectively agree on their mutual obligations, but in the employee's mind, there is a perception of agreement.

A normative contract captures the psychological contract at the group level. In other words, where a group of employees working for the same employer hold a common set of beliefs regarding the employer's obligations to them and their obligations to the employer, a normative contract exists. The primary difference with the psychological contract is the level at which the contract is captured—normative contracts exist at the group level and psychological contracts exist at the individual level. An implied contract differs from a psychological contract in terms of the perspective adopted—the observer. An implied contract captures the attributions of a third party/outsider regarding the terms, acceptance, and mutuality of the contract in contrast to the “eye of the beholder” perspective adopted by a psychological contract.

Psychological contracts may not be enforceable (in contrast to legal contracts), they reside at the individual level (in contrast to social and normative contracts), and they capture subjective beliefs regarding obligations (in contrast to the objective stance of legal and the third-party perspective of implied contracts). Thus the psychological contract offers a distinctive and complementary lens to viewing “contracts” and in doing so offers a valuable framework for understanding the exchange integral to the employment relationship.

CONCEPTUAL GROUNDING OF PSYCHOLOGICAL CONTRACTS

The theoretical basis of psychological contracts draws on social exchange and the norm of reciprocity. Social exchange involves unspecified obligations such that when one party does another a favor, there is an expectation of a future return. This type of exchange relationship relies on both parties accepting the norm of reciprocity—when one exchange partner provides another with a benefit, there is an obligation on the recipient to return a benefit at some future point. The timing of the benefit and the nature of the benefit are not specified, which requires the donor to trust that the beneficiary will reciprocate at some future point. Because the relationship is long term, the recipient's willingness to remain obligated to the donor and the donor's trust in the willingness of the recipient to "repay" serve to strengthen the ongoing conferring of benefits and the discharge of obligations during the course of the relationship. In stark contrast, economic exchanges are tangible and do not require trust, as the investment in the relationship is minimal and time limited.

The distinction between economic and social exchange is paralleled in the literature on the psychological contract where two types of psychological contracts are distinguished: transactional and relational contracts. These contracts can be differentiated based on their focus, time frame, stability, scope, and tangibility. A transactional contract is one where what is exchanged is economic and extrinsic, and it remains static and observable over the specified length of the relationship. An example of a transactional type of contract would be seasonal work where an employee is hired to work for a specific period of time in return for economic rewards. The terms of the contract are tangible and remain static over the length of the relationship, for example, piecework whereby the employee is paid based on the quantity of strawberries picked. Finally, the scope of the contract is narrow where there is little spillover between work and personal life. When the seasonal worker's shift has ended, he or she has no obligation to the employer, and thus there is little chance that the worker's employment situation would affect their personal life. In contrast, doctors would be expected to help at the scene of an accident even though they are not on call, and as such, the boundary between work and personal life is porous.

A relational type of contract is manifested in employment relationships where employers hire employees at entry level with the view that they will be developed and remain with the employer until retirement. As the employer cannot specify in advance what an employee will have to contribute under a variety of unforeseen circumstances, the content of what is exchanged will be dynamic over the course of the relationship; it will involve an exchange of tangible and intangible resources that may not be specified and thus contain an element of ambiguity. The boundary between an individual's work life and personal life is permeable, as the employer provides a sense of identity and self-esteem for employees and thus the employer becomes important to an individual's self-identity.

Although both types of contracts are extremes, they reflect the potential gamut of types of employment from seasonal work to entry-retirement relationships. Within each, the nature of what is exchanged, the timing of the exchanges, and the perspective of each party to the exchange are very different. In personal relationships, the difference is akin to a "date" and marriage. The two parties in a relational exchange offer a range of benefits (status, love, money, services), have a view that they are entering a long-term relationship that facilitates delayed reciprocation that in turn enhances trust in the relationship.

CHANGES IN THE EMPLOYMENT RELATIONSHIP

Times are changing, and not surprisingly these changes have significant implications for the employment relationship. In particular, two general trends are visible: the decline in a collectivist and legalistic approach to employment relationships and the rise in different types of work arrangements as organizations respond to deregulation, increased uncertainty, and volatility in the economy and the pressures emanating from globalization. Together, these trends have given rise to increasingly diverse employment relationships that inject a degree of ambiguity as to the nature of what is exchanged in the employee-employer relationship.

In many countries, traditional labor laws have become less influential in determining the employment relationship. Declining trade union membership on a worldwide basis and the increasing proportion of individuals being employed in sectors not traditionally covered by labor statutes have resulted in fewer

employees' employment conditions being negotiated on a collective basis and fewer employment conditions being subjected to regulation by legal standards. Even in countries (e.g., Sweden) where trade union membership is among the highest worldwide, there has been a decline in membership and, arguably with it, a decline in collectivistic and solidaristic values.

Parallel to these changes, organizations have come under significant pressure to become more flexible and respond to changing market conditions. Technological advancements have changed not only where work is done but also when it is done, and they have given rise to and facilitated the view of a 24/7 society. In addition, the workforce has become more diverse, and to speak of the traditional male sole breadwinner is no longer appropriate. In addition to facing demands to become more outwardly flexible, organizations are confronted with pressures to become inwardly flexible, where employees themselves are increasingly expecting organizations to be more flexible in terms of the employment conditions being offered (e.g., variation in working hours, support facilities for young children, support for career sabbaticals, working from home part of the working week, etc.).

The need for organizational flexibility is leading employers to adopt more diverse employment arrangements, and this is taking the form of the increasing use of temporary employees, on-call contracts, fixed-term contracts, agency employees, seasonal workers, independent contractors, floats, and part-time workers. The diversity in employment arrangements is evident in a recent Bureau of Labor Statistics report, where 8.6 million U.S. workers identify themselves as independent contractors, 2 million as on-call day laborers, 1.2 million working for temp agencies, 0.5 million working for organizations that provide a client service on the client's site, 23 million as part-timers, and 7 million holding multiple jobs. The complexity of the current changes in the employment relationship is reflected in the rise of employees falling in the domain of multiple agency relationships, in which an employee works for two organizations simultaneously: the agency and the client organization. Furthermore, organizations are adopting greater flexibility in terms of business risks as they transfer some risks to employees through the introduction of profit sharing and profit-related pay schemes, share ownership, and finally differentiate between core and peripheral employees. Concurrently, employees are seeking individualized opportunities that fit their

career and work-family relationships and thus are expecting greater flexibility on the part of their employer to provide opportunities for the achievement of these goals.

In the context of changing societal expectations for speedier responses from organizations, the decline in legalistically driven regulatory frameworks, and the ever-decreasing collectivist approach to the employment relations, organizations are faced with the opportunity and pressure to develop idiosyncratic employment relationships with employees. In these changing circumstances, a conceptual framework is needed that allows researchers to explore diverse types of employment relationships, and the psychological contract offers this prospect.

FORMATION AND DEVELOPMENT OF THE PSYCHOLOGICAL CONTRACT

Individuals begin to form their psychological contracts during the anticipatory socialization phase, at which point their anticipatory contract consists of a naïve and imperfect schema about the nature of the exchange. An individual's contract schema originates in childhood and adolescence, where family, school, peers, and media influences as well as direct interactions with working individuals shape beliefs about what one should give and receive in an employment relationship. An additional influence is past work experience, and together these influences shape the lens through which an individual interprets a new employment relationship. Therefore, when organizational agents involved in the recruitment and selection stage send signals to potential employees regarding what the organization promises to give and requires in return, these cues are being interpreted by employees in the context of their own schemata. Furthermore, individuals' psychological contract schemas are shaped more implicitly through their inferences about perceived implicit promises made, interpretations of ambiguous or indirect statements, as well as the more subtle cues such as body language or how questions are answered.

Employees bring their anticipatory schema to the encounter stage, and during their first few months at work, they begin to experience what it is like to work in the organization, and this begins to modify their anticipatory psychological contract. During this stage, newcomers engage in a sense-making process where they actively search for information with the view of

making their psychological contract more complete and thus reducing the uncertainty and making their organizational experience more predictable. As a consequence of this sense-making process, employees' perceptions of employer obligations are adapted based on their interpretation of their organizational experience. For example, the promise of rapid promotion during the recruitment stage could be interpreted by the newcomer as promotion within six months, but based on their socialization experience (and more accurate information), they may revise their interpretation as meaning promotion after two years contingent upon an excellent performance rating at the annual performance review. Consequently, individuals may adapt their psychological contract schema as a result of actively searching for information as part of a reality check—a test between the anticipations of and the reality of the organizational experience.

Another process that shapes an individual's schemata is the norm of reciprocity. Here, employees adapt their psychological contract contingent upon how they perceive the behavior of the employer. Employees may adapt their obligations and contributions based on their perception that their employer has fulfilled its obligations to them. Thus, the ongoing conferring of benefits and discharging of obligations over time is likely to increase the number and diversity of the obligations exchanged as individuals attempt to create a positive imbalance, thus alleviating the tension associated with being in debt to the other party.

Once an individual's psychological contract schema is fully developed and reality tested, it becomes highly resistant to change, and individuals will take steps to preserve their initial schemata rather than fundamentally revise their contract. However, a fundamental revision may be necessary when organizational circumstances dictate a drastic change in its exchange relationship with employees. For example, in response to severe competitive pressures, organizations may consider moving a group of employees from permanent employment status to a contingent one or outsourcing the function to a different organization. Thus, an employee's contract schema that included job security, career development, and support in return for loyalty and performance may be irrevocably challenged.

Organizational agents may hold different psychological contract schema in terms of what is promised to employees and what employees are required to contribute in return. Thus, while employees may be

experiencing contract breach (e.g., as a consequence of moving to contingent status), organizational representatives may not have held the same schemata, and hence the divergent views and experience is a consequence of incongruence.

Incongruence arises when the two parties to the exchange have different perceptions regarding each other's obligations and the extent to which those obligations have been fulfilled. In other words, the employer and employee may disagree on whether an obligation exists or the specifics of that obligation. For example, both parties may agree that the employee is obligated to work overtime when needed, but the extent of the overtime and whether the overtime is compensated may be subject to differing perceptions. Consequently, incongruence can lead to either party perceiving that the other has not fulfilled one or more obligations, and this occurs as a consequence of both parties having a different perception regarding the existence and or meaning of the obligation. Organizations, therefore, need to take steps to minimize the occurrence of incongruence and hence reduce the likelihood of the resultant perception of contract breach.

Organizations can attempt to manage incongruence in a number of ways. First, they could take steps to ensure greater consistency in the signals sent by different organizational agents. For example, during the recruitment process when employees are forming their psychological contract, recruiters need to exercise caution that they don't make promises that others in the organization cannot fulfill or have no intentions of fulfilling (i.e., provide realistic job previews). Therefore, organizations need to ensure coordination and communication among agents to increase the likelihood of employees receiving similar messages irrespective of the source.

In addition to consistency in communication, organizational agents can communicate with employees on a regular basis to discuss mutual obligations. Frequent regular communications can serve as a mechanism for the adjustment of obligations and provide the opportunity to discuss and resolve divergent views. Agents may also influence employees' attributions of why they did not receive what they were expecting through communication—adequate justification for a decision can mitigate the effects of contract breach or reduce the likelihood of breach occurring. The use of formal and informal communication channels can serve to increase agreement between organizational agents and employees concerning their mutual obligations and the

fulfillment of those obligations, thereby reducing the subsequent development of contract breach due to differing perceptions.

CONSEQUENCES OF THE PSYCHOLOGICAL CONTRACT

A central thrust of much of the research on the psychological contract has focused on its consequences on employee psychological and behavioral outcomes. Specifically, researchers have examined the consequences of perceived contract breach that can occur as a result of incongruence or renegeing. The latter reflects an employer's unwillingness or inability to fulfill its obligations to employees. An employer may be unwilling to deliver on a promise to promote if the employee has underperformed or an employer may not be able to deliver on a promise of job security due to financial pressures.

The empirical evidence is strongly supportive of the negative consequences of perceptions of psychological contract breach. In terms of psychological outcomes, contract breach is associated with reduced employee obligations to the employer, lower trust in the employer, reduced affective commitment to the organization, greater intention to exit the organization, increased commitment to trade unions, and increased cynicism toward the subsequent employer. Empirical research has established a link between psychological contract breach and behavior: perceptions of breach are associated with reduced in-role and extra-role performance, less fulfillment of employee obligations, and increased acts of retaliation against the organization. Irrespective of the type of employee or cultural setting, the empirical evidence is reasonably clear: When employees perceive that their employer has broken a promise to them, negative consequences occur. However, the intensity and nature of these consequences may vary across individuals and situations.

Individual dispositions play a role in how individuals interact in exchange relationships. Some individuals will contribute to the organization contingent upon how well they perceive the organization as treating them. These individuals who are high on exchange ideology will contribute to the organization as long as they believe their employer is fulfilling its obligations. On the other hand, individuals who are low on exchange ideology will continue to contribute to their employer even if they feel they have been treated badly or unfairly. Individuals will also vary in terms of the

degree to which they have internalized the norm of reciprocity. Individuals who are high on creditor ideology will "overpay" the employer for benefits received. These individuals do not want to be in debt and thus will return benefits to the employer to a greater value than the benefits received. Individuals who are low on creditor ideology are likely to "underpay" the employer for benefits received. Similarly, individual dispositions are likely to affect whether individuals perceive a contract breach. Individuals who are high on self-esteem and who are "entitleds" are more likely to interpret the slightest discrepancy as a psychological contract breach. These types of individuals are more likely to think that they have fulfilled their obligations to their employer and that the employer has not adequately fulfilled its side of the exchange.

How employees react to contract breach is not solely dependent upon their dispositions but also the justice context in which the breach occurs. Organizations can mitigate the effects of contract breach by providing a credible justification for the breach (interactional justice). For example, a pay freeze is a consequence of the severe financial situation of the organization. Organizations can also conform to the tenets of procedural justice (e.g., bias suppression, advance notice, appeals mechanism, representativeness) in breaching an individual's psychological contract. Therefore, in the case of the pay freeze, it is applied consistently throughout the organization, giving advance notice and allowing employees to appeal the decision. Finally, distributive justice may come into play after a contract breach as a way of honoring the spirit but not the letter of the contract. In this case, the organization substitutes a benefit in lieu of the broken promise (e.g., increasing entitled vacation time). Therefore, different facets of justice have a role in the breaking of promises but also in minimizing the effects of broken promises.

Significantly less research has been conducted on how employer representatives react to employee psychological contract breach; in this case, the employee has not fulfilled his or her obligations to the employer. The little research that does exist points to managers, as organizational representatives, rating an employee lower on performance and organizational citizenship behavior when they perceive the employee as having breached his or her obligations to the employer. Therefore, it looks as if negative evaluations follow the perception of breach by either party in the exchange relationship.

CAREER MANAGEMENT IMPLICATIONS

Many psychological contracts theorists have argued that a “new deal” is emerging in the employee-employer relationship in response to the increasingly diverse pressures facing organizations. As organizations are no longer in a position to offer job security and a “career for life,” they are emphasizing flexibility and employability. Thus, job security is being replaced with job security based on an individual’s value in the marketplace. Although individuals may no longer have a job with the same organization, as a result of their value they will have a job with an organization for their working career. As a consequence, organizations are emphasizing giving employees the opportunity to develop a broad range of skills, and in return employees must be willing to change jobs and become more flexible. This in turn will increase their marketability and hence their future employability in the marketplace.

The implication is that the nature of careers is changing as well as the view of what constitutes career success. In place of a linear trajectory within a single organization is the idea of a “boundaryless career” in which individuals may have a number of employers and a number of jobs within the life of their career. Therefore, career success is defined (among other criteria) as one of individual marketability, where an individual is able to add value to the existing organization and concurrently is deemed marketable by external organizations. In this respect, the goal of managing individual careers becomes one of remaining employable throughout one’s career.

Who, therefore, is responsible for career management in organizations? Traditionally, organizations took responsibility, and organizational career management was planned and managed by the organization. The type of formal activities may range from training courses to mentoring. Therefore, it was the organization that was responsible for facilitating and managing the careers of its employees. However, the onus of responsibility is shifting toward individual employees, where employees are increasingly expected to self-manage their own career. This clearly places greater ownership on employees to take steps to manage and promote their own career. Employees, therefore, need to engage in continuous improvement in their own job and take steps to increase their preparedness for job mobility. Thus, the deal has changed from a guarantee of a career to the opportunity to have a career.

The implications for the exchange relationship are quite clear—“It takes two to tango”—and organizations

need to offer different career management interventions in return for employees proactively managing their own careers and implicitly being self-starters, flexible, and adaptable to new experiences. Thus the responsibility for career management lies with the two parties to the relationship, and the idea that the employee is the passive recipient of organizational career management interventions is slowly becoming outdated.

Organizations need to offer a different set of career supportiveness practices such as providing opportunities for employees to develop their skills, build internal and external networks that will increase their social capital, and develop mentoring relationships. The benefit to an organization is having an enhanced knowledge base and also having externally marketable employees who will increase the quality of its applicant pool. In return, employees need to take advantage of the opportunities provided by the organization and concurrently create further opportunities to enhance their marketability to any organization by engaging in networking activities internal and external to their organization. Furthermore, in taking responsibility for their own career, individuals need to consider expanding and updating their portfolio of skills so as to remain an attractive investment to their current employer and marketable to external organizations. To draw an analogy, lifelong marriage has been replaced by serial monogamy.

The implications of the changing nature of careers for the psychological contract is that organizations need to exercise caution in the promises they make to employees, particularly during the recruitment stage, to avoid perceptions of contract breach in relation to career issues arising at some future point in the relationship. When employees join the organization with traditional career expectations in mind, organizations should take steps to ensure that when newcomers undergo their reality check, their expectations of what the organization is willing to do to assist employees in developing their career is explicitly, consistently, and accurately communicated. This will facilitate congruence between employees and employer representatives and help avoid the consequences associated with perceptions of contract breach relating to career management.

PYGMALION EFFECT

The *Pygmalion effect* is a special case of self-fulfilling prophecy (SFP) in which raising a manager's expectations regarding worker performance boosts that performance. The Pygmalion effect debuted in educational psychology when psychologists experimentally raised elementary school teachers' expectations toward a randomly selected subsample of their pupils and thereby

produced significantly greater gains in achievement among those pupils in comparison to pupils in the control group. Subsequent experimental research has replicated this phenomenon among adult supervisors and subordinates in a variety of military, business, and industrial organizations and among all gender combinations. Both men and women lead both men and women to greater success when they expect more of them. Through the medium of interpersonal expectancy effects in various mentoring relationships, the Pygmalion effect undoubtedly plays a major, albeit largely unheralded, role in career development.

Several theoretical models have been proposed to explain how a leader's expectations influence subordinates' performance. Common to all these models is a causal chain that begins with the impact of the leader's expectations on, and his or her own behavior toward, subordinates, which arouses some perception or motivational response on the part of the subordinates and culminates in subordinate performance in accord with the leader's expectations. Self-efficacy has emerged as the key motivational variable in this causal chain. Self-efficacy is an individual's belief in his or her ability to perform successfully. Self-efficacy has been shown to be a key determinant of performance. When individuals believe they have what it takes to succeed, they try harder; however, those who do not believe they can succeed, refrain from exerting the effort that would apply the ability that they do have toward performance, and they accomplish less than they could. The Pygmalion-at-work model posits that having high expectations moves the leader to treat followers in a manner that augments their self-efficacy, which in turn motivates the subordinates to exert greater effort in their work, eventuating in enhanced performance. Thus, the Pygmalion effect is a motivational phenomenon initiated by the high performance expectations held by a leader who believes in followers' capacity for success. In a largely unconscious interpersonal process, leaders with high expectations lead their followers to success by enhancing their self-efficacy.

The SFP is a double-edged sword: As high expectations culminate in improved performance, low expectations can depress performance in a negative SFP process dubbed the Golem effect. "Golem" means oaf or dumbbell in Hebrew and Yiddish slang. Leaders who expect dumbbells get dumbbells. Another variant of SFP is the so-called Galatea effect. This is an intrapersonal expectancy effect in which self-starters fulfill their own prophecy of success; believing in their own capacity to excel, they mobilize

their internal motivational resources to sustain the effort needed for success even without any external source of high expectations. Finally, some research has shown group-level expectancy effects in which a manager's high expectations for a whole group, as distinct from particular individuals, culminate in that group's exceeding the performance of groups in the control condition.

A fascinating but elusive aspect of interpersonal SFP involves the communication of expectations. Some of this communication is verbal and conscious, but much of it is not. Teachers and managers exhibit numerous nonverbal behaviors through which they convey their expectations, both high and low, to their pupils and subordinates. When they expect more, they unwittingly smile more, nod their heads affirmatively more often, draw nearer, maintain more frequent and longer eye contact, speak faster, and show greater patience toward those they are mentoring. These nonverbal behaviors serve to "warm" the interpersonal relationship, create a climate of support, and foster success. Other ways in which leaders favor those of whom they expect more include providing them with more input, more feedback, and more opportunities to show what they can do, while those of whom less is expected are left, neglected, "on the bench."

Meta-analyses have abundantly confirmed the validity of the Pygmalion phenomenon in management as in education. The experimental design of this body of research confirms the flow of causality from leaders' expectations to follower performance. What remains to be shown is the practical validity of the Pygmalion effect. Although abundant field-experimental replications have produced the effect in military and civilian organizations, attempts to get managers to apply it through managerial training have been less successful. Managers' prior acquaintance with their subordinates appears to be a barrier to widespread practical application. Virtually all the successful replications have been among newcomers whose managers had not previously known them. Familiarity apparently crystallizes expectations, as managers do not expect their subordinates to change much. Therefore, the most effective applications may be made among managers and their new subordinates. Thus the Pygmalion effect may be most relevant in the early stages of career development. These may be the most important, formative years.

Organizational innovations and other digressions from routine can occasion conditions conducive to

Pygmalion effects. For example, when organizational development programs unfreeze standard operating procedure or when the organization undergoes profound change in structure or function, a window of opportunity opens for managers quick of mind and action to piggyback on these unsettling events and raise expectations in order to promote effective change and successful outcomes. In one classic example, the introduction of job rotation and job enrichment produced significant improvements in production when accompanied by information that raised expectations from the new work procedures, but neither innovation produced any productivity improvement when expectations were not raised. The implications for practical application are clear: Change presents managers with opportunities for creating productive Pygmalion effects. It is incumbent upon those who want to lead individuals, groups, and organizations to success to convey high expectations when the opportunity presents itself. Conversely, cynicism or expressions of doubt about reorganization or other potentially disruptive changes condemns them to failure. Thus the practical agenda is twofold: first, managers and other mentors must counteract any manifestations of contrary expectations, and second, they must implant high expectations.

The essence of the Pygmalion effect is that managers get the workers they expect. Generalizing to career management, one can prophesy that one gets the career one expects. Expect more and you will get more. However, the converse is true too: Expect less and you will get less. All the mentors who have a hand in career development can and should play a Pygmalion role by cultivating in themselves high expectations regarding their mentees' developmental potential and by fostering in the mentees themselves high self-expectations regarding their own potential for success. High expectations are too important to be left to chance or whim; they should be built into all career development programs to make sure they take root.

QUALITY OF WORK LIFE (QWL)

The term *quality of work life* (QWL) refers to the degree of satisfaction and contentedness an employee experiences with respect to his or her job and the overall work situation. QWL has been linked with a number of positive outcomes both for individual workers and for employing organizations. QWL programs sprang from the humanistic theories of management that became popular in the 1950s and 1960s, all of which emerged from the human relations movement in management and industrial/organizational psychology. Examples of QWL goals and strategies suggested by these early theories include.

1. *Decrease the conflict between the employee and the organization.* This goal may be achieved if the formal structure of the organization is changed to allow employees to be more active than passive, to be more independent than dependent, to assume a longer rather than shorter time perspective, and to hold positions that are at least equal to those of their peers.
2. *Enrich the job.* Management can accomplish this step by, at least, increasing the number of tasks that employees have to perform and preferably giving them more control over their jobs.
3. *Use participative or employee-centered leadership.* Employees must enjoy self-expression in the organization. The organizational structure should be modified to allow for group-centered leadership. The work unit should have responsibility for defining the group's goals, evaluating behavior, and providing team direction. In addition, the work unit should experience rewards and punishments collectively.

During the early years of the movement, much research was conducted to document instances where QWL programs resulted in an increase in productivity and employee growth and self-development. Thus management's efforts to satisfy the needs of the workers have been an impetus behind the QWL movement in management thought and practice. More recently, the trend in QWL research has emanated from two sources, with one source referred to as the management perspective and the other as the quality-of-life view.

QWL FROM A MANAGEMENT PERSPECTIVE

Management scholars often do research on QWL initiatives where the program's design is guided by management's self-interest to promote profitability. Organizations have found that programs designed to increase job satisfaction and empower employees can increase employee productivity and job performance. In turn, higher levels of productivity and performance serve to increase the organization's profitability. Based on this perspective, much research has focused on specific QWL programs to examine the effects of these programs on employee productivity as well as job satisfaction.

Research has shown that *teamwork*, characterized by reciprocal trust and respect among team members, serves to enhance employee productivity and job satisfaction. Teamwork can be induced through role clarification (clarifying and negotiating role expectations of each team member), problem solving (educating team members on how to solve problems by first defining the problem, followed by generating possible

alternatives for corrective action, selecting the best alternative, implementing the corrective action, and monitoring the outcome of the corrective action), goal clarification and prioritization (the team is instructed to develop measurable performance goals and prioritize these goals), and conflict resolution (the team is taught how to resolve conflicts through a built-in process to review decisions, team members are induced to learn more about the specialty fields of one another through planned mutual instructions, roles are clarified, and greater communication and openness are encouraged).

Jobs generating higher levels of involvement involve *parallel structures*, also known as collateral structures, dualistic structures, or shadow structures. Jobs involved in parallel structures provide members with an alternative setting to address problems and propose innovative solutions free from the formal organization structure. *Quality circles* are an example of parallel structures. Quality circles consist of small groups of 13-15 employees who volunteer to meet periodically, usually once a week for an hour or so, to identify and solve productivity problems. These group members make recommendations for change, but decisions about implementation of their proposals are reserved for management. Research has shown that parallel structures and quality circles do play an important role in employee productivity and job satisfaction.

Research has shown that the *ethical corporate mission and culture* of an organization can influence employee productivity and job satisfaction. Employees believe that being associated with an ethical organization gives them a sense of meaning and purpose in their work. Examples of these organizations include the religious-based or values-based organizations where the founders or managers are guided by general religious or philosophical principles.

An organization's *work schedule* has been researched as a QWL program affecting employee productivity and job satisfaction. Specifically, research has shown that matching the time preferences of employees with the time demands established by organizations is likely to enhance job performance and job satisfaction. The match between the individual's ideal and actual time behaviors brings a sense of temporal symmetry in which the rhythm of people's lives matches their preferred lifestyles. Time congruity serves to reduce work and nonwork role conflict and allows the individual to meet work and nonwork demands with minimal stress.

Substantial research has shown that *participation in decision making* and *high-involvement programs* contribute positively and significantly to work motivation and satisfaction. High-involvement programs are thought to be a conduit to help employees express their thoughts and feelings in important organizational decisions. As such, high-involvement programs serve to enhance person-environment fit in the work domain. Allowing employees to participate in important organizational decisions amounts to providing employees with greater work resources that help employees meet work demands more readily.

Job design is the process of defining and structuring job tasks and work arrangements to allow optimal accomplishment. This process may determine the amount of satisfaction that workers experience at work. The best job design (referred to as *job enrichment*) is one that meets organizational requirements for high performance, offers a good fit with employees' skills and needs, and provides opportunities for job satisfaction. Research in this area has differentiated hygiene factors (or dissatisfiers that are in the job context such as pay) from motivators (or satisfiers that are in the job content—the actual work that people do). Examples of motivators are work opportunities for achievement, recognition for good performance, work itself, responsibility, and advancement and growth. Building motivators into the job enriches the job and increases worker satisfaction and motivation to work.

Total quality management (TQM) has also been treated as a QWL program. TQM is an aspect of organizational control. The idea underlying TQM is that all members of the organization are committed to high quality results, continuous improvement, and customer satisfaction. TQM also prescribes employee involvement and empowerment. Research has shown that TQM plays an important role in job performance and employee satisfaction.

The policy to *promote from within* is yet another QWL program. Self-actualization is the desire to become anything that one is capable of becoming. Progressive firms engage in practices that aim to ensure that all employees have the opportunity to self-actualize. Promotion and career advancement are important in that regard. Progressive companies have promotion-from-within programs, which means that open positions are filled, whenever possible, by qualified candidates from within the company. Those companies typically hire at entry level and then train and develop personnel to promote them to higher

levels of responsibility. People are hired at entry-level positions based on their potential for advancement within the company and on their having the right values. Research has shown that companies that have policies to promote from within have employees who are more productive and satisfied with their jobs than companies that do not have such policies. Also, progressive companies provide *educational and training resources* to help employees identify and develop their potential. This may be accomplished with programs of career planning, company internships, and tuition assistance.

There are many *incentives plans* that organizations use to reward their employees and satisfy employee needs for self-actualization, self-esteem, and social recognition. These include individual incentive programs, group incentive programs, profit-sharing plans, and gain-sharing programs. Research has shown that these programs do play a significant role in employee productivity and job satisfaction.

The goal of *alternative work arrangements* is to minimize work-family conflict and help employees balance the demands of their work and family lives. The most common type of work-family conflict is time-based conflict experienced when the time devoted to one role makes the fulfillment of the other difficult. Common programs that manipulate work arrangements include full-time work-at-home, part-time work-at-home, flextime, compressed workweek, and part-time work arrangements. Alternative work arrangements typically affect job satisfaction by reducing work-family conflict. Operationally speaking, alternative work arrangements attempt to restructure one's job to allow for more flexibility in managing the hours devoted to work and the hours that are available for family commitments. These restructurings could include adjusting the employee's arrival and departure times to and from work, restructuring hours at work in order for the employee to be at home at certain times, limiting the number of evenings per week where the employee is expected to work at the office, limiting weekend work at the office, limiting travel, and making special arrangements at work to attend to family needs.

With respect to *employment benefits*, many firms offer at least basic employment benefits to their employees, which play an important role in employee productivity and job satisfaction. Examples of employee benefits include health insurance, retirement/pension benefits, and supplemental pay benefits.

Furthermore, there are many *ancillary programs* described in the QWL literature designed to meet employee nonwork needs. These include child care programs, elder care programs, fitness programs, social programs and events, employee assistance programs, educational subsidies, counseling services, credit union, and others. Among the lesser known QWL programs are lakefront vacations, weight loss programs, child adoption assistance, company country club memberships, tickets to cultural activities and events, lunch-and-learn programs, home assistance programs, subsidized employee transportation, food services, and executive perks.

QWL FROM A QUALITY-OF-LIFE PERSPECTIVE

While an economic orientation may remain a necessity for business organizations, it need not preclude a focus on overall employee well-being. QWL programs are organizational development efforts that result not only in job satisfaction but also *life satisfaction*. Thus, much research has been conducted to understand how specific QWL programs influence employee life satisfaction.

Specifically, this line of research has examined the spillover between job satisfaction and life satisfaction. Substantial research has documented the fact that job satisfaction is positively correlated with life satisfaction. People segment their feelings or compensate for divergent affective reactions across life domains (work life, family life, social life, etc.). Also, people experience reciprocal *spillover* between job satisfaction and life satisfaction. Research has shown that the spillover from one's experience in a particular life domain to one's satisfaction/dissatisfaction with life in general may be affected by a variety of moderators such as organizational commitment. That is, employees who have a higher level of organizational commitment tend to experience a greater spillover effect than those who expressed lower levels of commitment.

Interestingly, both job and life satisfactions share a substantial dispositional component. A top-down approach to the study of job and life satisfaction suggests that common traits (e.g., positive and negative affectivity) influence both. In fact, although personality removes a huge chunk of the variance from the job-life satisfaction relationship, the link still remains. Such traits may gauge the broader construct of life satisfaction. Life satisfaction is a higher order concept

that encompasses domain satisfactions. It is interesting to note that situational influences on reports of life satisfaction—the bottom-up approach to the study of life satisfaction—have been found to account for a significant amount of variance in life satisfaction.

QWL research based on the quality-of-life perspective has indicated that a number of organizational factors can explain the job-life satisfaction link. One such factor is *organizational structure*. Bureaucratization is associated with an increase in job dissatisfaction and life dissatisfaction. That is, workers in a decentralized bureaucracy experience a greater spillover between job satisfaction and life satisfaction than workers in a centralized bureaucracy. Fostering decentralized bureaucracies allows workers to enjoy greater work discretion and lesser immediate supervision. Work discretion and low levels of supervision reduce work role stress, which in turn reduces negative affect and dissatisfaction in work life. This reduction of negative affect and dissatisfaction in the work domain serves to decrease negative affect in overall life through spillover, contributing to life satisfaction.

Another factor moderating the job-life satisfaction link is *occupational status*. Research has shown that different jobs carry different levels of social status, with clerical and sales scoring moderate in both social status and job satisfaction and unskilled car workers scoring lowest in both social status and job satisfaction. Spillover occurs between job satisfaction and life satisfaction moderated by occupational prestige. Specifically, occupational prestige is a poor predictor of both job and life satisfaction, except for the highest status occupations. High-prestige jobs often nourish self-esteem and generate positive affective experience (i.e., job satisfaction and life satisfaction) that is not generated by low-prestige jobs.

Research continues in the context of both programs of research—QWL from a management development perspective and from a quality-of-life perspective. Much more is needed to study the various QWL programs to better understand their effects not only on job performance and job satisfaction but also on life satisfaction. Different QWL programs tend to affect different role identities in various ways. Some are effective in generating more resources to facilitate the realization of role expectations. Some are effective in

reducing conflict within a specific role identity or between two or more role identities. Others are designed to clarify and articulate role expectations to match work and nonwork demands.

R

RACIAL DISCRIMINATION

Forty years have passed since the Civil Rights Act of 1964 made it illegal to engage in racial employment discrimination in the United States. Many scholars agree that this enactment has played a significant role in reducing this type of discrimination. Indeed, all accounts seem to suggest that blatant or outright prejudice is seen infrequently in modern workplaces. Nevertheless, a new and subtler form of prejudice, which is known as *aversive* or *modern*, has taken its place. Holders of these beliefs feel that *racial discrimination* is a thing of the past, minorities are pushing too hard for further change, and many of the gains attained by minorities have been unwarranted. Consequently, despite legislation outlawing racial discrimination and a reduction in old-fashioned prejudice, systemic inequalities have persisted, racist attitudes have evolved, and discrimination continues.

The purpose of this entry is to acquaint readers with the current state of knowledge concerning racial discrimination and its impact on careers. To begin, discrimination is defined comprehensively. Subsequently, the effects of racial discrimination on careers are examined at two stages: pre- and postorganizational entry. At the preentry stage, factors such as teacher and guidance counselor prejudice, inequalities in schools, questionable higher education admissions criteria, and biased personnel selection practices are discussed. At the postentry stage, the focus shifts to systemic discrepancies in human resource management practices such as employee placement, performance appraisal, promotions, compensation, and

layoffs. In short, a comprehensive look at how discrimination affects career development and progression is provided.

To provide conceptual clarity, any discussion of discrimination must begin with a definition. Within the context of employment, racial discrimination can take one of two forms: adverse impact or disparate treatment. Adverse impact refers to situations wherein members of a particular racial group are intentionally or inadvertently systemically disadvantaged. For instance, if a cutoff score on a test is used in making hiring decisions and this criterion places Native Americans at a relative disadvantage (i.e., the proportion of Native Americans meeting this threshold is less than four-fifths of that of the majority group), then it can be said that this procedure results in adverse impact. Conversely, disparate treatment is an intentional discrepancy in the treatment afforded to members of different racial groups by employers or fellow employees. For example, executives at Texaco in the 1990s explicitly decided that African Americans in general were less qualified for managerial positions and therefore promoted them considerably less often. In this entry, both forms of discrimination are considered and discussed.

PREENTRY DISCRIMINATION

Racial discrimination can have a significant impact on an individual's career before he or she ever applies for a job. During primary education, which remains highly racially segregated despite the outcome of the *Brown v. Board of Education* case 50 years ago, minority and majority group members tend to undergo

very different experiences. For instance, racial and ethnic minority youth are disproportionately more likely to attend schools that are disadvantaged in terms of the resources (physical and human) available to promote student intellectual and emotional development. Hence, the facilities, educational materials, curricula, and instruction received often tend to be inferior to those experienced by much of the majority group. In addition, minority youth are more likely to drop out of school, which contributes further to their subsequent disadvantaged position in the labor market.

Within this segregated school system, minority youth often encounter teachers and counselors who harbor prejudice and bias against them. For instance, evidence indicates that minority students are disproportionately more likely to be placed in vocational courses and less likely to be placed in college preparatory courses than their majority group counterparts, irrespective of their test scores. Studies also show that teacher prejudice and bias tends to result in lowered expectations of student performance. These lowered expectations produce a type of Pygmalion effect, wherein students are treated differently according to the teachers' perceptions and ultimately produce outcomes that confirm the teachers' initial bias. Furthermore, teachers' low expectations often result in students developing and holding low self-expectations that produce negative self-fulfilling prophecies (i.e., you don't expect to accomplish much, so you don't). This helps explain why minorities in secondary and postsecondary education tend to perceive fewer vocational opportunities than their White counterparts. Consequently, before officially beginning their careers, many minorities' prospects have been irrevocably diminished.

Another obstacle to minority achievement is getting into college. Although other criteria are often involved in the admissions process, the two most important tend to be high school grades and standardized test scores, such as the Scholastic Aptitude Test (SAT) and American Collegiate Test (ACT). Working against minorities is the fact that high grade point averages earned at economically disadvantaged schools receive less weight during admissions decisions than those from schools with more resources. In addition, a number of questions have been raised regarding whether the SAT and ACT, the most commonly used standardized tests, are culturally biased in favor of majority group members. Regardless of this alleged bias (which has yet to be adequately verified

or refuted), a more pressing issue with regard to these tests is their ability to predict collegiate academic performance. Recent research suggests that reports of their validity in this regard may have been exaggerated. Thus, by relying heavily on test scores when making admissions decisions, schools may not only be adversely impacting minorities (who tend to score lower), but the variance in these scores that forms the basis of their decisions may not translate into actual differences in college grades.

Individuals who manage to achieve in spite of the aforementioned obstacles must then obtain employment befitting their credentials. Despite laws prohibiting discriminatory personnel selection, recent empirical results suggest that inequalities persist. In fact, evidence indicates that many employers consider a White male candidate with a criminal record to be more hireable than a Black male without one. Merely being thought to be a minority may be enough to disqualify applicants from further consideration. For instance, having a name linked to minority groups (e.g., Jamal or Lakisha) on one's résumé considerably decreases the probability of receiving a callback from a prospective employer. Furthermore, increasing the quality of the credentials on the résumé has no effect for these individuals, irrespective of whether the position applied for is at the entry level or executive level. One potential explanation for such blatant discrimination is that those responsible for hiring have formulated or encountered business-oriented rationales for why the company should hire majority, as opposed to minority, group members. Individuals who endorse the tenets of modern racism tend to view these rationales as an adequate justification to discriminate against minorities.

After the initial stages of job seeking, discrimination often continues to act as a hurdle to be overcome. Many companies use cognitive ability tests to screen job applicants. Although these tests usually do an adequate job of predicting performance, their use as a screening mechanism often has an adverse impact on the hiring of minorities. Furthermore, interviewers, who are often White, tend to be biased in favor of members of their own racial and ethnic groups. More recently, these findings have been extended to include panel interviews, indicating that panels are apt to discriminate against minorities unless there are minorities on the panel. Interestingly, it appears that even when interviews do not introduce racial bias into the selection process, interviewers may retain prejudiced

impressions of the minority applicants (e.g., that they are less intelligent than White applicants) that they have chosen to hire. Clearly, discrimination remains an obstacle to attaining employment for many racial and ethnic minority group members.

POSTENTRY DISCRIMINATION

Unfortunately, the impact of racial discrimination on careers is not limited solely to the preemployment experiences discussed above. In fact, research suggests that it may be equally, if not more, pervasive after minorities have been hired. Initially, minorities tend to be placed under the supervision, and in the immediate company, of other minorities when hired. Although the repercussions of this practice may not be immediately apparent, its implications for the careers of minorities are grave. By limiting the workplace interaction between minority employees and their majority coworkers and supervisors, who tend to hold the balance of power within U.S. organizations, companies are constraining minorities' advancement and developmental opportunities. Effectively, these individuals are less able to form mentoring relationships with those in power, less likely to be assigned to work on high-level projects, and less likely to be identified early as prospective future organizational leaders.

Discrimination also tends to rear its head in the process of performance appraisal. Evidence indicates that minorities receive lower performance evaluations and subsequently are less often recommended for promotions. Although many experts have contended that these differences are attributable to actual performance differences, several findings suggest otherwise. Rather, it appears that even after accounting for any existing differences in human and social capital, racial differences in promotions persist. It has been demonstrated recently that the impact of these promotional discrepancies increases over time. This suggests that employers, indeed, are engaging in discriminatory appraisal processes and that the effects of this type of discrimination on minorities grows over the course of their careers. These artificial constraints on minorities' career advancement possibilities collectively represent what is commonly referred to as the glass ceiling effect.

Given the inequalities in placement, appraisals, and promotions cited above, it is not surprising that a considerable pay gap remains between the compensation received by majority and minority group members.

This gap is especially prominent for Hispanics and those of African descent who receive between 70 and 75 cents for every dollar received by their White counterparts in comparable positions. Similar to promotions, it appears that these disparities in compensation cannot be attributed solely to differences in human capital. Instead, majority group members tend to enjoy disproportionately favorable returns for their human capital investments (e.g., education, training, experience) relative to their minority counterparts. In fact, evidence indicates that minorities even receive lower payoffs than comparable White employees when switching jobs from one organization to another. Furthermore, the latter are more likely to have social ties to organization members who aid them in negotiating higher starting salaries. Perhaps even more disturbing is that any initial pay gaps only tend to widen with time, leaving minorities further disadvantaged as their careers progress.

A less often discussed source of discrimination that affects minorities originates from customer preferences, whether they are actual or perceived. It seems that organizations whose clientele are primarily White are less likely to hire minorities based on their belief that their customers prefer to see employees of their own racial or ethnic group. This tendency to try and match employees to customers is even more pronounced when the degree of employee-customer contact required for the positions is high. Accordingly, the race of a company's customers also predicts wages. Organizations that hire more minorities are those that serve a greater proportion of minorities and, therefore, typically pay their employees lower wages. What this means for minorities is that their occupational options often are restricted to those organizations that pay less and cater primarily to members of their own groups.

Further complicating the careers of minorities is the old adage "last hired, first fired," which suggests that minorities are discriminated against in the making of termination as well as selection decisions. Belief in this adage appears to be relatively high among minority and majority group members alike. In fact, minorities have reported perceiving greater discrimination concerning terminations than hires. Moreover, 72 percent of all respondents in a recent study reported believing that minorities are unfairly targeted for layoffs. Recent experimental evidence corroborates this belief, indicating that White employees are less likely to be laid off than non-White (e.g., Asian American, African American, and Hispanic) employees.

In conjunction with the discrimination experienced when attempting to secure employment, this contributes to a vicious cycle of unemployment that disrupts the careers of many minorities.

A final, and somewhat less systemic, form of racial discrimination occurs in the form of prejudice and harassment from coworkers. Despite the fact that these actions are less likely to be formally institutionalized than those discussed thus far, the impact on victims' careers can be equally damaging. For instance, the amount of prejudice and discrimination one experiences elevates stress levels, blood pressure, and reported illness while deteriorating mental health and general well-being. Studies show that many minorities are exposed to discriminatory treatment at work on a routine, if not daily, basis. Such hostile environments are said to have a negative diversity climate, which tends to lower commitment to the organization and one's career, and satisfaction with one's job, manager, and career. As might be expected, more diverse companies tend to have more positive diversity climates, and consequently, voluntary turnover among minorities is considerably lower in these organizations. Thus the impact of this consistent disparate treatment on the career development of its recipients is significant.

CONCLUSION

It is important to note that all racial and ethnic minorities tend to experience discrimination. Whereas most examination of the topic has focused on African and Hispanic Americans, some evidence indicates that those of Asian descent often are victims of discrimination as well. In particular, there appears to be a glass ceiling limiting the advancement prospects for members of this group as well. This is an important realization, because many readers likely endorse the "model minority" stereotype (i.e., that Asian Americans exhibit positive characteristics that make them distinct from other minorities) and therefore may doubt the occurrence of discrimination against this group.

Although the moniker "reverse discrimination" is a misnomer, because discrimination does not inherently require that its victims be of a particular race, it is important to acknowledge that minorities are not alone in reporting experiences of racial discrimination. In fact, survey data suggest that a considerable proportion of majority group members believe that they have been discriminated against because of their racial group membership. Experimental research

investigating this topic, however, is relatively limited. Consequently, it is difficult to ascertain with any degree of confidence the extent to which White employees are subjected to racial discrimination in American workplaces.

The fact that the level of discrimination faced by racial and ethnic minorities is less than it once was is encouraging. Nevertheless, it remains a pervasive deterrent to career success. Its impact in many cases can be traced from inequalities and discriminatory treatment during childhood and adolescence, to biased human resource management criteria and systems. Its presence is felt as well in many everyday interactions between minority and majority group members. Many scholars argue that legislative changes have contributed to a marked decline in the significance of race in the workplace. Nevertheless, the findings of several recent studies clearly demonstrate that employment discrimination remains prevalent. Moreover, until systematic inequalities impacting early career development are addressed, efforts to achieve postentry equality (e.g., affirmative action plans, diversity management programs) will have only marginal utility in leveling the playing field. In sum, it is impossible to comprehend the impact of racial discrimination on minorities' careers without considering the entire career.

RATER ERRORS IN PERFORMANCE APPRAISAL

Anyone who rates another person's performance has the potential to commit a *rater error* in the evaluation of that performance. A rater error is defined as an inaccuracy that makes its way into an employee's appraisal that results from a bias, either conscious or unconscious, on the part of the rater. Rater errors represent a significant concern for organizations as they try to equitably evaluate the performance of their employees. Since it is virtually impossible to eliminate rater errors from the performance appraisal process, it is important for organizations to take steps to minimize their impact in misjudging an employee's overall performance. Ongoing training for managers in understanding the sources of rater errors is one technique that can help. In addition, many organizations have moved to multisource approaches to performance appraisal, such as 360-degree assessments, to smooth out the rater errors and thus minimize the degree of inaccuracy in an employee's evaluation.

What are the types of rater errors and why do they occur? One type of rater error is the halo effect. This error occurs when an employee is seen by the supervisor as highly competent in one or more areas

and, as a result, is rated highly in other areas. For example, if an employee is a good record keeper but is occasionally late, the supervisor might overlook the tardiness because the positive work habit overshadows the problem behavior. The opposite of this is the horn effect, which occurs when the employee is seen as weak in one or more areas and is rated low in other areas based on that weakness. An example would be where an employee's poor customer service skills negatively influences the evaluation of other relevant skills or causes the rater to overlook the employee's superior skills when preparing the appraisal.

Another rater error is the recency effect, which occurs when a supervisor considers only the most recent performance rather than the performance over a year (or the length of time the appraisal covers). This can be a serious issue if the employee has performed well all year, only to have a performance problem right before the evaluation takes place. Of course, the opposite can also be true, where an employee's performance improves a few months before the appraisal and the manager only recalls the recent performance progress at the time of assessment.

Bias occurs when a supervisor has prejudices against certain employees based on gender, age, religion, ethnicity, race, weight, disability, or some other non-job-related aspect. An additional rater error is strictness, which occurs when an appraiser believes that no employee can ever be worthy of the highest rating since "no one is perfect." The opposite effect is called the leniency error. This happens when the supervisor believes that all employees put forward their best efforts, so they should all be worthy of a higher rating. A related error is called central tendency, which occurs when the rater believes that all employees are average and should fall somewhere in the middle of the rating scale.

Contrast takes place when the appraiser rates one employee based on the work of other employees, rather than based on the performance standards for a particular position. One employee may be a "shining star," which would make all other employees seem average in comparison, or an employee could be a constant performance problem, which then makes all of the other employees seem like superior performers in comparison.

Sampling error occurs when the supervisor has observed only a small portion of the employee's work and bases the rating only on what was witnessed. This situation might occur when an employee telecommutes or works in another location. It might also

occur if the supervisor is new to the position and has worked with the employee only a short time. Ideally, a performance appraisal should take into consideration all of an employee's work during the period of evaluation, even if more than one supervisor's ratings needs to be considered.

The final type of rater error is known as *similar to or different from me*. This type of error occurs when supervisors give higher ratings to employees who are similar to them in personality, interests, or other non-job-related issues. Of course, the opposite can also be true where supervisors give lower ratings to those employees who are not like them.

Rater errors are most common when one person is evaluating the performance of another. It is for this reason that ongoing training in performance appraisal is important. Companies and individual raters can find themselves in legal trouble if an employee is terminated for a poor performance appraisal based on rater errors. In addition, performance should be based on only job-related items and not on personal feelings. Each employee should be provided with his or her job description and job expectations prior to their performance review. There should be no surprises for the employees during the review about performance expectations. This is why consistent, ongoing feedback on performance is important. It should not be something that is discussed only once or twice per year—it should be a regular occurrence. Furthermore, corrective performance counseling should be provided on an ongoing basis so that the employee can improve performance all year. And finally, every appraisal process should include a method to appeal or disagree with the outcome.

REALISTIC RECRUITMENT

The primary method in *realistic recruitment* is the realistic job preview (RJP). The RJP is the presentation of realistic—often quite negative—information about an organization to a job candidate. It is given to job candidates during the selection process to help them make an informed job choice, should a job offer be made. A second realistic recruitment strategy is to use certain recruitment sources (e.g., employee referrals), which communicate realistic information to job candidates while avoiding others that do not (e.g., newspaper ads). Finally, four selection methods that also communicate realistic information to job candidates are briefly mentioned, because their primary intended purpose is for selection rather than recruitment.

THE RJP

An RJP contains accurate information about job duties, which can be obtained from interviews with “subject matter experts” or from a formal job analysis. The RJP also contains information about an organization's culture, which can be obtained from surveys, interviews with current employees, and exit interviews. There are four criteria for selecting the specific information to include in the RJP: (1) it is important to most recruits, (2) it is not widely known outside the organization, (3) it is a reason that leads newcomers to quit, and (4) it is related to successful job performance after being hired. Because of the need to tailor make the RJP, based on both job and organizational information, it is not really a specific technique. Rather, it is a general approach to recruitment, or “philosophy,” as some might say. Furthermore, organizations often differ on the particular means for presenting realistic information to job candidates, for example, (1) a brochure, (2) a discussion during the job interview, or (3) a video. Combinations of these three specific techniques are sometimes used. Combining the latter two is probably the best approach, as discussed below.

One important purpose of the RJP is to increase the degree of fit between newcomers and the organizations they join. There are two types of fit affected: (1) person-job fit and (2) person-organization fit. Good person-job fit typically results in better newcomer performance, as well as indirectly on increasing retention. Good person-organization fit typically results in reduced quitting, as well as indirectly on increasing

job performance. To the extent that an RJP affects job choices by candidates, also known as self-selection, it can improve either or both types of fit.

RJP information is communicated to job applicants prior to organizational entry. Realistic information that is disseminated after organizational entry has been defined as newcomer orientation, which is different from the RJP in several ways. The most important difference is that the primary purpose of newcomer orientation is to help new hires cope with both a new job and a new organizational culture. Thus, newcomer orientation teaches solutions to common newcomer adjustment problems during organizational entry. In contrast, the RJP presents the adjustment problems without the solutions. This is because one purpose of the RJP is to discourage job candidates who are likely to be misfits with the job and/or organizational culture.

For a long time, the RJP was thought to affect newcomer retention more so than job performance, as reported in a 1985 review by Steve Premack and John Wanous. However, a 1998 review by Jean Phillips found a stronger effect of the RJP on job performance than Premack and Wanous did, while reaffirming the same effect of the RJP on retention of new hires. As of this writing, the Phillips review is the most recent one that is available.

Some RJP methods are better than others. Specifically, the best RJP technique for hiring better performers is a video. The best RJP method to increase new hire retention is a two-way conversation between a job candidate and a job interviewer during a job interview.

The main explanation for a video RJP increasing the performance of new hires is that recruits are shown a role model performing critical job duties successfully. Role models are an effective way to demonstrate both interpersonal and physical skills that are part of most entry-level jobs.

Explaining why RJPs increase new hire retention, however, has been more complicated. There are four different hypotheses. First, the information provided in an RJP helps job candidates choose more effectively among job offers. This process of self-selection is believed to increase person-organization fit, as mentioned earlier. Furthermore, to the extent that job candidates feel free to accept or reject the job offer, the more likely they are to be committed to the choice itself, as suggested by decades of research on cognitive dissonance. Second, the RJP can “vaccinate” expectations against disappointment after organizational entry, because the most dissatisfying job and organizational

factors have already been anticipated. Third, the information in an RJP can help newcomers cope more effectively with the stress of being in a new environment, originally called “the work of worry” by Irving Janis. Finally, an RJP can enhance the perceived trustworthiness or supportiveness of the organization to job candidates, thus increasing their initial commitment to the organization. Support for any one of these hypotheses does not necessarily mean that others are refuted, however. All can be viable explanations.

Several guidelines for designing and using the RJP can be derived from the two reviews, using sophisticated quantitative methods, that Phillips and Wanous have done. First, self-selection should be explicitly encouraged. That is, job candidates should be advised to carefully consider whether to accept or reject a job offer. This can be done best during the job interview, which may be an important reason why it is the best method for increasing new hire retention. Second, the RJP “message” must be credible. Credibility can be achieved by using actual employees as communicators, whether in a video and/or a job interview. This may explain why using only a brochure is the least effective of all methods. Third, how typical employees feel about the organization, not just sterile facts, must be part of an RJP. Again, employee feelings can be best provided in a video and/or a job interview. Fourth, the balance between positive and negative information should closely match the realities of the job itself. This requires careful data collection and analysis before developing an RJP. Finally, the RJP should normally be done before, rather than after, hiring, but not so early that the information is ignored. (An exception might be to position the RJP at the end of executive recruitment, although there has been no research on executives.)

Research continues to identify the boundaries for the RJP.

- First, if the retention rate for new hires is very low, the job is probably so undesirable that an RJP will have no effect on job survival. For example, one study of newly hired self-service gas station attendants revealed that not 1 of the 325 new hires lasted as long as nine months. In fact, many quit by the end of the first month. In organizations with very high retention, the RJP may not be able to improve on that already high level. Because of this, the RJP is probably most effective when the one-year job retention rate for newcomers is in the 50 percent to 80 percent range. Estimates for using the RJP to increase job retention for an

organization with a 50 percent job retention rate (for the first year after being hired) range from increasing it up to 56 percent to increasing it up to 59 percent.

- Second, if the relevant labor market has relatively few job openings, the RJP will have little effect on a job candidate's job choice, because the chance of obtaining multiple job offers is low. Furthermore, a very tight labor market means that new hires tend to stick with a job even if they would prefer to leave it.

- Third, the RJP appears to be more effective when job candidates have some previous job knowledge or work experience, because they can better understand the information that is provided.

- Fourth, both Phillips and Wanous found that the RJP increases newcomer retention more so in business organizations than in the military. The primary reason for this difference in job survival rates is that there are restrictions on attrition from the military.

Translating the impact of the RJP into dollar terms (utility analysis) can be done by calculating the difference between the number of new hires needed without using an RJP versus the number needed when using one. Consider an organization that wants to hire and retain 100 new employees. If the job retention rate for the first year is 50 percent, the organization will need to hire 200 in order to retain the target goal of 100. If the RJP increases job retention from 50 percent up to 56 percent, it would mean hiring only 178 people. If the RJP increases job retention from 50 percent up to 59 percent, the organization would have to hire only 169 new people. For a fast-food chain of restaurants (e.g., McDonald's, Wendy's, Burger King, Pizza Hut) that typically hires over 100,000 newcomers corporation-wide at a cost of \$300 to \$400 per hire, the dollar savings in recruitment and hiring can be in the tens of millions of dollars.

The RJP may also be relevant for other aspects of human resource management. They could easily be used for preparing managers for international assignments. Although intuitively appealing, there has been no rigorous research on this topic, which is puzzling because the costs of failures in international assignments for executives is far greater than for lower paying, entry-level jobs that typify most studies of the RJP.

REALISTIC RECRUITING SOURCES

Besides the RJP, there are other ways that realistic information can be communicated to job candidates.

One recruitment strategy is to hire from those sources that have higher job retention rates and higher job performance. A rigorous review of this research by Michael Zottoli and Wanous found that inside sources (referrals by employees and rehires) had significantly better job retention rates than those from outside sources (newspaper ads and employment agencies). Furthermore, inside sources produced better job performers, although their effect on performance was less than on retention. However, the effect of recruitment source on retention and performance are both significant. Their usefulness in dollar terms can be estimated in the same way as for the RJP. Although the number of recruitment source studies (25) is less than those of the RJP (40), there seem to be enough studies so that the results of recruitment source research should be taken seriously now. Unfortunately, no study has yet examined an organization that combines the RJP with inside recruitment sources. Thus, the effect of combining both of these realistic recruitment methods is unknown at present.

Six hypotheses have been offered to explain the link between recruitment source, on the one hand, and job survival and job performance, on the other. Some of these are identical to those concerning the RJP. First, inside recruits have more accurate information, which results in less disappointment among newcomers. Second, having accurate information enables job candidates to make better job choices. Third, inside recruits fit better with the organization because those who referred them know what it takes to be both successful and not to quit. Fourth, those from employment agencies or newspaper ads may know more about the full range of job possibilities and thus have higher turnover than those from other sources because of this greater knowledge. Fifth, source differences might be the result of systematic differences in the types of people from each source. Sixth, those referred by friends might be treated better by experienced employees and thus, have higher retention than other new hires.

A second recruitment source strategy is to set up a company Web site that communicates realistic information to potential job candidates. Unfortunately, there is no rigorous research on real organizational Web sites as of this writing. Studies of students responding to fictitious Web sites are just now beginning to be published. However, the trustworthiness of research using college students reacting to fictitious Web sites has yet to be established.

The Texas Instruments (TI) Web site (www.TI.com) is an example of how a Web site might be used for realistic recruitment. Job seekers are directed to a section where a self-scored survey can be taken. The purpose of the survey is to assess both person-job fit (14 questions) and person-organization fit (18 questions), which TI refers to as “job content fit” and “work environment fit” respectively. Job seekers are asked to rate certain items on a 5-point scale (*Strongly Agree, Agree, Neutral, Disagree, Strongly Disagree*). After responding to the 32 items, the job seeker is then given an overall score. The score shown is a simple dichotomy: You fit or you do not fit at TI. In addition to overall fit, the job seeker is also shown TI’s “best answer” to each of the questions right next to one’s own answer. TI is careful to remind job seekers that the TI best answers are not “right vs. wrong.” Rather, they indicate TI’s best estimate of its typical work content and typical organizational culture. Unfortunately, how these “best answers” were determined is not provided.

REALISTIC SELECTION METHODS

Although the RJP and recruitment sources are the two major topics in realistic recruitment, there are four selection methods that may also communicate realistic information, thus complementing both the RJP and the use of inside recruitment sources. These include (1) probationary employment, (2) “structured job interviews” (i.e., the situational interview and the behavior description interview), (3) work sample tests (both verbal and motor skills tests), and (4) assessment centers. Research on these four has concerned job performance rather than retention. Because these are primarily selection methods, rather than recruitment methods, detailed analysis of them is beyond the scope of this entry. As predictors of job performance, however, their validity and utility are both fairly well established.

RECRUITMENT

Recruitment is typically defined as activities engaged in by an organization with the purpose of attracting potential employees. Internal recruitment refers to the processes used to attract current employees to apply for job openings in the firm. External recruitment refers to the processes involved in attracting individuals who are not currently employed by the firm to job openings in the firm. In general, however, the term *recruitment* is used to describe external recruitment, which involves the processes of identifying and attracting applicants for open positions, keeping the applicants interested in the position and the organization, and ultimately turning the applicants into employees. Much of the recruitment research on which our current knowledge is based has examined larger firms. Although evidence indicates that larger firms are somewhat more formal and bureaucratic in their recruitment than smaller firms, it seems likely that many of the findings, which are based on larger firms, are applicable to smaller firms.

Recruitment is influenced by and influences other human resource management and career development practices used by firms. The first step in recruitment is

identifying potential sources of applicants. However, before a firm can identify potential sources, the firm needs to have conducted a job analysis, which provides information about important attributes needed by employees to perform the job successfully. Information about such attributes influences sources used to advertise the position and to attract candidates. For example, firms may use different sources to attract secretarial support staff versus chief financial officers. The recruitment process, which involves attracting applicants, is conducted concurrently with the selection process, which involves evaluating the suitability of the applicant for the position. Thus firms need to balance the processes used to “sell” the firm to applicants with the processes used to evaluate the fit of the applicant to the firm.

Evidence indicates that a firm’s human resource management practices can influence organizational performance and thus can provide a firm with a competitive advantage. Recruitment is an important human resource management practice because it influences the characteristics and quality of the applicant pool, which subsequently influences the success of subsequent human resource management practices such as selection, socialization, and training and development. Firms that attract more and higher quality applicants can be more selective, which can result in higher quality employees and fewer, or perhaps different, training and socialization needs.

The firm’s recruitment processes influence other important outcomes in addition to the quality and the diversity of the applicants. Important outcomes relative to the recruitment process are the percentage of applicants that remain in the applicant pool during the recruitment process and the percentage of applicants who subsequently accept a job offer. In planning their recruitment process, firms typically use a recruitment yield pyramid, which shows the ratio of invites to acceptances at various recruitment stages. For example, a recruitment yield pyramid might present information about the number of applications expected, the percentage of those applications that will be invited to interview with the firm, the percentage of applicants who will accept that invitation, the percentage of applicants who will be offered a job following the interview, and the percentage of applicants who accept the job offer. In addition to outcomes measured during the recruitment process, firms should consider posthire outcomes such as job survival rates, absenteeism, length of employment, and job performance.

The first step in the recruitment process involves informing potential applicants of the job opening and encouraging high-quality applicants to apply for the position. Evidence indicates that organizational characteristics can influence applicant attraction to the firm and actual application decisions. For example, location of the job opening appears to be an important organizational characteristic that influences applicant attraction and application decisions. In addition, both industry and size of the firm appear to influence attraction to the firm as an employer, at least for some applicants. Perhaps some of the more important organizational characteristics influencing applicant decisions are whether the applicant is familiar with the firm and the firm’s reputation or image. Applicants tend to be more likely to pursue employment opportunities with firms with whom they are familiar. Note that familiarity can result from specific recruitment activities as well as from nonrecruitment activities such as media exposure, advertisements, and product usage. In general, firms with better reputations tend to attract more and higher quality applicants than firms with less positive reputations. A firm’s reputation is theorized to influence applicant attraction through two related mechanisms: (1) reputation sends a signal about working conditions in the organization, such that firms with more positive reputation are perceived as having better working conditions; and (2) individuals may feel more pride (enhanced self-esteem) from working with well-known firms with positive reputations.

There are many methods, typically called *recruitment sources*, that can be used to notify potential applicants of job openings: newspaper advertisements, advertisements in professional journals and newsletters, job fairs, Internet job boards, school placement offices, private and government employment agencies, and referrals by current employees. Although the evidence is being accumulated, the quality of applicants appears to vary depending upon the recruitment source. In general, internal and informal sources, such as referrals by employees and rehires of former employees, lead to longer job survival and somewhat better job performance than do external and formal sources such as newspaper ads, school placement services, and employment agencies. Several mechanisms have been proposed for such relationships. The realistic information mechanism proposes that applicants who learn about the job from inside sources are provided with more accurate information about working conditions, which leads to more realistic expectations

and better job attitudes, job survival, and job performance. Similarly, the prescreening mechanism proposes that potential applicants may obtain better quality information about the position and poor-fitting applicants will self-select out of the applicant pool. The individual difference mechanism proposes that different recruitment sources target, and therefore attract, applicants who differ in terms of important individual differences such as applicant quality or fit with the position. Current evidence does not indicate which mechanism best explains the increased effectiveness of internal sources and, most important, all three mechanisms may be occurring simultaneously. Nonetheless, current research does support a prescription to provide applicants with realistic information about the job.

In an attempt to attract many applicants and then keep them in the applicant pool, traditional recruitment activities may overemphasize the positive aspects of the position and perhaps ignore or minimize the negative aspects. Although such a strategy may attract more applicants and allow the firm to be more selective, the job may not meet the expectations of the individuals hired, which can lead to dissatisfaction and subsequent turnover. Thus many firms now provide what has been called a *realistic job preview* (RJP) in an attempt to align applicant expectations with the realities of the job. In general, but not always, realistic job previews provide applicants with more negative information about the job than do traditional recruitment activities. Thus, firms are concerned about whether applicants who receive an realistic job preview RJP self-select out of the applicant pool. Evidence suggests that applicants provided an RJP typically do not self-select out of the applicant pool, and that RJP typically lead to somewhat less turnover and somewhat higher performance, although the effects are not large. Nonetheless, the accumulated evidence supports the importance of providing applicants with realistic information about the job and working conditions.

As noted above, recruitment is most effective when firms attract a large number of qualified applicants and keep those applicants interested in the job (i.e., in the applicant pool) while they are being assessed for their fit with the job and the organization. Evidence suggests that the firm's recruitment processes (e.g., job postings, initial interviews, site visits) can influence applicants' attraction to the firm and their decisions to stay in the applicant pool and to accept/reject

job offers. Although applicants want to know what it would be like to work at a firm, they typically have incomplete information about the job and the organization and thus experience uncertainty. Thus, in an attempt to understand what it would be like to be an employee of the firm, applicants may interpret recruitment activities as providing signals about working conditions in the firm. For example, unimpressive recruitment materials may signal that the company does not invest much in developing human resources and result in low applicant attraction to the firm.

Considerable evidence indicates that the initial interview influences applicants' perceptions of the firm as an employer and attraction to the firm. In general, applicants are more attracted to firms when the interviewer is more personable, is interested in the candidate, and is knowledgeable about the firm. Although the evidence is somewhat mixed, interviewer demographic characteristics, such as gender, race, and age, typically do not influence applicant attraction to the firm. Some evidence suggests that applicants prefer line recruiters versus staff recruiters, although it is important that the recruiters receive training in how to conduct interviews. Notably, recruiters can influence applicants' perceptions of job and organizational attributes that, in turn, influence attraction to the firm. Thus, the evidence indicates that interviewers have an important influence on applicant attraction to the firm since they provide information about the job and the organization and applicants tend to interpret interviewers' behaviors as providing signals about working conditions in the firm.

Typically, following the initial interview in campus-recruiting programs, a subset of applicants is invited for a site visit (i.e., a visit to the site of the job opening). The recruitment processes involved in site visits can influence applicant attraction and retention in the applicant pool. For example, long delays between the initial interview and the site visit invitation may lead applicants, particularly high-quality applicants, to infer the firm is not interested in them and thus to drop out from the applicant pool. The site visit typically provides applicants with detailed information about working conditions in the firm and opportunities to meet and interact with potential coworkers and supervisors. In general, employees met on the site visit tend to have more influence on applicant acceptance decisions than do employees met during the initial interview. More broadly, evidence indicates that the likableness of individuals met on the site visit and

applicants' evaluation of the site visit are related to job offer acceptance decisions.

As noted, since recruitment and selection are conducted simultaneously, an important question concerns how applicants react to selection procedures used by firms. Even a valid selection procedure can be detrimental to a firm if applicants withdraw from the applicant pool following the procedure. Although little research has investigated whether applicant reactions to selection procedures lead to applicant withdrawal, considerable research has investigated how applicants react to selection procedures and whether such reactions are related to applicant attraction. Applicants tend to evaluate interviews, work samples, résumés, and references most favorably followed by cognitive ability tests, personality inventories, and biodata; honesty tests and graphology were evaluated least favorably. In general, applicants react more positively to selection procedures when they believe that the procedure is related to job duties and predicts job performance. More broadly, research indicates that applicants who perceive selection procedures as fair and job related are more attracted to the firm as an employer, and indicate they are more likely to accept a job offer from the firm, although further research is needed to investigate actual job offer decisions. Nonetheless, the research indicates that to keep applicants attracted to the firm as an employer, firms should attempt to make the relationship between the selection procedures and job duties as transparent as possible to the applicants without, of course, affecting the validity of the procedure.

The final step in the recruitment process is turning applicants into employees (i.e., having applicants accept the job offer and subsequently report for work). Scholars have proposed three mechanisms describing influences on job choice decisions. The *objective factors mechanism* theorizes that job choice decisions are made based on attributes of the job. The *subjective factors mechanism* theorizes that job choice is based on perceived fit of applicant's needs and the ability of the firm to meet such needs. Finally, the *critical contact mechanism* theorizes that applicants have difficulty in differentiating among firms and therefore are influenced by recruitment contacts (i.e., the interview, site visit) with the firm. These mechanisms are not conflicting, and there is evidence to support each of them.

In support of the objective factors mechanism, considerable research indicates that "vacancy characteristics" are a strong influence on job acceptance

decisions. Not surprisingly, pay and benefits tend to be important characteristics that influence job choice decisions. In addition, individuals are more likely to accept job offers when the job is perceived as providing challenging and interesting work and when applicants see opportunities for development of skills and advancement in the firm. Interestingly, evidence suggests that the factors influencing job offer rejections may be different from the factors leading to acceptance. For example, applicants may eliminate potential jobs based on factors such as location, although location does not, typically, influence job acceptance decisions. Such evidence supports a model suggesting that applicants have a threshold for certain job attributes and eliminate jobs that do not meet the minimum level for a threshold (e.g., location). The remaining alternatives are then compared based on other job attributes (e.g., type of work).

Whereas the objective factors mechanism suggests that the level of certain attributes influence job choice decisions, the subjective factors mechanism theorizes that applicants determine their fit with the firm by considering their needs and the ability of the firm to meet such needs. In support of person-organization fit models, considerable research indicates that characteristics of applicants influence their reaction to organizational attributes. For example, although, in general, people are more attracted to higher paying firms, compensation tends to be more important to individuals who are more materialistic and/or have a higher need for pay than to individuals who are less materialistic or with a lower need for pay. More broadly, research also indicates that applicants' perceptions of their fit with the firm influence their job choice decision. However, although research supports the importance of person-organization fit for job choice decisions, less is known about which attributes of the person and which attributes of the organization are most important to consider when assessing fit.

Finally, the *critical contacts perspective* suggests that because applicants have difficulty differentiating among firms, they use recruitment contacts to assess how they will be treated as an employee. Stated differently, recruitment contacts are interpreted as providing signals about working conditions. Considerable evidence supports the belief that applicants interpret recruitment contacts as a signal about working conditions. However, the information value of recruitment contacts as a signal of working conditions is theorized to be the greatest when applicants have the least

information about the firm, because they have little other information about the working conditions beyond those suggested by the firm's recruitment activities. Based on such logic, recruitment contacts would be expected to have a stronger influence on whether applicants stayed in the applicant pool than on final job choice decisions, since applicants with a job offer presumably have learned more about working conditions. Nonetheless, recruitment contacts can influence the number and quality of applicants who are given job offers if applicants withdraw from the applicant pool during the recruitment process. Furthermore, some evidence suggests that when there is a delay between accepting a job offer and reporting for work (such as with college graduates), applicants are more likely to report for work if the firm keeps in contact with them after they accepted the offer.

Given the importance of human resources management for firm success and the importance of attracting top talent, considerable research has investigated recruitment processes, although much of it has focused on the recruiter and examined the initial interview. Furthermore, while research has provided insight into factors related to applicant attraction, we know less about factors that lead to applicant decisions to apply for, or to accept, a job. Researchers have begun investigating how image and reputation influence application decisions and factors that predict job acceptance. Such research will benefit organizations participating in the "war for talent."

REDEPLOYMENT

Redeployment is a strategic course of action taken by an organization to redirect or reallocate its current human resources: its employees. Continued utilization of effective human capital is primary to the life of an organization. Redeployment, which comes as a result of business circumstance or necessity, can be viewed as an intended transitional process. While employers may use redeployment as a reactive measure, the benefit of this continued process would be prolonged use or preservation of valued human capital. From a strategic perspective, the process would include taking measures to assess value attached to an employee's expertise, knowledge, skills, and abilities. Then the organization would have to determine where the resources can be best used in response to the organization's internal need to change. Redeployment is used when a company shifts a surplus of human resources from one department or division to another or to other units of its business that are in need of staff.

Change can come in many forms. For example, an organization could experience a merger, acquisition, downsizing, right-sizing, restructuring, or many other situations requiring a need to shift its resources and still retain assets attached to its valued employees. Redeployment is an effort to harness human knowledge that is already rooted, grown, and matured in an organization. This effort to harness resources would benefit an organization as it attempts to minimize the loss of valuable employees.

As a strategy, redeployment can be very effective. As employers set out to strategize and remain market

competitive, there is a need to retain expertise, knowledge, and know-how where possible. For example, knowledge-based organizations yield effective results through the use of redeployment maneuvers. The maneuvers should parallel the organization's business practices to respond to and counter market needs. As well, new business is constantly being won or lost. Employers are most efficient when they are able to retain their skill set, knowledge base, educational and practical experience, and corporate culture. Employers seek to redeploy employees and retain knowledge within the organization and minimize the drain on their intellectual knowledge base. Consistency of services would be promoted in the redeployment of human resources. As well, redeployment enables employers to provide services without loss of quality talent. Employees would take from the redeployment a sense of good faith on the employer's part. In return, valued employees are retained within the organization that can enhance an employee's organizational loyalty. Redeployment permits management to redirect its human resources in a manner that is both beneficial to the valued employees and the organization as it moves through phases of change. As employers manage staffing needs, the redeployment of staff augments effective human resource management practices. Redeployment is opportunistic for an organization's staff. It allows organizations to make knowledge shifts to sections of the organization where this knowledge can be utilized.

As organizations reallocate their knowledge resources, those transferable resources are put to use in new arenas; new work facets are experienced expanding and compounding employees' duties and responsibilities within the organization. When there is a need to redeploy employees, managers assess in advance when resources will become available and can plan in advance for their redeployment to another line of business. Employees who are redeployed—redeployees—can be considered for vacant and new positions, including any positions made vacant by various forms of voluntary or involuntary turnover. Retraining can augment redeployment. Recognizing that different job families and levels of employees will have varying needs as they transition, employers can train in an effort to enhance the knowledge base of employees as required.

Redeployment processes can include many facets. Redeployment policy and procedures should be developed internally as a proactive measure. The option to

be redeployed can be pushed as a benefit of the organization or an alternative to a reduction in force or layoff. Due consideration should be given to employees considered for selection or interested in being redeployed. In response to a surplus of staff, a manager or supervisor would assess the skill level of the employee and the viability of continued employment. Once this realistic assessment has taken place, there would be a need to look at alternative positions or locations within the organization where an employee's skill set would be beneficial. Successful deployment could manifest effective outcomes for the organization as a whole.

As an extension of career development, redeployment could be a successful means of progression where an organization faces change. This change could promote opportunities for advancement and growth of an employee or a group of employees possessing the talents, skills, education, and expertise that can be transferred and redeployed in an organization. Employees can gain being given an opportunity to use their skill set in other areas of the organization. Training opportunities can also aid employees in their professional development. In addition, employees who are transferred or moved to other areas will benefit from being exposed to new business units. Employees will grow in flexibility as they are challenged with new experiences. Redeployment could be viewed as negative; still, the process is advantageous to employees. Strategic shifts and maneuvers to preserve the longevity of an organization's knowledge base are crucial to the success of the organization. Redeployment is not a standard means of career pathing or movement within an organization; however, it is a process or measure by which organizations can open doors of opportunity to employees. The door would permit employees to continue working for the organization while the organization capitalizes on the strength of a consistent knowledge base. Employers seek expeditiously to capture and harness the value brought to the organization by its employees. Consistency of knowledge is a benefit to the organization and to the organization's client base. Even in the face of adversity, an organization that redeploys its employees smoothly transitions through change to provide continued service to its customers without interruption in quality or value received by the customer.

REFERENCES FOR EMPLOYMENT

Although much more is written about effective résumés and interviewing, written or oral statements about an individual's suitability for a position, commonly referred to as *references*, should not be underestimated as tools in the job search process. In fact, references may well tip the scale in favor of an applicant in a job interview or in the making of a job offer. Consequently, selecting and preparing individuals to provide references should be done with the same care and attention to detail given to other aspects of the job search process.

The first consideration is to choose individuals who can provide the most appropriate references for the job being sought. References might be personal, professional, or academic. Effective references are provided by individuals who know the applicant well, who can be specific about the applicant's skills, personal qualities, experience, and career goals, and who will respond with enthusiasm. Thought should also be given to selecting references who are credible because of their professions or personal reputations and who are effective communicators.

After developing the list of possible references, it is critical to determine each individual's willingness to serve as a reference and then to prepare the individuals to provide helpful, accurate information. The applicant should supply each with a current résumé. When a potential position is identified, a description of the job should be forwarded to the individuals selected as the most appropriate references for that

particular position. It serves the applicant well to inform the references about why this job is of interest and why the applicant is a strong candidate. Employers are typically interested in knowing about an applicant's interpersonal and teamwork skills, leadership qualities, quantity and quality of work output, as well as the ability to perform particular tasks associated with the job. The applicant should remind the references of examples of achievements corresponding to areas of importance to the employer.

Some employers request that an applicant submit letters of reference with the application. However, more typically, the employer will ask for a list of references, some of whom will be contacted by telephone. Consequently, the applicant must supply accurate information about how to contact each reference. The reference list, tailored to the particular job being sought, may be appended to the résumé accompanying the application letter or provided at the interview. It is helpful to categorize and annotate the references. For example, a professional reference may be annotated as follows: "Colleague on a team redesigning company payroll system, 2003-2004." If an employer requires completion of an application form, references can be copied onto the form. It is critical that the applicant notify the reference at the time his or her name is provided to a potential employer.

If employed and seeking a new position, an applicant may need to request deferral of contact with the current employer until a job offer has been made, perhaps contingent on a satisfactory reference from the current employer. The applicant should stay in touch with references during the job search. If some references are contacted by telephone, the questions asked can be good feedback to the applicant. All references should be notified and thanked on completion of the job search.

REINFORCEMENT THEORY

Reinforcement theory is the basis for the prediction and control of human behavior through the use of contingent rewards that strengthens the behavior and increases its subsequent frequency. Reinforcement theory explains learning through the linkages or connections that are made between behavior and environmental contingencies. It emphasizes the importance of observable, measurable behavior. Environmental contingencies (behavior and its linked-up consequences) are the primary unit of analysis.

Reinforcement theory can be contrasted with cognitive learning theories that attempt to understand and explain the causes of human behavior in terms of internal, mental processes and indirect measures of thoughts, feelings, intentions, and subsequent behavior. Reinforcement theory has its historical roots in Ivan Pavlov's (1849-1936) classical (S-R) conditioning, Edward L. Thorndike's (1874-1949) law of effect, John B. Watson's (1878-1958) experiments with human conditioning, B. F. Skinner's (1904-1990) operant conditioning (R-S), and, when applied to behavior management in the workplace, Fred Luthans and Robert Kreitner's organizational behavior modification (O.B. Mod.).

REINFORCEMENT THEORY AND LEARNING

The most significant contribution of reinforcement theory is its implications for learning in general and for managing behavior in particular. Thorndike's early studies (with cats in a puzzle box) provided the well-known law of effect: Behavior followed by positive environmental consequences will increase in strength and subsequent frequency, while behaviors followed by negative or no environmental consequences will decrease in strength and subsequent frequency, and, over time, disappear. As the major premise of reinforcement theory, learning results from the connection between behaviors and environmental contingencies.

Basic research over the years has supported reinforcement theory. For example, Pavlov successfully conditioned dogs to salivate to the sounding of a bell associated with the presentation of food (stimulus-response or S-R). Watson was able to condition "little Albert" to dread white rats by associating them with loud noises. Drawing from Thorndike's law of effect, Skinner refined reinforcement theory, showing that contingent consequences, and not just antecedent stimuli, were most important in predicting and controlling

behavior. He distinguished between respondent conditioning (Pavlovian S-R connection) and operant conditioning (the organism operates on the environment in order to obtain a desired consequence, or the R-S connection). Skinner's extensive studies provided the foundation not only for reinforcement theory but also the behaviorism school of thought in psychology and behavior management (or O.B. Mod.). In summary, reinforcement theory and learning says that behavior is a function of its contingent consequences. Applied to behavior management and O.B. Mod., it simply says that "You get what you reinforce."

REINFORCEMENT THEORY AND BEHAVIOR MANAGEMENT

Reinforcement theory provides an approach and specific guidelines for managing behavior. The application of rewards contingent upon the individual exhibiting desired performance behaviors will increase the probability that these behaviors will strengthen and be repeated. As the association or connection is formed between these behaviors and their contingent positive, desired consequences, the individual will learn that increasing the frequency of these behaviors will lead to receiving more of the desirable rewards. This reinforcement approach is called positive reinforcement. For example, if working harder with no errors results in more financial rewards, workers will work harder and try to be accurate.

Another, less effective, reinforcement approach in behavior management is the withdrawal of undesirable, noxious consequences. Individuals are reinforced not only by receiving what they desire but also by avoiding negative consequences. When certain behaviors result in avoiding undesirable consequences, individuals learn to repeat these behaviors more frequently, which is referred to as negative reinforcement. Most important, both positive and negative reinforcement have the same effect of increasing behavior, but the process is different. Under negative reinforcement, workers complete a task on time in order to avoid being chewed out by their supervisor and possibly being fired, whereas under positive reinforcement, they complete the task on time in order to be recognized by the supervisor and possibly receive a raise in pay.

There are other approaches that can be used to decrease the frequency of undesired behaviors. When behaviors are followed by the removal of desired rewards or the application of undesirable consequences, individuals decrease the frequency of their

behaviors. This approach is referred to as punishment and should not be equated with negative reinforcement. Again, negative reinforcement increases behavior, punishment decreases behavior. Under punishment, individuals can learn that reducing or stopping certain behaviors is tied to the elimination of negative consequences or the receipt of positive consequences. For example, service employees will decrease behaviors such as being short or rude with a customer because they know that if they do, they will be punished with admonishment from the supervisor and possibly being fired.

Another approach that can also be used to decrease and over time eliminate undesirable behaviors is to receive no consequences for the behavior. This approach is referred to as extinction. When no consequence (positive or negative) follows a certain behavior, individuals tend to switch to alternative, hopefully more rewarding behaviors, causing the behavior with no consequence to fade away. For example, attention-seeking disruptive behaviors by a work team member will decrease over time if ignored and the desired attention is not forthcoming.

According to reinforcement theory and considerable research, positive reinforcement is a much more effective strategy of managing behavior than negative reinforcement, punishment, or extinction. However, a punishment approach may take effect sooner and thus may be necessary in dangerous situations. For example, if workers are violating safety regulations, exposing themselves or coworkers to imminent danger, then immediate punishment may be both essential and effective in decreasing such potentially destructive behaviors. On the other hand, research has clearly shown that the long-term psychological disadvantages of punishment, which tend to manifest themselves in terms of stress, burnout, revenge, turnover, decrease in commitment, and many other negative outcomes, outweigh the potential benefits. Moreover, positively reinforced behaviors not only lead to more effective performance but also tend to be more resistant to extinction. When the positive consequences decrease over time, the behavior is sustained and may become self-reinforcing. On the other hand, punished behaviors tend to be only suppressed and tend to return soon after the negative consequences disappear.

REINFORCEMENT SCHEDULES

Although it is vital for consequences to be contingent upon behavior in order for reinforcers to have an

impact, it is not necessary for consequences to actually follow behavior every time. Initially, it is important that positive (or negative) consequences follow the behavior to get it tracking in the desired direction. This continuous schedule allows a clear association to be established between behavior and its contingent consequences. However, once this link is created, several other reinforcement schedules can be effectively applied.

Reinforcers can be contingent upon sustaining certain behaviors over time. This is referred to as an interval schedule. For example, paying people weekly for successfully accomplishing assigned tasks would be an example of an interval schedule. On the other hand, some behaviors are not practiced on a regular time basis and thus do not lend themselves to be reinforced on an interval schedule. For example, commissions based on number of cars sold would be an example of a ratio schedule of reinforcement.

Contingent reinforcers would be effective if administered as the desired behavior is sustained over a certain time period (interval) or as it is repeated a certain number of times (ratio). However, in addition, contingent reinforcers can also enhance desirable behaviors if administered at fixed or variable reinforcement schedules. On a fixed interval schedule, the worker is paid every two weeks and on a fixed ratio schedule, and the car salesperson is paid a certain amount for every three cars sold. However, if the interval or ratio at which an individual receives reinforcers is variable, and thus uncertain, such reinforcers will still increase the frequency of desired behaviors. In fact, research shows that the variable-interval and variable-ratio schedules are related to even stronger, sustained behavior, as well as being more resistant to extinction, than the fixed schedules. For example, an employee is rarely promised to get promoted upon exhibiting the behaviors desired by the manager or the organization for a fixed amount of time or for adequately performing the job a certain number of times. However, if employees realize that hard work, productivity, and commitment are related to promotions in this organization (and see themselves and others being promoted accordingly), productive behaviors are likely to result. The promotions are given on a variable schedule and, if fair, can lead to sustained productive behavior and be resistant to extinction.

REINFORCEMENT THEORY IN THE WORKPLACE

Significant applications of reinforcement theory to the workplace have been demonstrated by Luthans

and others and have been referred to as organizational behavior modification, or simply O.B. Mod. The O.B. Mod. approach attempts to predict and manage workplace behavior through five specific steps of application: (1) identify critical performance-related behaviors, (2) measure the frequency of these behaviors, (3) analyze the existing antecedents and consequences, (4) intervene with positive reinforcers, and (5) evaluate the results.

Through more than three decades of experimental workplace studies, Luthans and colleagues, as well as many other behavioral management researchers, have been able to clearly show consistent findings regarding various types of reinforcers that can be effectively utilized in workplace settings to increase performance. Specifically, three types of reinforcers were found to result in significant improvements in workplace performance when administered through the five-step O.B. Mod. model: money, performance feedback, and social recognition. Meta-analytical research findings on the studies over the years show that the application of O.B. Mod. in the workplace increases performance by an average of 17 percent. Interestingly, although feedback and recognition involve little if any direct cost, they can yield results that are similar to, and sometimes higher than, monetary rewards. Moreover, unlike money, both feedback and recognition tend to resist satiation. In other words, rarely do employees get “filled up with” or “tired of” too much feedback or recognition. Unfortunately, these nonfinancial rewards tend to be less emphasized and are greatly underutilized in managing today’s human resources at all levels and types of organizations.

As emphasized earlier, the key to effective reinforcement is that rewards need to be administered contingently upon performance. For example, for monetary rewards to reinforce desired (i.e., those that help attain goals of performance) behaviors, they need to exhibit variation in amount and timing that is directly related to performance. A monthly, fixed-amount paycheck is often not contingently reinforcing performance. For performance feedback to be effective, it needs to be positive, immediate, graphic, and specific. An annual performance appraisal session to justify why an employee will (or will not) receive a pay raise is too often insufficient. For recognition to enhance performance, it should be in the form of personal, one-on-one attention and appreciation. The employee knows the manager has observed the desired behavior and recognizes the contribution.

A random pat on the back or an occasional “Good job!” is not contingent and therefore is not sufficient and is not an effective way to proactively manage behavior through recognition.

REINFORCEMENT THEORY AND CAREER DEVELOPMENT

Reinforcement theory is not limited to performance management. It can also be applicable to many other areas of human resource management such as career development. Increasingly, managers are struggling with their employees’ diminishing loyalty and organizational commitment and engagement. However, such attitudes should be no surprise for managers, considering what is being reinforced in today’s organizations. In light of the present and likely future high rate of change and increasing uncertainty facing employees, organizations are no longer capable of providing job security and long-term growth opportunities for their employees. Frequent mergers, acquisitions, restructurings, and layoffs are making single-organization careers very rare.

In terms of reinforcement theory, employees are frequently observing that those who align their personal goals with their organizations’, solely depend on their employers for development and growth, and do not explore other opportunities are the ones who face the most negative consequences in times of change. On the other hand, those who take charge of their own careers, take advantage of their organizations for personal development and growth, never cease their job search and career exploration activities, and minimize their own emotional attachment to their organizations tend to be rewarded for such behaviors. In other words, employee career-oriented behaviors are changing as a function of their consequences.

Another example of the role reinforcement theory can play in providing insights into career development concerns new graduates entering the workforce. Throughout school and college years, students are conditioned to a teacher-student relationship that is characterized by well-defined expectations, clear performance standards, and frequent, objective feedback (grades) at regular, short-time cycles. This is in contrast to most manager-employee relationships, where flexibility and adaptability is expected, performance expectations and standards are continuously shifting, and longer time cycles may elapse before feedback, usually subjective, is provided. In other words, consequences in the academic environment may tend to be

more contingent upon performance than consequences found by those starting off their careers in the workplace environment. This may help explain initial feelings of confusion and lack of direction for new entrants in a career.

Besides providing insights for the beginning phases of career development, reinforcement theory can also be used to analyze mid-career issues and crises. When reaching the middle of their career, many employees experience career plateaus; they feel stuck at a particular level of their careers. In such dead-end situations, the most common reactions are job dissatisfaction, frustration, unhappiness, and lack of motivation. In terms of reinforcement theory, what these employees are experiencing is a lack of reinforcing consequences for their life's work. They are undergoing an extinction process in which their work behaviors are followed with little or no consequences. From a career development perspective, unless these consequences for mid-career employees are given attention and better managed, potentially productive employees, with considerable human capital in terms of experience and tacit knowledge, will become apathetic, indifferent, and disengaged. Reinforcement theory provides understanding and support for effective career development that features lateral career movement, job rotation, international assignments, dual-career ladders, work-life balance, and other initiatives that provide mid-career employees with positive consequences that would continue to reinforce their performance. On the other hand, a traditional career often dead-ends with no reinforcing consequences.

LIMITATIONS AND RECENT DEVELOPMENTS

Although a reinforcer is any environmental consequence that strengthens and increases the frequency of the behavior, it is important to remember there are individual differences on what this reinforcer may be and the weight or relative importance of it. Despite the proven generalizability of money, feedback, and recognition in workplace settings, the contingent application of such rewards in each specific setting, as well as the frequency, amount, administration logistics, and continuously changing relative importance of each reward, continues to challenge the implementation of organizational behavioral modification programs.

Besides these individual differences, reinforcement theory also provides little understanding or explanation

of how reinforcers work because it does not integrate the cognitions and thought processes that cause contingent consequences to shape behavior. Still another limitation is that many situations involve multiple, competing contingencies that interact to shape behavior. Reinforcement theory does not attempt to handle these interactions, which often result from the social context within which contingent reinforcement (or punishment) occurs.

More complex social cognitive theory (SCT) extends reinforcement theory to address the limitations noted above. Albert Bandura's SCT is based on the continuous reciprocal interaction between the person (cognition), the environment (physical context, including organizational structure and design, and social context, i.e., other people), and the behavior itself. Under SCT, behavior is not only a function of its contingent consequences as in reinforcement theory but is also influenced by the cognitive processes of symbolizing, forethought, observation, self-regulation, and self-reflection.

For example, from an expanded SCT perspective, the role of contingent reinforcers in enhancing performance can be better understood and explained in terms of outcome utility, informative content, and regulatory mechanisms. Monetary rewards tend to be highest in outcome utility (they have direct and instrumental value in acquiring desirable material things). Feedback, on the other hand, is usually highest in its informative content, which individuals tend to seek and value. However, with appropriate (contingent) administration, money and recognition can also be of high informative content. Finally, recognition is strongest as a regulatory mechanism. While immediate recognition and attention takes place in the present, the cognitive capacity for forethought allows for future rewards (e.g., a promotion) to be imagined, linked to present behavior, and thus serves as a reinforcer. In addition, the cognitive capacity for self-regulation in turn allows for present behavior to be shaped accordingly. In other words, SCT provides a depth of understanding, as well as more informed application, in contrast to the more pragmatic reinforcement theory.

Today's managers, as well as scholars in the behavioral sciences, education, and organizational behavior, have generally come to the realization that we can no longer emphasize any one aspect of the social cognitive triad (the person, the environment, and the behavior itself) at the expense of the others. The social cognitive theory integrates the objectivity and predictive

capacity of reinforcement theory, with the depth, realism, and application of social cognitive perspectives. Reinforcement theory contributes greatly to behavior management for performance improvement and has many implications for modern human resource management such as career development. Social cognitive theory is a new development that extends reinforcement theory to overcome some of its limitations and provides a depth of understanding needed for today's increasingly complex and ever-changing environment.

RELIGIOUS DISCRIMINATION

Religious diversity and discrimination are realities of the modern workplace. In a recent survey of people in the United States, over 90 percent professed a religion, representing more than 1,500 religious denominations. Indeed, during the past decennia, the religious makeup of the workforce in Western countries has changed considerably due to increasing globalization,

immigration trends, shortages in the labor market, and the reintegration of the older and often more religiously observant workers in the workforce. Religious beliefs are not simply turned off when a person enters a workplace. Ignorance of religious practices may lead to misunderstandings and conflicts among employees and foster prejudice and discrimination. In the United States, claims of workplace intolerance on religious grounds presented to the Equal Employment Opportunity Commission climbed about 30 percent from 1992 to 2000. Similar trends are reported in Western European countries. The Dutch Equal Treatment Commission, for example, reported twice as many complaints about *religious discrimination* and harassment at work in 2003 compared to 2002.

Organizations dealing proactively with religious diversity at work may do so for several reasons. First, conflicts in the workplace can adversely affect job performance and lead to turnover. Valuing religious workers in a way they feel accepted and included in the workforce may foster a more productive and profitable work environment. Second, the growing diversity of the workforce necessitates an openness to diversity in the recruitment and selection process in order to attract and retain the best employees.

DEFINITIONS

Religion can be defined in many different ways and from several different viewpoints, including philosophical-theological (Plato, Kant, Foucault), sociological-political (Durkheim, Marx), historical-anthropological (Malinowski, Lévi-Strauss), evolutionary (Bellah, Tylor), psychological (Allport, Freud, Vergote), or legislative (Equal Employment Opportunity Commission, Religious Freedom Restoration Act). Put differently, how one defines religion depends on the particular context in which religion is considered. For a consideration of religious discrimination in the workplace, the legislative and social science perspectives are of particular interest.

From the legislative perspective, the protection of employees' religious rights while at the workplace falls under the concept of freedom of religion, as protected in international human rights law (cf, the United Nations Declaration on the Elimination of All Forms of Intolerance and Discrimination Based on Religion and Belief, 1981; the Oslo Declaration on Freedom of Religion and Belief, 1998). In the United States, this protection is mostly derived from Title VII

of the Civil Rights Act of 1964 and guidelines promulgated by the Equal Employment Opportunity Commission. Although different accents can be found in national and international acts and laws, they all formulate some perspective on religion, including nondiscrimination principles as well as varying forms of occupational exceptions.

According to the Equal Employment Opportunity Commission's Guidelines on Discrimination Because of Religion (29 CFR Part 1605-U.S. federal legislation), religion is defined as both beliefs and practices that are sincerely held. For example, an employer may not refuse to hire an applicant because of that person's Islamic faith (belief). Also, an employer may not fire a Muslim because of religious practices, such as breaks for prayer time during official working hours (practice). Moreover, these beliefs and practices should be sincerely held, which means that U.S. law is not confined to organized religions such as Islam, Christianity, Hinduism, Buddhism, and Judaism. Wiccans, Pagans, and Atheists are legally protected against religious discrimination in the workplace as well.

Employers should reasonably accommodate the religious observances (beliefs and practices) of their employees unless doing so would impose an "undue hardship" upon the employer (Title VII of the Civil Rights Act 1964). For example, a company may legally reject an applicant who refuses to cut his beard for religious reasons because of commercial and sanitary concerns (*EEOC v. Sambo's of Georgia, Inc.*). However, where appropriate, employers should consider accommodations to prevent or resolve religious work conflicts by offering flexible scheduling of working hours, by permitting employees to swap shifts, by relaxing grooming or clothing requirements, by transferring employees to different locations or functions, and by permitting unpaid or accrued paid absence leave due to religious needs. If there is a business necessity for certain hours or other requirements, the employer should explore the employee's accommodation needs without making any explicit inquiry or reference to religious forms as a basis of a potential conflict. Nevertheless, occupational exceptions are allowed. Religious schools, for example, may impose religious requirements upon the hiring of teachers and administrators.

From a legal perspective, religious discrimination at the workplace can be defined as taking two forms: (1) refusal to employ or accommodate employees based on sincerely held beliefs and practices (disparate

treatment discrimination) and (2) a treatment on the basis of inadequately justified factors other than religion that disadvantages members of a religious group (disparate impact discrimination). Disparate treatment discrimination occurs when a member of a religious group is treated less favorably than a similarly situated member of the same or another religious group. It may take the form of quid pro harassment when an employee should submit to religious practices in exchange for job benefits or to avoid adverse actions. Far more commonly, however, is a second form, namely the hostile work environment. Disparate impact discrimination occurs when a behavior or practice that does not involve religion directly has an adverse impact on members of a religious group without a sufficiently compelling reason. An example is firing employees who do not dress professionally when such a policy results in proportionately more dismissals of members of certain religious groups. These practices are unlawful unless a compelling business-related reason can be supplied to justify them. This might be the case when the wearing of religious symbols, haircuts, or dress may endanger employees' safety or sanitary conditions at the workplace. From a legal standpoint, it always remains open to the employer to argue that discrimination can be justified for business-related reasons. Moreover, in some instances, organizations are legally allowed to require codes of conduct and occupational requirements that discriminate against (prospective) employees on other grounds. Complaints that are not considered discrimination from a legal point of view may still be perceived as discriminatory from the individual's perspective.

The legal definition includes actions the organization might take (e.g., prohibiting the wearing of religious clothing) in the name of customer preference. The definition further implies that people may discriminate against adherents of other faiths as well as of the same faith. For example, an employer may decide not to hire an applicant of the same faith because the applicant appears not to be a regular churchgoer or performs poorly when being questioned about religious matters during the interview.

From the perspective of the social sciences, increasing attention has been paid to religiosity and spirituality at the workplace. Although related to religion, scholars overall recognize that spirituality differs from religion in that it is not necessarily formal, structured, or organized. Spirituality is broadly described as the deeper, more mysterious part of

being, referring to some interconnectedness with the universe. Religion, on the other hand, is considered as a more institutionalized way through which a person's spirituality is manifested.

From a social science perspective, discrimination is often discussed in terms of overt or blatant discrimination and subtle discrimination. Examples of blatant religious discrimination are personal belongings being destroyed because of religious beliefs, not being allowed to have some time off from work to observe religious holidays or prayer breaks, not being allowed to wear certain forms of clothing, including head covering, and being rejected from selection on the basis of religious background. Most discrimination, though, is more subtle and indirect. Examples of subtle religious discrimination are supervisors keeping employees with faiths different from their own less well up to date about business. Being mocked or ridiculed because of religious beliefs or practices can take both overt and subtle forms.

ANTECEDENTS AND CONSEQUENCES OF RELIGIOUS DISCRIMINATION

The psychological literature on discrimination provides models to clarify when individuals will perceive discrimination, including antecedents of discrimination, coping mechanisms, and consequences. While it is beyond the scope of this entry to review all of the literature, presented below are some key conclusions regarding religious discrimination in the workplace.

In general, the visibility and perceived controllability of a stigmatizing attribute will affect whether an individual is discriminated against, with greater visibility and greater perceived controllability contributing to greater stigmatizing treatment. Religion is not typically a visible characteristic but can become so in the workplace by an individual's appearance (wearing religious symbols or clothing) and actions (praying during breaks or at meals). As the psychological research predicts, greater religious discrimination occurs when religion is made salient. Discrimination may also be more likely to occur when religious practices are seen as controllable (e.g., praying, fasting) and therefore able to be suppressed in the work environment.

While no systematic research has been done on motives for religious harassment in the workplace, the social-psychological literature has pinpointed prejudice and stereotypical beliefs as determinants of

discriminatory practices in general. Other potential determinants are dissimilarities in beliefs, anxiety of the unknown, competition between groups, self and group preservation (e.g., need to uphold individual or group status, dominance, or power), and personality characteristics (e.g., ethnocentrism, authoritarianism, dogmatism). Furthermore, research on diversity climates in the workplace indicates that certain organizational contexts may promote greater tolerance of a diversity of viewpoints and behaviors and greater support for individual differences.

Even within the same situation, some people may feel more discriminated against compared to others. For example, individuals who are high in religious group identification may attribute negative treatment by employees to religious discrimination when situational cues to religious prejudice are ambiguous, where those less identified would be more likely to do so. Treatment may be seen as justified rather than attributed to prejudice, depending on an individual's belief in the dominant ideology (e.g., belief in a just world), stigma consciousness (expectation of being stigmatized), group identification, and other personal characteristics. A strong belief in a just world, for example, may lead members of low-status groups to fail to consider treatment as injustice.

Research on perceived discrimination has shown cognitive, affective, behavioral, and physiological consequences, affecting such factors as the victims' social status, psychological well-being, physical health, and performance. Theories on stress and coping argue that the relationship between personal/situational determinants and outcomes of perceived discrimination is mediated by the degree one's identity has been threatened or challenged. Religious identity threat results when a stigma-relevant stressor is potentially harmful to one's religious identity and exceeds one's resources to cope with the demands. Religious stigmatization may also lead to identity challenge instead of threat. Antireligious slurs, for example, may not be perceived as threatening when one has sufficient coping mechanisms (being assertive, being optimistic, having social support, etc.). Coping mechanisms can be emotion focused (e.g., praying) or problem-focused (e.g., adapt to dress code). They may result both in disengagement strategies (e.g., absenteeism, turnover) and in engagement strategies (e.g., complain, claim, or challenge religious harassment). Whether one challenges religious discrimination may not only depend on the resources

available but also on the perceived social costs associated with making a discrimination claim. Complaining may affect interpersonal relationships, the way others perceive the complainant, and the complainant's self-esteem. Consequently, people may be motivated to deny, minimize, or ignore religious discrimination to avoid additional devaluation or exclusion. Just as some individuals may be more prone to discrimination than others, a single person may respond differently to religious discrimination in different situations. For example, one might deny outlets of religious harassment on a train or in a shopping center but might not deny them at the workplace. Clearly, a person-by-situation approach is needed to fully understand the determinants and effects of religious discrimination on individuals.

CONCLUSION

To date, religious discrimination in the workplace has mostly been considered from a legislative point of view. Remarkably, almost no systematic, psychological research on religious discrimination, including its forms, antecedents, and consequences, has been conducted. Empirical studies have shown spirituality as an effective mechanism for coping with occupational stress. But what if these beliefs become a source of occupational stress themselves? Most chapters or books on workplace diversity and workplace spirituality/religion only slightly touch upon spiritual/religious diversity and discrimination at the workplace. However, in line with the growing cultural diversification of the workforce and the political climate after September 11, 2001, it can be expected that religious diversity and discrimination in the workplace will become a growing concern in the future. Just as with cultural diversity issues, employees, managers, customers, and shareholders will encounter religious diversity much more frequently, both inside and outside organizations.

Attempts to deal with religious discrimination in the workplace have highlighted its complex, subjective, and multifaceted nature. In courts of law, discrimination decisions are often based on comparing testimonies of both observers and victims. Social psychological research has shown that victims and observers may use different decision rules in deciding whether or when an action reflects discrimination (e.g., gender, age). Future research could investigate how this applies to perceptions of religious discrimination. Understanding how perceptions of religious

discrimination are formed may especially be relevant to understanding and dealing with subtle forms of discrimination.

Religious diversity within the workplace can be viewed negatively, as some empirical studies show more stress, more turnover, and less interpersonal attraction in culturally diverse working groups. The negative view on religious diversity has even fostered the idea of a complete secularization of the workplace as a way to minimize potential religious frictions. However, people may not leave their religious beliefs at home. Banning any form of religious expression at the workplace is unrealistic. Interestingly, organizational research has also shown some potential benefits for organizations such as enhanced creativity, innovation, and reduction of groupthink in culturally diverse working teams. In the same way, while religious expression might sometimes cause problems, at other times it might be very helpful (or at least inconsequential) for the organization. In the future, exploring the consequences of religious diversity in the workplace and assessing the contributors to religious discrimination are likely to be the focus of greater research attention.

RÉSUMÉ

Every job search is inherently discouraging. Whether someone has 2 years of work experience or 20, the search for a job will run into disappointments, primarily because of the intense competition in the job market. There simply are more qualified applicants for every job that is advertised, resulting in discouragement when it minimizes the chance to be noticed as a potential candidate. However, a well-written *résumé* can help the job applicant get noticed for the relevant skills and qualifications, thereby maximizing the chances of being called for an interview.

Writing a solid *résumé* requires that a person choose the best format to describe work experience associated with the skills related for a job or chosen career path, and that the *résumé* address four fundamental objectives: (1) identification of work accomplishments, (2) quantification of work performance, (3) concise narrative of previous job roles, and (4) the connection between experience and a targeted job and industry. Before discussing the details of these objectives, an overview of *résumé* formatting is needed.

The traditional *résumé* format starts with the heading of Work Experience, which follows a chronological sequence of employment history beginning with the most current job and ending with the first job held. This chronological sequence is a standard for all *résumés*, regardless of format, and should not be altered. The other headings in a traditional format are Education and Skills/Activities. When listing education, be sure to include the most recent credential completed first followed by any previous credentials. If a person completed a bachelor's degree, there is no need to list a high school diploma on the *résumé*.

It is appropriate for individuals with less than two years of work experience to include GPAs next to the academic diploma or degree obtained. When reviewing *résumés* that show more than two years of work experience, employers are less concerned or impressed with GPAs and more interested in assessing actual work history and job performance. However, if

a person graduated with honors, it is acceptable to identify educational attainment with the appropriate distinction such as *cum laude*, *magna cum laude*, or *summa cum laude*.

When deciding what to list under Skills/Activities, only include computer skills, language skills, or other work-related skills specific to your profession. For activities, it is wise to refer only to volunteer involvement, trade group, or professional association affiliations and to avoid references to religious affiliation or personal interests like cross-country skiing, guitar playing, etc.

Other guidelines regarding the *résumé* format to keep in mind are as follows: use bullets to separate your duties and tasks when describing each of your jobs; use font size of 11 or 12 with the exception of your name, which can be set at 14 font but not larger; and do not use the heading References Upon Request. This is an unnecessary use of space on a *résumé*. It is now a common hiring practice to request and check references of candidates who are likely to be offered a position. Last, it is okay to have a two-page *résumé*. A general rule of thumb is to allow two-page *résumés* for people who have three or more years of work experience.

The objectives mentioned earlier are paramount to a well-written *résumé* regardless of how brief or seasoned your employment history. The first objective is to highlight accomplishments. This can be done by identifying general tasks associated with each job while being specific on some of the results of the job performance. In other words, in describing a job task, try to explain how, by doing that task, a positive result was accomplished. See how Example B improves upon Example A below:

Example A

Created an Access database to track travel expenses for sales team.

Example B

Created an Access database to track travel expenses for sales team, resulting in cost savings.

The second objective is to quantify a task or output whenever possible. Adding relevant and factual data, whether it is percentages or raw numbers, shows the level of complexity related to a job and amplifies your accomplishments. The recruiter who is seeking a

results-oriented person for a sales position is likely to respond positively to the résumé that makes references to data supporting the percentage of revenue increase or number of accounts brought in by the candidate in current or previous roles. Quantification also helps the recruiter understand the complexity of job performance, which may otherwise be interpreted as mundane. For example, there is a difference between managing a staff of 3 people and managing of staff of 30. Using Example B from above, notice the difference when a simple data set is included.

Created an Access database to track travel expenses for a 12-person sales team, resulting in a year-end cost savings of 20%.

The third objective is to provide a concise narrative of job tasks that highlights technical skills and demonstrates relevant personal abilities. Too many résumés simply list duties associated with a job that consequently comes across as one-dimensional and uninspired. In describing jobs, provide explanations of the tasks and the context of how and why these tasks were performed. Notice the dynamic tone in the examples below when compared to how they were written before.

Before

Used software tools for data analysis.

Assisted manager with consulting assignments.

After

Used SAS software tools for data analysis of infant mortality rates for a sociology class project on teen pregnancy.

Supported branch manager on complex consulting projects by monitoring budget expenses and reviewing project progress reports.

Finally, for the fourth objective, a résumé should be written so that it links work experience with a target function and industry. Beyond determining a candidate's qualifications to perform a job, employers are also looking for a candidate whose experience is relevant to the industry or the culture of the company. Therefore, it would be helpful to identify work and academic accomplishments, and include in the résumé, the ones that are most aligned or valued by the industry and

relevant to the targeted function. Also, appropriate industry-related jargon and buzzwords should be included sparingly in the narrative of a résumé, especially when describing an accomplishment.

The résumé is the most important tool in the job search. Before an employer decides to interview an applicant, a judgment is made on a person's qualifications and abilities solely on the quality of the résumé. It is imperative that a résumé reflect the factual documentation of the applicant's employment history while communicating how value was contributed to past employers and why these accomplishments are relevant to the job being sought.

The four objectives outlined in this entry are timeless points of reference when revising a résumé throughout various career progressions. But the most important résumé tip of all is to proofread. Employers will rarely be inclined to interview a person whose résumé has spelling and grammatical errors no matter how well all four objectives are addressed.

RETENTION PROGRAMS

In the first half of the twentieth century, employment careers were often characterized by long periods of stable, uninterrupted employment at a single firm. However, contemporary career models are becoming more episodic in nature. Gone are expectations of career-long, stable employment. They have been replaced by expectations of substantial job mobility. Because workers are more accustomed to and accepting of job change, the task of designing programs that will convince workers to maintain current employment (i.e., effective *retention programs*) has become significantly more challenging.

Organizational attritions take various forms (e.g., quits, layoffs, retirements), but it has become customary in the domain of retention research to focus on voluntary quits. This focus is rooted in assumptions about the controllability of turnover behavior. Voluntary turnovers are controllable, it has been argued, because effective management intervention might potentially convince prospective quitters to stay. In contrast, involuntary turnovers (e.g., layoffs, firings) are more commonly viewed as irrevocable events—driven more by circumstance than personal volition.

Attempts to depict the turnover process have borrowed heavily from attitudinal and decision-theory frameworks. Typically, turnover models describe a series of cognitive and affective events that flow toward a decision to quit or stay. Decisions to quit (or stay) are products, in these models, of rational choice.

Attitudinal mechanisms have a central position in turnover theory. Affective tone (i.e., positive or negative) is thought to act as a routing mechanism—determining behavioral directionality. Positive affect predisposes an individual toward staying. In contrast, negative affective tone predisposes an individual toward quitting. Studies evaluating these ideas have usually supported them. For example, a substantial body of research on job affect (i.e., job satisfaction) convincingly shows that levels of job satisfaction and dissatisfaction reliably predict stay/leave decisions. Extending this position further, studies of organizational affect (i.e., organizational commitment) have also shown that attitudes toward the organization impact turnover in a similar fashion.

Organizational retention programs often attempt to capitalize on the knowledge of the affect-turnover linkage. For example, organizations have employed survey feedback as a component of their retention programs. Studies show that the administration of an employee attitude survey, followed by dissemination of the results to participants, results in attitude-score improvements. Attitude-score improvements should lead, in turn, to downstream improvements in employee retention rates.

A similar approach underlies the use of job redesign as a retention strategy. Job redesign involves reconfiguring a job so that the job will provide intrinsic rewards, like job satisfaction, to the worker. As workers experience more job satisfaction on their current job, they correspondingly become less interested in leaving the job for some alternative position.

Realistic job previews represent yet another retention strategy rooted in expectations about the value of

positive affect. During processes of employee recruitment, realistic job previews challenge recruiters to present the hiring organization in an accurate light—even if that light shines on unflattering details about the firm. Presenting prospective employees with a realistic picture of their future employer helps to defuse the disappointment mechanisms that often follow misleading recruitment pitches. If disappointment and its attendant dissatisfaction can be avoided, the chances of longer term retention of new recruits become better.

Although important, job affect is not alone in accounting for individual turnover. Job search is another important mechanism shaping these decisions. Quit/stay decisions are substantially impacted by the visibility and accessibility of alternative sources of employment. In essence, contemporary turnover models assume that individuals will be most inclined toward quitting when an alternative job is perceived to be superior (e.g., more pay, more promotion opportunity) to the currently held position.

Retention program sponsors can make use of this insight by adjusting the relative attractiveness of jobs within the current organization. Adjusted enough, they may overtake external alternatives in terms of relative attractiveness. If the present job is deemed comparable to or better than an external job alternative, individuals may choose to forgo a job change altogether. Other things equal, employees will often favor the status quo over undergoing a major change in their life circumstances.

To improve job attractiveness, retention program sponsors may introduce periodic reviews of salary and benefit packages as a means of sustaining market competitiveness. However, job comparisons are not limited to compensation issues. Focusing on long-term career progress, workers may also evaluate the advancement and professional growth implications of a job move. Retention program sponsors can address these issues in a number of ways. They can eliminate dead-end jobs by restructuring promotion paths so that advancement opportunities are open to more individuals. They can create career ladders and implement “promotion from within” policies to send the message that employees will be given every opportunity for advancement with their current employer. They can also take steps to improve access to training and development opportunities for workers. Workers understand that skill and knowledge acquisition are the main currencies of career advancement, and they may reject a job change, even

one offering more money, if the learning opportunities associated with the current job are seen as providing the best avenue toward long-range personal betterment and fulfillment.

Increased job mobility is making the task of retaining valued employees even more difficult in contemporary business environments. To increase the chances of program success, program developers must face the challenge of developing retention programs that respond to the unique needs and concerns of key employee populations.

RETIREMENT

Broadly conceptualized, *retirement* is the departure from a job or a career path, usually occurring sometime after the age of 50, where the individual retiree displays a limited or nonexistent psychological attachment to work after the departure. Retirees are normally differentiated from nonretirees based on several criteria, including tending to spend less time working for pay, having a source of income that is specifically designed for retirees, and viewing themselves as a retired person.

Actually, retirement was not always an understood phase that occurs after decades of work life. Retirement is a concept that became a virtual birthright as a

part of the expanding industrial economy during the last century. It was the celebrated passage allowing an individual to leave the workplace and stop punching the time clock or to hang up the work clothes for good. In that context, individuals would simply go through the standard steps in preparing for a happy retirement, including planning for life after one's career ends, securing financial resources, and considering what to do with all of the additional free time. However, beginning during the 1980s, the trend toward earlier and earlier retirement (made possible by more generous Social Security benefits and pension plans) began to shift back toward both delaying retirement for a number of years and continuing to work at least part time after initial retirement. Many workers were also setting a pattern for retiring and going to work for another employer.

Thus this entry describes retirement according to the clear direction experienced by many recent "retirees," that is, that retirement is not the end of career development but rather a new career phase that can continue to feature meaningful work, but it might involve alternate work schedules and thereby allow for the rather comfortable combination of outside work with personal "retirement" pursuits. This direction in the thinking about retirement is supported strongly by the members of the baby boom generation who will begin retiring in great numbers in the early part of the twenty-first century. This oversized generation has already set the pattern for so much of the American culture, and now they will undoubtedly also change the perspective on the life and career phase called retirement.

By 2010, when the baby boom generation is expected to be retiring in great numbers, the United States's labor market must find ways to keep older workers on the job longer. There simply will not be enough people to fill open positions in the job market. Demographically, the United States's population is aging, and the generation following the boomers is much smaller in size. Labor shortages could occur if existing older workers, who possess many of the skills needed by corporations, were to retire and immigration does not sufficiently make up the loss. Other industrialized nations are facing the same issues due to aging societies in the midst of technological economies. The level of need is great enough to require an increase in employment of 25 percent for those over 55. Otherwise, there is concern that when baby boomers start retiring, the labor force may well shrink. A greater

participation rate by the aging baby boomers is one scenario that could resolve that concern.

STRUCTURAL FACTORS IN THE RETIREMENT DECISION

There are a number of variables to consider when analyzing the feasibility of delayed retirement by older workers. These factors take into account the reality that the contingent of older workers represent different segments of the population and are individuals with personal options in a democratic society. They vary by experiences, skills, educational level, income, and preparation for retirement. The restructuring occurring in the workplace, including layoffs, downsizing, and rightsizing, may be understood, at least partially, in the context of the phenomenon of transitioning from a goods-producing economy to a services-producing economy. It is an era characterized by knowledge, information, and technology, rather than manufacturing. Though change is always difficult to deal with, and a reasonable period of time is required for people of any age to cope with major transitions in their work life, technological advances are not incompatible with aging, and the increasing deemphasis on physical labor will be shown to be an advantage for older workers. The service economy and the restructuring brought about by technology renders their work less physically demanding. In fact, technology can be perceived alternatively as a factor that contributes to the extension of the work life for people in the later stages of their careers.

Another structural factor influencing the retirement decision is educational level. Education level is linked to income levels among the baby boomers and is strongly linked to labor market factors. Older employees who continue in the workforce tend to have a college education, whereas those who have retired are more likely to have a lower level of education. Furthermore, education level is linked to income, and income tends to be the most important factor in the retirement decision. More specifically, the point of reference for the retirement decision is replacement income, or the percentage of preretirement income replaced by Social Security, pensions, and savings. Therefore, expected income replacement rates affect retirement decisions such that as expected replacement income increases, the probability of planning to stop working increases.

Another structural factor that acts as a determinant in the retirement decision of older workers is their

level of preparation for retirement. For example, many baby boomers might need to continue working longer because of deficits for Social Security and Medicare, discontinuance of defined benefit plans, and low savings rates. A problem with defined contribution plans is the ability for people to cash out before retirement. Only about one-third of the early disbursements are returned to retirement funds or other investments. In other words, many workers are spending significant portions of their retirement funds before they reach retirement.

TRAINING FOR OLDER WORKERS

Older workers are experienced, and they represent stability. They often can be productive immediately or with little training. They are valuable but not always valued by organizations. Younger workers will require training programs (with older workers serving as mentors) as organizations need to teach valuable work skills. Older workers will not have to move aside to make room for the young. Their presence provides a better personnel mix, in that they can pass on the workplace culture, skills, and experience. Mentoring less experienced workers is also one way to confront the career plateau.

If older workers are to delay retirement and continue as productive workers, then they must become or remain up to date in workplace skills. Training can integrate older workers into the work environment so that they can continue to add value. Because of the rate of change in the business environment and with technological innovations, all workers need retraining every four to five years. Therefore, the need for training may be the same for older workers as for younger workers. However, training will often be by computer, and there is a perception that older workers are less technologically able than younger workers.

The structural factors in the economy would, on balance, facilitate the retention of older workers in the workforce. During the 1980s, labor market trends were favorable for older workers; after job displacement was so high in the early 1980s, there were shortages, and older workers were sought. Then with the recession in the early 1990s, displacements returned en masse, especially for workers aged 55 to 64, with unplanned and early retirements becoming a big factor. Another economic slump could result in an earlier than projected exit of the baby boomers from the workplace that, in turn, could lead to exacerbation of

the projected employment shortage for later in the twenty-first century.

THE CHANGING WORKPLACE

The traditional workplace in a manufacturing environment could be described in terms of a given work location with workers assigned to well-defined jobs on a regular schedule. In the transition to a service economy, more emphasis has been placed on skills, and many employees are referred to as *knowledge workers*. Much of the work performed by knowledge workers can be performed from most any location—not necessarily in the employer's office. Indeed, the concept of the workplace is in question as more and more workers are telecommuting with the approval of their employers. Nor is there the constraint of full-time regularly scheduled work assignments. The changing workplace can be particularly advantageous for older workers who may not want to continue working full time but want to continue working, whereas employers can still realize the skills and experience of their older workers.

FLEXIBLE WORK HOURS AND SCHEDULES

More employers are providing the option of non-traditional work schedules and the provision of alternate work arrangements. There is some recognition that the experience of older workers is valuable, and many would welcome continued employment in the context of policies that support flexible work schedules for a blending of work and personal pursuits. Such alternate work arrangements as flexible work schedules, part-time work, job sharing, phased retirement, and independent contracting could be seen as remedies for pension plans that penalize work after a certain age and limits on Social Security earnings. Allowing people to organize their own time, redesigning work-around projects, rethinking jobs to avoid long daily hours at the job site, and encouraging telecommuting are strategies that provide the flexibility that many older workers are seeking.

PHASED RETIREMENT AND BRIDGE JOBS

Bridge jobs, or phased retirement programs, are desired by many older workers. *Phased retirement* refers to arrangements that provide for employees approaching retirement to ease into retirement gradually by reducing their work time and job responsibilities.

Phased retirement includes short-term projects, job sharing, part-time jobs, work at home, and telecommuting. Many Americans are separating from the labor force gradually, moving into part-time or short-term positions either in the same career or in a new pursuit. Bridge jobs and other accommodations could entice older workers to delay retirement if they were financially able to retire.

IMPLICATIONS

Highly educated, highly skilled, and technically able older workers are the ones whose irreplaceable experience is needed in tighter labor markets. Fortunately, with pensions, financial assets, and opportunity costs to consider, highly skilled older workers may be more inclined to participate longer in the workforce. Projected labor shortages, along with research that fails to show an association between age and decline in performance, should motivate employers to find ways to retain their successful older workers. Encouraging older workers to work longer would help alleviate the economic burden of entitlements, Social Security, and Medicare, effectively confront labor shortages, and provide the work opportunities desired by older workers themselves.

The barriers to the employment of older workers include corporate entrenchment, that is, attitudes that are difficult to change, higher costs of employing older workers, and pension rules that discourage continued employment. Business and government officials are considering policy changes that would allow older workers to both work and receive pension distributions without changing employers, and the prorating of benefits for older workers based on cost may help alleviate the higher costs for older workers. Attitude changes are reliant on educating employers on the need to accommodate older workers and their realization that there may be no better alternative than to rethink the employment of older people.

RETRAINING

Retraining has taken on increased significance over the past two decades as globalization and economic restructuring in many Western, industrialized nations has resulted in widespread worker displacement. Traditional industries, such as farming, manufacturing, and natural resource extraction, have been particularly affected. Changing consumer demands for individualized rather than mass-produced products has contributed to the changing nature of work and the reorganization of many work environments. In addition, declining natural resources has led to the collapse of certain labor-intensive industries altogether and the downsizing of others. The skills and knowledge required of individuals who work in labor-intensive industries are, in many cases, industry specific and not easily transferable to other forms of employment. The result is an increasing number of unemployed individuals with little or no opportunity for reemployment without specific forms of intervention.

Differentiating between retraining and training requires an understanding of the underlying concepts and the target populations. The term *displaced worker* is used with specific reference to individuals who have been permanently displaced from employment. The term *displacement* is applied to workers who suffer job loss through structural reorganization and industry decline and who are unlikely to find reemployment without some form of intervention. While

an unemployed individual may hope to acquire work with his or her current skills and knowledge, displaced individuals often have a skill set and knowledge base not easily transferred to other jobs or economic sectors. Thus retraining targets a specific population: displaced workers.

Traditional training programs, whether provided publicly or privately, can supply the kinds of skill upgrading and job search assistance needed by the unemployed who have existing, transferable skills. The needs of workers displaced by industrial decline often differ significantly. For many working in traditional industries, higher levels of education are not normally required for the vast majority of jobs in that industry. As such, workers displaced through industrial decline often have comparably lower levels of education. Displaced workers with lower levels of education, coupled with industry-specific skills and knowledge, require particular kinds of training programs. It is more appropriate to use the term *retraining*, as opposed to simply *training*, when referring to the needs of displaced workers. The use of the term *retraining* recognizes that the particular needs and circumstances of displaced workers are quite different from those of the unemployed in general.

Research and writing specifically devoted to retraining is sparse. When research and writing is undertaken on retraining, it is more often subsumed within the broader fields of adult education and lifelong learning. Within the field of adult education, research and writing on training is primarily concerned with training as it occurs in the workplace and with continuing education. Little consideration has been given to the particular needs of displaced workers and thus retraining. Lifelong learning has historically focused on learning across the life course generally. More recently, writings on lifelong learning have begun to focus on the role of lifelong learning in the context of globalization and economic restructuring. Emphasis has been placed on the importance of skill and knowledge acquisition throughout life as preparation for, and maintenance of, employment in a global economy. Yet even with the recognition of the need for lifelong learning as a result of economic restructuring, research on lifelong learning remains broad based and general and does not focus on the specific particularities of worker displacement and retraining.

Research conducted on retraining focuses almost exclusively on the analysis of statistics associated

with worker displacement, the implications of displacement for the individual, retraining outcomes, and rates of return. For example, issues such as wage levels prior to and following displacement, earnings loss, and reemployment percentages have dominated the research. Studies have also focused on specific retraining programs at the local level, with little national or international comparison. The implications of both displacement and retraining for individual workers, their families, and their communities are featured prominently in studies on retraining. The research highlights the various barriers facing the displaced worker not only in undertaking retraining but also in securing employment following that retraining. Education levels, individual motivation, the potential for reemployment locally, family commitments, and the availability of personal or institutional financial support are common points of analysis in studies on retraining.

That workers displaced by industrial decline require specific kinds of training interventions is now more widely recognized among policymakers and those who provide training. As such, retraining programs have become popular as a means of meeting the needs of changing labor markets and individuals displaced by industrial decline. In recent years, this recognition has manifested itself in the development of retraining programs that provide technical and soft-skills training. In determining the most effective kinds of technical training, attention must be paid to local labor markets and the kinds of employment available. Technical skills training that does not meet the needs of the local labor market will not help displaced workers in securing employment. Since many workers displaced through industrial decline have lower education levels, retraining programs should provide opportunities for basic academic upgrading. It is not uncommon for those working in traditional industries to have held one job, in one industry, from a young age. With no experience in finding employment or in transitioning from one job to another, the provision of soft-skills training becomes key if these workers are to be successful in finding employment. Skills such as résumé writing and interview strategies as well as job search and transition counseling can assist the displaced worker in coping with displacement and in securing employment.

In summary, retraining is specific to displaced workers. Displaced workers are those workers who find themselves unemployed with few opportunities

for reemployment without distinct forms of intervention. Therefore, displaced workers require particular kinds of training to secure alternative employment. Retraining programs must be cognizant of these needs and provide displaced workers with technical and soft-skills training as well as basic academic upgrading if they are to be relevant and successful.

REVERSE DISCRIMINATION

Reverse discrimination claims often arise out of an employer's attempt to honor either affirmative action programs or diversity initiatives focusing on attracting more women and minorities in the workplace. Lawsuits alleging reverse race discrimination generally fall under the rubric of Title VII of the Civil Rights Act of 1964, as amended, or the Fourteenth Amendment to the U.S. Constitution, depending on whether the employer is a private or a public entity. Suits also may arise under the equal protection clauses of various state constitutions or other state or local

laws prohibiting discrimination on the basis of race, sex, color, ethnicity, and/or national origin.

Reverse discrimination is defined as discrimination against Whites or males in employment or education. Even as early as 1978, the U.S. Supreme Court made it clear that it does not support laws that provide for reverse discrimination in employment. The Supreme Court determined that it is not acceptable to discriminate against individuals regardless of their minority status when it decided that reverse discrimination is not acceptable either legally or constitutionally.

In reverse discrimination lawsuits, plaintiffs will claim that they are not being afforded the same benefits or opportunities that other individuals are being afforded on the basis of their race (Caucasian) and/or gender (male). This unequal treatment is against the law. Success of the suit is not dependent upon whether the individual is a member of a protected category; rather, the focus of the inquiry is on whether all individuals, regardless of race and/or sex, are afforded the same benefits and/or opportunities under the law.

Issues often arise regarding how reverse discrimination is related to affirmative action initiatives. Affirmative action programs analyze statistics and request that certain governmental agencies consider certain patterns of the past and opportunities of the future to attract women and minorities to the workforce. As a result, often an employer will give more favorable treatment to women and minorities in an effort to achieve certain affirmative action initiatives. Such action is not necessary and, in fact, is prohibited by the law.

To state a prima facie case of reverse discrimination, a plaintiff must “present sufficient evidence to allow a fact finder to conclude that [the employer] is treating some people less favorably than others based upon a trait that is protected under Title VII.” *Iadimarco v. Runyon*, 190 F.3d 151, 161 (3d Cir. 1999). The burden then shifts to the employer to articulate a legitimate, nondiscriminatory reason for the rejection or termination. Once a reason is articulated, the plaintiff must prove by a preponderance of the evidence that this decision is merely pretextual and that the real reason for the employment action is discriminatory.

The U.S. Supreme Court has recognized that an employer who discriminates will almost never announce a discriminatory animus or provide employees or courts with direct evidence of discriminatory intent. Accordingly, the Court fashioned the burden-shifting analysis to allow plaintiffs to proceed without direct proof of illegal discrimination where circumstances are such that

common sense and social context suggest that discrimination has occurred. *McDonnell Douglas, Inc. v. Green*, 411 U.S. 792 (1973). In the “ordinary case,” where a minority plaintiff alleges race-based employment discrimination, the plaintiff “must carry the initial burden under the statute of establishing a prima facie case of racial discrimination . . . by showing (i) that he belongs to a racial minority; (ii) that he applied and was qualified for a job for which the employer was seeking applicants; (iii) that, despite his qualifications, he was rejected; and (iv) that, after his rejection, the position remained open and the employer continued to seek applicants from persons of complainant’s qualifications.” *McDonnell Douglas*, 411 U.S. at 802.

Once the plaintiff establishes a prima facie case, “the burden then must shift to the employer to articulate some legitimate, nondiscriminatory reason for the employee’s rejection.” *Id.* at 802. However, “the defendant need not persuade the court that it was actually motivated by the proffered reasons.” *Texas Dept. of Community Affairs v. Burdine*, 450 U.S. 248, 254 (1981). For purposes of defeating a plaintiff’s motion for summary judgment, “it is sufficient if the defendant’s evidence raises a genuine issue of material fact as to whether it discriminated against the plaintiff.” *Id.* If the employer offers some evidence of a legitimate, nondiscriminatory reason, then plaintiff must “be afforded a fair opportunity to show that [employer’s] stated reason for [plaintiff’s] rejection was in fact pretext.” *McDonnell Douglas*, 411 U.S. at 804.

Inasmuch as the first prong of this test requires plaintiffs to establish their identity as a member of a minority group, the literal application of the test would preclude its use by plaintiffs alleging reverse discrimination. In fact, the historical context of Title VII allowed for some debate as to whether Congress intended to extend its reach to practices that have come to be known as reverse discrimination. However, in *McDonald v. Santa Fe Trail Transp. Co.*, 427 U.S. 273, 283 (1976), Justice Marshall, writing for a unanimous Court, stated: “The Act prohibits all racial discrimination in employment, without exception for any group of particular employees.” Thus the dictates of Title VII “are not limited to discrimination against members of any particular race [and Title VII] proscribe[s] racial discrimination in private employment against Whites on the same terms as racial discrimination against nonwhites.” *Id.* at 278-79, 280. No doubt because of this country’s history of race relations, most Title VII plaintiffs have been members of a minority group, and the first prong of the *McDonnell Douglas*

test was stated in the context of that history. However, the holding of *Santa Fe Trail* as well as the language of *McDonnell Douglas* itself clearly establishes that the substance of the burden-shifting analysis applies with equal force to claims of reverse discrimination. Accordingly, reverse discrimination plaintiffs must show that the challenged employment action was based upon a protected characteristic (i.e., their race or their sex), regardless of what that characteristic may be.

REVERSE MENTORING

Scholars as well as business practitioners have long recognized the importance of mentoring for organizations and the people in them. In recent years, an innovative type of mentoring has extended the traditional mentoring model by turning roles upside down with *reverse mentoring* relationships. Traditional mentoring relationships have been defined as those in which a more experienced person helps a less experienced organization member develop and advance at work. In contrast, reverse mentoring is a relationship in which a younger employee provides guidance and advice to an older upper-level manager or executive. Reverse mentoring happens from the bottom up, rather than the traditional top down.

Research shows that traditional mentoring relationships can offer both organizations and their members a wealth of benefits. Similarly, initial anecdotal evidence shows many benefits of reverse mentoring. While there

is no existing research that examines reverse mentoring, companies that have created and encouraged these relationships report positive changes in the culture of the organization, better positioning of company products and campaigns to the younger market, creation of higher standards, improved knowledge of technological issues, and increases in effective cross-gender and cross-cultural communication throughout the organization. Senior-level managers and executives in the unusual role of protégé report benefits that include exposure to fresh approaches, being more in touch with the changing needs of the upcoming business generation, better knowledge and understanding of the people who work for them, having a sounding board, and feeling excited about learning something new. Young mentors report feeling valued by their companies, satisfaction in having their expertise and knowledge confirmed, increased exposure to high-level executives, and appreciation for proving their skills.

REVERSE MENTORING IN PRACTICE

The practice of reverse mentoring has been successfully introduced in many organizations. Former chief executive of General Electric Corporation, Jack Welch is typically credited with formalizing the concept of reverse mentoring when he encouraged approximately 500 GE managers to become students of those lower in the company hierarchy. The program at GE was specifically focused on creating mentoring relationships that would build a new skill set for protégés while giving mentors a unique opportunity to interact with higher-level managers with whom they otherwise would not have a relationship.

Proctor & Gamble's Mentoring Up program was created to increase communication between junior-level female managers and senior-level male managers, determine why female managers were leaving the company, raise consciousness about work-related issues affecting women, and reduce future turnover of women. Another P&G reverse mentoring program was created to provide senior management new perspectives and better understanding of company culture in biotechnology. Internationally, AMP-Pearl in the United Kingdom implemented a reverse mentoring program by pairing 12 young employees with assistant directors, helping managers understand the shift in the business environment caused by technology. As a result, the company experienced a positive change in its corporate culture. Wharton Business School pairs established executives with Wharton students to learn,

create, and operate e-businesses. Students bring their knowledge of the latest technological developments to the table and create a working partnership with outside senior executives. The unique mentoring experience provides an opportunity for the executive managers to keep up to date on technology trends and provides opportunities for business school students to create relationships with business leaders.

CREATING AN ENVIRONMENT FOR SUCCESSFUL REVERSE MENTORING

Developing a reverse mentoring program takes planning and development to succeed. As with traditional mentoring, there are bound to be informal relationships as well as formal reverse mentoring programs. In either case, there is a delicate balance between individuals in the relationship. A key ingredient for success is to ensure that both parties are interested and willing. Senior-level people must be open-minded to learning from a less experienced worker. The younger worker must be open-minded and feel comfortable with the relationship. Companies suggest that creating mentoring relationships outside of reporting lines is critical for the younger mentors.

Some of the basic steps in setting up an effective reverse mentoring program are to set clear objectives, treat each other with respect, consider generational differences, identify specific assignment of duties in the partnership and defined rules of conduct, and develop measurable outcomes to determine program effectiveness. As with any mentoring program, training helps the mentor, the protégé—and the program itself—be successful.

Organizations are motivated to encourage reverse mentoring and implement such programs. For example, these relationships give both partners the opportunity to learn about and understand how to work with a generation other than their own. Upper-level managers learn how the new generation of employees wants to be managed and how they can translate that understanding into greater long-term success for the business.

THE FUTURE OF REVERSE MENTORING

Many reverse mentoring programs grew out of the need for upper-level managers to be more in tune with the changing technological age. Nevertheless, companies and people reap other benefits from these

relationships. As organizations continue to establish formal mentoring programs, they are sure to consider reverse mentoring. Moreover, as the composition of the workforce inevitably continues to change along with attitudes of its new members, reverse mentoring can provide mutually beneficial partnerships for lower-level employees and upper-level managers to communicate and learn from one another. Thus it will become increasingly important to understand these nontraditional reverse mentoring relationships. If the growing trend of more top name corporations establishing reverse mentoring programs is any indication of the power of these programs' success, it is sure to continue in the future.

ROKEACH VALUES SURVEY

The *Rokeach Values Survey* (RVS) was originally developed in 1973 by Milton Rokeach. The RVS is one of the most extensively used measures of human values and is utilized by career counselors to assess clients' values as they relate to the world of work. The RVS is a 36-item inventory consisting of 18 terminal values or end states (e.g., happiness, an exciting life, world of peace, world of beauty, national security, social recognition) and 18 instrumental values (e.g., logical, cheerful, imaginative, honest, broad-minded,

ambitious, clean). This instrument was initially designed for rank-order scaling, but more recent studies have provided evidence that ratings on a five-point scale yield similar results, if higher ratings are limited to a small number of the values.

Rokeach developed the RVS based on interviews and in-depth reviews of language and of the existing literature on values. Unfortunately, Rokeach was unable to identify an underlying structure for his value system. Later research by Shalom H. Schwartz provided evidence that the RVS contains 10 motivational types, each of which incorporates two or more of the terminal and/or instrumental values. For example, the motivational type Power includes the end states of social power, wealth, authority, and the instrumental value of preserving public image. The motivational type Achievement contains the instrumental values of successful, capable, and ambitious. The motivational type Universalism incorporates the instrumental values of broad-minded and protecting the environment and the terminal values of social justice, wisdom, world at peace, a world of beauty, unity with nature, and equality.

Schwartz presented evidence that the 10 motivational types are arranged in a circumplex, with more highly related values placed contiguously. From the top right position, moving clockwise, the motivational types are as follows: Universalism, Benevolence, Conformity and Tradition (the preceding two motivational types occupying the same wedge), Security, Power, Achievement, Hedonism, Stimulation, and Self-direction. Furthermore, the motivational types located on opposite sides of the circumplex represent opposing values and thus can be conceptualized as being positioned along two underlying dimensions of the circumplex. These dimensions are described as follows: (1) values emphasizing independent thought and action and openness to change versus values placing more emphasis on submissive self-restriction, stability, and tradition; and (2) values emphasizing acceptance of others and concern for others' welfare versus values highlighting the pursuit of one's own success and dominance over others. In short, motivational types related to openness to change are found on the opposite side of the circumplex as those related to conservation. Similarly, motivational types related to self-transcendence are located opposite those related to self-enhancement.

Values can be conceptualized as learned beliefs about preferred ways of behaving or being, which act

as guiding principles in one's life. Understanding the structure of personal values systems is a vital part of comprehending the motivational foundation to all behavior, including work-related behavior. To this end, the RVS is used by career counselors to access and bring to awareness a client's hierarchical organization of work-related needs, desires, and goals. The importance of assessing values lies in deepening the self-awareness of the career client and allowing the client to access underlying motivations for career-related decisions. In addition, when this information is considered in conjunction with other work-related variables such as interests, self-efficacy, and abilities, the result is a more complete and multidimensional view of the career client and the relevant career choices.

ROLE MODELS

There are two primary views of *role models*. One, the traditional view, depicts role models as persons critical to an individual's career development process. They often occupy socially important roles, such as leaders, managers, teachers, and coaches. They offer individuals a way to refine their developing identity by providing an image of someone they would like to become. Role models provide inspiration to individuals, and this motivates them to emulate aspects of their role models' behavior or style. In this view, role models are exemplary figures offering essential clues to identity and career achievement.

A second, more recent view depicts role models as cognitive constructions devised by individuals to construct their ideal or "possible" selves based on their own developing needs and goals. Rather than focusing on the actions of a prominent person, however, the

second view focuses on the perceptions of the individual. The individual is seen as piecing together a composite role model from attributes derived from a range of possibilities, both real and imagined. The emphasis in this view is on an active learning process from multiple role models, rather than a focus on selecting a particular exemplary person.

The term *role model* draws on two prominent theoretical constructs: the concept of role, and the tendency of individuals to identify with other people occupying important social positions, and the concept of modeling, the psychological matching of cognitive skills and patterns of behavior between a person and an observing individual. These two aspects of role models reflect two different theoretical traditions. The first, role identification theories, emphasizes the notion that individuals are attracted to people based on similarity. They may perceive similarity in terms of attitudes, behaviors, goals, or a desired status position, and they are motivated to enhance that similarity through observation and emulation. The second, social learning theories, suggests that individuals attend to models because they can be helpful in learning new tasks, skills, and norms. Identification theories place relatively more emphasis on the motivational and self-definitional aspects of role models, while modeling theories emphasize the learning aspects.

In discussing role models, it is important to distinguish them from two other types of career developmental relationships, behavioral models and mentors. Behavioral modeling focuses on matching specific actions and attitudes between an individual and a model. Typical examples of behavioral modeling in organizations involve supervisors or trainers illustrating specific task skills and performance goals and norms. The basis of the behavioral model relationship, then, is to facilitate individuals' learning of specific tasks and skills by vicarious observation. The basis of a mentoring relationship is distinguished by an active interest by a mentor in advancing an individual's career, and the mentor is understood to provide both career-related and psychosocial functions. In both cases, the focus of these constructs is on the actions of the superior other (a mentor or behavioral model) in helping to develop the individual.

The basis of the role model relationship, in contrast, is identification and social comparison processes. The individual makes other people role models by identifying with them or comparing upward to them: The focus is on this cognitive process rather than on direct

action by the model. Indeed, interaction between the individual and his or her role models is not required. Individuals can be understood to have a "portfolio" of role models who can be observed for specific attributes and abilities, and the type of learning revolves around role expectations and self-concept definition rather than specific skills (as provided by behavioral models) or career advancement (as provided by mentors).

Given the lack of conceptual clarity surrounding the role model construct, it is not surprising that widely differing approaches have been taken in empirical research. Most research has examined children and adolescents identifying with parental role models. A secondary group of studies focuses on role models as a component in college students' selection of careers, with a special focus on the need for, and frequent lack of, role models for women and minority students. Within organizations, role models have been primarily examined as one part of the socialization process and through a behavioral modeling lens. In terms of the latter, studies have found that social information conveyed through role models is related to increased learning of specific skills, higher goal setting, and increased performance levels.

Such research has not convincingly shown, however, whether role models are critical in career development and achievement, and how. While most empirical research has investigated the traditional understanding of role models outlined above, recent research has applied a more fine-grained qualitative approach to examining how individuals perceive and relate to their role models, especially as they are socialized to new organizational roles. Four key processes characterize the findings of this research. First, these studies find that individuals seek a variety of role models from whom they derive attributes and behaviors that can be helpful in their development. These role models may be predominantly "positive," that is, illustrate behaviors or traits the individual wishes to emulate, or predominantly "negative," that is, illustrate attributes the individual wishes to avoid. Second, rather than assume that individuals seek traditional role models, these studies tend to find that individuals differ to the extent that they seek a "global" role model, one from whom they can adopt a wide repertoire of attributes, versus seeking a "specific" role model who provides an exemplar of a relatively narrow trait.

Third, individuals use the role model attributes they observe as clues to creating their "ideal self"—the self they would like to become. Role models are particularly

helpful in imagining this ideal self because by observing role models, individuals can provisionally try out different styles or behaviors to see which ones best suit their developing style. Finally, these processes must be understood as dependent on time. While attention paid to role models may be most intense during the early career stage, as individuals mature in their organizational career, they do not necessarily stop looking for role models. Rather, their role models tend to change, often from more positive to more negative and from more global to more specific.

The lack of conceptual clarity surrounding role models has produced a puzzling result: The idea of role models is widely and popularly known, but this wide knowledge masks a superficial understanding of how important role models actually are in career development. While research based on the traditional view suggests that having role models is better than not having them, the research lacks compelling links to dependent variables such as satisfaction, performance, and commitment. Research emphasizing role models as cognitive constructions might offer new hope for expanding our understanding of role models.

This research might provide the conceptual clarity that leads the way to new answers about this widely known yet paradoxically little understood concept.

S

SABBATICALS

Sabbaticals, which were first introduced at Harvard in 1880, have become a form of paid leave offered to faculty by nearly all United States universities, more than 80 percent of four-year colleges, and 60 percent of two-year colleges. Sabbaticals, derived from the Hebrew *Shenath shabbathon*, or year of rest, commonly are defined as paid leaves of absence for purposes of personal and/or professional development. These leaves may be granted for varying periods of time, usually with full or partial compensation and continued benefits. Historically, the primary purpose of the sabbatical has been to increase scholarly productivity. In addition, sabbaticals serve as a reward for tenured faculty who have given good service to the university and as an incentive to energize and improve faculty performance. Sabbaticals are considered to be an important part of academic life because faculty are expected to continue to develop as scholars, researchers, and professionals throughout their careers. In recent years, the sabbatical concept has been broadened to include opportunities for personal renewal as well as professional development, with the goal of enhancing the value of the faculty member to the institution.

A unique feature of sabbaticals is that they typically are characterized by a complete disengagement from regular work responsibilities. Release time relieves faculty of specific day-to-day responsibilities so that they can concentrate their time and energies in chosen scholarship, teaching, or service activities. Eligibility requirements for sabbatical leaves typically

require formal application and approval for the sabbatical, at least one year of service at the institution following the sabbatical, and a report on sabbatical accomplishments. In addition to individual faculty benefits, sabbaticals also have been reported to benefit institutions through improved faculty morale, increased scholarly output, and improved teaching.

During the past few years, organizations outside of academia, such as public schools, businesses, and health care, have recognized the potential merit of sabbaticals for their employees. Sample titles of articles published in business publications clearly indicate interest in nonacademic sabbaticals (e.g., “Time for a Sabbatical,” “Sabbaticals Gain Popularity,” “Why Sabbaticals Make Sense”). Articles on sabbaticals also have appeared in such diverse publications as the *Journal of Accountancy*, *British Medical Journal*, *Family Practice Management*, *Journal of Academic Librarianship*, *Bioscience*, and the *Journal of Education for Business*.

Most faculty report using their sabbaticals for research (49 percent) or writing (21 percent). Other reported benefits of sabbaticals include burnout prevention; increased job satisfaction; personal and professional growth; time to develop new projects, areas of interest, or skills without normal interruptions and responsibilities; new perspectives and attitudes; travel and networking; improved mental and physical health; and increased energy and enthusiasm for career. Clearly, these kinds of reported benefits may accrue to employees in other careers where sabbatical-type opportunities are offered.

Even within academic settings, there is some evidence that the sabbatical experience may differ for

faculty from different disciplines. In one study, counselor educators reported placing a higher priority on personal and social development than noncounseling faculty and perceived themselves as more motivated, more enthusiastic, and better institutional citizens postsabbatical. Critics of sabbaticals have questioned the effectiveness of release time, citing a lack of substantial evidence to support their effectiveness. Thus a continued challenge is to document sabbatical accomplishments in ways that are meaningful to and valued by administrators and other supervisors.

SCHOOL-TO-WORK TRANSITION

As the concept of lifelong learning is embraced by more and more people, *school-to-work (STW) transitions* are now likely to occur many times over the course of an individual's lifetime. The school-to-work transition discussed here, however, will focus on only one of these transitions, the non-college-bound student's entry into full-time employment after high school. Relative to other countries (Germany, for example), the United States has only recently turned attention to this important stage in a youth's life, spurred in large part by the perception of the failure of many of its public schools, particularly those located in urban and rural areas. As evidence of this failure, critics of the secondary educational system in the United States point to increased dropout rates and a growing pool of high school graduates who are inadequately prepared for today's more demanding entry-level positions. For the non-college-bound high school student, then, the transition to work lies at the nexus of what some have portrayed as a failing

educational system and a dynamic, increasingly complex business community, whose entry-level jobs demand a knowledgeable and highly skilled workforce.

An early warning sign of the deteriorating quality of primary and secondary education in the United States was reported in *A Nation at Risk*, published in 1983 by the National Commission of Excellence in Education. This report brought to light the widespread illiteracy rate among adults and children, as well as the significant academic gap between majority and minority group members. To remedy these failings, the report recommended school reforms that emphasized a more rigorous, academic-based curriculum to help prepare more students for postsecondary education.

This recommendation to improve the academic preparedness of U.S. high school students set the stage for enhancing the focus on educational programs for students who traditionally did not pursue postsecondary education, that is, for students considered to be in the "forgotten half" (as termed in a report by the William T. Grant Foundation) or classified as "at risk" (of dropping out of school). Unlike reforms focusing on high-achieving students, school reforms for the students in the lower half focused greater attention on vocational preparation than academic achievement.

To some, this focus on vocational preparation was a way to further institutionalize a tracking system in educational institutions, one that is based on, and perpetuates, a rigid partitioning of students by social class, offering little opportunity for future growth. These critics claimed that the reforms for the forgotten half meant that students from lower socioeconomic classes are steered into less academic, vocational programs, while students from higher socioeconomic classes continue to be given opportunities to prepare for postsecondary education. Since education is an investment in human capital with a return in the form of lifelong earnings, this system may act as a further constraint on academic and career choices for those students from lower socioeconomic classes.

Despite these misgivings, emphasis in programs for at-risk youth continued to be placed on vocational, rather than academic, objectives. Federal legislation played a major role in funding many of these school-to-work programs. One of the more influential pieces of legislation in the STW movement was the Carl D.

Perkins Vocational and Applied Technology Act, which was signed into law in 1990. The Perkins Act continues to provide federal funding for vocational-technical education programs that prepare high school students for occupations that do not require an advanced or baccalaureate degree. At its heart, this act promotes active partnerships between businesses and education, incorporating both school-based and work-based learning.

While the Perkins Act continues to make federal funds available to state-sponsored school-to-work programs, the legislation that had perhaps the most influence in the proliferation of STW programs in the United States was the School-to-Work Opportunities Act (1994-2001). The intent of this act was to create a national framework for linking school and work, in lieu of what it called a lack of a “comprehensive” and “coherent” system facilitating youths’ transitions into full-time employment. The funding mechanism under this act provided that federal funds be given directly to the states, a mechanism that allowed states considerable freedom to create their own programs linking school and work. Programs were eligible for funding under the act as long as they included three basic elements: work-based learning, school-based learning, and activities that connected the two. Since states were given the freedom to create their own programs, a number of different school-to-work models have been funded under this legislation. For example, in 1996, 64.2 percent of all U.S. high schools offered some type of school-to-work activity. While this act, then, offered flexibility to address local issues and helped these programs grow, it could be argued that by funding different STW program models, the act failed to create a comprehensive U.S. system to facilitate the transition of high school youth into the workforce.

Given the scope of the School-to-Work Opportunities Act, it isn’t surprising that many different activities and models fall under the umbrella of school-to-work. These activities may last from as little as one-day job-shadowing experiences, to work and educational experiences that may last up to six years. These include such activities as job shadowing, mentoring, internships, registered apprenticeships, youth apprenticeships, cooperative education, tech prep education, and career academies. Since the sunset of the School-to-Work Opportunities Act, perhaps the most widespread SWT programs are the tech prep and career academy models.

Tech prep programs were funded by the School-to-Work Opportunities Act and continue to be eligible to receive funding under the Perkins Act. These programs are planned courses of study in technical fields that use 4 + 2, 3 + 2, or 2 + 2 formats. The “+2” designation indicates that the program lasts two years beyond secondary education and culminates with an associate degree or certificate. As such, they incorporate both academic rigor and technical development and competence, responding to the claim that career prep programs often limit educational achievement. These programs focus on technical preparation in engineering technology, applied science, mechanical, industrial, or practical art or trade, agricultural, health, or business. As of 2004, there were over 700,000 students participating in tech-prep programs across the United States.

The career academy model began in 1969 and has grown nationwide since that time. Academies were first developed by members of the business community in Philadelphia to meet increased demands for qualified, entry-level employees. Although many school districts in the United States have incorporated the academy model, the Philadelphia Academies is one of the few organizations that continues to operate as an independent, not-for-profit liaison between the schools and business. Career academies are organized as small learning communities (“schools within schools”), focus on a particular career theme, such as business, technology, law, or health care, and offer students employment preparation along with a college prep curriculum. Academies also actively pursue partnerships with the business community in order to offer employment to students while in school and provide developmental activities such as employment interview training and mentors. Career academies, as recognized by the National Career Academy Coalition, are now located in over 1,500 U.S. high schools and serve a significant number of students, over 10,000 in the Philadelphia area alone.

The extent of the business community’s involvement in school-to-work activities is the subject of a growing number of research studies. These studies have generally shown that larger organizations are more likely to participate in these activities than smaller ones. One study reported that 170,000 private organizations (each employing more than 20 people) were active partners in formal school-to-work partnerships. Of these, over 91 percent reported they offered work-based learning activities for high school or

community college students. Researchers have speculated on employer motivation for their participation. One reason may be corporate altruism, as many employers report their desire to help their communities was the main reason for their participation. However, some researchers have argued that the most important reason employers participate in these programs is for economic benefit. First, employers may receive positive publicity in their communities as they actively engage in STW programs, which may generate additional business for them. Second, participating in these programs can also help employers fill short-term job openings with inexpensive labor, as well as to help them meet their longer term labor needs by hiring graduates of the programs.

While research on employers has identified multiple motives of employer participation, the impact of these interventions on students is more difficult to determine, given the complexity of isolating the effects of an academic program on a student's motivation to participate in the program, learn, and achieve academically. Ideally, combining work-based and classroom-based learning should enhance student motivation to learn, as it allows the students to see the relevance of what they learn to their job performance and, longer term, to their careers. Some research has, in fact, made a connection between student participation in work-based learning programs with academic and employment outcomes. In one of the more rigorous studies of career academies, for example, a nationwide, longitudinal review showed evidence that participating in a career academy program had a positive, significant effect on future earnings of the young men in the sample that was studied. This same study showed that these earnings effects were not achieved by sacrificing academic performance, as the researchers found no significant differences in graduation rates between academy and nonacademy students in their sample.

In addition, research has also reported a positive relation between participating in adult-youth, work-based mentoring programs in urban settings with academic performance and attitudinal changes. One study showed evidence that participating in such a mentoring program was positively associated with GPA and school attendance. Furthermore, students who reported having a mentor at work had higher levels of self-esteem, compared to students who did not work, and students with mentors in formal mentoring programs held stronger beliefs that school was

relevant to work, relative to those who worked without a mentor.

However, questions have been raised over the extent to which learning in a work environment takes place in school-to-work programs. Often, educators assume that learning will take place as a consequence of the student's mere presence in a work environment. In some programs, however, experience has shown that students are placed in environments and hold positions that do not require the acquisition of knowledge or the development of new skills. Some employers are also not interested in making the effort that is required to integrate academic and work-based learning, a critical step to ensure that learning takes place on the job. In addition, detailed lesson plans are not developed by the schools, nor are specific learning goals established at the outset of the program, making assessment of what is learned problematic. School personnel may also fail to follow up with the students about their work experiences. The multiplicity of these requirements and the need to carefully coordinate activities across school and work boundaries add to the challenge of creating successful STW programs.

Research has also provided useful insights into the nature of a youth's STW transition, which can be helpful to administrators designing and managing STW programs. For example, there is evidence of an association between postgraduation employment outcomes and early (12-15 years of age) educational experiences. Specifically, a positive relation has been found between academic self-efficacy (confidence in one's ability to do well in school) and academic performance at this early age, with job satisfaction and the likelihood of later employment (21 years of age). This reinforces the importance of focusing on both academic and vocational objectives in STW programs.

Additional research of the transition into the workforce has also shown changes in the youth's sense of self, explicitly an enhanced self-confidence, an increased valuation of one's personal life outside work, and increased ambition. Research has reported evidence of a dynamic interplay between personality development and work experiences that may also be useful to administrators of STW programs. While personality characteristics may be a factor in the student's choice to enter an STW program, as well as the type of work chosen by the youth, the experience in the program may also have an effect on the youth's personality. This interaction between personality and work

experience is consistent with what is known as the corresponsive principle, that is, that work experiences are likely to deepen the personality factors and characteristics that led the person to that experience in the first place. For example, a student who enjoys taking charge of things may be more inclined to enroll in an STW program because it offers work opportunities that allow for autonomy and the chance to influence and lead others. The student's experiences in this position may then reinforce that original desire to take charge.

U.S. public policy toward STW transitions may best be described as a loose combination of activities and pedagogical models bridging the worlds of school and work. These programs are created and administered at the state and local levels and, in general, have not been subject to careful, rigorous assessment of their effectiveness. However, this lack of sound research evidence should not imply that there is little need to focus attention on this transition and provide resources to facilitate it. Many school districts and communities continue to be plagued by low academic achievement of its youth and high dropout rates, particularly among youth from lower socioeconomic classes, and employers continue to question the qualifications, skills, and abilities of those in the entry-level labor pool. As such, STW programs remain crucial to help prepare students not only for the increasingly complex work environment but to offer opportunities for all youth to lead productive, satisfying lives and become positive contributors to society.

SELF-AWARENESS

Awareness is a central concept in career development. It has been defined as a relatively complete and accurate perception of individuals' own qualities and the characteristics of their environment. The two types of awareness identified in the literature are self-awareness and environment awareness. *Self-awareness* refers to the realistic and accurate perception of one's interests, values, skills, limitations, and lifestyle preferences. In its most basic form, self-awareness requires individuals to take the time to develop insights into themselves and assess what is meaningful to them in their lives. Both self-awareness and environment awareness are inarguably important for successful career decision making and career management. Different theorists have used different constructs to refer to self-awareness such as self-concept, self-image, vocational identity, and self-observation generalization.

ROLE OF SELF-AWARENESS IN CAREER DEVELOPMENT

All major career development models have attempted to explain how individuals obtain and utilize self-knowledge to make career choices and shape their career development. A fundamental assumption that has guided most, if not all, major theories of career development is that self-knowledge is essential

for making career progress and developing satisfying careers. Similarly, most of the models of career management subscribe to the notion that career success and satisfaction will most likely be achieved by individuals who develop insights into themselves and their work environments. Self-awareness also plays a critical role in self-management models. Simply put, self-management has been described as a process of influencing oneself. It encompasses self-assessment, self-monitoring, self-evaluation, and other related processes.

In order to fully appreciate the role of self-awareness in career development, it is important to first understand the nature of contemporary careers. There have been a number of environmental changes that have had a profound influence on the basic foundation of personal and career development. For example, it has been widely documented that the rapidly changing workplaces, combined with organizational, technological, and social transitions, have left few external benchmarks of effective career development and have fostered the trend toward self-managed careers.

Furthermore, with changes in the psychological contract and traditional organizational opportunity structures, changes in the meaning of career success, and greater awareness of the impact of family and lifestyle issues on one's career, employees have been compelled to design their own personal and career development plans. This has been accompanied by limited assistance from organizations for the development and management of these career plans. In such rapidly changing and uncertain times, there has been an increased pressure on employees to develop a set of career competencies that would enable them to develop insights into themselves and their environment. Such career competencies are believed to be important in achieving career success and satisfaction.

Self-awareness is important for career development for reasons other than the ones identified above. Self-awareness, conceptualized as both a personality trait and a skill, has been argued to be critical in regulating individual performance and achieving managerial excellence. A thorough awareness of one's interests, values, talents, and lifestyle preferences enables individuals to set appropriate career goals, develop appropriate career strategies, and regulate their behavior successfully.

Support for the notion that realistic career goals are likely based on accurate self-assessments and self-awareness comes from several studies on students and

working professionals. Researchers have found that students who reported extensive self-awareness were more likely to develop satisfying and appropriate occupational goals than those who were relatively unaware of themselves. Similarly, self-awareness has been found to be an important factor that enabled individuals to develop realistic job expectations, attain higher levels of job satisfaction, and a greater degree of fit with their chosen work environments.

Research suggests that individuals can develop self-awareness by engaging in self-assessments and self-exploration. Employees at all organizational levels frequently make such self-assessments. For example, when individuals enter organizations, are transferred, or cope with organizational change, there is a pressing need to appraise, evaluate, and/or assess oneself.

Similarly, engaging in self-assessments may become even more important when individuals experience greater ambiguity about environmental demands such as those encountered during career transitions or experienced during personal or family crises. This does not mean that self-assessments are important only during times of dramatic change in people's lives. Rather, it is equally important for individuals to be sensitive to changes in themselves even during less momentous periods in their lives. Such ongoing assessments of oneself, reflected in self-awareness, enables individuals to achieve their goals in an organization—whether the goals are basic survival, good performance, rapid advancement, or something else. It also enables them to be flexible enough to make career decisions that are more in tune with, and reflective of, their emerging selves.

IMPORTANCE OF SELF-EXPLORATION IN ENHANCING SELF-AWARENESS

To develop an accurate and realistic awareness of oneself, it is important to engage in self-exploration. Engaging in self-exploration requires individuals to seek information about a variety of personal qualities, such as interests, values, talents, abilities, shortcomings, and any attitudes that are relevant to career decision making. Work is not the only significant role in people's lives, and it is important to examine a variety of nonwork interests and values. Hence, self-exploration also requires individuals to understand what they want from their nonwork roles, what significant values, interests, and talents can be satisfied through nonwork pursuits, and what their lifestyle preferences are.

The first step in any self-exploratory activity is to collect data and information about one's values, interests, abilities, and lifestyle preferences. There are a number of well-established techniques that are available to help individuals perform self-exploration. These techniques can be broadly categorized as individual assessment instruments, organization-sponsored self-exploration programs, and informal means of self-assessment.

TECHNIQUES FOR SELF-EXPLORATION

Individual assessment instruments, as the name suggests, help individuals gain a better understanding of their interests, values, personality factors, aptitudes, and lifestyle preferences. These instruments are intended to serve as a general guide to informed career decision making and are not meant to provide a conclusive answer to one's career direction. Some of the most widely used individual assessment techniques are the Strong Interest Inventory, the Vocational Preference Inventory, the Self-Directed Search, the General Aptitude Test Battery, the Myers-Briggs Type Indicator, the Rokeach Value Survey, and the Life Style Inventory.

Some of the assessment tools such as the Strong Interest Inventory, the Vocational Preference Inventory, and the Self-Directed Search provide specific information on an individual's pattern of interests that are suitable for certain occupation types. The other assessment tools identify general thinking and value patterns that are useful for career decision making. In general, the various interest inventories, aptitude tests, and personality and lifestyle measures offer helpful insights to individuals who are faced with the task of making an initial career choice or those who seek to change their career direction. These self-assessment tools are not intended to serve as a definitive guide to career selection.

In addition to the above individual assessment techniques, a variety of organization-sponsored self-exploration programs are also available. These programs are typically offered through career management or assistance centers. They offer individual self-assessment opportunities through career planning workshops, career workbooks, and assessment centers. Career planning workshops involve a structured group format in which participants interact with one another to formulate, share, and discuss personal information that leads to self-analysis and eventual

self-awareness. Career workbooks are structured to accomplish the same objective as career planning workshops except that these workbooks are self-paced, self-directed, and designed to be completed by individuals themselves. Finally, assessment centers are used to provide feedback on individuals' personality styles, strengths, and shortcomings. In addition to aiding self-awareness, this feedback can also be used to guide individuals' career planning process.

Employees can also obtain self-information through other formal and informal feedback sources and mechanisms. Performance appraisals are one example of a formal feedback mechanism that can contribute to employees' self-exploration process by providing them with information on their strengths and weaknesses. In situations when feedback is not spontaneously provided or is somewhat constrained, employees may solicit feedback or infer it from a variety of informal cues by engaging in active feedback-seeking behaviors. Active feedback-seeking is an important component of the self-assessment process. It is also an integral part of the self-regulation process in which individuals monitor the opinions and expectations of their superiors, peers, and subordinates.

In addition to the above self-exploration techniques, individuals can also engage in informal self-exploration activities such as writing a diary, analyzing their highs and lows in life, fantasizing about their ideal jobs, and conducting other exercises designed to provide self-insights.

Despite the availability of a variety of self-exploration instruments and programs, self-exploration is not always effective and does not always produce an enhanced and accurate self-awareness. The next section describes some of the challenges that accompany any type of self-assessment or self-exploration activity.

ACCURACY OF THE SELF-ASSESSMENT PROCESS

It is widely agreed that accuracy in self-assessments is a desirable goal. However, the question that has confronted employees and researchers alike has been whether accuracy in self-assessment is an attainable goal. This is a particularly important area of inquiry because self-exploration entails using the self as the source of feedback. Some studies have shown that the self is the most available and trustworthy source of feedback, while others have shown that self-assessments are prone to a variety of errors and

misjudgments. Recently, research has begun to address the reasons why individuals' assessments of themselves might or might not be accurate and the ways in which these assessments may deviate from accuracy. There are a number of barriers to effective self-exploration that have been identified in the literature, and these obstacles are discussed next.

BARRIERS TO EFFECTIVE SELF-ASSESSMENT

Because people live and work in environments that are changing and are also often complex and ambiguous, it is no surprise that inaccuracies in self-assessments occur. Inaccuracies in self-assessments have been shown to arise from three broad categories of problems that individuals face. The first one deals with the information problem and relates to either too much or too little information. Individuals' environments may contain a surfeit of complex cues that need to be interpreted accurately. Faced with this abundance of cues, individuals' perceptual processes may get constrained, which may distort their self-assessment accuracy and eventually their quality of awareness. To compound these problems, some environments contain cues that are ambiguous, which may lead to multiple interpretations for every cue. This might happen commonly in organizations that are undergoing a transition, causing them to give off ambiguous cues regarding what is appropriate and expected behavior. Self-assessment inaccuracies are only natural and to be expected in such an environment.

Another set of challenges that can impede self-assessment proficiency deal with individuals' own personality factors such as their self-esteem and their level of anxiety. Because self-exploration and self-assessment activities involve information about oneself, the process of acquiring and using such information can cause anxiety and be a threat to one's self-esteem. Researchers have pointed out that anxiety can be a serious threat to self-assessment accuracy. Because highly anxious people focus on their anxious feelings rather than the information at hand, they may not be able to benefit from much self-exploration. In addition, highly anxious people may get defensive about any threatening self-related information and may distort, dismiss, or misinterpret that information, resulting in an inaccurate self-assessment.

Further complicating this picture is the influence of self-esteem on self-exploration and self-assessment processes. Individuals with low self-esteem tend to

distort ambiguous cues in ways that are consistent with their low self-images. They also tend to underestimate positive evaluations from others and generally tend to accept more negative feedback than those with high self-esteem. It has been suggested that individuals need to balance their desire for accurate assessment with their desire to maintain a positive self-image. However, when the balance is tipped toward creating or maintaining a particular self-image—whether positive or negative—inaccuracies in self-assessments are bound to occur.

Related to this issue is the problem of self-presentation that unfavorably influences self-assessment accuracy. The self-presentation problem refers to the dilemma that individuals face in seeking information while protecting their images as self-assured, confident people. It has been suggested that individuals who experience such self-presentational pressures are constrained in their self-assessment activities not by their environment but by their own perceptions of the costs involved to their self-image. Some researchers point out that the primary cost of seeking any information or help is that it exposes the seeker's uncertainty and need for help. As a result, such individuals tend to rely more on their own self-observations and seek only limited amounts of feedback and other information, which has the effect of contributing to a lopsided understanding of oneself.

The previous discussion highlighted some of the inaccuracies that may occur in the self-exploration and self-assessment processes and the underlying reasons for these inaccuracies. In examining self-assessment inaccuracies, there are three questions researchers have had to grapple with. First, what is the cost of these inaccurate self-assessments for both individuals and organizations? It has been suggested that since self-assessments involve judgments about the self, they tend to have a strong impact on both psychological and behavioral processes. For example, self-assessments, whether accurate or not, may affect individuals' self-efficacy expectations, their persistence at a task, and in some cases, even their future aspiration levels. Furthermore, because self-appraisals tend to serve as guides for future action, it is possible that individuals with inaccurate self-views would either hastily act on something (e.g., a career goal), mistakenly quit tasks, or fail to alter their behavior when the environment demands it.

The information on the organizational costs of individuals' inaccurate self-views tends to be less clear.

However, it has been shown that inaccurate self-views, particularly inflated self-views of organizational leaders, might lead these leaders to commit themselves and their financial resources to a losing course of action.

The other two questions that have challenged researchers studying self-assessment accuracy have been more philosophical ones but have pragmatic implications. One of them deals with the extent to which accuracy in self-assessment is a desirable goal to strive for. This issue challenges the basic usefulness of accurate and realistic self-awareness and questions whether there might be a greater value in seeking information that is self-enhancing rather than being merely accurate. The second question asks us to think about the criteria that would constitute self-assessment accuracy. In other words, is accuracy in the eyes of the beholder (the person engaging in self-exploration), or does some outside observer determine the accuracy of one's self-assessment? These issues have generated much debate, but conclusive guidelines are yet to emerge.

In conclusion, researchers interested in understanding the nature of self-awareness continue to fine-tune the questions they ask and are broadening their focus to examine a variety of contextual and interpersonal pressures that influence the exploratory activities leading up to self-awareness. We know about some of the important outcomes of self-awareness, and researchers continue to investigate other immediate and long-term outcomes of self-awareness.

SELF-CONCEPT

Throughout the history of career development, ideas about the *self-concept* have played a critical role in theory development, research, and counseling practice. Scholars in career development and humanistic psychology have developed perhaps the most commonly used definition of self-concept. In short, the self-concept is thought to refer to conceptions of oneself—in other words, the "I" or "me." The self-concept includes both affective dimensions (such as self-esteem) as well as content dimensions. In addition, the self-concept has been understood from various conceptual and theoretical perspectives, reflecting recent innovations in career development theory.

HISTORICAL CONSIDERATIONS OF THE SELF-CONCEPT

Self-concept and its roots are best understood in the context of the history of career development and vocational psychology. Within these fields, the idea of person-environment fit set the stage for research and practice throughout the century. The earliest ideas about the self-concept emerged as a logical outgrowth of initial ideas about maximizing person-environment fit. In order to help individuals learn about themselves, counselors increasingly used tests and other measurement tools to provide clients with information about their interests, skills, and personality. One means of integrating these observations about individuals was to embed the intrapersonal attributes of an individual under the rubric of the self-concept.

Other contributions to the notion of self-concept grew out of humanistic psychological traditions. In this conceptual perspective, client-centered therapy was used to help individuals move toward a more positive and achievable self-concept in contrast to an unobtainable and idealized sense of self-concept. The goal of psychotherapy, according to this perspective, was to help individuals gain knowledge and insight about their experiences, which in turn would lead to a better understanding of their identity and enhance the clarity and confidence of their self-concept.

Building on an integration of early conceptual contributions from humanistic psychology and person-environment fit perspectives, scholars in the career development field began sustained research into the nature of the self-concept. Using life span development ideas as an organizing rubric for theoretical advances, life experiences related to work and career were seen as integrally connected to overall psychological functioning. Scholars suggested that by looking at an individual's context (i.e., family, history, social relationships, economic factors, psychological functioning), we can better understand how one's sense of vocational identity and self-concept begin to unfold.

These pioneers promoted the idea that it is important for people to know themselves in order to be satisfied in their work lives. One way of understanding this self-knowledge and other internal aspects of an individual is through the construct of the self-concept. According to the tenets of this construct, satisfaction in work roles is related to the degree to which people can implement their self-concept.

THE SELF-CONCEPT IN CAREER DEVELOPMENT THEORY AND PRACTICE

The role of the self-concept as a key element of career development theory and practice is evident in most of the major theoretical positions and counseling approaches. For example, the self-concept has been described as a matching theory by which individuals simultaneously consider their personal attributes and the attributes desired by certain occupations. The self-concept is understood as having multiple dimensions, including developmental, psychological, personal, and social aspects. Upon closer examination, the self-concept has been described as being composed of dimensions and metadimensions by leading career development theorists. Dimensions are considered to be the components of personality or the traits that

people assign to others and themselves. Metadimensions of the self-concept are described as the characteristics of the traits that people attribute to themselves. In other words, metadimensions can be used to explore the tone and similarities among personality traits.

Self-esteem is one such metadimension that has affective characteristics. Self-esteem is characterized by evaluative and affective aspects of the self-concept that relate to one's subjective sense of self. The degree of self-esteem associated with a trait or the degree of clarity or abstraction associated with a self-description (such as, "I am moderately good at math") is a prime example of how metadimensions can illuminate an exploration of an individual's self-concept. The ability an individual possesses to integrate interpersonal evaluations with the self-concept contributes to the consistency and accuracy in one's self-esteem in addition to one's level of self-confidence. The level of one's self-esteem in relation to the self-concept is important in career decision making, as research has demonstrated a connection between the self-concept and occupational preferences. For example, a young woman may view herself as a good student in math and science; however, due to the impact of sex role socialization, she may attach negative affect to these self-perceptions, thereby inhibiting her capacity to construct a meaningful and maximally rewarding career.

Within the career realm, individuals may have a more circumscribed occupational self-concept, which reflects a subdimension of the overarching self-concept. The occupational self-concept refers to the translation of general beliefs and feelings about oneself to the working context. The individual described in the previous paragraph may have an occupational self-concept that reflects a strong avoidance of math and science with a corresponding self-concept that suggests more "feminine" attributes, such as caregiving and nurturing. However, the process of career development and matching between an evolving self-concept and evolving situations is never truly complete. In the example above, the woman with a self-concept that has sought to disavow her interests in science and math could change due to life experience and/or counseling.

Career development is thought to be characterized by developing, synthesizing, compromising, and implementing self-concepts. These self-concepts result from an interaction of inherited aptitudes, physiology, opportunities to play various roles, and evaluation of the extent to which the roles gain approval of superiors and peers. Furthermore, the self-concept has

been described as the glue that might cement global theories of career development with well-assembled segments of preexisting theories.

The self-concept develops over time through interactions and experiences with aptitudes, physical qualities/skills, and opportunities to observe various work roles. Although the self-concept starts to develop in childhood and further crystallizes in late adolescence, it can change and transform over time due to one's experiences in the world. One prominent way of understanding the development of the self-concept is based on a three-tiered stage model: formation, translation, and implementation. The formation stage is devoted to differentiation of the self from others and identification with those who can serve as models. The translation stage builds upon the previous stage in that an adult role model may be used for reality testing. Individuals evaluate the extent to which their available role models are similar or dissimilar to them and the extent to which their own attributes would be suitable for a particular occupation. An example of this might be a male adolescent considering a career in teaching that would follow in his mother's footsteps. Over time, that individual would learn about the skills required for this occupation and in turn would conduct a self-assessment to determine if this occupation would be congruent with his self-concept. This analysis may lead to commitment or rejection of the teaching occupation. The implementation stage of this model occurs as this individual activates his plan through pursuing higher education or employment in the chosen occupation. In the present example, this adolescent may have had a summer job teaching swimming, and he determined through feedback from others in addition to his own self-assessment that teaching would be an ideal occupation. His next step would be to attend college so that he could implement his professional plan, reflecting an implementation of his general self-concept into an occupational context.

Another informative approach utilizes four sequential stages to describe ways in which the self-concept changes as one moves through the career decision-making process. This model includes awareness, planning, commitment, and implementation. The awareness stage is characterized by an increased awareness of place in time in regard to an individual's present state, the past, and speculation as to where an individual is headed. The self-appraisal within the awareness stage can lead to satisfaction with current circumstances or, alternatively, anxiety over past decisions that have resulted in dissatisfactory present circumstances.

The planning stage involves exploration and crystallization of career decision making. Through exploration, an individual is able to expand alternative scenarios for the decision at hand and then assesses the relationship between these scenarios and his or her self-concept. Once an individual is able to settle upon a specific option through gathering more information on alternatives and/or increasing self-knowledge of relevant values and priorities, he or she can transition into the commitment stage.

The commitment stage begins within an individual's internal resolution to commit to a decision. Next, the individual cautiously shares this decision with close friends or family members to elicit feedback. Once the commitment has been openly stated and encouragingly accepted by an individual's close family, friends, and colleagues, one's self-concept is then further consolidated. Implementation is the last stage of this four-step process and occurs when an individual successfully establishes contingency plans, internalizes the positive aspects of the decision, and reduces the negative aspects of the decision.

This four-step model of career decision making was established with the college population in mind. Consequently, the decision to major in a certain subject is a relevant illustration of this model. As an individual enters college, self-awareness peaks in regard to a student's past, present situation, and future aspirations. In some cases, the decision to major in a certain subject takes place prior to the start of college, with the awareness and planning stages occurring during high school. A female high school student who has received strong encouragement and praise for her mathematics and science skills from her teachers and family members might have easily arrived at a decision to major in engineering before stepping foot on her college campus. For this individual, college begins with the commitment stage as she determines which courses are necessary to implement her decision to major in engineering. There is a possibility of regression to the planning and even awareness stage if this student discovers extreme dissonance in her chosen major in regard to her self-concept (i.e., this intended engineering major finds out that she is most interested in the business and strategic side of technology as opposed to engineering concepts). The planning and awareness stages are revisited, and a new major, such as business, may be established as she tests her new ideas on her close friends and colleagues and against her evolving self-concept. While this model is

sequential, it is not static; rather, it is a dynamic process by which an individual will move forward and backward through the stages as necessary.

Self-concept theory is flexible and malleable, much like the career trajectories of those it seeks to describe; different parts will be applicable to different individuals at different points in time.

THE CULTURAL AND RELATIONAL CONTEXTS OF THE SELF-CONCEPT

There are several new advances in self-concept theory and research that focus on the role of context in shaping the formation and expression of one's self-concept in the world of work. Context is typically understood as contemporary and historical factors relating to familial, relational, social, cultural, political, and economic influences that affect an individual's development across the life span. Current contextualist research in career development includes in-depth explorations of the interface of work with relational and cultural factors.

Recent movements to contextualize career concerns have explored the connections between interpersonal relationships and work. Relationally oriented theorists have proposed that individuals achieve a sense of self-concept that is created and re-created in multiple contexts (including the work world) principally through their social interactions and relationships. According to this view, the self-concept is rooted in a relational matrix in which the individual's past and current relationships are viewed as having the potential to inform individuals about their own attributes and to nurture their self-esteem and sense of inner cohesion.

Research advances regarding the cultural context of self-concept development view the self as both defined and embedded in an array of relationships within Western and non-Western cultures in different configurations and extents respectively. Culturally prompted constructions of the self-concept evoke a multitude of implications and outcomes, involving motivational, cognitive, and emotional processes as they relate to the world of work. Such explorations raise further questions regarding the degree to which the self-concept is established through culture and historical forces and its impact on work and career development.

The field of career development benefits from a growing understanding on how the self-concept develops and functions within a relational and cultural matrix. Career development practitioners and scholars

are better able to assist individuals in work and career objectives with more explicit consideration of cultural and relational aspects of context.

CLOSING COMMENTS

Many of the theoretical advances on the role of the self-concept in career development occurred at a time when career trajectories were fairly stable, at least for a very visible (although not inclusive) cohort of the workforce. What, then, are the implications of the self-concept as careers become more complex, less orderly, and at times unpredictable? A close look at the research and theory on the self-concept suggests some plausible answers to this question. First, the notion that the self-concept can shift, based on contextual influences, is an integral notion that is common in most theoretical statements in career development. Second, the knowledge that the self-concept is multidimensional is also critical.

Considering these two observations in tandem suggests that many core aspects of the self-concept, such as values, interests, and beliefs about oneself, may function to provide a sense of coherence in a changing world. At the same time, the observation that the self-concept is malleable offers theorists and practitioners optimism about how individuals can cope with rapidly changing norms about career development. For example, individuals who lose their information technology jobs due to outsourcing may in fact be able to hold on to the fact that they are competent, capable, and talented workers with great skills and interests in computer technology. Yet at the same time, they may have to shift some of their interests perhaps to secondary areas, which they might not have considered in the past, in order to adapt to the changing world of work.

The scholarship on the self-concept has functioned as a bridge to unite many theories in career development. Moreover, the self-concept serves each of us as a coherent span that links our self-perceptions, attitudes, and feelings about ourselves. Hopefully, as more and more people across the globe have opportunities to construct their own careers, the wonderful privilege of being able to implement one's self-concept in the world of work will become an expected part of the transition to adulthood.

SELF-DIRECTED SEARCH (SDS)

According to the publisher, Psychological Assessment Resources, the *Self-Directed Search* (SDS) developed by Dr. John L. Holland is the mostly widely used career interest inventory in the world. It has been translated into over 25 different languages. The SDS is based on Dr. Holland's RIASEC theory that both people and work and study environments can be classified according to six basic types: Realistic, Investigative, Artistic, Social, Enterprising, and Conventional (RIASEC). The SDS enables users to choose occupations and fields of study that best match their self-reported skills and interests. It is based on the idea that people whose job and work environments most closely match their personal style and interests tend to consider themselves satisfied and successful with the occupational choices they have made.

The SDS Form R (SDS:R) is the most common version of the instrument. In its assessment booklet, users answer questions about their occupational aspirations in a Daydreams section, which can be scored separately to yield a vocational aspirations code, or expressed interest code. Sections with lists of activities, competencies, and occupations follow the Daydreams section. The final section includes ratings for ability self-estimates across the six RIASEC areas. These latter five sections of the SDS:R can be self-scored to produce a three-letter summary code that designates the three personality types an individual most closely resembles. This is called the assessed code.

The SDS is both a stand-alone career planning simulation that imitates an interest inventory as well as a psychological test. The original paper-and-pencil SDS:R has been revised four times, most recently in 1994, and includes the *Assessment* booklet, the *Occupations Finder* (1,335 occupations employing 99 percent of U.S. workers and updated with additional information on technology occupations in 1999), and the *You and Your Career* booklet, which discusses the scientific ideas supporting the SDS, how to interpret the scores and codes, the personality characteristics associated with codes, and some suggestions for successful career planning. Normative data for the 1994 edition of SDS:R were derived from a nationally representative sample of 2,602 students (high school and college) and working adults in the United States.

While most counselors have basic information about the SDS:R paper version, the other varied SDS formats and versions are less widely known. A computer-based version of SDS:R provides for faster administration and more efficient use of the inventory. The computer generates a 10- to 12-page *Interpretive Report* for users based on SDS summary scores and a 1- to 3-page professional summary for counselors.

Besides these various formats of SDS:R, other versions of the SDS include Form E (Easy) for persons with poor English language or reading skills, SDS: Form CP (Career Planning) for adults working in organizations, and SDS: Career Explorer for middle school students. These alternative formats of the SDS have the same basic features of SDS:R.

EXPRESSED INTERESTS

In his writings, Holland has urged counselors to pay close attention to what persons say about the occupations they are considering. Occupational

aspirations are equal to or exceed predictions of future occupational activity available in standardized inventories. In other words, persons' expressed interests may be just as predictive of future occupational activity as their assessed interests.

An important innovation in the measurement of aspirations in the SDS Daydreams section was the coding of aspirations using the RIASEC typology. This procedure enables a counselor to examine not only the occupation named but also its RIASEC code. When the first two or three aspirations belong in the same RIASEC category, the predictive power of the first aspiration equals or exceeds the efficiency of an interest inventory.

MEASURING ASSESSED INTERESTS

The SDS has been described as a career planning simulation because it provides an opportunity to observe a career planning event under controlled conditions that might occur in real life. In this case, the SDS *Assessment* booklet provides a way for counselors to observe how persons may be engaging in educational and career decision making. The SDS is also a standardized assessment instrument. The items in the *Assessment* booklet have desirable psychometric properties and are based on RIASEC theory. The SDS has been subjected to the same rigorous test development standards as other professionally published tests, and the SDS manuals describe a complex, theory-based test development process begun in 1970.

The Activities section of the SDS:R *Assessment* booklet consists of 11 items for each of the six RIASEC types, and they cover hobbies and activities that are done for fun or leisure, and users can endorse them as "like" or "dislike." These items are included in the SDS because they effectively measure interests in relation to RIASEC theory.

In the Competencies section, users describe their skills, the kinds of things they had learned to do in the past, as well as discuss the skills they might want to develop in the future. This kind of information is practically important, because it is reasonable to believe that persons completing a career assessment will consider their history of skills and education or work-related accomplishments. The Competencies section of the SDS:R includes 11 items that are marked "yes" or "no" for the six RIASEC areas.

The next section of the SDS:R is Occupations. Longer than the previous two sections, it includes 14

items (occupational titles) that are endorsed "yes" or "no" for each of the RIASEC areas. Holland included this section because he wanted to make sure he obtained a good measure of the person's RIASEC typology and because he wanted to get a picture of the positive and negative feelings the person had for various occupational titles.

The final section of the SDS:R *Assessment* booklet is Self-estimates. It includes the six RIASEC scales, which are rated twice (from 1 to 7) with respect to ability and skill. Users are asked to rate themselves "as you really think you are when compared with other persons your own age."

SUMMARY

When the SDS was first introduced, some critics viewed it as "simplistic." However, more recent reviews have noted that the use of Holland's inventories is "extensive." The SDS is unique in several ways: (a) It is self-administering, self-scoring, and self-interpreting; (b) it is based on Holland's theory; and (c) it is supported by extensive research. The SDS is an inventory with desirable psychometric characteristics that incorporates a person's history of vocational daydreams, which can be used to increase predictive validity and to form an impression of a person's goals and background that encourages the immediate preliminary exploration of more than 1,000 occupations. Because it is self-scored and can be interpreted by most people, it encourages a person's active participation in the resolution of career problems and questions.

SELF-EFFICACY

The concept of *self-efficacy*, as originated by Albert Bandura of Stanford University, has become one of the major variables used in understanding and facilitating individual career development and is also becoming important in the study of organizational and team effectiveness. As originally proposed, self-efficacy expectations refer to a person's beliefs concerning his or her ability to successfully perform a given task or behavior. These efficacy beliefs are behaviorally specific rather than general. The concept of self-efficacy must therefore have a behavioral referent to be meaningful. We could refer to perceived self-efficacy with respect to mathematics, initiating social interactions, using a computer software program, or teaching children to read. Because self-efficacy expectations are discussed in reference to a specific behavioral domain, the number of different kinds of self-efficacy expectations is limited only by the possible number of behavioral domains that are important for some defined purpose.

Self-efficacy expectations are postulated to have at least three important behavioral consequences: (1) approach versus avoidance behavior, (2) quality of performance of behaviors in the target domain, and (3) persistence in the face of obstacles or disconfirming experiences. More specifically, low self-efficacy expectations regarding a behavior or behavioral domain are postulated to lead to avoidance of those behaviors, poorer performance, and a tendency to give up when faced with discouragement or failure. If, for example, mathematics self-efficacy expectations were low in a given individual, we would expect that person to avoid mathematics course work and math tasks, to perform poorly on math exams or job-related materials based on mathematics, and to give up readily when faced with difficult math tasks and problems.

The first behavioral consequence, approach versus avoidance behavior, has a profound impact on career development because approach behavior describes what people will try, while avoidance behavior refers to things they will not try. It thus encompasses both the content of career choice, that is, the types of

educational majors and careers an individual will attempt, and the process of career choice, that is, the career exploratory and decision-making behaviors essential to making good choices.

The effects of self-efficacy expectations on performance can refer to effects such as performance on the tests necessary to complete college course work or the requirements of a job-training program. Finally, the effects of self-efficacy on persistence are essential for long-term pursuit of one's goals in the face of obstacles, occasional failures, and dissuading messages from the environment, for example, gender- or race-based discrimination or harassment in the workplace.

Research over the past 25 years has shown that self-efficacy is, indeed, important in relation to career behavior, including choices, performance, and persistence. Reviews of this research are well beyond the scope of this entry, but it is fair to say that self-efficacy expectations regarding both career activities and the processes of career decision making and job search have an important relationship to the nature of educational and career choices and the effectiveness of career decision-making behaviors. Self-efficacy is also an important concept in understanding and facilitating the functioning of employed individuals.

The next section briefly mentions domains of self-efficacy that have relevance to initial career choices and the effectiveness of career decision making. Domains to be mentioned include occupational self-efficacy, including self-efficacy for scientific/technical careers, mathematics self-efficacy, self-efficacy with respect to basic activity dimensions of career behavior, and career decision-making self-efficacy.

SELF-EFFICACY IN INITIAL CAREER DECISIONS

A number of researchers have studied perceived self-efficacy with regard to specific content domains of educational and career choices—because self-efficacy is postulated to influence approach versus avoidance behavior, and domain-specific self-efficacy expectations help us to understand the nature of people's choices and, if appropriate, provide a means of increasing the range of possible career options.

The earliest studies of career self-efficacy used efficacy beliefs regarding specific occupations, for example, law, engineering, teaching, and sales. Typical categorizations of occupations as traditionally male dominated (e.g., engineer) and traditionally

female dominated (e.g., social worker) occupations were used. A number of studies have shown significant gender differences in self-efficacy with respect to these occupational groups and, more important, that low self-efficacy expectations reduced perceived career options. Thus, low self-efficacy with regard to male-dominated occupations has been found useful in explaining women's continued underrepresentation in these career fields.

A related area of research has employed a more focused set of occupational titles, specifically those in scientific and technical careers. Research has shown that high versus low scientific/technical self-efficacy is significantly predictive of grades in science and technical courses, in persistence in an engineering major, and in range of career options in the sciences and engineering. Research has shown that Bandura's hypotheses hold not only in unselected groups of students but among those who have made tentative career choices.

Other researchers have examined a more fundamental aspect of consideration of scientific and technical careers, and that is mathematics self-efficacy. Twenty years of research on this construct have suggested its vital importance to educational achievement and career options. Measures of math self-efficacy, using everyday math tasks (e.g., balancing a checkbook), self-efficacy for math course work (e.g., calculus), and self-efficacy for solving math problems, have consistently shown large gender differences in math self-efficacy, with males being significantly more confident than females. Empirical research has also supported the predictive relationship of math self-efficacy to math performance and achievement and the importance of math self-efficacy to the science- or math-relatedness of career choices.

There are now also a number of measures of self-efficacy for important dimensions of vocational activity, for example, artistic, business, and social areas. Other inventories assess self-efficacy with respect to narrower domains of vocational activity. These domains include such activity areas as science, teaching, helping, leadership, mechanical activities, sales, data management, and using technology. Overall, research using such measures suggests that they too predict educational aspirations and occupational group membership. Also increasingly useful in career research and counseling are parallel measures of self-efficacy and vocational interests in research and career counseling. The most common paradigm for

this would be assessment of both self-efficacy and interests with respect to one or more domains of vocational activity; for example, both interests in science and perceptions of self-efficacy for science would be assessed. Those activity domains for which there is both high interest and high self-efficacy are targeted for career exploration. However, those areas where there is interest but low efficacy may be brought into the realm of career possibility if self-efficacy can be increased through interventions based on Bandura's theory (see next section). Thus the concept of self-efficacy can help to increase the range of career options open to a given individual.

In addition to career self-efficacy measures designed to predict the type of options considered versus avoided, or the nature of the choices made, self-efficacy theory has also been applied to the process of career decision making. There is now strong evidence to support the importance of self-efficacy in evoking exploration of the self and environment as they pertain to educational and career options. One of the most popular concepts is that of self-efficacy for making career decisions. A frequently used measure assesses self-efficacy with respect to five groups of tasks necessary to making career decisions: (1) accurate self-appraisal, (2) gathering occupational information, (3) goal selection, (4) making plans for the future, and (5) problem solving. A number of studies have shown career decisional self-efficacy to be related to indicators of educational and career adjustment, including career indecision, vocational identity, whether or not students have declared college majors, career exploratory behavior, and academic and social adjustment. Other researchers have developed and examined measures of self-efficacy relative to aspects of the processes involved in the career search. Also, and not surprisingly, there is evidence that self-efficacy for social interactions is significantly related to overall career decision self-efficacy and decisional progress. This makes sense if one considers that some level of social confidence may help in the process of gaining occupational information as well as in the job search process itself—even the most highly skilled job candidates may jeopardize their chances of employment if they perform poorly in a job interview.

Thus these examples of behavior domains studied should illustrate the broad applicability to career development of the self-efficacy construct. Self-efficacy can now be considered one of the major variables influencing the nature and effectiveness of career

choice behaviors. In addition, however, the concept has a very useful feature of having embedded within the theory the means of increasing behavior-relevant self-efficacy expectations via four types of experiences, which Bandura called sources of efficacy information. He theorized that our initial learning of efficacy expectations derives from these sources of information and that they can also be used to increase self-efficacy expectations at any time subsequently. The sources of information are (1) performance accomplishments, that is, experiences of successfully performing the behaviors in questions; (2) vicarious learning, or modeling; (3) verbal persuasion, for example, encouragement and support from others; and (4) lower levels of emotional arousal, that is, lower levels of anxiety, in connection with the behavior.

Past performance accomplishments serve as indicators of capability and are the most influential sources of efficacy information. Bandura has indicated that success promotes strong beliefs in one's personal efficacy. Failure weakens beliefs of personal efficacy, especially if the failure occurs before efficacy beliefs are firmly established. In addition, once a moderate level of self-efficacy develops, establishment of a strong, resilient sense of personal efficacy requires succeeding on difficult, rather than easy, tasks. Succeeding only on easy tasks is unlikely to teach the perseverance necessary in most worthwhile real-world endeavors.

The second source of efficacy information is vicarious learning, or modeling. Observing another person successfully engaging in a behavior can increase the efficacy of the observer, though observing failure in a model can likewise reduce perceived self-efficacy.

Social persuasion from others can be effective in enhancing and sustaining a sense of personal efficacy if the target behavior is within realistic boundaries. That is, social persuasion that is well beyond what the individual is actually capable of doing will not be effective, as the negative results of the individual's inadequate performances will constitute more powerful feedback than will unrealistic social persuasion. Rather, persuasion and encouragement should be focused on realistic challenges rather than impossible tasks, failure on which will be detrimental to perceived efficacy.

The fourth source, emotional arousal, refers to somatic information conveyed by physiological and emotional states. Physiological indicators can refer to

indices of autonomic arousal such as sweating and fast heartbeat or physical indicators such as fatigue or windedness. Anxiety is the most commonly discussed type of emotional arousal. Self-efficacy can be enhanced by reducing the extent to which the individual experiences these indicators, for example, by managing stress and anxiety responses and by increasing physical fitness levels.

There is now research showing the effectiveness of theory-based interventions in increasing self-efficacy. Specifically, there is evidence that using Bandura's four sources of efficacy information in an integrated treatment program can increase individuals' self-efficacy with respect to targeted behavioral domains.

Finally, Bandura's original theory postulated the existence as well of outcome expectations, which refer to the expected consequences of successful behavior. That is, successful performance is not always followed by a desired outcome, and individual beliefs regarding the predictability of desired outcomes can also differ. Social cognitive career theory integrates self-efficacy and outcome expectations, as well as vocational interests, in a comprehensive model of career choice behavior.

ORGANIZATIONAL SELF-EFFICACY AND COLLECTIVE EFFICACY

In addition to many useful inventories of self-efficacy related to career choice and decision making, the concept of self-efficacy has been found to be very useful as well in studying the career development and adjustment of employed individuals. Usually self-efficacy is conceptualized as relevant to some task or set of tasks required in the workplace. Research has shown that the higher the self-efficacy, the more likely one is to engage and persist in task-related activity. Research has also shown that higher self-efficacy predicts more positive job attitudes, training proficiency, and job performance, and that higher self-efficacy serves as a buffer of the potentially negative effects of stresses on overall psychological well-being.

Another important area of research is that on managerial self-efficacy. The general task faced by managers involves gathering and processing large and often complex pieces of information so that effective decisions can be made. Research has suggested that people high on managerial self-efficacy are more able to remain task focused, rather than self focused, and efficient yet creative in their decisional processes, in

the face of organizational setbacks. Studies using manipulations to threaten the efficacy beliefs of otherwise talented managers have shown progressive deterioration in their performance. They were inflicted with increasing self-doubt and became more erratic in their thinking processes. Poorer organizational outcomes and an increasing tendency to blame others for performance decrements were observed. Conversely, managers whose efficacy beliefs were strengthened set increasingly challenging goals and were able to use efficient and creative-thinking processes to reach them. Not surprisingly in the latter case, organizational outcomes were enhanced. Finally, other research has shown that managers' self-efficacy with respect to technical, human relations, administrative, and conceptual managerial tasks were related to the success of managers as gauged by promotions, increased responsibilities, and salary.

Although much organizational research has focused on self-efficacy for a given individual, there is increasing interest as well in generalizing self-efficacy to group levels of analysis. Bandura defined collective efficacy as a group's shared perception of its collective capabilities to organize and execute the courses of action required to produce a given level of achievement. Collective efficacy has been shown to be related to group motivation and performance. Some current research is examining the antecedents of collective versus individual efficacy. A particular focus as an antecedent of collective efficacy is the leadership climate within the organization, and some research findings now suggest that leadership climate does influence collective efficacy.

A more specific use of the overall concept of collective efficacy is that of "team efficacy." Collective efficacy can refer to the collective belief systems of teams, departments, or entire organizations, whereas team efficacy refers to beliefs within a defined work team. Furthermore, team efficacy, like collective efficacy, refers to more than just the sum of the self-efficacy beliefs of the team members; rather, it describes a shared belief in the capabilities of the collective operating as a unit. Research on team efficacy suggests that it, like collective efficacy more generally, is positively related to group performance. Again, specific research on the antecedents of team efficacy is under way.

In summary, the concept of self-efficacy has broad applicability to the understanding and facilitation of career development and organizational behavior and

functioning. Self-efficacy and collective efficacy are some of the most interesting and useful concepts in the career development literature.

SELF-ESTEEM

Self-esteem is of central importance to the psychological health and well-being of individuals in Western cultures. This importance is well documented, as self-esteem has been implicated in a vast array of phenomena, including depression and suicidal ideation, loneliness and peer rejection, academic achievement, and life satisfaction. When scholars and laypeople use the term *self-esteem*, they generally are referring to people's self-esteem level. In recent years, however, it has become clear that self-esteem is a multifaceted construct of which only one component is its level. We describe these various components later in this entry. For now, we focus on self-esteem level, which refers to the extent to which people's global feelings of self-worth, liking, and acceptance typically are

positive (high self-esteem level) or negative (low self-esteem level). We use the term *self-esteem* more generally to refer to global feelings of self-worth, liking, and acceptance.

DISTINGUISHING SELF-ESTEEM LEVEL FROM RELATED CONSTRUCTS

People encounter the term *self-esteem* frequently in everyday conversation, novels, newspaper and magazine articles, television and radio programming, and so forth. Self-help books heartily proclaim to have the secret to improving your self-esteem and that of loved ones. Unfortunately, although everyday usage of a scientific term can buttress laypeople's knowledge of the construct, in the process the scientific term itself often becomes much less precise, sometimes to the point of total ambiguity. This ambiguity can be costly, as two people using the term may be doing so in extremely different ways and therefore draw very different, perhaps opposite, conclusions. Two terms with which self-esteem often is confused are *self-confidence* and *self-evaluations* (self-appraisals).

Self-confidence refers to the expectations that individuals have regarding whether or not they can bring about desired outcomes. For example, individuals high in social self-confidence have positive expectations that most other people will like them or that audiences will be attentive to them when they are giving a presentation. These positive expectations may emanate from positive self-evaluations of their own speaking ability and/or from the belief that most people are friendly and easy to get along with. Conversely, individuals who are low in social self-confidence expect that others will not enjoy conversing or listening to them. Recall that high self-esteem level reflects people's own feelings of self-worth, liking, and acceptance. Whether people like and accept themselves need not relate to their expectations that others will share in those feelings. Although high self-esteem and high self-confidence often go hand-in-hand, it is easy to think of people who possess a great deal of self-confidence (in the social domain, or in other domains, such as achievement or athleticism) yet who do not like or value themselves very much. In fact, high self-confidence with respect to a given activity (such as expecting to get away with cheating) may also produce decreases in one's feelings of self-worth.

Self-evaluations refer to people's judgments or ratings of their standing along specific dimensions that comprise their self-concepts. Frequently, self-evaluations

are made of one's physical attractiveness (one's body or facial characteristics), intelligence (global or more specific components, such as mathematic or writing ability), social skills (how funny one is), and so forth. Given that these appraisals have a "good versus bad" quality to them, some researchers have taken to referring to these self-appraisals as domain-specific self-esteem. We think that this is wrong, because in so doing, people are giving short shrift to both self-evaluations and self-esteem. Each is a meaningful construct, with differing antecedents, structural and functional properties, and consequences. Moreover, the relation between specific self-evaluations and global self-esteem is a matter of some consequence. Over the years, several different viewpoints have emerged.

The first view is that global self-esteem is not separable from specific self-evaluations; instead, it is reducible to the total of an individual's success/aspiration assessments. This view, made famous by William James in 1890, asserts that self-esteem reflects the ratio of one's "successes" to one's "pretensions" or aspirations (i.e., what is important to the person). Stated differently, self-esteem is a summary evaluation that reflects the sum total of these success/aspiration assessments (i.e., "How well am I doing in those domains that are important to me?"). While this summary evaluation will certainly be informative with respect to the person's achievements, it is not the same thing as a person's feelings of self-worth, liking, and acceptance. A second view maintains the distinction between self-evaluations and self-esteem and holds that specific self-evaluations comprise the building blocks of individuals' global self-esteem. An empirically driven approach, this bottom-up perspective says that we can best predict global self-esteem from specific self-evaluations when we weight them by qualities such as importance to the person's self and the certainty with which the person makes the evaluation. Although not without controversy, research generally supports some of the contentions of the bottom-up perspective. However, strong associations between self-evaluations and self-esteem do not mean that they are substitutable for each other, nor does it mean that they each possess the same functional significance. A third view suggests that global self-esteem spreads out and affects domain-specific self-evaluations (a top-down approach) and not vice versa (a bottom-up approach). For example, a top-down approach suggests that if people generally like themselves, they will tend to rate themselves positively across a wide variety of specific domains.

Our view, shared by others in the field, is that both top-down and bottom-up directions of influence can occur, and that which direction of influence is more powerful varies from person to person and dimension to dimension. Regardless of one's stance on the directionality issue, we believe that it is crucial to maintain the distinction between specific self-evaluations and global self-esteem (feelings of self-worth, liking, and acceptance). A couple of examples highlight this distinction. For example, it is easy to think of individuals who dislike and generally are unhappy with themselves, despite being very competent and proficient in a number of aspects of their lives; conversely, other people are very happy and content with themselves despite not being "superstars" at anything. Consequently, we believe that it is confusing and misleading to claim that someone has low self-esteem in some domains (school achievement) but high self-esteem in others (e.g., social acceptance). Rather, we argue that the correct terminology is that people have domain-specific self-evaluations, some of which may be high and some of which may be low.

MEASURING SELF-ESTEEM LEVEL

Self-esteem measures generally consist of a series of potentially self-descriptive statements. The number and content of specific items, as well as what form responses take, vary considerably from measure to measure. Typically, respondents indicate the extent to which they agree or disagree with each statement or the extent to which each statement is true or characteristic of them. Two of the most widely known and used self-esteem measures are Susan Harter's Self-perception Profile for Children and Morris Rosenberg's Self-esteem Scale.

The Self-perception Profile for Children is designed to measure both global levels of self-esteem and specific self-evaluations (i.e., scholastic and athletic competence, social acceptance, physical appearance, and behavioral conduct). Researchers frequently use it in research involving elementary school children in Grades 3 and higher. One of its valuable features is that it allows researchers to examine whether self-evaluations relate to global self-esteem. Research and theory indicate that, in general, self-evaluations of competence, social acceptance, and physical attractiveness relate to global self-esteem.

The Rosenberg Self-esteem Scale is the most commonly used instrument to assess self-esteem levels in

adolescents and adults. Examining its items reveals a considerable strength of the measure as well as a potential weakness (shared by all self-esteem measures). Its strength is that it is very brief, consisting of only 10 items that clearly tap global feelings of self-worth and satisfaction. A potential downside is that the items' obviousness may prompt people to give responses reflective of psychological health even if these responses are not accurate self-descriptions.

THE NATURE OF LOW SELF-ESTEEM

Considerable research and theory suggest that low-self-esteem individuals are generally unhappy and dissatisfied with themselves. However, some researchers have suggested that rather than having an intense dislike for themselves, low-self-esteem individuals are uncertain and confused individuals whose self-feelings are predominantly neutral. Data from numerous studies suggest that low-self-esteem individuals typically give responses on self-esteem inventories that hovered around the midpoint of response scales (which therefore on average seemed to reflect neutral self-feelings). Very few low-self-esteem individuals in these studies consistently endorsed statements reflecting clear dislike or dissatisfaction with themselves.

Moreover, other influential research showed that low-self-esteem individuals possessed self-concepts lacking in internal consistency and temporal stability, which they held with little confidence (i.e., low-self-concept clarity). Still other important work showed that low-self-esteem individuals had pockets of favorable self-judgments, which seemed inconsistent with the idea that believing that one possessed no redeeming qualities is a core characteristic of low self-esteem.

The view that low-self-esteem individuals possess neutral self-feelings seems to contradict longstanding findings linking low self-esteem to depression and suicidal tendencies, especially among children and adolescents. Moreover, it seems inconsistent with clinical observations that portray the therapeutic setting as heavily concerned with issues of poor self-worth and negative self-concepts.

How, then, is the controversy to be resolved? One possibility is that only a small percentage of people in the general population truly have low self-esteem. A second possibility is that pressures to present oneself in a positive light mitigate against individuals giving extremely negative responses on a self-esteem

measure. Stated differently, self-presentational concerns may temper the negativity of low-self-esteem individuals' public responses but not their actual personal feelings of self-worth. Additional research is needed to assess the validity of these explanations.

THE NATURE OF HIGH SELF-ESTEEM

Considerable theory and research on self-esteem reveals that high self-esteem confers many benefits to individuals and that it relates to many positive psychological outcomes. Increasingly, however, it has become clear that high self-esteem also has a dark side, as it sometimes relates to maladaptive outcomes such as heightened aggressive behavior. Therefore, it is extremely important to determine when high self-esteem relates to positive psychological functioning and outcomes and when it does not. One critical factor is the extent to which high self-esteem is fragile or secure. Individuals with fragile high self-esteem appear willing to go to great lengths to preserve, maintain, and enhance their positive, yet vulnerable, feelings of self-worth. Defensiveness and other maladaptive processes characterize these individuals. In contrast, individuals with secure high self-esteem like, value, and accept themselves, "warts and all." They have well-anchored feelings of self-worth and generally display healthy psychological and interpersonal functioning.

Recent theory and evidence suggest several ways to distinguish between secure and fragile high self-esteem that employ theoretical distinctions between various kinds of self-esteem. Importantly, existing research indicates that these constructs behave in parallel fashion across studies, suggesting that they are tapping a broader construct reflecting fragile versus secure self-esteem.

STABLE VERSUS UNSTABLE SELF-ESTEEM

One way to distinguish between secure and fragile high self-esteem involves the extent to which a person's current feelings of self-worth fluctuate across time and situations. These short-term fluctuations in one's immediate, contextually based feelings of self-worth reflect the degree to which one's self-esteem is unstable; the greater the magnitude of fluctuations, the more unstable one's self-esteem. Stability of self-esteem is conceptualized as distinct from self-esteem level, which reflects the positivity of one's typical or general feelings of self-worth.

Unstable self-esteem reflects fragile and vulnerable feelings of self-worth that are subject to the vicissitudes of internally generated and externally provided positive and negative experiences. Moreover, people with unstable self-esteem are highly ego-involved in their everyday activities, that is, they experience their self-esteem as continually "being on the line." Researchers have examined a number of implications of this characterization. For example:

1. Daily negative events have a greater adverse impact on individuals with unstable as opposed to stable self-esteem. Individuals with unstable self-esteem have especially adverse reactions to daily hassles, as reflected in the greatest increases in depressive symptoms.
2. Everyday positive and negative events have a greater immediate impact on the self-feelings of people with unstable rather than stable self-esteem.
3. People with unstable self-esteem have a weaker sense of self than do people with stable self-esteem. Researchers found that the more individuals' self-esteem was unstable, the more they regulated their goal strivings in terms of external pressures and guilt avoidance and the less in terms of personal importance and interest, the less confident they were in their self-knowledge.

Importantly, a growing body of research supports the usefulness of distinguishing among high-self-esteem individuals based on how much their immediate feelings of self-worth fluctuate. That is, people with unstable high self-esteem are more defensive and self-aggrandizing than are their stable high-self-esteem counterparts. For example, unstable as compared to stable high-self-esteem individuals are more prone to anger and hostility and increased depression in the face of daily hassles, and they report increased tendencies to "get even" in response to hypothetical partner transgressions. Moreover, the more high-self-esteem individuals' feelings of self-worth are unstable, the lower their psychological health and well-being. These and other findings indicate that whereas unstable high self-esteem can be characterized as fragile, stable high self-esteem can be characterized as secure.

CONTINGENT VERSUS TRUE SELF-ESTEEM

A second way to distinguish between fragile and secure high self-esteem is to determine the extent to

which individuals' feelings of self-worth are dependent upon the attainment of specific outcomes or the matching of interpersonal or intrapsychic standards of excellence. Individuals with contingent high self-esteem are preoccupied with their standings on specific evaluative dimensions (e.g., "How smart am I?"), how they are viewed by others ("Do people think I am attractive?"), and they continually engage in setting and meeting evaluative standards to validate themselves. High self-esteem that is contingent is fragile, because it remains high only as long as one is successful at satisfying relevant criteria. Moreover, the strong need for continual validation drives the person to seek more and more successes. Should these successes cease, the person's self-esteem likely will plummet. In contrast, true high self-esteem reflects well-anchored and secure feelings of self-worth that neither depend on the attainment of specific outcomes nor require continual validation. Theorists speculate that true high self-esteem develops when one's actions are self-determined and congruent with one's inner core self rather than a reflection of externally imposed or internally based demands. Activities are chosen and goals are undertaken because they are of interest and importance and feelings of self-worth arise naturally out of these activities. In contingent self-esteem, pursuing self-esteem is the individual's "prime directive." In true self-esteem, feelings of self-worth are the by-product of pursuing one's interests and developing one's skills in a self-determined manner.

Researchers have developed several measures of contingent self-esteem that promise to be useful in fleshing out its relation to various aspects of psychological functioning and well-being. For example, people with highly contingent self-esteem (similar to individuals with unstable high self-esteem) react especially strongly to potentially threatening events. Moreover, researchers have provided evidence that individual differences exist in the specific contingencies on which people base their high self-esteem. Whereas some people base their self-esteem primarily on outcomes related to competence and performance, other people base their self-esteem on outcomes related to their physical attractiveness or social acceptance. Researchers have shown that the particular domains on which self-esteem is based influence people's behavioral choices, goal strivings, and emotional reactions. For example, among medical school applicants, the daily self-esteem of individuals whose self-esteem was contingent on academic competence

was especially likely to rise with news of acceptance and decline with news of rejection.

IMPLICIT SELF-ESTEEM

Another way to distinguish secure from fragile high self-esteem involves a consideration of both explicit and implicit feelings of self-worth. Researchers generally characterize implicit self-esteem as relatively automatic emotional or evaluative associations with the self that involve little or no effort or conscious guidance. A similar definition is that implicit self-esteem involves self-evaluations that occur unintentionally and outside of awareness. Explicit self-esteem involves deliberate, consciously held self-evaluations that are measured by self-reports.

Several different procedures have been used to examine implicit self-esteem and its implications for psychological functioning. One procedure, called the Implicit Association Test (IAT), involves the use of reaction time methods to assess the strength of associative links between self-defining or non-self-defining terms and various positive and negative stimuli. A second procedure, the "name letter task," involves comparing people's ratings of letters in their names with ratings of letters not in their names.

A number of recent studies have focused on discrepancies between implicit and explicit self-esteem and defensiveness or self-promotion. Findings from this research warrant several conclusions. First, both the IAT and the name letter effect appear to be reliable and valid measures of implicit self-esteem. Second, discrepant explicit/implicit self-esteem appears to reflect fragile high self-esteem. Using the name letter effect measure, a team of researchers reported that heightened compensatory self-enhancement (i.e., unrealistic optimism, claiming that a highly flattering personality profile is self-descriptive) was observed among individuals with high explicit/low implicit self-esteem. Using the IAT, a different research team found that individuals with high explicit/low implicit self-esteem scored highest on a measure of narcissism and were especially defensive (exhibited high in-group bias and dissonance reduction), compared to individuals with high explicit/high implicit self-esteem. Thus, a growing body of research suggests that whereas high explicit self-esteem coupled with low implicit self-esteem is fragile, high explicit self-esteem coupled with high implicit self-esteem is secure.

SUMMARY

The foregoing review reinforces the view that self-esteem has multiple components and that to understand fully its place in psychological functioning we must understand these components. Although they differ in their specifics, all are based on the conviction that there is more to self-esteem than whether it is high or low. Importantly, existing research supports the contention that each component reflects an aspect of self-esteem fragility and/or vulnerability. Moreover, researchers increasingly are finding interrelations among these various constructs. For example, measures of unstable and contingent self-esteem are significantly correlated. In short, evidence attesting to the interrelations among these various "fragility" components is quickly accruing, much of it within the past few years. We hope that future researchers will ride this wave of activity and push toward the direction of a complete understanding of complex self-esteem processes.

SELF-LEADERSHIP

One of the primary aims of *self-leadership* is to achieve higher performance and effectiveness through behavioral and cognitive strategies that individuals use to influence themselves. It is a comprehensive view of self-influence that considers behavior to be a result of factors both internal and external to the individual.

Considered to be an advanced form of the self-influence process, self-leadership reflects three important premises. First, leadership is considered as an ongoing dynamic. Second, what an individual thinks and does is not without consequences. Third, all individuals have the ability to, and do, exercise leadership, at least over themselves, although they may not be skillful in their self-leadership practices at a given point in time.

Self-leadership theory is grounded on two main areas of psychology. First, social cognitive theory explains human behavior in terms of the reciprocal interactions between the individual and the environment, as well as human abilities to learn through social action, to perceive effectiveness, and manage and control oneself. Second, intrinsic motivation theory maintains that motivation is particularly potent when individuals engage in activities that they enjoy and/or consider meaningful.

More precisely, the concept of self-leadership builds on the notion of self-management, which is the ability of individuals to manage their own behaviors, and on the recognition of values and beliefs in work situations as sources of natural motivation. While self-management is primarily concerned with control, self-leadership is also interested in values. Furthermore, while self-management is concerned with the question of how to achieve a goal or standard, self-leadership is also interested in what the goals and standards should be and why they are worthy of pursuing.

Control systems include both organizational-control and self-control systems, where the first originate from organizational values and culture and where the latter originate from individual values and beliefs. Individuals largely govern their own values (which they objectify through standards), and individual values significantly guide behavior. Therefore, people tend to be moved to modify or create the situations where they are involved, by acting to reduce the level of perceived discrepancy between their own values and those of the organization.

In other words, the management of the interface between the two levels of control systems (organization and self) is largely determined by individuals. This is because, even though individuals may not have control of organizational values, they are the ones who largely decide their own values, which in turn influence their own behavior and determine how they may have an impact on the environment. Therefore, individual action is not completely submissive to the

organization. Indeed, when individuals decide upon their own values, they are influencing their own behavior, that is, they are exercising self-leadership.

Furthermore, individuals who manage their own behaviors have less need for formal leaders in the traditional sense because they are exercising leadership themselves. Self-leadership may constitute a substitute for leadership because self-leadership strategies such as self-planning, self-direction, self-monitoring, and self-control may replace otherwise needed supervision. This implies that self-leadership is closely related to empowerment in organizations, the sharing of power between the leader and the follower, and organizational structures that allow power sharing.

This close relationship among organizational forms, power, and leadership has been widely discussed. It is suggested that the flattening of traditional organizational structures leads, inevitably, to empowerment strategies and distributed decision-making processes, giving way to more organic types of organizations. Such organizational practices characterize new, nontraditional leadership approaches where the relationship between leadership and power gains a renewed impetus.

The exercise of self-leadership involves both behavioral and mental activity that enhance the effectiveness of the mind and body through the interplay of four main types of strategies, each targeted at different areas: world-altering and self-imposed strategies, natural rewards strategies, redesign of one's mental world, and team self-leadership.

Self-leadership scholars are also concerned with work ethics simply because their interest in the relation between behavior and values recognizes that value systems of organizations and employees may differ. The concern is that despite the potential hopefulness implied by complete optimal self-leadership in a given high-performing work system, one should be aware that it may not always be feasible to achieve high levels of self-leadership. Thus, more than being interested in efficiency and performance at work, self-leadership is also concerned with the moral and ethical aspects of how that may be attained.

Commentary on self-leadership would not be complete without addressing the view that the "self" consists of all conscious and unconscious states of a person. This notion introduces the (un)consciousness dimension of the self into the leadership debate. As such, the concept of self-leadership might be described more precisely as the noticeable and unnoticeable

processes of influencing oneself. One may ask, If these processes occur in unconscious ways, how can individuals be fully aware of the consequences of their own thoughts and actions? Moreover, to what extent can researchers themselves be fully aware, explain, and understand actual leadership phenomena? While it is beyond the scope of this discussion to elaborate on these questions, they are offered here for consideration and reflection by leadership scholars.

Given that the notion of self refers to conscious and unconscious aspects of the mind and body, self-leadership views that account only for the conscious aspects of the leadership process leave out issues that may be essential for its full understanding. Addressing unconscious aspects of self-leadership might help explain, for instance, why optimal self-leadership may not be possible for every employee and why there are limitations in measuring self-leadership.

In conclusion, based on distinct philosophical assumptions that guide self-leadership theory, this research stream constitutes a valuable framework for understanding personal and social development, and in particular with regard to career development. First, it recognizes that personal values may have an important role in shaping thoughts and actions, including those related to professional careers. Second, it provides specific strategies and techniques that may help individuals to select career paths that fit their personal values and lead to natural motivation in work. Third, it signals that achieving complete convergence of organizational and individual values as well as power sharing may be difficult, if not impossible, organizational objectives. Last, self-leadership provides a distinctive lens for debating and reflecting on leadership ethics.

SELF-MONITORING

Self-monitoring refers to the extent to which one attends to social cues and attempts to adapt behavior to control the image one presents to others. First introduced by Mark Snyder in 1974, this construct identifies individual differences in how people react to their social environments. Snyder believed that people differ in the extent to which they rely on their environments to guide their behaviors versus relying to a greater degree on their inner beliefs or states. Self-monitoring is typically assessed through the use of a 25-, 18-, or 13-item true-false, self-administered questionnaire consisting of such items as "I would probably make a good actor/actress," "I may deceive people by being friendly when I really dislike them," and "In different situations and with different people, I often act like very different persons." Several subscales of the self-monitoring scale have been identified, such as Acting, Extraversion, and Other-Directedness, although the majority of studies consider the scale as a whole.

Individuals high in self-monitoring are considered to be "social chameleons," better able to understand their social environment, more flexible and skillful in their use of expressive behaviors, and acting more in anticipation of the outcomes of their own behavior than individuals low in self-monitoring. Low self-monitors, on the other hand, tend to show greater behavioral stability across social situations, displaying behaviors that they believe are consistent with the images and beliefs they hold about themselves, and focusing less on the consequences that might be associated with the display of those behaviors.

It is possible for individuals to attempt to manage the impressions they make on others at all levels of career development. For instance, prospective employees may attempt to market themselves to interviewers, interviewers may attempt to impress interviewees in

order to draw the best candidates, workers may attempt to impress their bosses and sell products to their clients, and so on. Typically, job selection involves matching one's own skills and abilities to the jobs available; therefore, it is not surprising that researchers have found significant correlations between self-monitoring and job search preparation. Specifically, studies indicate that high self-monitors engage in greater analysis of their own interests and abilities and conduct more research on the companies with whom they wish to work than low self-monitors. In relation to job choice, low self-monitors indicate a preference for jobs that are compatible with their personalities, while high self-monitors show a preference for jobs involving well-defined roles and responsibilities. This information should be of interest to recruiters; the more clearly they can specify the attributes necessary for a job, the better high self-monitors can determine their abilities to meet the requirements and low self-monitors can determine the extent to which their personalities are consistent with the job requirements.

Once job seekers have identified careers of interest, they must engage in interviews. These interviews provide ample opportunity for job seekers to manipulate images of themselves. Although limited, research indicates that high self-monitors may be more likely to tailor the images they present in interview situations, expressing greater positive emotions and hiding negative emotions. These differential emotional presentations have been linked to higher ratings of competence by mock interviewers. Although low self-monitors may also manipulate their self-presentations, some research indicates that when low self-monitors attempt to create false images for interviewers, they feel greater amounts of stress and lower self-esteem than high self-monitors, who actually feel more successful following their self-presentations.

Interviewers can also differ in their level of self-monitoring, and research indicates that these differences are related to the types of information about candidates they deem important, as well as hiring decisions. Generally speaking, high self-monitors seem more willing than low self-monitors to form stereotypes and use them in rating interviewees' appropriateness for jobs. For instance, high self-monitors are more likely to select an applicant for a job whose appearance fits the image expected for the position, whereas low self-monitors are more likely to select an applicant whose personality and qualifications seem appropriate for the job.

Most occupations involve a great deal of interpersonal interaction on a daily basis; therefore, it is not surprising that self-monitoring is linked to differences in job performance and promotion. Low self-monitors attend to more internal cues while working, while high self-monitors attend to external cues, including the expectations of coworkers and bosses. High self-monitors exhibit stronger communication abilities and perceived persuasive ability. Job level has also been shown to be associated with self-monitoring, particularly when the job involves interacting with different types of people. For instance, individuals high in self-monitoring have shown greater success in boundary-spanning positions (jobs requiring employees to serve as go-betweens, filtering information between parties) as compared to individuals low in self-monitoring, even independent of job experience. Low self-monitors, however, may perform better in relatively homogenous groups, in occupations with lesser amounts of interpersonal contact, and in jobs requiring a great deal of self-motivation and direction. Finally, there are some findings of significant correlations between leadership and self-monitoring such that individuals with higher self-monitoring scores are perceived as more effective leaders, although these findings have primarily been for female rather than male managers. It has been suggested that in many fields, leadership behaviors are perceived as primarily masculine; therefore, females high in self-monitoring may benefit the most from their abilities to adapt to specific occupation expectations.

As with the interviewing processes, those making the ratings of job success may also be influenced by their own levels of self-monitoring. Some studies indicated that high self-monitors are more lenient and inaccurate in their ratings of coworkers, and seek to manipulate information to justify their ratings more than low self-monitors, especially in situations in which there are obvious consequences contingent on the ratings.

The final stage of career development that has been studied for its relationship to self-monitoring is organizational commitment and retention. High self-monitoring has been linked to lower levels of interpersonal commitment, less stable social bonds, and less organizational commitment and retention.

In addition, although high self-monitoring is related to greater occupational success for some types of jobs, this success may come with a price. High self-monitoring is associated with greater occupational stress and more

stress-related illnesses such as high blood pressure. The constant monitoring of their behaviors and situational cues may cause high self-monitors to experience more physical and psychological distress than their low self-monitoring counterparts.

Any situation involving the opportunity for people to strategically present themselves may be impacted by the interactants' levels of self-monitoring. A weakness of the research regarding self-monitoring and career development overall, but most particularly in regard to job interviews, is its overreliance on college students as both the source and the target of evaluation in many of these studies; however, increasing numbers of field studies are examining the relationship of self-monitoring to workplace issues, increasing the external validity of these findings.

SEX DISCRIMINATION

Discrimination refers to a person's behavior toward another based on the other's social characteristics, such as age, sex, ethnicity, or national origin. Thus, *sex discrimination* is differential treatment of women and men. Inappropriate discrimination (for example, excluding workers from certain jobs or offering them lower wages based on their sex) is a topic of importance to the study of careers.

Discrimination is usually distinguished from prejudice, which may be defined as a negative attitude

toward a social group and members of that group, usually based on a faulty and inflexible generalization or stereotype. Discrimination against women (or men) does not necessarily involve prejudice toward women (or men). While being prejudiced is not illegal, discriminating in favor of one sex and against the other sex may be illegal under certain circumstances in a number of countries.

Thus, the study of sex discrimination is typically concerned with negative and potentially illegal behavior that may or may not be based on prejudice and has the effect of disadvantaging and sometimes denying certain rights because of a person's sex. Furthermore, while individuals may discriminate against one sex by treating them differently from the other sex, institutions may also discriminate based on sex through their policies and procedures. For example, decades ago many airlines had a no-marriage policy for female flight attendants, and they would terminate them if they married or when they turned a specific age, typically about 35. Policies may also appear sex neutral on their face but differentially affect the sexes. For example, the practice of laying off employees with the least seniority will usually result in higher layoff rates among women than men, as more women than men may have interrupted their work history to have and raise children or tailor their career to the needs of their spouse's career. Requiring managers to spend a certain number of years working in different locations, including different countries, in order to advance to senior management positions is also likely to have the effect of discriminating against women. Whether such practices may be considered illegal depends on whether or not they are based on a business necessity, a condition that itself may be open to debate.

In the United States, there are two different kinds of illegal sex discrimination: disparate treatment and disparate impact. Requiring female but not male flight attendants to quit their job when they marry is an example of disparate treatment. Policies that result in lower pay for jobs held predominantly by women that are of comparable worth to those held predominantly by men is an example of disparate impact. Finally, sexual harassment is treated as a type of sex discrimination under the law in the United States, based on the notion that except in the rare instance of so-called equal opportunity harassers, harassment is based on the target's sex, whether the harasser is engaging in heterosexual or homosexual sexual harassment.

WHY DOES SEX DISCRIMINATION EXIST?

Some economists and other social scientists argue that sex discrimination cannot exist because the discriminatory employer (i.e., one who has a "taste" for discrimination) would have to forgo qualified women and pay higher wages to hire all men, thereby raising labor costs. Higher labor costs would make that employer noncompetitive and should be driven out of business. There are many problems with this argument. For example, if all employers have the same taste for discrimination, then they are all equally competitive. In addition, what constitutes a job qualification is a messy process. Furthermore, if most CEOs and all U.S. presidents are men, it may appear that men are more qualified by virtue of being male. Customers, coworkers, managers, and executives may treat women differently, and/or they may devalue the work done by women. If people believe that our society is more or less a meritocracy, they may wonder why would there not be more women in those jobs if there were as many qualified women as qualified men. In addition, women's occupational status may go unacknowledged. How many women managers or female faculty have been mistaken for secretaries or administrative assistants? How many male nurses have been mistaken for doctors? Virtually all societies exhibit some task specialization by sex, complicating the issue of sex discrimination.

Social scientists have used several concepts to explain sex discrimination, including sex-role spillover, stereotyping of people and jobs, tokenism, a lack of fit, and homophilous social networks, described below.

Sex-role spillover is an outgrowth of role theory. When the expectations associated with being male or female trump the expectations associated with a particular job (or work role), sex-role spillover occurs. Thus it is the carryover to the workplace of gender-based roles that are usually inappropriate or irrelevant to work, and it occurs when, for example, female managers or professors are expected to be more caring and nurturing than male managers or professors. Sex-role spillover also occurs when men are expected to conform to a stereotype—to assume the leadership role in a mixed-sex group or pay the bill at a business lunch with a female colleague. Sex-role spillover occurs because gender is a more basic social category than any particular job that men or women hold. It is rare to forget a person's gender, less rare to forget that person's occupation. In the past, job titles were themselves gendered (e.g., steward vs. stewardess, actor vs. actress,

waiter vs. waitress). Because gender is such a visible characteristic and sex roles are strongly reinforced, both sexes may feel more comfortable behaving in accordance with sex roles than in violating them.

Stereotyping is another process that helps to explain sex discrimination. Gender stereotypes consist of a set of beliefs about the characteristics that men and women are likely to possess. Both people and jobs are subject to stereotypes. Research has shown, for example, that the stereotype of manager is more similar to the stereotype of men than it is to the stereotype of women. Furthermore, some traits viewed as positive in men (e.g., competitiveness) may be viewed less positively in women; thus the claims that “he is assertive; she is a bitch.” Similarly, characteristics valued in women such as sensitivity may be viewed negatively and considered a weakness in a man. Thus when a job calls for nurturing behavior, some may turn to women workers, and when firmness is needed, a woman may be passed over in favor of a man who is assumed—based on stereotype—to possess more of it than a female colleague.

Tokenism occurs when someone with a visible social characteristic is relatively rare in a work group or organization. The lone female executive or male secretary is an example. Token status increases stereotyping because being different from others in the work group makes it easier to stereotype. In addition, because the token is visibly different from others in the same job or work group, tokenism creates performance pressures. When the solo woman makes a mistake, it is visible and may reflect on all women, whereas if one man among many men makes mistakes, it will be viewed as his problem, not a shortcoming of all men. Token status also leads to polarization, or an exaggeration of differences between men and women.

The concept of lack of fit helps to identify the conditions under which gender discrimination might flourish. A woman will be viewed as being a poor fit in a job held mostly by men, and a man will be viewed as being a poor fit in a job held mostly by women. Lack of fit is more likely in jobs that are numerically dominated by one sex or the other, require activities (like being outdoors) that are associated more with one sex than the other, and/or attributes viewed as critical for success are more strongly associated with one sex than the other. Where ambition and firmness are required, men will be viewed as a better fit than women; women will be viewed as a better fit in jobs requiring warmth, nurturing, or dealing with annoyed

customers. A lack of fit may help account for the fact that women, particularly those in nontraditional jobs, sometimes have a more difficult time than men in finding a mentor.

Social networks consist of the people with whom one interacts in any given domain, such as work. Social networks are characterized by gender homophily, that is, people tend to interact with others of the same sex. One explanation for the underrepresentation of women in top management positions is that they do not hold key positions in occupationally related social networks. An individual’s worth in relation to a specific network is referred to as his or her “social capital” for that network. Individuals holding key positions in important networks have high social worth or social capital. If women are not valued as much as men, they have less social capital, leading to possible exclusion from the important networks that would help to propel them into upper level management positions.

EVIDENCE FOR SEX DISCRIMINATION

The evidence shows considerable disparities between men and women: in pay, in promotion rate, in level in the organizational hierarchy. The basic question is, To what extent are these differences caused by sex discrimination? Although there is considerable research bearing on this issue, particularly with respect to pay, the results are apparently not compelling enough for many people to rule out possible competing explanations.

According to U.S. Census data, in 1999 the median earnings of the 83 million full-time, year-round (FTYR) workers in the United States was \$33,000; the mean was \$43,000. About 10 percent of earners made more than \$75,000 a year. For full-time workers in 2002, the average woman earned 77 percent of the wage of the average man, an increase in 5 percentage points since 1999. This reduction is partly due to the decline in the number of relatively high-paying skilled and semiskilled blue-collar jobs held mostly by men. Among the highest paying occupations, the gender gap is bigger. For example, among physicians and surgeons, full-time, year-round women make 63 percent of the wages of comparable men. This “cost of being female” persists no matter how one defines earnings or income, in all race and ethnic groups, across educational levels, over the life cycle, within detailed occupational categories, across cultures, and in the past as well as in the present.

Researchers have attempted to account for these pay disparities, primarily using a statistical technique known as regression analysis. Typically, they attempt to include all factors that might legitimately explain the fact that the average man has a higher income than the average woman. Invariably, after these “legitimate” variables (e.g., education level, hours worked, experience) are taken into account, some wage disparity remains. Whether that amount can rightfully be attributed to discrimination, or whether some legitimate but unmeasured factors can account for the difference, is debated, with some researchers convinced that discrimination is the explanation while others hold out for some other unmeasured factors. Others may provide explanations like gender differences in negotiating behavior or level of expectations, where research typically shows that women have lower pay expectations than men. Of course, gender differences in pay expectations may simply reflect reality (since women’s pay is on average lower than men’s in the same job) or an underlying gender difference that disadvantages women, or both. Similarly, researchers have tried to account for other gender differences such as in performance ratings. One study found that, controlling other variables, women received relatively lower performance ratings than men when the proportion of women in a work group was small.

ALLEVIATING SEX DISCRIMINATION

One area of research focuses on the success or failure of attempts to alleviate discrimination faced by working women, including the impacts of laws and other programs aimed at providing equal opportunity, addressing affirmative action, establishing the comparable worth of jobs, and eliminating sexual harassment. Researchers have identified more than 100 different mechanisms that might assist organizations in reaching these goals. These activities can be divided into two types: identity-blind activities (such as formal mentoring programs, flexible work schedules, and employee assistance programs) or identity-conscious activities that consider one’s sex or race. These include targeting women (or other underrepresented groups) in hiring and promotion considerations, targeting women for management training, establishing a women’s interest group in the workplace, and the like. In general, the identity-blind practices and policies are more common and preferred by most people. It is the identity-conscious practices,

however, that are effective in that only they result in high levels of employment status for minority and majority women and minority men. Thus, working environments that target activities for women result in better outcomes for women. Some research shows, however, that if others believe women and minorities were hired or promoted only because of their sex or race, preferential treatment can lead others to believe those women and minorities were not qualified.

Laws are not the only approach to alleviating problems of sex discrimination. Mere information can counter stereotypes and reduce sex-role spillover. Thus providing relevant information, such as information about a worker’s qualifications or performance, can constitute a deterrent against sex discrimination. More generally, the type of solution sought depends on the way the problem is defined. Four models of problem definition and some problem-solving strategies that follow from them can be identified. They are (1) the individual-deficit model wherein the problem is defined as problem people, (2) the structural model wherein organizational structures and policies hamper women, (3) the sex-role model wherein social roles and role expectations and role stereotypes hamper women, and (4) the intergroup model wherein men and women are viewed as opposing groups fighting over a limited amount of desirable jobs, power, and influence. Perhaps because they are the cheapest and easiest to implement, most proposed solutions fit the individual-deficit model. These solutions also fit people’s beliefs in strong and pervasive gender differences. Women and men are assumed to prefer different job attributes (with men preferring power and recognition and women preferring good coworkers and an opportunity to help others). A meta-analysis of this literature found only limited support for this view. Furthermore, that research showed that women’s aspirations were more similar to men’s as gender barriers to opportunity declined in the 1980s and 1990s. Yet, most “solutions” to gender inequality aim to correct women’s “deficits” through training and self-help materials targeted at them. Examples include assertiveness training and how to write a business plan or obtain venture capital. Increasingly, men too are targets of training aimed at sensitizing them to issues like sexual harassment and sex discrimination.

Overall, the topic of sex discrimination has attracted substantial research attention over the past 25 years or so. While the field is not bereft of theory, much of the research continues to be descriptive, an

approach well suited to a topic that is fraught with misperceptions and misinformation.

SEXUAL HARASSMENT

Sexual harassment is behavior of a sexual nature that harms those exposed to it. The behavior may be intentional or unintentional, aimed at an individual or group, initiated by an individual or group, initiated by employees or outside parties such as customers, initiated by men or women, and targeted at men or women. Many countries have laws designating certain

forms of sexual behavior at work as illegal sexual harassment. Although both men and women can be targets of sexual harassment, women are overwhelmingly more likely than men to be targeted. Estimates of the sexual harassment targeted at women range from 40 percent to 85 percent, whereas estimates for men are around 15 percent. It is important to note, however, that while most harassers are men, most men are not harassers. Individuals who experience sexual harassment often suffer negative emotional consequences (such as fear) and psychological consequences (such as depression).

Sexual harassment often has a substantial impact on career development. The career development of targets of harassment can be affected in a variety of ways. For example, targets of harassment may become less dedicated to their job, be denied promotions or wage increases, leave an organization voluntarily to escape the behavior, or even be fired from an organization for failure to comply with sexual advances or for reporting such advances. The career development of sexual harassers may also be affected negatively. For example, harassers working in organizations with a low tolerance for sexual harassment are likely to be disciplined, up to and including termination. Furthermore, in organizations that do not have adequate investigative procedures for dealing with complaints of sexual harassment, individuals accused but not guilty of sexual harassment may suffer negative career consequences.

SEXUAL HARASSMENT FROM THE LEGAL PERSPECTIVE

Two Types of Sexual Harassment

Discrimination in employment on the basis of gender is prohibited under Title VII of the 1964 Civil Rights Act (as amended). Since sexual harassment is based on gender, it is prohibited under Title VII. In accordance with U.S. law, there are two types of sexual harassment: quid pro quo and hostile environment. When sexual conduct is made a condition of employment or used as the basis for employment decisions, it is classified as quid pro quo ("this for that" in Latin). An example of quid pro quo harassment would be a supervisor firing an employee for refusing sexual advances. Another example would be a supervisor increasing the pay of an employee only if unwelcome sexual advances were accepted. The effect of sexual

harassment on career development is obvious in such cases of quid pro quo harassment.

Hostile environment sexual harassment is the second form of illegal sexual behavior in the workplace. Such behavior has the purpose or effect of substantially interfering with work performance or creating an intimidating, hostile, or offensive work environment. An example of hostile environment sexual harassment would be one coworker repeatedly telling sexually graphic stories to another who did not want to hear them. Another example would be an employee repeatedly sending pornographic e-mail (e.g., pictures, jokes, or discussion) to other employees who did not want to see it. Most sexual harassment is hostile environment harassment between coworkers. This makes sense in terms of organizational structures: There are many more nonsupervisory employees than there are supervisory employees. Thus quid pro quo situations are less likely to occur.

UNWELCOME BEHAVIOR

In order for sexual behavior in the workplace to be considered sexual harassment from a legal perspective, it must be unwelcome. Therefore, not all behavior of a sexual nature at work is illegal. For example, many organizations allow employees to engage in consensual workplace romances. One potential problem with these romances is that if the romance ends, one of the parties may continue to make sexual advances, which, although previously welcome, are now unwelcome by the other party. In general, the courts have been reluctant to label targets of harassment as welcoming the behavior. When employees complain about the behavior, stating that it is unwanted, the behavior is considered unwelcome unless there is extensive evidence proving otherwise. Therefore, determining if the sexual behavior meets other criteria is essential in determining if it is illegal.

SEVERE OR PERVASIVE BEHAVIOR

In addition to being unwelcome, sexual behavior must be severe or pervasive to be considered sexual harassment. In other words, asking coworkers to go on a first date when they are not interested, telling one a sexually explicit joke, or making a few comments on a coworker's sexuality are not likely to be considered severe or pervasive by the courts. However, sexual behavior does not have to result in a nervous breakdown to be considered harassment either.

The experience of Kimberly Ellerth at Burlington Industries, however, demonstrates behavior that is severe and pervasive, thus constituting hostile environment sexual harassment. Ms. Ellerth was subjected to several comments of a sexual nature by her supervisor. For example, he made remarks about her breasts, told her to "loosen up" because he "could make life very hard or very easy" for her, and said that he didn't have time to talk to her over the phone about a business issue unless she told him what she was wearing. Finally, while rubbing her knee during a promotion interview, he told her that she was not "loose enough." Hostile environment harassment often results in harassed employees leaving the organization in which the harassment occurred. This can be problematic in terms of career development because it may appear that the employee lacks stability, and thus is not a viable candidate.

EMPLOYER LIABILITY

An employer is liable for sexual harassment when it "knew or should have known" about the behavior and did not take appropriate action to remedy the situation. It is relatively easy to determine if an employer knew of a behavior. For example, a waitress at one restaurant told her manager that she did not want to wait on a particular table because the customers were sexually crude with her. He told her to wait on them anyway; when she did, they sexually assaulted her. In this situation, the manager clearly knew about the behavior yet did nothing to change it. In fact, it was allowed to escalate. It is more difficult to determine if an employer "should have known" about sexual harassment. In cases where organizations have not made clear the process for employees to report sexual harassment, they will be less likely to report it. Since such organizations do not receive complaints of harassment, they may claim that harassment does not occur there. However, if there were an effective reporting process, targets would be more likely to report their experiences; thus the organization would know about them. For example, several employees had reported sexual harassment to a manager in the organization, but this manager did not believe it was his duty to either make others in the organization aware of it or address it himself. Essentially, the "should have known" phrase means that employers can still be liable for sexual harassment even when they are ignorant of the harassment.

CAUSES OF SEXUAL HARASSMENT

Microlevel Explanations

There is very little research on the topic of initiators of sexual harassment. What little research there is, however, indicates that certain types of people are likely to engage in sexual harassment in certain types of situations. For example, men who have a higher likelihood to sexually harass tend to believe in rape myths and hold traditional gender stereotypes. However, despite an inclination to harass, these men typically refrain from doing so when their behavior results in negative repercussions for them such as a written warning or potential for termination. It also appears that sexual harassers can be classified into different categories. For example, some harassers cast a wide net and harass multiple targets on multiple occasions. At the other extreme are harassers who are genuinely interested in pursuing a consensual relationship but do not have the social skills to do so. It should be noted, however, that it is not the harasser's intention that counts but rather the effect of the behavior on the target or others in the workplace.

Research indicates that sexual harassment is more frequent in occupations in which one gender is in the majority. Examples of predominately male occupations include firefighters, police officers, and blue-collar workers. White-collar professions such as law and investment banking are also male dominated. One explanation for the high levels of sexual harassment in these occupations is that since there are so few women in the occupation, gender becomes a defining characteristic of the workforce. Expectations of women outside the workplace are then carried into the workplace. An example would be that to the extent that women are considered sex objects or passive outside of work, they will be considered as such on the job as well. Thus sexual behavior that might be acceptable in a nightclub or fraternity house is seen as acceptable on the job. Another theory is that sexual harassment in predominately male occupations is a method for maintaining a masculine social identity. Sexual harassment is used to communicate that women are not welcome in the profession, that is, as a method for protecting turf. Sexual harassment can also be used to get women to quit their jobs or to keep them from entering the occupation in the first place.

Recent theorizing on sexual harassment conceptualizes it as a specific form of workplace aggression. Sexual harassment occurs "because of sex"; thus it does

not have to be sexually motivated. For example, incidents like those described previously do not occur out of sexual interest but rather as a means of intimidation and often with the explicit intention to harm. Workplaces characterized by sexual harassment often exhibit other forms of aggression such as threats and verbal abuse.

Macrolevel Explanations

One theory regarding sexual harassment is that the power and status differences between men and women in society are carried over into the organizational setting. Accordingly, sexual harassment can be used to maintain the status quo in society. To the extent that sexual harassment hinders the career development of women, women will have less power and status and therefore will be less likely to improve their lot in society.

As stated earlier, employees who are inclined to engage in sexual harassment are more likely to do so in situations allowing them to avoid negative repercussions. Research indicates that cultural aspects influence the occurrence of sexual harassment. For example, if a norm of the organization is for employees to boast about their sexual exploits over the past weekend, employees who are new to the organization are likely to conform to this practice. Similarly, the behavior of top management sets the tone for behavior of other organizational members. Therefore, if top management uses sexual slurs, other employees receive the message that such behavior is accepted, if not encouraged, by the organization.

Structural aspects of organizations, such as hierarchical reporting relationships, have been proposed to contribute to sexual harassment. This theory is plausible because men are more likely than women are to be at higher levels within organizations and to be sexual harassers. Quid pro quo harassment is made possible through organizational hierarchy because it establishes a system in which higher-level employees are responsible for making employment-related decisions regarding lower level employees reporting to them. This structure often offers no system of checks and balances.

RESPONSES TO SEXUAL HARASSMENT

Organizational Responses

Structural aspects of organizations can be modified to minimize sexual harassment. An essential element

is to have a strong communication program regarding the issue. Many employees are confused by the concept of sexual harassment. Some believe that merely telling coworkers that “they look nice today” is harassing, while at the other extreme some believe that sexually explicit language is fine as long as there is no physical touching involved. Indeed, a reading of the case law on sexual harassment indicates the complexity of this topic. For example, it is not completely clear at what point sexual behavior at work becomes “severe or pervasive.” Given the intricacies of sexual harassment, employees should receive training on the types of words and behaviors prohibited in the organization. However, they must also be made aware that there is no exhaustive list of behaviors to avoid.

Organizations trying to create structures that minimize sexual harassment should also establish proper processes for reporting claims of sexual harassment and ensure that all employees understand these reporting mechanisms. It is essential that employees be provided with a variety of reporting channels, because they may not feel comfortable speaking about the harassment to a particular individual. Employees reporting harassment should always be allowed to report to someone other than their supervisor, because the supervisor could be the source of harassment. Finally, it is essential from both a legal and career perspective that employees are not retaliated against for reporting sexual harassment.

In addition to ensuring a fair process for employees claiming that they have experienced sexual harassment, it is also essential to ensure a fair process for those accused of harassment. Detailed procedures for investigating sexual harassment complaints must be developed and communicated. Organizations with zero tolerance policies for harassment must be especially thorough when conducting investigations, because employees found to be harassers will be terminated. This job loss may impact the future career development of such employees.

Target Responses

Despite organizational efforts to minimize sexual harassment, it still occurs. Thus targets of harassment must respond to it in some way. Most targets do not want to see their harassers punished; they simply want the harassing behavior to end. The most common response is to ignore the behavior or try to laugh it off. Another passive response is to avoid the harasser.

Both ignoring the behavior and avoiding the harasser can have career-related implications. For example, if the behavior is ignored, it is likely to continue. Harassment becomes more stressful as the number of occurrences increases over time. Exposure to consistent stress can result in increased sick leave, inability to concentrate at work, and decreased productivity. Furthermore, such harassment eventually begins to have negative consequences for others in the work area in addition to the intended target of harassment. Rather than ignoring or avoiding the situation, some targets seek social support from friends or relatives. Social support helps alleviate some of the stress of harassment whether or not the target takes further action, but it does not remedy the situation.

Confronting the harasser or reporting it to management or an outside organization is the least common response. Many targets are embarrassed by the situation, intimidated by the harasser, think that their complaint will not be taken seriously, or fear retaliation for reporting. Targets who report their harassment tend to experience higher levels of stress than those who do not. This may be due to the process of going through the investigation and possible rejection by other members of the organization for coming forward. Alternatively, it may be that targets only report the most serious forms of harassment, which are more likely to result in high stress levels. In other words, it is not clear if the harassment leads to stress, which then leads to reporting, or if harassment leads to reporting, which then leads to stress. In conclusion, sexual harassment is a stressful event for those experiencing it regardless of how they respond to it.

SEXUAL ORIENTATION AND CAREERS

Although gay men and lesbians constitute between 4 percent and 17 percent of the workforce, a larger proportion than many other minority groups, they remain an understudied population that is often "invisible" in the careers literature. It is important to understand the unique challenges faced by lesbians, gay men, and bisexuals in the workplace and to appreciate how these challenges influence their career decisions, paths, and processes.

Lesbian, gay, and bisexual (LGB) workers face at least three unique challenges that influence their careers and workplace experiences. First, since sexual orientation is not visible, LGB workers face the ongoing and often stressful decision about whether or when to disclose their sexual identity in the workplace. Although many LGB employees fully disclose their sexual identity in the workplace, the majority of them conceal their sexual identity to some degree at work. Some may choose to avoid the topic, while others may "pass" as a heterosexual. In some extreme cases, LGB workers may counterfeit a heterosexual

identity in order to avoid the negative repercussions they fear may occur if their true identity was revealed.

It is important to recognize that disclosure of a gay identity is not an all-or-none decision but occurs on a continuum ranging from full disclosure to nondisclosure. Individuals may disclose their sexual identity to various degrees in both work and nonwork settings and may selectively disclose their gay identity to coworkers, supervisors, friends, and family. In general, the decision to disclose, or "come out of the closet," occurs with each new social interaction and is conducted on a careful case-by-case basis that weighs the risks and benefits associated with disclosure in that relationship.

The disclosure decision is complicated by a number of factors. One complication is that since sexual identity is not visible, LGB workers are often assumed to be heterosexual. Although some LGB workers may desire to keep their sexual identity private, coworkers' assumptions about their sexuality often force the issue and make LGB workers choose between immediate disclosure of their identity or implicitly "passing" as a heterosexual by letting the assumption of a false identity continue. The expectation that LGB workers should not discuss their sexual orientation in the workplace fails to recognize the effects of this assumption of heterosexuality or the fact that heterosexual workers regularly reveal their heterosexual orientation through casual reference to a spouse, a family picture, or a wedding ring.

Another complication in the disclosure decision is that LGB workers may lose control over the disclosure process. For example, they may confide their sexual identity to a few trusted coworkers, but this information may be spread to others in the organization, including those who hold negative views toward homosexuality. As a consequence, LGB workers are often uncertain as to who knows and who doesn't. In addition to this uncertainty, LGB workers face the ongoing threat of having their sexual identity intentionally or unintentionally disclosed by others (e.g., being outed). The decision to disclose a gay identity in the workplace is therefore a complex decision that is often a source of stress for many LGB workers.

The second challenge that affects the careers and workplace experiences of LGB workers is that discrimination against LGB employees who are gay, or simply appear to be gay, is legal in most workplaces in the United States and abroad. As a consequence, LGB employees are particularly vulnerable to

discrimination, and existing research indicates that between 25 percent to 66 percent of gay and lesbian employees face discrimination in the workplace. However, this estimate is generally recognized as conservative, as a sizable proportion of LGB employees do not reveal their sexual identity and are therefore unlikely to be the direct target for sexual orientation discrimination in the workplace. Because discrimination against LGB workers is widespread and fierce, the stakes involved with disclosure are steep. Disclosure of a gay identity has been found to result in social rejection, job termination, and even physical assault. LGB citizens are targeted for hate crimes in both work and nonwork settings, and the fears associated with disclosure of a gay identity in one setting can create a general state of stress that spills over into other settings.

The third challenge to LGB workers' careers is that they encounter significant barriers to obtaining developmental relationships that provide career support, guidance, and assistance. Mentors, peers, and social networks provide important career resources for heterosexual employees, but these relationships may be limited or severely restricted for LGB workers. Many heterosexuals hold negative attitudes toward homosexuality, view homosexuality as morally wrong, are psychologically threatened by LGB workers, or are simply uncomfortable interacting with or engaging in social activities with LGB workers. These individuals may avoid developing relationships with openly gay workers or they may only develop relationships with gay workers who conceal their sexual identity. This severely limits the pool of individuals who can provide career assistance to LGB workers. This situation is worsened by the fact that LGB workers may avoid entering developmental relationships with heterosexuals, or may keep a social distance after entering these relationships, for fear of negative reactions or rejection if their sexual identity is disclosed or involuntarily revealed. Finally, even in relationships characterized by disclosure and acceptance, many heterosexuals simply cannot fathom the challenges faced by their LGB colleagues and may give them career advice that may be more effective for heterosexuals than for gay men and lesbians. One outcome of this situation is that the gay community becomes an important source of support for LGB workers, and LGB workers may look to other gay colleagues for mentoring, networking, and career support. However, the lack of openly gay and lesbian executives (e.g., the

"lavender ceiling") suggests that the power base associated with these developmental relationships may constitute a limitation in their effectiveness.

These three unique challenges—the decision to disclose a stigmatized identity, the intense vulnerability to workplace discrimination, and the restricted access to effective developmental relationships—combine to have a significant impact on the careers of LGB workers. These challenges have not been adequately addressed in the careers literature. Since most career theories were developed on heterosexual samples, they fail to explain some of the core career challenges and processes experienced by LGB workers. In particular, two processes central to the careers of LGB workers that have not been addressed include the role of discrimination in career choice and the role of sexual identity in career development processes.

Discrimination may play a central role in the careers of LGB workers. Traditional theories of career choice hold that workers chose careers or organizations based on the degree of fit between the requirements and attributes of the occupation or position and the individual's skills, values, interests, and abilities. The role of discrimination in career and occupational choice is not addressed in traditional models of career choice. However, LGB workers' vulnerability to discrimination, combined with the force, prevalence, and potency of this discrimination, makes sexual orientation discrimination a central factor in career decisions for many LGB workers. Their choice of careers, occupations, and workplaces may be driven not only by their perceived fit between their skills, values, and abilities and the environment but also by the fit between their group membership and the climate of the organization or occupation. LGB workers may seek safe haven environments that protect them from discrimination and, by allowing them to disclose their sexual identity at work, help them avoid the stress associated with hiding their sexual identity or maintaining different identities in work and nonwork settings.

Safe haven environments may enter into a cycle that supports "gay friendly" workplace climates and occupational climates. Safe havens attract new LGB workers, who may become a critical mass that becomes visible in the organization, occupation, or profession. As they become more visible, LGB workers may take an active role in institutionalizing inclusive climates and developing practices and policies that support the careers of LGB employees (e.g., domestic partner benefits, inviting gay partners to

company social events, developing professional organizations for LGB workers within an occupation, including sexual orientation in diversity policies, practices, and training). These environments also offer greater opportunities for LGB workers to break through the lavender ceiling by reaching positions of power, which in turn places them in the position of being able to sustain and protect safe haven cultures.

Once an LGB worker finds a safe haven, he or she may be reluctant to leave the organization or occupation, even for a career opportunity that provides more opportunities, resources, or a better fit with their individual career interests and aptitudes. LGB workers may also be reluctant to leave safe havens because these environments are more likely to foster developmental relationships involving both gay and heterosexual mentors and peers. Heterosexuals who select to work in safe havens are often more comfortable working with LGB colleagues and may be more sensitive to the challenges faced by their gay colleagues. Safe haven environments also increase the pool of gay men and lesbians who are able to assume mentoring and career coaching roles with their younger and less experienced colleagues.

Safe havens may be particularly valued among LGB workers who have experienced sexual orientation discrimination in the past and among those who have disclosed their sexual identity in their current workplace and are simply unwilling to go back "into the closet" in a new position, even if the position offers greater career opportunities, benefits, or compensation. The relative scarcity of safe haven environments also means that once an LGB worker finds a safe haven, he or she may remain in that organization for a relatively long period of time. Future research is needed that examines the long-term effects of this process on career plateaus and career satisfaction among LGB workers.

Career choice of LGB workers is not only influenced by discrimination and the presence of safe havens but also by the development of their sexual identity. The development of a gay identity occurs in stages that unfold over time. While some LGB individuals recognize their sexual identity very early in life, others may not come to terms with their sexual identity until much later in their lives. This means that some LGB workers may choose careers that are not receptive to their sexual orientation (e.g., occupations associated with day care and primary school education, law enforcement, criminal justice, politics, the military, and some religions) before they self-identify

as gay. Coming to terms with their sexual identity may therefore create a career crisis in which LGB workers may either hide their newly discovered sexual identity or change their occupation. This career crisis is simply not encountered among heterosexual workers.

In fact, most theories of career development are based on heterosexual models of adult identity and life development and may therefore have limited applicability to LGB workers. These theories assume that sexual identity is stable and consistent over the course of an individual's adult life. They hold that identity issues are resolved by early adulthood, thus allowing individuals to focus on career-development issues in their early adulthood. While these assumptions hold for heterosexuals, they do not capture the experiences faced by LGB individuals, who may be in the middle of their lives, careers, and even heterosexual marriages before they recognize their true sexual identity. This recognition does not happen immediately; the development of a gay identity usually unfolds over stages involving denial, awareness, testing, acceptance, and finally integration as the individual gradually accepts and discloses his or her sexual identity across life domains. This identity transition may occur at any time in the life of LGB individuals and can create disrupted and nonlinear career paths and even derail the careers for many LGB workers.

In addition to disrupting careers, the recognition of a gay identity may result in the loss of established developmental relationships as well as other relationships that provide personal, social, and career support. Mentors, social networks, peers, friends, and even family may be lost before the LGB individual has developed other supportive relationships that take their place. Moreover, the loss of these developmental and supportive relationships often occurs at the precise time in which they are needed the most: a life transition involving changing perceptions of self, career needs, and career fit. This situation may lead to a turbulent career crisis, and increases the potential for disrupted or derailed careers.

These sexual identity processes require using a longitudinal lens when viewing the careers of LGB workers. Instead of the discrete linear career stages experienced by heterosexuals, LGB individuals may encounter recursive career stages that involve continual reevaluation based on their stage of sexual identity development and the availability of supportive developmental relationships and safe havens. In fact, there may be a complex interplay between stages of identity

development, career satisfaction, and organizational or occupational choice. For example, LGB individuals who are in the early stages of identity development and have not self-identified as gay may select organizations and occupations based on criteria unrelated to their sexual identity and may experience career satisfaction even in organizations that do not support their identity and/or protect LGB workers from discrimination. However, LGB individuals who are at the integration stage of their sexual identity development may feel a strong internal need to disclose their identity in their workplace and may experience acute career dissatisfaction and identity stress if their organization fails to meet their developmental need for identity integration. This may lead to a recursive career state in which they reassess their career needs and goals, as well as their organization and occupational choices, in light of their emerging sexual identity. In essence, LGB workers who were satisfied in their careers and workplaces may face career and psychological conflict as their sexual identity unfolds and the lack of fit between their identity and their environment emerges.

In conclusion, LGB workers face unique career and workplace challenges not encountered by their heterosexual counterparts. The career decisions and processes of LGB workers need to be viewed within the broader context of the longitudinal development of their sexual identity, their decisions to disclose their identity, and the organizational and occupational environments that either support or stigmatize their identity. The impact of sexual orientation on the careers of LGB workers is not a function of a single event but is a result of multiple internal and external factors that unfold longitudinally over the course of a career. We have just begun to examine the careers of LGB workers and uncover the assumptions of heterosexuality that permeate existing theory and research on careers. Future investigations will help scholars, students, career counselors, and human resource management professionals in understanding the career and workplace challenges encountered by LGB workers.

SINGLE PARENTS AND CAREERS

By the mid-1990s, 1 of every 4 families in the United States with children under 18 was a single-parent family, up from 1 of 10 in 1970. Oddly enough, no plausible explanation for this increase has been found, either within distinct subgroups or in an overall sense. The career development of single parents cannot be considered as intentional, as most single parents have not actively chosen that status. For the most part, the

career development of single parents begins in the same way that it occurs with other individuals, but the status of single parenthood disadvantages them in the labor force as soon as that status is reached. In particular, a lone mother has less time than a couple does, both to care for children and to advance her career.

Single mothers of young children work more hours than married mothers with young children. Moreover, as married working moms have decreased their participation in the labor force in the past decade, many single moms have increased their working hours, although there are data to suggest that some are actually working fewer hours than they did in 1970. Single parenthood is becoming increasingly common, and it is estimated that more than half of all children will spend some time without two parents at home. Furthermore, most single parents, especially mothers, are economically disadvantaged, having to hold jobs without much career potential. Lone mothers typically occupy the bottom rungs of income distribution in the United States, Great Britain, and Norway, as well as other affluent nations. Indeed, single-mother-headed households are more likely than any other family households to live in poverty. For many low-income mothers without access to low-cost day care, the question of whether work is worthwhile or provides opportunity for advancement is relevant.

Single parents can be displaced homemakers, adolescent mothers, or single fathers. Single parents are not solely defined by their marital status, nor are all single parents alike within that status. For instance, divorced fathers with sole custody do not have the same backgrounds as unwed adolescent mothers, and so it is difficult to talk about career development for single parents per se. As Susan Whiston and Briana Keller have pointed out, career development is context bound. Individuals who become single parents earlier in life are more disadvantaged with respect to educational, career opportunities, and acceptable standards of living than those who have had the chance to get adequate training and work experience before they became single parents. Moreover, women with college educations are more likely to postpone childbearing than women with less education. Even when women are adequately trained, however, the careers they enter are likely to pay less than men's careers, and when they enter the same careers as men do, they are paid less. As recently as the mid-1990s, female accountants earned less than 75 percent of male accountants' salaries. This difference in salary holds for many other traditional male occupations.

Beyond the economic issues facing single parents, little is known about single parents' attitudes and role conceptions. In a unique study of Air Force officers and enlisted personnel, Terri Heath and Dennis Orthner found that single men and women did not differ much in their adaptation to work and family responsibilities. They did, however, find that men and women differed in their compartmentalization of roles. Organizational satisfaction was women's most important predictor in their ability to manage work and family role; career stage was more predictive for men. In addition, prior research has found that although single female parents experienced higher role strain than their married counterparts, they displayed equivalent levels of job motivation, performance, and absenteeism, and higher levels of job satisfaction.

Attitudes toward single parents (mostly mothers) continue to be remarkably negative, irrespective of how these households are constituted. Female college students raised in traditional households hold more negative attitudes than those raised in single-parent families. Employer attitudes toward single parents have been found to be problematic as well.

In short, the career development of single parents can be difficult if they become single parents before they have college educations, if they cannot find affordable child care, if they work in environments hostile to their status, or if they work in occupations with little room for career advancement. If, however, single parents are college educated and employed in middle-class careers, their attitudes toward work and multiple roles are not particularly different from their married counterparts.

SIXTEEN PERSONALITY QUESTIONNAIRE (16PF)

The *Sixteen Personality Questionnaire (16PF)* is one of the oldest commercially available measures of normal adult personality. It is used in a variety of settings, including personnel selection, counseling, career development, and outplacement consulting. The inventory has also been utilized extensively in academic settings to advance the understanding of personality structure, its roots, and predictive power. Over 1,200 articles and book chapters involving the 16PF have been published to date, and many new studies are under way.

The 16PF was created by Raymond B. Cattell who, at the time, was a professor of psychology at the University of Illinois. Cattell's main research interest was to identify the primary elements of human personality. He called those elements traits—entities whose organization and dynamic interrelationships lead to the behaviors one can observe or wishes to predict. Rather than adhering to some a priori theory, Cattell used a mathematical technique called factor analysis to identify basic traits among a large set of behavioral observations. He started with the list of approximately 4,500 adjectives describing human behavior that was developed in 1936 by Gordon W. Allport and Henry S. Odbert. Cattell then successively reduced this list to 171 terms representing synonym groups, 35 surface-trait variables, and finally, 16 primary traits that formed the basis of his future personality questionnaire. Specifically, Cattell factor analyzed empirical data from two sources, peer ratings (observations of people in everyday situations) and self-reports (questionnaire responses to a large number of behavioral statements), in an attempt to determine which primary traits would be identified similarly from the respective sources. The results generally converged to a 16-dimensional structure that was used as the basis for the first edition of the 16PF questionnaire published in 1949. Since then, four revisions have been conducted to improve and refine the instrument, which is now copyrighted and distributed by the Institute of Personality and Ability Testing (IPAT).

PSYCHOMETRIC STRUCTURE OF THE 16PF

In 1993 the 16PF was revised to produce the fifth edition. The best items from the five forms of the fourth edition (Forms A, B, C, D, and CAQ Part 1), as

well as a number of new items, were combined to create an improved form. The items were designed to meet criteria, such as a lowered reading requirement (fifth grade), increased item-scale correlations, and the elimination of items with overt gender, race, or social desirability biases.

The fifth edition 16PF contains 185 items, which can be completed in 35-50 minutes in the paper and pencil mode, and 20-35 minutes when administered via computer. The first 170 items utilize a three-option response format (endorse, cannot decide, and not endorse) and ask a respondent to decide whether each statement is true of his or her behavior. Each item is designed to measure 1 of 15 primary personality traits or to detect socially desirable responding (aka impression management or faking). Consequently, the items can be divided into 16 relatively homogeneous scales that are traditionally labeled by a word descriptor and by a capital letter from the English alphabet: Warmth (A, 11 items), Emotional Stability (C, 10 items), Dominance (E, 10 items), Liveliness (F, 10 items), Rule-Consciousness (G, 11 items), Social Boldness (H, 10 items), Sensitivity (I, 11 items), Vigilance (L, 10 items), Abstractedness (M, 11 items), Privateness (N, 10 items), Apprehension (O, 10 items), Openness to Change (Q1, 14 items), Self-Reliance (Q2, 10 items), Perfectionism (Q3, 10 items), Tension (Q4, 10 items), and Impression Management (IM, 12 items). Note that the IM scale is not part of the 15 personality factors but was added to the inventory as a check on response distortion. Respondents receiving high scores on the IM scale would be flagged as possibly attempting to enhance their scores.

The last 15 items in the inventory utilize a multiple-choice format (verbal or math question stem followed by several response options) and measure a factor called Reasoning (designated by the letter B). The inclusion of this factor, which essentially represents cognitive ability, differentiates the 16PF from most other personality questionnaires. Whereas developers of subsequent personality inventories viewed Reasoning as something conceptually distinct from personality (i.e., part of a separate cognitive ability domain), Cattell's decision to include the Reasoning scale in the 16PF actually makes the inventory more useful for career development, because most occupational counseling applications require knowledge of one's general cognitive ability as well as one's vocational preferences. It is recognized that this unique feature of the 16PF can cause confusion among test

users and students regarding the number of personality factors the inventory actually assesses. In accordance with the current perspective that personality and cognitive ability are indeed conceptually distinct domains, the 185 items of the 16PF fifth edition actually assesses 1 general cognitive ability factor, 15 personality factors, and 1 impression management/social desirability factor.

Recent psychometric studies of responses to the fifth edition 16PF items have shown that the 15 personality scales (commonly referred to as Primary Factors) are unidimensional and can be combined, if desired, to form five second-order factors (i.e., Global Factors). These five Global Factors closely correspond to the Big Five personality dimensions, which are relatively stable traits describing one's behavior over a wide range of social and work situations. Because the Big Five taxonomy is now effectively the dominant view of normal adult personality, it is used in many selection, counseling, and career development applications. The ability of the 16PF to estimate Big Five's scores is thus advantageous for current and future applications.

RELIABILITY AND VALIDITY

The psychometric properties of the fifth edition of the 16PF are well documented in its technical manual. The mean test-retest reliability (aka coefficient of stability) for the Primary Factor scales over a two-week and two-month period are 0.80 and 0.70 respectively. The internal consistency-reliability (aka coefficient alpha) averages 0.76. Reliability coefficients for the Global Factor scales are higher, because they are aggregates of several positively correlated Primary Factors. Given the length and breadth of the scales, the reliability estimates are considered sufficiently high to provide meaningful personnel and career guidance.

Validity studies reported in the technical manual and in the research literature provide a considerable amount of evidence regarding the construct and criterion-related validity of the primary and global 16PF scales. Many studies have found high correlations between trait scores for 16PF scales and those of other well-known personality inventories (i.e., the Personality Research Form, the California Psychological Inventory, and the NEO Personality Inventory). This suggests that the 16PF scales do indeed assess the traits they are purported to measure. Occupational and social psychologists have also found 16PF scales to be good

predictors of a number of important social outcomes, ranging from leadership effectiveness to drug use to creative achievement. As indicated by a recent comparative study of several major personality instruments, the 16PF was among the best in predicting a number of behavioral acts.

MEASURING INTERESTS WITH THE 16PF

A majority of theoretical and empirical writings view basic and vocational interests as conceptually distinct from personality and cognitive ability traits. In essence, it is believed that interests primarily influence the motivation to attempt an activity, while ability and personality determine the likelihood of effectively completing an activity. Yet despite this distinction, there is usually a moderate degree of correspondence between interests, abilities, and personality. Thus because the 16PF already measures both personality and ability, it is possible to generate interest scores from responses to the 16PF Primary scales by way of multiple regression.

Several research projects have been conducted in an effort to develop 16PF prediction equations for a variety of vocational preference indicators. Two studies warrant specific attention. In the first study, 233 adults were given the 16PF fifth edition along with the Campbell Interest and Skills Survey (CISS) and measures of leadership qualities and preferences for structured environments. The CISS is one of the most widely used tools in career development programs, and it is therefore natural that it was used as the initial basis for the 16PF's career development applications. The main outputs from the CISS are its seven Orientation Scales depicting broad areas of one's interests (i.e., influencing, organizing, helping, analyzing, etc.), 29 Basic Scales reflecting interests in broad categories of work fields (i.e., Management, Sales, or Social Service), and 58 Occupational Scales representing the most narrow aspect of vocational interests (i.e., Architect, Musician, or Psychologist). Using scores on the 16PF Primary Factor scales, researchers were able to predict with a relatively high degree of accuracy the following: 7 CISS Orientation Scales, 17 CISS Basic Scales, and 57 CISS Occupational Scales. Scores on all these scales are reported in the Personal Career Development Profile (PCDP), which is a computer-generated report based on responses to the 16PF. To avoid duplicating the CISS terminology, the Orientation, Basic, and Occupational scales are referred in PCDP as Career Activity Interest, Career Field

Interest, and the Occupational Interest scales respectively. In addition, the PCDP also contains scores on Broad Patterns scales and Leadership-Subordinate Patterns scales that were derived from other measures administered in the study.

A second notable multiple regression project involved the Strong Interest Inventory (SII) and was aimed at augmenting the 16PF's ability to predict broad behavioral patterns as well as career and occupational interests. This study involved 385 adults who were administered the SII together with the 16PF Fifth Edition. Using 16PF Primary Factor scores, researchers were able to predict the following: 4 SII Personal Style scales, which in the PCDP classification are placed into the Broad Patterns section of the report, 22 SII Basic Interest scales, and 69 female-normed, and 66 male-normed SII Occupational scales. Note that because 12 of the 22 SII Basic scales had content very similar to the CISS Basic scales, only 10 nonoverlapping SII Basic scales were actually added in the PCDP report.

In sum, the results of various research projects have shown that the 16PF fifth edition reasonably predicts many criterion scale scores of the CISS, SII, and other instruments used to measure vocational interests. These predicted scale scores are organized into 10 Broad Patterns Scores, 10 Leadership-Subordinate Role Patterns, 7 Career Activity Interests, 27 Career Field Interests, and 98 Occupational Interests. Predicted scores on Occupational Interests are reported in reference to three different norms: males and females, obtained from the SII, and combined gender, based on the CISS. Further details of these studies are described in the 16PF's technical manual and in the Personal Career Development Profile manual.

USES OF THE 16PF IN CAREER DEVELOPMENT APPLICATIONS

The 16PF Basic Interpretive Report and the 16PF Personal Career Development Profile Report provide information that can be used in career development applications. Specifically, the Basic Interpretive Report generates scores on the Primary and Global Personality Factors, six Holland Theme scores (these are generated from equations developed by regressing scores from the Self-Directed Search onto 16PF Primary Factors), and several predicted criterion scores, such as leadership and creative potential. The Holland types on which the respondent scores highest are discussed in several

interpretative paragraphs and are accompanied by a brief list of relevant occupations.

The Personal Career Development Profile Report first presents an extended narrative that describes a respondent's problem-solving, stress-coping and interpersonal interaction styles, work settings preferences, and career/lifestyle activity interests in a user-friendly, nontechnical manner. The narrative is followed by several detailed score reporting pages, which discuss one's standing on the Primary and Global Factor scales, Broad Pattern scales, Leadership-Subordinate Role Pattern scales, Career Activity Interest scales, Career Field Interest scales, and Occupational Interest scales. This information is reported numerically and graphically (horizontal bar graph). The wealth of information provided has proven helpful to both professional counselors and individual test takers. According to the technical manual, the main uses of the PCDP report are the following:

- Selection and placement (finding the right person for the right job)
- Assessment centers (identifying hidden talents of employees and training them to further their careers)
- University-, company-, and consultant-sponsored career development and management programs
- Outplacement consulting programs (assisting displaced persons in undertaking career transitions and job searches)
- Career and personal development counseling (providing career guidance and advice for selecting specific educational or training programs)

CONCLUSION

In the past two decades, the workplace environment has changed from largely "manufacturing-style" organizations, characterized by hierarchical structures and well-defined jobs, into "service-style" organizations with flat structures, fluid jobs, and the extensive use of teams. The development of new technologies and increased global competition have added additional layers of uncertainty to what is already an unstable job market. It is reasonable, therefore, to assume that many of today's workers will experience a career-related crisis or transition at some point in their work lives and that a large proportion of workers will encounter prolonged periods of unemployment or find it necessary to change careers more than once. To deal with these potential pressures in advance, organizations and employees are increasingly turning toward

career development programs that use personality, cognitive ability, and interest information to provide career advice. In this regard, the 16PF is a highly useful instrument because of its unique capacity to provide information regarding all three of these individual difference variables in a single test administration. To our knowledge, no other instrument currently provides such an integrative approach to psychological assessment.

SOCIAL CAPITAL

An inclusive understanding of the concept views *social capital* as the potential resources derived from

an individual's social relationships as well as valued resources available from the organization of that social network of relationships. Individuals or groups exchange social capital to gain access to needed resources from others in the social system or to enhance image through association with the social system. An individual in good standing in a group has social capital to request assistance from members of that group or could mention association with the group to impress others and gain access to otherwise unavailable opportunities. In the business environment, a greater number of promotions and salary increases are samples of benefits for employees with social capital, and searches for a new job are facilitated by the use of social capital.

The value of social capital varies with the task for which it is needed. Resources needed for careers include information, trust, status, sponsorship, and opportunities for development or visibility. Social capital extracted from work organization relationships is more valuable for promotions, while social capital derived from external networks is more valuable for a career shift to a new profession. The lack of social capital can result in constrained opportunities and accomplishments. The bottom line for careers is that one wants social capital for the help it provides in reaching career goals.

EXAMPLES OF SOCIAL CAPITAL

How often do you call on others to fix a computer glitch? Understand a customer's problems? Identify the best company or job for you? These are examples of information resources available because of connections through a social network due to the exchange of social capital. Such connections can help the individual accomplish what otherwise might be difficult, time consuming, or impossible. Having the ability to get timely information from others, such as a company's difficulties while job seeking or a new boss's personal format preferences for compiling a report, can help an individual avoid career setbacks. Investment in relationships and the social structure of those relationships provides social capital that can be used to acquire specific information when needed.

An individual who invests time in maintaining a strong relationship with a mentor can exchange social capital from that investment for resources from the mentor. Mentors can provide information about political traps not readily seen by a newcomer in an

organization or by someone new to a position in the hierarchy. They can also provide constructive feedback for personal development, sponsorship for advancement opportunities, and moral support in times of difficulty. Association with the mentor can lead to higher status in an organization. Not surprisingly, someone who has one or more strong mentoring relationships will have more social capital to draw on for career development and advancement. The mentor also builds social capital from the relationship, since the organization is benefiting from the mentor's investment in the protégé. The mentor can exchange social capital with the organization for leadership opportunities.

There are three dimensions of social capital: relational, structural, and cognitive. The relational dimension of social capital involves trust between the parties, norms of behavior within the group, expected obligations among the group's members, and identification with the group. A work organization with hierarchical relationships contains status differences that facilitate or constrain access to others. A senior executive, for example, is likely to have more immediate access to the expertise of individuals throughout the company than a floor manager. The status provides authority, which is social capital that has value. Status and status symbols, such as job titles, are social capital because of the impressions of success they create. Thus where one is positioned in the network increases or decreases the social capital derived from that network.

Social capital also lies in the structure of the network itself. The structural dimension of social capital includes the number and nature of relationship ties, the network configuration, and the organization of the network in terms of its practices. The size, location, diversity, and closeness of ties within the network can make it easier or more difficult to access relationships and, consequently, affect the amount of social capital one has available to exchange for needed resources. A large, dispersed network makes it more difficult to identify and to reach the needed resources. For example, a business executive has access to a wide number of people, including employees in the work organization, customers, and fellow members of professional organizations, as well as associates in personal networks affiliated with the executive's family, neighborhoods where the executive has lived, schools, and religious and social organizations. This network of relationships consists primarily of weak ties with many people. If the executive's child wants to go to a particular

college and needs a recommendation from an alumnus of that school, sorting through all the personal connections could be time consuming. However, a large, diverse set of relationships increases the likelihood of finding someone with the needed resources for different situations. In this manner, social capital can be utilized for a greater variety of tasks.

On the other hand, the closeness of relationships creates greater trust, facilitates the sorting process, and increases the possibility that the other person will feel inclined to help. This is possible because more is known about those with close ties and the closer relationships allow for stronger trust. Yet closer relationships are more often found among similar individuals, and networks of similar individuals might not provide resources needed for changing needs.

A third dimension of social capital, the cognitive dimension, includes shared narratives, language, and codes. As an illustration of this aspect of social capital, consider the terminology that MBAs develop through their studies. They form a kindred group that shares case study examples and metaphors of leadership and organizations. Members of this group have social capital at their disposal for exchanging information.

HOW SOCIAL CAPITAL PROVIDES VALUE

The norms and purpose of a social structure will affect the amount of social capital that can be extracted from the relationships of that social network. Family relationships can carry stronger expectations for supporting one another than professional relationships. This is seen in the advancement of family members over others to senior-level positions in a family owned business. In such a case, there are expectations of keeping the business family owned and run and that family members will rise to the occasion to keep the firm in business. It is an expectation based on trust, beliefs, and obligations: trust in the capabilities and motivations of family members to perform well, the belief that family members are privileged, and the obligation to give family members advancement opportunities and support. In contrast, two people who have met briefly through professional encounters will not feel compelled to help each other with a business problem if they see each other as business competitors. However, they may exchange information about their graduate programs. There is an expectation for showing pride in your alma mater but also an expectation of confidentiality surrounding specific business issues as well as

sanctions for violating confidentiality. The old adage, “Don’t air dirty laundry in public,” is relevant here and implies that certain types of information and modes of behavior can be shared within a specified network but not beyond. Groups with strong ties among its members are said to have a strong “bonding” form of social capital.

There are two schools of thought about how network structure affects social capital. One view asserts the value of rich, closed networks where everyone is connected and shares freely within the network. A family business is an example. Here this bonding form of social capital within the family is maximized when the network has strong enough ties to understand the specific needs of individuals and has built trust among the members to exchange social capital. This closed network type of social capital is used to explain how groups of individuals such as racial groups are advantaged or disadvantaged. For example, being a member of a company golf league where the latest news about impending company changes is shared may provide social capital for an executive, putting nonmembers of the league at a disadvantage. Obviously, country clubs hosting the league that do not allow women or racial minorities disadvantage those groups in the company. A less obvious aspect of this example is that women and certain minority groups are less likely to have acquired the game of golf in their younger years to play well enough to join the league. The construction of the league itself exacerbates the gap between the advantaged and disadvantaged groups and limits their available social capital relative to the league members. Moreover, this network might have been closed to particular individuals earlier in life than may be apparent. Members of the golfing community form a bond of relationships with its own vocabulary and ways of viewing the world.

The other school of thought, structural holes theory, purports that positioning within a network where one can supply needed information from personal networks not available to others creates more social capital. The person who always knows somebody who can help is seen as having a great deal of social capital. Furthermore, that person can choose to use that social capital as a bargaining tool, such as exchanging introductions for a choice project assignment. Again, the strength of the relationship affects the social capital that can be extracted from the ties. If the boss’s son is a fan of your friend who plays in a rock band, an introduction can become a bargaining tool for career advancement opportunities. The tie with the boss only needs to be

strong enough to know about the boss’s son’s fondness for your friend’s band and strong enough to provide the opportunity for you to express career ambitions to the boss. The tie with your friend needs to be strong enough to impose a favor. The ability to act as a liaison between other networks is what establishes the value of social capital according to structural holes theory. This type of social capital is referred to as bridging and is used to explain the competitive advantage that some have over others because they have social capital to exchange in groups that are closed to others.

Social capital is an asset that with investment grows to yield greater possibilities for future benefits. It has value because it can be traded to obtain other valued assets. Since social capital is derived from a social system, it is dependent on the collectivity of that system. If the structure fails, or if the members change norms, or if the level of trust one is granted within the system falls, social capital will be affected negatively. Withdrawing capital from the social network or structure comes with an expectation of future payback with an uncertain time horizon. If there is a violation of reciprocity, the group member will receive sanctions and lose social capital.

When the concept of social capital is applied to the organizational level, there are reciprocal implications at the individual level due to the “collectivity” nature of social capital. Just as an individual can use an organization’s reputation to build social capital, so too can an organization use the visibility of an associated prominent individual to improve its reputation. In both cases, the relationship is exploited for gain. For this reason, social capital is referred to as appropriable when used between or within levels of analysis. Negative perceptions from associations are also possible, and they decrease the value of social capital.

Social capital can be a complementary form of capital. For example, an entrepreneur with limited funding for a growing enterprise can call on friends and family for free support or advice. Similar to physical and intellectual capital, social capital needs maintenance. The activity of maintaining social capital is staying connected with one’s network and attending to the members’ needs. A strong level of trust may minimize the amount of maintenance needed.

SOCIAL CAPITAL AND CAREERS

The career competencies framework of knowing-why, knowing-how, and knowing-whom can be used

to examine the value of social capital to careers. The identity exploration competency of knowing why is enhanced by constructive feedback from others that can be obtained with the use of social capital. Social learning is one example of how using social capital to get closer to experts assists the development of job-related capabilities, or knowing-how. Social capital buys access to relevant people, or knowing-whom, and thus presents access to opportunities as well as resources and information for personal skill development and identity sense making.

Social capital helps individuals find educational and developmental opportunities to qualify for more career options. It can also facilitate job searches through a greater awareness of opportunities and with introductions to prospective employers. Social capital is associated with greater career success, whether success is defined as the number of promotions, level of salary, or career satisfaction. Career success is achieved through the exchange of social capital for information, resources, and sponsorship.

Entrepreneurs have an extensive list of needs, and social capital can facilitate the process of starting a business by providing access to information and resources. The goodwill of others can be tapped to provide goods and services in the early stages of a start-up when one has social capital.

Career success may not be associated exclusively with individual exchanges of social capital. The combination of individual and organizational level exchanges can promote career success. Exceptional team or organizational performance can draw attention to an individual's capabilities. Social capital facilitates group effectiveness that can lead to individual career success by providing access to resources outside the group through bridging behavior. Also, the bonding form of social capital helps the group utilize its internal resources. A high-performing organization leads to an impressive résumé and notoriety that can open doors for individual opportunities.

Finally, other types of human capital that lead to career success can be enhanced by social capital. Intellectual capital, for instance, is increased when social capital is used to gain more information and resources that lead to the creation of greater knowledge than possible without assistance. Companies that recognize the connection screen for social capabilities and networks as well as intellectual abilities in job interviews, given the complexity of organizational life and the resulting need for teamwork.

BUILDING SOCIAL CAPITAL FOR BUILDING A CAREER

Simply put, the sources of social capital are relationships and the network structure of those relationships. Another saying, "Network, network, network," applies here. Much of career building is associated with competitive advantage, so weak ties to a variety of networks are especially valuable. Professional organizations in one's functional area offer continuous development and connections to current opportunities. The development of a mentoring relationship outside one's current work organization gives one social capital that is more applicable across situations. In addition, spending time with coworkers throughout an organization develops trust and sets the stage for bonding through the development of shared stories and language. This bonding creates a market for the use of social capital derived from external networks to create a competitive advantage for career advancement within the organization.

Building social capital entails the development of strategically significant relationships and maintaining those relationships. Barriers may exist to entering some groups, and identification with certain groups may constrain behavior (e.g., religious and cultural groups). However, the formation of weak ties such as professional relationships may be possible with some well-developed skills.

The development of certain cognitive and social skills can improve the ability to build and use social capital. Aspects of emotional intelligence help an individual interact with others effectively. The ability to think strategically and to identify political coalitions helps an individual identify strategic opportunities to use social capital. These are skills that are developed through practice. Even though some people are endowed with more social capital from birth, the skills needed for increasing one's stockpile of social capital can be learned, so building social capital is theoretically possible for everyone.

SOCIAL COGNITIVE CAREER THEORY

Social cognitive career theory (SCCT) is a relatively new theory that is aimed at explaining three interrelated aspects of career development: (1) how basic academic and career interests develop, (2) how educational and career choices are made, and (3) how academic and career success is obtained. The theory incorporates a variety of concepts (e.g., interests, abilities, values, environmental factors) that appear in earlier career theories and have been found to affect career development. Developed by Robert W. Lent, Steven D. Brown, and Gail Hackett in 1994, SCCT is based on Albert Bandura's general social cognitive theory, an influential theory of cognitive and motivational processes that has been extended to the study of many areas of psychosocial functioning, such as academic performance, health behavior, and organizational development.

Three intricately linked variables—self-efficacy beliefs, outcome expectations, and goals—serve as the basic building blocks of SCCT. Self-efficacy refers to an individual's personal beliefs about his or

her capabilities to perform particular behaviors or courses of action. Unlike global confidence or self-esteem, self-efficacy beliefs are relatively dynamic (i.e., changeable) and are specific to particular activity domains. People vary in their self-efficacy regarding the behaviors required in different occupational domains. For example, one person might feel very confident in being able to accomplish tasks for successful entry into, and performance in, scientific fields but feel much less confident about his or her abilities in social or enterprising fields, such as sales. SCCT assumes that people are likely to become interested in, choose to pursue, and perform better at activities at which they have strong self-efficacy beliefs, as long as they also have necessary skills and environmental supports to pursue these activities.

Self-efficacy beliefs are assumed to derive from four primary sources of information: personal performance accomplishments, vicarious experiences (e.g., observing similar others), social persuasion, and physiological and emotional states. Personal accomplishments (successes and failures with specific tasks) are assumed to offer a particularly compelling source of efficacy information, but the nature of the social models and reinforcing messages to which one is exposed, and the types of physiological states one experiences while engaged in particular tasks (e.g., low levels of anxiety), can all affect one's self-efficacy regarding different performance domains.

Outcome expectations refer to beliefs about the consequences or outcomes of performing particular behaviors (e.g., what will happen if I do this?). The choices that people make about the activities in which they will engage, and their effort and persistence at these activities, entail consideration of outcome as well as self-efficacy beliefs. For example, people are more likely to choose to engage in an activity to the extent that they see their involvement as leading to valued, positive outcomes (e.g., social and self-approval, tangible rewards, attractive work conditions). According to SCCT and the larger social cognitive theory, persons' engagement in activities, the effort and persistence they put into them, and their ultimate success are partly determined by both their self-efficacy beliefs and outcome expectations.

Personal goals may be defined as one's intentions to engage in a particular activity (e.g., to pursue a given academic major) or to attain a certain level of performance (e.g., to receive an A in a particular course). In SCCT, these two types of goals are, respectively,

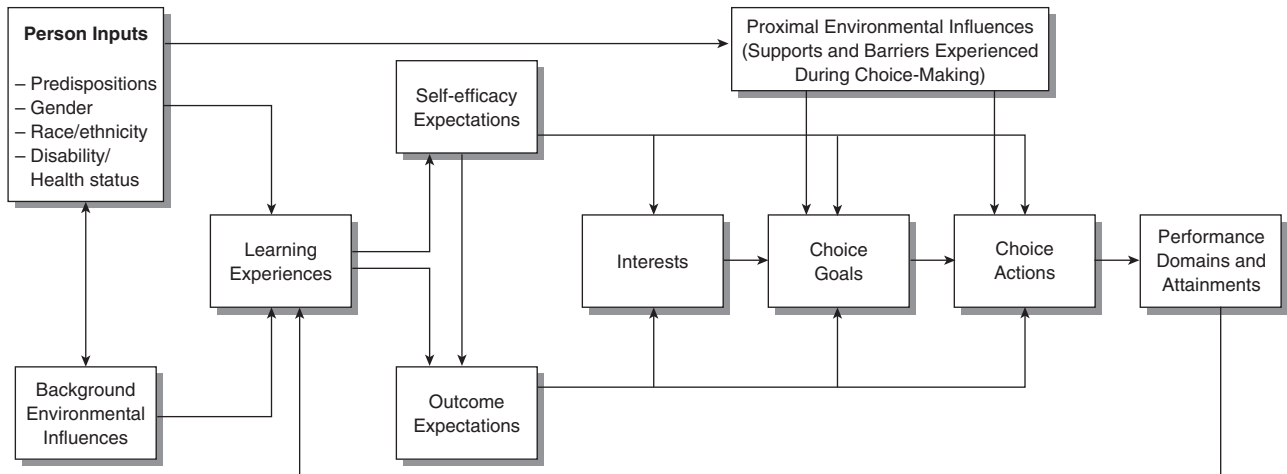

Figure 1. A Simplified View of How Career-related Interests and Choices Develop over Time, According to SCCT

SOURCE: Adapted from Lent, R. W., Brown, S. D. and Hackett, G. 1994. "Toward a Unifying Social Cognitive Theory of Career and Academic Interest, Choice, and Performance" [Monograph]. *Journal of Vocational Behavior* 45:79-122.

referred to as choice goals and performance goals. By setting goals, people help to organize and guide their own behavior and to sustain it in the absence of more immediate positive feedback and despite inevitable setbacks. Social cognitive theory posits that goals are importantly tied to both self-efficacy and outcome expectations: People tend to set goals that are consistent with their views of their personal capabilities and of the outcomes they expect to attain from pursuing a particular course of action. Success or failure in reaching personal goals, in turn, becomes important information that helps to alter or confirm self-efficacy beliefs and outcome expectations.

SCCT'S INTERESTS MODEL

Self-efficacy, outcome expectations, and goals play key roles in SCCT's models of educational and vocational interest development, choice making, and performance attainment. As shown in the center of the figure above, interests in career-relevant activities are seen as the outgrowth of self-efficacy and outcome expectations. Over the course of childhood and adolescence, people are exposed, directly and vicariously, to a variety of occupationally relevant activities in school, at home, and in their communities. They are also differentially reinforced for continuing their engagement, and for developing their skills, in different activity domains. The types and variety of activities to which children and adolescents are exposed is

partly a function of the context and culture in which they grow up. Depending on cultural norms, for example, girls are typically exposed to and reinforced for engaging in different types of activities than are boys.

Through continued activity exposure, practice, and feedback, people refine their skills, develop personal performance standards, form a sense of their efficacy in particular tasks, and acquire certain expectations about the outcomes of activity engagement. People are most likely to develop interest in activities at which they both feel efficacious and from which they expect positive outcomes. As people develop interest in an activity, they are likely to develop goals for sustaining or increasing their involvement in it. Further activity involvement leads to subsequent mastery or failure experiences, which, in turn, help to revise self-efficacy, outcome expectations, and, ultimately, interests within an ongoing feedback loop.

Interest development may be most fluid up until late adolescence, the point at which general interests (e.g., in art, science, social, or mechanical activities) tend to become fairly stable. At the same time, data on the stability of interests suggest that interest change does occur for some people during their postadolescent years. SCCT posits that such changes, when they do occur, can be explained by changes in self-efficacy beliefs and/or outcome expectations—more precisely, by exposure to potent new learning experiences (e.g., parenting, technological advances, job training or

restructuring) that enable people to alter their sense of self-efficacy and outcome expectations in new occupational and avocational directions.

In sum, people are likely to form enduring interest in an activity when they view themselves as competent at performing it and when they expect the activity to produce valued outcomes. Conversely, interests are unlikely to develop in activities for which people doubt their competence and expect negative outcomes. Furthermore, SCCT posits that for interests to blossom in areas for which people have talent, their environments must expose them to the types of direct, vicarious, and persuasive experiences that can give rise to robust efficacy beliefs and positive outcome expectations. Interests are impeded from developing when individuals do not have the opportunity to form strong self-efficacy and positive outcome beliefs, regardless of their level of objective talent. Indeed, findings suggest that perceived capabilities and outcome expectations form key intervening links between objective abilities and interests.

SCCT'S CHOICE MODEL

SCCT's model of the career choice process, which builds on the interests model, is also embedded in the figure above. Arising largely through self-efficacy and outcome expectations, career-related interests foster particular educational and occupational choice goals (e.g., intentions to pursue a particular career path). Especially to the extent that they are clear, specific, strongly held, stated publicly, and supported by significant others, choice goals make it more likely that people will take actions to achieve their goals (e.g., seek to gain entry into a particular academic major, training program, or job). Their subsequent performance attainments (e.g., successes, failures) provide valuable feedback that can strengthen or weaken self-efficacy and outcome expectations and, ultimately, help to revise or confirm choices.

As illustrated in the same figure, SCCT also emphasizes that choice goals are sometimes influenced more directly and potently by self-efficacy beliefs, outcome expectations, or environmental variables than they are by interests. Interests are expected to exert their greatest impact on academic and occupational choice under supportive environmental conditions, which enable people to pursue their interests. However, many adolescents and adults are not able to follow their interests either unfettered by obstacles or with the full support of important others. The choice making of these persons is constrained by such

experiences as economic need, family pressures, or educational limitations. In such instances, people may need to compromise their interests and, instead, make their choices on the basis of such pragmatic considerations as the type of work that is available to them, their self-efficacy beliefs ("Can I do this type of work?"), and outcome expectations ("Will the job pay enough to make it worthwhile?"). Cultural values (e.g., the degree to which one's choices may be guided by elder family members) may also limit the role of personal interests in career choice.

SCCT posits conditions that increase the probability that people will be able to pursue their interests as well as conditions where interests may need to be compromised in making career-related choices. Collectively labeled "environmental influences" in the above figure, these conditions refer to the levels of support (e.g., family financial and emotional support), barriers (e.g., lack of finances, inadequate levels of education), and opportunities available to the individual. Simply put, SCCT hypothesizes that interests will be a more potent predictor of the types of choices people make under supportive rather than under more restrictive environmental conditions. Under the latter conditions, one's interests may need to be bypassed or compromised in favor of more pragmatic, pressing, or culturally acceptable considerations.

SCCT'S PERFORMANCE MODEL

SCCT's performance model is concerned with predicting and explaining two primary aspects of performance: the level of success that people attain in educational and occupational pursuits and the degree to which they persist in the face of obstacles. SCCT focuses on the influences of ability, self-efficacy, outcome expectations, and performance goals on success and persistence. Ability (as reflected by past achievement and aptitudes) is assumed to affect performance via two primary pathways. First, ability influences performance and persistence directly. For example, students with higher aptitude in a particular subject tend to do better and persist longer in that subject than do students with lesser aptitude. (Ability or aptitude may be thought of as a composite of innate potential and acquired knowledge.) Second, ability is hypothesized to influence performance and persistence indirectly through the intervening paths of self-efficacy and outcome expectations.

In other words, performance involves both ability and motivation. SCCT emphasizes the motivational

roles of self-efficacy, outcome expectations, and performance goals. Specifically, SCCT suggests that self-efficacy and outcome expectations work in concert with ability, in part by influencing the types of performance goals that people set for themselves. Controlling for level of ability, students and workers with higher self-efficacy and more positive outcome expectations will be more likely to establish higher performance goals for themselves (i.e., aim for more challenging attainments), to organize their skills more effectively, and to persist longer in the face of setbacks. As a result, they may achieve higher levels of success than those with lower self-efficacy and less positive outcome expectations. Thus favorable self-efficacy, outcome expectations, and goals help people to make the best possible use of their ability.

It should be emphasized that self-efficacy is seen as complementing, not substituting for, ability. Indeed, SCCT does not assume that self-efficacy will compensate for inadequate task ability. It does, however, predict that the performance of individuals at the same ability level will be facilitated by stronger versus weaker self-efficacy beliefs. For example, academically able adolescents who underestimate their academic talents, compared to their equally able peers with more optimistic self-efficacy beliefs, are likely to set lower goals for themselves, experience undue performance anxiety, give up more quickly in the face of obstacles, challenge themselves less academically, and consequently experience less academic success.

Social cognitive theory notes that large overestimates of self-efficacy can also be self-defeating. For example, job trainees whose self-efficacy drastically overshoots their current skills are likely to set unrealistically high performance goals and to take on job tasks that are beyond their current grasp, which may occasion failure and discouragement. According to Bandura, self-efficacy beliefs that modestly exceed current capabilities are probably optimum because they are likely to lead people to set challenging (but attainable) performance goals and to engage in activities that stretch their skills and that further strengthen their self-efficacy and positive outcome expectations.

EMPIRICAL SUPPORT AND PRACTICAL APPLICATIONS

A substantial body of research has accumulated suggesting that SCCT and its major elements offer a useful framework for explaining educational and

vocational interest development, choice making, and performance. Sufficient data have, in fact, accumulated to yield several meta-analyses relevant to SCCT. Meta-analysis is a research strategy that can be used to integrate findings and draw conclusions about the strength of hypothesized relations among variables. Meta-analyses of SCCT's interest model have revealed substantial support for its major hypotheses. In particular, self-efficacy beliefs and outcome expectations have each been found to account for a sizable amount of the variation in vocational and educational interests.

Meta-analyses have also supported SCCT's choice hypotheses. For example, it has been shown that career-related choices are strongly predicted by interests and, to a lesser extent, self-efficacy beliefs and outcome expectations. Consistent with SCCT's assumptions about the importance of environmental and cultural influences, some recent research also suggests that interests may play a smaller role in the choice-making process of adolescents and young adults from particular cultures. Specifically, those from a culture characterized by collective decision making were more inclined to choose a career path that was consistent with the preferences of their family members and with their self-efficacy beliefs rather than one that necessarily fit their personal interests. Other research supports SCCT's hypotheses that interests are more likely to translate into goals, and goals are more likely to promote choice actions, when people are faced with choice-supportive environmental conditions (e.g., relatively low barriers and high supports for their preferred educational/occupational path).

Meta-analyses relevant to SCCT's performance hypotheses have found that self-efficacy is a useful predictor of both academic and occupational performance. Research on the sources of information, or learning experiences, from which self-efficacy beliefs are assumed to derive has found that performance accomplishments typically show the strongest relations with self-efficacy in corresponding activity domains (e.g., successful performance in math-related classes is associated with higher math self-efficacy). The other (vicarious, persuasion, emotional) sources have also been found to relate to self-efficacy, although typically to a more modest degree than personal accomplishments.

Finally, SCCT has sparked a number of efforts to design and test interventions aimed at various facets of

career development. In particular, SCCT suggests a number of targets at which educational and career programs can be directed. These include efforts to expand interests and nurture career aspirations in children and adolescents, facilitate career goal setting and implementation in adolescents and young adults, and promote successful work adjustment (e.g., satisfaction, performance) in adult workers. Reflecting the central role that SCCT accords to self-efficacy and outcome expectations, the interventions that have been proposed or tested to this point tend to rely heavily on experiences that promote these expectations (e.g., exposure to personal mastery experiences and support, access to accurate information about work conditions and outcomes). Extensions of the theory to a number of subpopulations (e.g., women of color, gay and lesbian workers, persons with disabilities) have appeared, and the theory has been applied to the study of career behavior in a number of countries and cultural contexts.

SOCIAL CONSTRUCTIONISM

Social constructionism is a postmodern perspective that emphasizes the socially constructed nature of knowledge. Underscoring the linguistic and relational nature of all knowledge, it emphasizes personal, social, and cultural processes that inform, and limit, the development of knowledge. In contrast to modernist notions of reality as singular, stable, universal, and nonhistorical, social constructionists emphasize that what is taken to be real represents consensually agreed-upon knowledge that results from coordinated, relationally contingent discourses. What is taken as knowledge or truth is therefore contextually and temporary bound; what is true in one time context or culture may not be true in other times, contexts, or cultures.

Social constructionists place a premium on understanding processes of knowledge construction because they emphasize that what is known is inseparable from the processes of inquiry that give rise to knowledge. The role of dialogue, broadly understood as coordinated actions among people, is central to the construction of knowledge. Given the relational embeddedness of knowledge, social constructionists blur the boundary between the personal and social domains, challenging traditional notions of individuality or the self.

THE SELF AND CAREER CONSTRUCTION

A social constructionist position carries significant implications for transforming traditional notions of vocational and career psychology. Career choices, for example, are understood as coordinated forms of discourse and relational enactment, rather than as products of rational, cognitive, or individual decision making. The traditional supremacy of rational processes, as reflected in concepts such as "career decision making," "self-efficacy," or "career interests," cede to relational and contextual processes that are understood as informing, scaffolding, or facilitating the emergence of given careers or career enactments, rather

than as determining or causing the choice or selection of a given career by a given person. Because career discourses are viewed as relationally, culturally, and temporally bound, career choice is viewed more as an artifact of communal interchange than as a reflection of a “correct,” “preferred,” or “effective” decision or selection on the part of the individual. From a social constructionist perspective, the “I” does not exist outside of language or discourse; it is in and through language that the “self” is constructed, together with his or her vocational options and career possibilities.

CAREER DEVELOPMENT AND NARRATIVE

The concept of the career narrative reflects many of the central tenets of social constructionism as applied to the area of career choice and vocational development. Individuals’ stories, their ongoing narrative accounts of their lives and experiences, play a central role in a constructionist account. Individual stories have crucial constructive roles in creating and maintaining relational dialogues at individual, social, and cultural levels. Within the context of these narrative constructions, individual accounts are no longer seen as personal instantiations of self-concepts, self-efficacy, vocational dispositions, decidedness, or development. Instead, the person is understood as drawing from and being constituted by the broader culture in which he or she operates. An exclusive privileging of self-agency is counterbalanced by attention to issues of social, institutional, and cultural context. An individual’s career narrative is understood as emerging from, and being supported by, broader narratives that are available from within the culture and society. The interplay between personal and institutional and cultural contexts necessarily introduces the role of political, social, and cultural forces in forging individual career choices and vocational development. The “choices” that individuals make are therefore bounded by the broader social and cultural metanarratives available in any given time and place, which situate career decision making more as an act of social and relational negotiation than as an act of personal choice and rational decision making.

As a result, social constructionism would position the career narrative that an individual tells about his or her vocational interests, experiences, decisions, and developments within a broader context. As such, it does not represent *the* career account so much as *one possible account*, a single voice abstracted from a

chorus of voices that jointly constitute the overall and ongoing performance of a career over time. The individual’s narrative is nested within a family system that operates within a given culture, within a particular society, economy, time, and place. An individual’s narrative regarding the pursuit of a career in medicine, for example, is understood as being developed in relation to the narrative accounts of his or her family (e.g., grandparents, parents, siblings, children), as well as accounts that follow from forces acting on global and local economies, developing technologies, and a range of cultural discourses regarding health care, social justice, and the meaning of a career itself.

CONSTRUCTIVE PROCESSES

Social constructionism highlights the constructed nature of knowledge, including the construction of such traditional concepts as vocational interests, traits, factors, career decidedness, self-efficacy, or self-concept. In each case these concepts are viewed as constructions that reflect emergent processes of coordinated action, consensually agreed-upon concepts that have no reality, truth, or value outside of themselves or the context that gives rise to them. Attention is turned from characteristics that a person *has*, to what a person *does*; in short, from *traits* to *processes*. Career itself is viewed not as a static entity, but as a dynamic, ongoing, and necessarily relational process. And it is the continuing coordination of relational action that supports the very existence of a career, as well as an individual’s participation within that career. Both the emergence of new careers and the disappearance of old ones underscore the dynamic nature of what can be called careers. Broader social, cultural, and historical forces continually work their influence on the world of work, supporting an ongoing fluidity in the nature of careers and the accounts that are forged in relation to them.

SOCIAL LEARNING THEORY OF CAREER DEVELOPMENT

People work at an incredibly wide number of jobs. A major question is How can we explain how people find their way into working at one occupation rather than another? The *social learning theory of career development* (SLTCD) is one of a number of theories that help explain how individuals make occupational choices. The SLTCD attributes occupational placement to an uncountable number of learning experiences, some planned but most unplanned, that influence the path through the occupational maze. Unlike traditional career counseling models, which aim to assist clients in making a decision about a career path, the SLTCD welcomes indecision as a sensible approach to a complex and unpredictable future. Career counselors can help clients reframe indecision as open-mindedness.

The world is extremely complex. No one knows what the future will hold. No one knows how interests will change, how new occupations will arise, or how new opportunities will be created. The SLTCD states that people should not expect to know exactly what they will be doing nor where they will be doing it in the future. Instead it advocates that people can create opportunities by their own actions. Individuals may not know in advance how their actions will generate opportunities, but it is quite clear that doing nothing creates nothing. Unexpected events arise when action is taken. New people are met, new activities are tried, and feedback is gained from every activity that is tried.

PLACING GREATER VALUE ON HAPPENSTANCE

Unplanned events and chance encounters often determine the paths individuals take both in their personal and their professional lives. In the SLTCD, happenstance is seen as more than random occurrences; it

is an outcome of earlier decisions and behaviors, and it is a valuable tool that prompts clients to take actions or make decisions that may have life-altering effects.

The SLTCD recognizes that many circumstances and events in clients' lives are out of their control. Genetic and environmental factors that influence clients' lives are good examples of circumstances in which they have little, if any, control.

GAINING GREATER CONTROL OVER HAPPENSTANCE

The SLTCD acknowledges that, although many events are out of clients' control, clients can actually create, recognize, and take advantage of these unplanned events. Counseling clients to keep an open mind and to recognize the opportunities afforded them when they encounter unexpected events can make a dramatic difference in the direction their career paths will take.

Take Thomas, for example. He was born into a large, loving family that taught him to be honest, hard working, and respectful of others. His parents did not have much money; however, they emphasized the value of learning. Thomas developed an early interest in mathematics. He learned how to count to 100 before he reached the age of 3, and by the time he was 10 years old, he was ahead of his entire math class and often found the class boring. In the fifth grade, Thomas's teacher realized that he needed a greater challenge and asked if he would like to tutor a few of his classmates during the weekly independent study hour. Thomas learned that he enjoyed helping his classmates master new mathematical skills.

It is not known why Thomas excelled in mathematics. Maybe his parents taught him to count at an early age. Maybe there is some genetic origin. He was fortunate to have a teacher who saw his potential and asked him to tutor. He seized that opportunity and found that he liked teaching others.

REFRAMING UNPLANNED EVENTS AS CAREER OPPORTUNITIES

The SLTCD orients clients to view past experiences as lessons for present actions. Unplanned events can be seen as career opportunities—not just unexplained accidents. Explicit attention should be paid to the client's desire for a satisfying life. Since each

person defines a satisfying life in different ways, it is important for career counselors to listen carefully to clients and encourage them to describe activities, both past and present, that energize them. Career counselors can teach clients that they need to recognize the potential opportunities in unplanned events.

Once clients understand how all of their experiences in life affect their decisions, they will see how each decision opens up the potential for new, often unexpected, events. Career counseling is much more complex than merely identifying a suitable occupation for a client. Career counseling today, in a time of uncertainty due to mergers, acquisitions, downsizings, and outsourcing, requires clients to embark on a journey of self-discovery and lifelong learning.

TRANSFORMING ACTION INTO LEARNING

Learning can be defined as either instrumental or associative. Instrumental learning occurs when a person takes action and observes the consequences of that action. Consequences might include comments from other people, observable results, or impact on others. Thomas learned that excelling in math had positive rewards. He enjoyed seeing his classmates improve as a result of his tutoring, and he felt good about the recognition he received from his teacher.

Associative learning occurs when a person makes connections between two phenomena or stimuli. Learning results from observation and conditioning; for example, watching and listening to other people and observing the positive rewards or punishment they receive from certain actions. Thomas observed that competence and enjoyment seemed to go together. He noted that some of his classmates could start out hating math while getting poor grades but then learned to like it after they understood it.

RECOGNIZING THE INFLUENCE OF GENETIC FACTORS AND ENVIRONMENTAL CONDITIONS

Genetic factors and environmental conditions, such as physical attributes and abilities (or disabilities), talents, aptitudes, birth family, birth location, and family resources work together with learning experiences to form a client's individual task approach skills. These skills include the ways in which clients cognitively process the world around them, including their beliefs, values, attitudes, feelings, work habits, goals, and expectations.

As a result of Thomas's early experiences tutoring his peers, he developed the ability to communicate technical information in a way that was easy for others to understand. Thomas came to value the relationships he fostered, and he developed respect for people who desired to learn.

MAKING SELF-OBSERVATIONS AND EVALUATIONS

A lifelong journey of learning depends upon self-observation and evaluation. Clients make generalizations about their performance in relation to the performance of others or in relation to their own past performance. In addition, clients evaluate whether they fulfilled or exceeded their own personal expectations or standards. Clients also generalize about their interests based on the activities they find enjoyable or challenging and about what is important to them and what brings them the most personal satisfaction.

Generalizations may be contextual, that is, dependent on the situation or others present when a learning experience occurred. Self-observation generalizations may or may not be accurate or consciously expressed. Thomas made the accurate self-observation generalization, "I am very good at math." After dropping one fly ball while playing baseball, he might have generalized inaccurately, "I am a terrible athlete." These self-observation generalizations can have a powerful effect on subsequent actions.

By the time he reached high school, Thomas generalized that he was excellent in math and was encouraged by his high school counselor to apply to a math and science college. He applied and was accepted at MIT. However, his math teacher told Thomas that the competition would be greater at MIT because almost all the students were excellent at math and science. Thomas began to worry about whether he could succeed at college.

ESTIMATING PROBABILITY OF SUCCESS IN SPECIFIC OCCUPATIONS

Learning experiences and the generalizations they engender enable clients to make estimates, rightly or wrongly, about the probability of succeeding or enjoying a specific career. From their experiences and interactions with others, clients develop interests, coping strategies, ethics, values, and standards. Clients' limited exposure to the world of work may lead them to

assume that certain occupations value or require skills and interests that they may, or may not, have developed. Consequently, clients may initiate an education program or take a job that may, or may not, satisfy them. Career counselors need to help their clients think about their actions as experiments. If the first educational major or work experience is not satisfactory, then the career counselor can encourage clients to take alternative actions.

RECOGNIZING THAT ENVIRONMENTS AND INTERESTS ARE CONSTANTLY CHANGING

Unlike previous generations who remained at the same job with the same company until retirement, today's workers often make multiple career changes during their lifetime. When companies unexpectedly merge, for example, persons who had initially expected to have secure employment may find that their jobs are no longer required or that there is an overlap with jobs in the other company. As a result some people will either have to leave or move into new positions. Unplanned events are a common occurrence in life, and how clients respond to them will determine whether their lives are filled with opportunity and adventure or with obstacles and disappointment.

The constant advancement of technology is producing new and unexpected products and services. Occupations that once existed, for example, elevator operators or typewriter repairpersons, are now virtually obsolete. However, people previously employed in one of these occupations can generate new interests and learn how to adapt their skills to fit into current employment needs.

Interests are learned and new experiences provide opportunities for people to discover new interests.

During his first semester, Thomas was invited by one of his professors to join the math club. Through membership in the math club, Thomas met an impressive scholar who introduced him to the complex world of computer science. After learning more about computers and how they are designed, Thomas changed his major from mathematics to electrical engineering.

EMPHASIZING LIFELONG LEARNING

Clients must not see their lack of a career plan as indecision but instead celebrate it as open-mindedness. People have a variety of learning experiences, both

planned and unplanned, as a result of the happenstance events they encounter. Career counselors must prepare clients for a counseling process that embraces happenstance as a necessary component. Counselors should ask clients to identify past instances of happenstance in their lives, examine specific actions that created these unplanned events, and then initiate new actions to generate further unplanned events. Clients should be encouraged to see unexpected events as opportunities for learning and exploration. Career counselors should point out that clients can initiate action that will actually create more chance events using their successes with prior happenstance events as evidence that the clients already know how to do it.

Specific client actions that might lead to career opportunities include researching a job opening or company, volunteering to work at a nonprofit organization, attending a seminar or training program, talking with friends or relatives about job concerns and aspirations, and interviewing or job shadowing someone employed in a field of interest to establish new contacts. Actions like these can be meaningful ways of learning more about interests and generating unexpected valuable information. Counselors need to support client action and, if necessary, address any blocks that may inhibit clients from taking risks.

Genetics and environmental factors combine to produce clients' perceptions of how the world is changing and how those changes produce career opportunities. Clients make generalizations on the basis of their observations of their own performance—both past and present. They use these generalizations to estimate their chances of success in various fields of endeavor. Since environments and client interests are constantly changing, career counselors need to help keep clients from becoming stuck in an initial job that may no longer be satisfactory and to see the opportunities that unexpected events create.

Thomas earned his PhD and was subsequently hired to teach engineering at a midwestern university. After 10 fulfilling years of teaching, Thomas's father became ill and passed away. Thomas took a sabbatical leave and returned to his hometown to help his mother with the family farm. Thomas found that he enjoyed the outdoor life and experienced a sense of purpose and pleasure while gardening. When the owner of a local market asked Thomas if he would be interested in selling some of his organic produce, Thomas took advantage of the opportunity. Within a year, Thomas expanded his organic garden and

began teaching others how to grow healthful produce using natural fertilizers and pest control.

Although Thomas had been very satisfied with his teaching career, the unexpected death of his father required that he make changes in his life. Thomas returned to his family farm with an open mind and soon discovered an interest in gardening. From the time Thomas was a young boy, he knew that he enjoyed teaching. However, Thomas could not have predicted that one day he would be teaching others how to garden.

By remaining open to new learning experiences and by making self-observations, Thomas found a second career that was satisfying to him and beneficial to the members of his community.

SOCIOECONOMIC STATUS

Socioeconomic status (SES) is the relative position of a family or individual along a hierarchical social structure, based on access to, or control over, wealth, prestige, and power. It is used to measure social class and social status. It is usually operationalized as a composite measure of income, level of education, and occupational prestige. Although these indicators of SES are separable, they tend to be correlated. In many ways, SES categories are archetypal "status groups"—categories of people with unequal amounts of prestige.

The status-attainment model, in stratification research, generally estimates the effects that individuals' socioeconomic origins, and other attributes, have on their life chances, specifically on occupational status. The model provides a parsimonious summary of the ways in which socioeconomic origins affect socioeconomic outcomes.

The model was initially developed by Peter Blau and Otis Duncan in their classic 1967 work, *The American Occupational Structure*, in which they demonstrated that SES of family of origin serves as a foundation for future occupational achievement. Family SES was found to affect the quality and quantity of education received, which affected career beginnings, and ultimately, occupational achievement. Subsequent studies validated and expanded on these findings. Later work also identified or explored limitations; for example, the model does not fully explain the gender wage gap, and family SES has been shown to have limited returns for African Americans.

COMPONENTS OF SES: WEALTH AND HOUSING

Wealth is an important component of SES but has often been overlooked in empirical research. Wealth confers advantages by providing a base of financial security, protecting against downturns in incomes, covering brief periods of unemployment, and helping to avert business losses (for example among struggling entrepreneurs). Up to 80 percent of capital accumulation can be attributed to intergenerational transfers of wealth. This is greater than the effect of parental income.

Owning one's home is the primary mechanism of equity accumulation for most families in the United States. Parents may use wealth, often in the form of property, to finance their children's educational and professional credentials. Housing is an important material mechanism by which socioeconomic advantage is passed on from one generation to the next. Home ownership is also salient to educational attainment in that the quality of the local school district is determined by the local tax base. Equity in a home may play an important role in financing postsecondary education (e.g., by providing a second mortgage to pay for college). Home ownership is also often cheaper in the long run than renting, so funds are freed up to finance education.

LINKS BETWEEN SES AND OCCUPATIONAL OUTCOMES

Norms

The cultural environment, including the immediate family environment and the surrounding community, influences norms and values. The environment provides norms and practices that affect entrance to and progression in professional careers. It has been shown, for example, that students who attend high SES schools are less likely to drop out of high school, and that girls who attend high SES schools are less likely to have a child before graduation, than are students with the same family background who attend low SES schools.

Human Capital

Human capital includes the cumulative educational, personal, and professional attributes and experiences that might enhance an employee's value to an employer. The children in disadvantaged environments tend not to realize their potential for intellectual development, an important component of human capital. Disadvantaged environments tend to suppress the influences of heritability.

Level of education is the most heavily researched human capital attribute. Blau and Duncan concluded that the impact of family background on SES works largely through the schooling system. Research from the careers literature indicates that returns from educational attainment in terms of pay and promotions are significant. Schooling increases the human capital attribute of intellectual development and therefore the earnings of even those children with the lowest ability levels. However, not only is the quality of schooling important to later career success, but so is the timing of the education.

Life-course-timing differences in educational attainment help explain wage differentials by midlife. Advantaged social origins lead to early postsecondary completion of degrees, which in turn yields higher wages. Advantaged men and women have parental, social, and economic resources that facilitate entry into high-quality postsecondary school tracks early in life for their children or enable their children to remain in educational institutions long enough to earn bachelor's and graduate degrees prior to market entry. This process is sequential and cumulative in its effects on wage gains. A pathway of cumulative disadvantage is

also evident: the least advantaged exit schooling early in life, do not return as adults, and earn low wages.

Social and Cultural Capital

SES is linked to social capital. Social capital is defined as the social networks, the reciprocities that arise from them, and the value of these reciprocities for achieving mutual goals. Children benefit from continued exposure to the social connections that parents have with others outside the family group, such as neighbors, school personnel, or work colleagues. For example, youths with well-connected parents and teachers tend to have choices in selecting work. If a youth's relatives are unemployed and their teachers lack job contacts, their choices are restricted to other kinds of contacts (such as peers) that do not lead to long-term earnings benefits.

An educational institution may confer three types of capital on its graduates: scholastic capital, which is one type of human capital and represents the amount of knowledge acquired; social capital in the form of personal contacts and network ties; and cultural capital or the value of its prestige. Ivy League schools, which represent very high-status schools in the United States, are beneficial in conferring social and cultural capital on graduates. It is also possible that graduates from these schools in the United States benefit from nepotism or favoritism.

COMPENSATING FOR LOW SES

Childhood social class differences cannot be completely overcome or compensated for by later life course circumstances, so a recommendation is to increase the transfer of social resources targeting children. Public policies responsible for early intervention programs such as Head Start are believed to make the social environment of these children more conducive to intellectual development. More accessible and higher quality job information and placement centers could also enhance employment and income.

Families could improve their SES and raise their children's chances of upward mobility if public policy and practice expanded opportunities for long-term financial gains in wealth. These opportunities could include increased education about investment opportunities, more extensive investment incentives, wider use of pension plans for companies and businesses, and increased home-buying incentives.

OCCUPATIONAL STATUS VERSUS SUBJECTIVE CAREER SUCCESS

The links between SES and career-relevant indicators are typically based on studies that measure occupational status. These measures of occupational status are based on the prestige standing of occupations, the educational levels of occupational incumbents, and the income levels of occupational incumbents. By contrast, there is an extensive career development literature that measures career success using subjective measures such as satisfaction with career and with facets of the current position. While these studies offer a finer textured, intraindividual understanding of the experience of career development and success than stratification studies, they typically do not include SES as a predictor. At this point, then, there is little information on the link between SES and subjective career success.

SPECIALTY CHOICE

For several professions, the initial career choices are followed by the need to choose a specialty within that profession. For example, physicians-in-training need to decide whether to specialize in pediatrics, orthopedics, psychiatry, or some other field. However, much of the career development literature has focused primarily on the initial career choice of a profession with relatively little attention to *specialty choice*. To provide an overview to the concept of career specialty choice, the tools available for the assessment of specialty choice in business and medicine are reviewed in this entry. References for the instruments reviewed in this entry can be found in the Frederick Leong and Elke Geisler-Brenstein article published in 1991.

SPECIALTY CHOICE IN BUSINESS

Students who have chosen a career in business can specialize in a variety of functional areas (e.g., finance, marketing). Edgar Schein identified a series of career anchors and developed an instrument to measure these career anchors for individuals who are pursuing business careers. In conducting a qualitative-longitudinal study of MBA students at the Massachusetts Institute of Technology, Schein identified several constellations of values and needs that tend to direct and anchor the individuals with regard to functional specialties within their business careers. In conducting this research, Schein developed an instrument called the Career Orientations Inventory in order to identify individuals' career anchors. Career anchors are viewed as a combination of values, needs, and interests. These career anchors include Technical/Functional Competence, Managerial Competence, Autonomy and Independence, Security/Stability, Service/Dedication, Pure Challenge, Lifestyle Integration, and Entrepreneurship.

The next instrument is not really a separate instrument as much as it is a special scoring of the Strong Interest Inventory to provide information on business specialties. These assessments are called the Strong Topical Reports, and there are three of them: the Leadership Management Style Report, the Organizational Specialty Report, and the Leisure Report. The instrument of most interest with respect to making a specialty choice is the Organizational Specialty Report, which was developed by Pierre Mayer. This report identifies whether individuals would be interested in working in a series of business areas of specialization within an organization. These specialty areas include administrative services, communications, finance and control, general management, human resources, legal, informational systems management, manufacturing management, research and development, marketing, and sales.

Another recent development in the assessment of business specialty interests is David Campbell's new instrument called the Campbell Work Orientations Scales (CWO). The CWO consists of three separate surveys. Of the three surveys within the CWO scales, the Campbell Interest and Skill Survey is the most relevant to specialty choice. The Interest and Skill Survey provides information on 29 interest scales, which are organized into nine clusters: agriculture, mechanics, military/athletics, science/mathematics,

art/music/travel, social/medical services, leadership/politics, management/finance, and advertising/marketing. Of the nine clusters, the first three are of most relevance to business career specialties: (1) public speaking, law/politics, leadership; (2) management, office practices, financial services; and (3) sales, advertising/marketing, and fashion.

SPECIALTY CHOICE IN THE MEDICAL PROFESSION

Three primary instruments have been used to assist physicians-in-training in selecting a medical specialty. Each of the instruments explores somewhat different personality aspects. The Medical Specialty Preference Scales (MSPS) developed by Harrison Gough assesses occupational interests in terms of different school subjects, occupational titles, and types of people based on items of the Strong Campbell Interest Inventory (SCII). George Zimney's Medical Specialty Preference Inventory measures students' preferences for specific medical activities and settings. Finally, the Myers-Briggs Type Indicator indicates a student's psychological type along four fundamental dimensions of personality.

For the development of the MSPS, the Strong Vocational Interest Blank (an earlier version of the SCII) was administered to 956 freshman medical students at the University of California School of Medicine in San Francisco. Their scores were examined for discriminant validity after the students had started practicing medicine. Ten criterion groups were established: anesthesiology, eyes, ears, nose, and throat (EENT), obstetrics and gynecology, surgery, family medicine and general practice, pathology, radiology, internal medicine, psychiatry, and pediatrics. The MSPS is scored by the vendor, Consulting Psychologists Press. Together with a computer-scored printout, the student also receives a four-page interpretive guide with general instructions on how to plot the raw scores on a profile for males or females as well as with information regarding how to interpret the profile.

The Medical Specialty Preference Inventory (MSPI) was developed with the dual purpose of providing medical students with information about their personal specialty preferences as well as providing students with information regarding various aspects of the medical specialties themselves. The instrument assesses preferences for six specialties: internal medicine, obstetrics and gynecology, pediatrics, psychiatry,

surgery, and family practice. Unlike the MSPS, the MSPI was developed based on the ratings of practitioners. A national sample of over 1,000 board-certified physicians in each of the six specialties rated each of 199 items directly related to the practice of medicine to indicate how characteristic they were of the general clinical practice in their specialty. The MSPI comes in the form of a 10-page booklet with 199 questionnaire items relating to the different aspects of medicine. Students rate each item in terms of how desirable it is for them in the practice of medicine.

The Myers-Briggs Type Indicator is widely used in career counseling. A large database of type preferences of medical students has provided type information for a large number of medical specialties and may prove useful to students in the process of medical specialty choice. Type tables compiled for large samples of medical students show that all types are represented in the medical field. An examination of type distributions in individual specialties, however, shows that certain types are more likely to be attracted to one specialty than to others. For example, introverted, intuitive thinkers were more likely to be found in pathology (INTJ and INTP), while extroverted, sensing-thinking types with a preference for orderly functioning (ESTJ) were more likely to be found in general practice.

SPIRITUALITY AND CAREERS

Although the desire to experience and express spirituality in one's work appears to be on the increase, there are two difficulties encountered as soon as one tries to discuss spirituality. The first is the fear that spirituality is inextricably linked to organized religions so that a particular religious focus will try to be imposed. The second is the sense that spirituality is so personal that no one can define it in a way that makes sense for

another. This entry therefore begins by tackling those two big issues: the definition of spirituality and the relationship of spirituality to religion. Following those sections, research and observations on the relationship between spirituality, work, and career are explored.

A DEFINITION OF SPIRITUALITY

There have been a number of studies in which people have been asked to define what spirituality means to them. Although these studies have ranged from large-scale explorations of many people's ideas to small, targeted studies, the answers have a remarkable similarity. They include the following ideas: a sense of connection to other people, a relationship to the environment or universe, feelings of guidance or purpose from within, connection to a transcendent power, a sense of harmony, and a sense of calling. These phrases have a common core of meaning: the self, the self in relationship, and a resulting sense of what to do or how to be. Therefore, the definition of spirituality that is used throughout this entry has two parts. It is as follows: Spirituality is a sense of connection to something beyond oneself and deep within oneself, a connection that informs the search for meaning, purpose, and integration in life.

RELATIONSHIP OF SPIRITUALITY AND RELIGION

Much of the research that served to define spirituality also explored the relationship between spirituality and religion. This research has been based primarily in the United States, although studies have also been conducted in Australia and New Zealand. The results of this research can generally be viewed on a continuum. On one end of the continuum are people who identify spirituality and religion as one and the same. At the other end of the continuum are people who see themselves as "individual seekers" involved in a highly personal journey, whose spirituality is not necessarily tied to religion. This personal journey might include practices such as prayer or meditation, activities that some would associate with religion. Research in the 1990s and into the twenty-first century suggests that Americans are moving more toward the latter end of the continuum. However, organized religion, personal spiritual searches, and what might be described as practices drawn from religion are intertwined for many people.

In *A Generation of Seekers*, Wade Roof described the many aspects of spiritual seeking, including career implications, particularly among the baby boomers, the generation born between 1946 and 1964.

The difference between religion and spirituality in the workplace is particularly important to Americans. In their research, Ian Mitroff and Elizabeth Denton found that employees in companies that they consider to be spiritual are more productive and less likely to leave. They also found that people wanted companies to honor spirituality and act in accord with the values of relationship and connection embodied in spirituality, but they did not want companies to be linked to particular religions. This observation supports the findings of other research that attempts to introduce spirituality into the workplace require a gentle touch that is imbued with both an understanding of and respect for diversity and differences.

SPIRITUALITY AND WORK

There are limited studies on the relationship of spirituality to work. However, those studies show outcomes for both the individual and the organization. Leaders describe their spirituality as keeping them focused on the values and needs of others. Furthermore, individuals who have explored their spirituality benefit their organizations through increased creativity, more ethical behavior, and team building.

Because spirituality is about both relationships with others and about a sense of purpose and meaning, it is strongly linked to the individual's value systems. Individuals may find that their values are more or less congruent with those of the organization for which they are working. Some research shows that individuals disengage from aspects of the work or leave the jobs completely when their spiritual values are no longer aligned with those of the organization. On the other hand, a recent study showed that congruence in spiritual values between individuals and organizations is positively associated with commitment to the organization.

SPIRITUALITY AND CAREER DECISION MAKING

Since spiritual congruence can lead either to commitment or to disengagement, it is clearly a factor in career decision making. Career purposes that have been linked to spirituality include developing oneself, developing unity with others, and expressing oneself. The

search to fulfill each of these purposes affects individual career decision making. In seeking to develop oneself, career decisions regarding integrity and growth affect career choices. In seeking to develop unity with others, career decisions around shared values or a sense of belonging are associated with career choices. The search to express oneself may be seen in career choices around issues of creativity, achievement, or influencing others to express themselves.

Perhaps the most familiar concept associated with spirituality and career decision making is the concept of calling. Sometimes calling, or vocation, is seen as being limited to religious occupations, but calling could be defined as recognizing one's gifts and using them in productive work. People who recognize and respond to their calling describe their work as fulfilling, even at times blissful. They express a sense of connection between themselves and their work. Identification of one's calling is often part of the spiritual journey, that is, calling is not necessarily evident early in life, nor is it static.

In sum, the essence of spirituality is the sense of oneness experienced with the self, with others, with work, and with the transcendent. Recognizing the difficulty of holding on to this transitory sense of unity, Deborah Bloch and Lee Richmond identified seven connectors uniting spirituality and career.

1. *Change*: Being open to change in yourself and the world around you
2. *Balance*: Achieving balance among the activities of your life such as work, leisure, learning, and family relationships as well as balance between the old and new
3. *Energy*: Feeling that you always have enough energy to do what you want to do
4. *Community*: Working as a member of a team or community of workers
5. *Calling*: Believing that you are called to the work you do by your particular mix of talents, interests, and values
6. *Harmony*: Working in a setting that harmonizes with your talents, interests, and values
7. *Unity*: Believing that the work you do has a purpose beyond earning money and in some way serves others

The seven ideas above can be seen as attempts to connect to the ineffable sought in the mysteries of the trinity, the One of Judaism, the Om of Buddhism, the

Oneness of Allah and the Hindu Vedas. In addition, for some the connections are evident in what appears to be a grand design emerging from discoveries in quantum mechanics and chaos and complexity science.

There is limited research at this time on the links between spirituality and career, the methods for incorporating spirituality in career counseling, and the outcomes of doing so. However, spirituality often incorporates knowing by intuition, and intuition is leading respected members of the field to recommend the incorporation of spirituality into counseling practice.

STANFORD-BINET INTELLIGENCE SCALE

The *Stanford-Binet Intelligence Scale* is an individually administered assessment of intelligence and cognitive abilities. The Stanford-Binet has a wide variety of uses, including school placement, determining the presence of a learning disability or developmental delay, and tracking intellectual development. Although undergoing various revisions, this assessment tool is the oldest and most influential test of its kind.

The test was originally developed in 1905 by Alfred Binet, a French psychologist, along with his colleague Theodore Simon, as a mechanism to identify schoolchildren who were in need of special education in France. The test consisted of 30 tasks of increasing difficulty that assessed such factors as attention, memory, and verbal skills. The test, referred to as the Binet-Simon scale, was revised in 1908 and 1911. In the revised version, tasks were clustered by the age at which most children could successfully complete them. The number of tasks successfully completed measured the child's level of intellectual performance, which Binet referred to as "mental age." To allow for a broader age range, adult tasks were added in the revision.

In 1916, the first U.S. revision was completed by Lewis Terman at Stanford University. Terman recognized the limitations of using the Binet-Simon scale in the United States because the research was based on a different population. While Terman employed many tests from Binet's scale, he incorporated new tests based on his own methodical research. His research provided a better representation of the population and included a higher and lower age range. The test was commonly referred to as the Stanford-Binet Scale.

The Stanford-Binet Scale was carefully standardized, based on extensive research by Terman and his team of graduate students. The test's organization, administrative procedures, and scoring instructions were made clearer. The most important aspect of Terman's revision was incorporating William Stern's concept of intelligence quotient (IQ). IQ was defined as the ratio of mental age to chronological age multiplied by 100. The concept of IQ replaced Binet's "mental age."

After over two decades, Terman and his colleague Maud Merrill released another revision in 1937. This revision addressed the limitation of the 1916 single-form version by developing two carefully equated scales: Form L and Form M. Each form consisted of 129 tests that contained more performance-based tasks and less verbal testing. The test covered Ages 2 through adult, and the test integrated the use of toys to keep younger test takers interested.

For their third revision, Terman and Merrill published Form L-M, which consolidated the best items from the two previous forms. The use of the traditional IQ was eliminated and replaced with Deviation IQ, which was based on a standardized score. In 1973, revised norms of the Stanford-Binet were released by Robert Thorndike.

The Stanford-Binet Intelligence Scale, fourth edition, was released in 1986 by Thorndike, Elizabeth Hagen, and Jerome Sattler. This revamped version used a point-scale as opposed to the age-scale from previous forms. The point-scale is an arrangement of tests into subtests with items organized by type and presented by varying difficulty. The subtests, which provided a score for each area, focused on the following: general intelligence, verbal reasoning, abstract/visual reasoning, quantitative reasoning, and short-term memory. The vocabulary section was used to help the administrator determine where to begin testing.

The most recent version of the Stanford-Binet Intelligence Scale, the fifth edition, was released in 2003 by Gale Roid. This edition uses both the point-scale and the age-scale format. The age-scale was reintroduced to keep the examinee engaged in the testing experience. In addition to the vocabulary test, the fifth edition uses both a verbal and nonverbal test to help the administrator determine where to begin testing. The 2003 revision continues to measure general intelligence and quantitative reasoning and adds knowledge, fluid reasoning, visual-spatial processing, working memory, and verbal and nonverbal IQ. Correcting upon a limitation of the previous version, the fifth edition allows for early recognition of individuals with developmental delays or cognitive difficulties by expanding the low-end items of the test. The high-end items were also expanded to allow for the identification of highly gifted individuals. Normal intelligence can still be assessed.

The most recent edition of the Stanford-Binet Intelligence Scale preserves the work from the early creators, including Binet, Simon, Terman, and Merrill, yet uses the modernized contributions of the more recent authors, Thorndike, Hagen, and Sattler. The revisions of the Stanford-Binet were necessary to stay current with recent trends in assessment tools and their uses. They are used in business and industry for placement and employee selection and in schools to identify children's scholastic strengths and weaknesses. Given the long history and continuing popularity, the Stanford-Binet Intelligence Scale will continue to be a useful instrument in the future.

STEREOTYPING OF WORKERS

Stereotypes are beliefs about the characteristics of a group of people, which lead to expectations about what individual members of that group will be like and how they will behave. Stereotypes are usually formed on the basis of membership in visible social categories such as race, gender, age, and disability status. Although the content of the stereotypes about groups varies, the process by which stereotyping influences how people are perceived remains the same. Stereotyping is a cognitive process that occurs when individuals are judged and evaluated on the basis of group memberships, rather than information about them as individuals.

People rely on stereotypes for cognitive reasons. Stereotyping simplifies the task of observing and understanding people. When a new person is encountered, it is expected that he or she will have characteristics that are consistent with the stereotype and will behave in a manner consistent with the stereotype. This process usually occurs automatically, outside of conscious awareness. Once activated, stereotypes influence the information about a person that is attended to, how that information is interpreted, and the impression that is formed about that individual. While stereotypes result in more efficient processing of information, they have potentially deleterious costs in terms of fairness and accuracy of judgments. Relying on stereotypes of a group to make judgments about an individual's behavior results in the perceiver glossing over the individual's actual characteristics and behavior.

Stereotyping of workers in organizations is a well-researched phenomenon. In the workplace, people are frequently called upon to make judgments and evaluate others for hiring decisions, promotions, job assignments, and salary increases. Research has demonstrated that stereotypes play a role in these decisions and result in biased evaluations of certain groups. The manner by which many of these decisions

occur in an organizational setting is through a matching process in which the attributes of an individual worker are compared to the attributes thought to be required for a specific job. When the worker's perceived attributes match the attributes thought to be required for a job, then that individual is expected to succeed. However, if the worker's perceived attributes are not seen as matching the attributes thought to be required for a given job, that individual is expected to fail. The perceived attributes of workers have been demonstrated to be heavily based on stereotypes, rather than information about them as individuals. This can then lead to erroneous expectations of success for some groups and failure for others. For example, it has been shown that high-level managerial, executive jobs are thought to require typically male attributes such as achievement orientation and aggressiveness. Thus when women (or the elderly, or African Americans) are evaluated for these types of jobs, they are not seen as a good match because the stereotypes of these groups are not seen as matching the typical male attributes required for the job. This perceived lack of fit between the attributes of the individual and the requirements for the job result in expectations of failure and biased evaluations of performance. When White men are evaluated for these types of jobs, they are seen as matching because of the overlap between the stereotype of males and the attributes required for success in managerial roles. This perceived fit between these attributes of the individual and the requirements for the job result in expectations of success and positively biased evaluations of performance. Thus, stereotypes lead to expectations of failure or success that result in biased evaluations in organizational settings. This has been found to be the case not only for women on male-sex-typed jobs but also for the elderly on young-typed-jobs, for African Americans on White-typed-jobs, and for people with disabilities for jobs thought to be physically demanding.

Stereotypes have also been shown to impact targets of a stereotype, as well as perceivers. Research has demonstrated that individuals who belong to groups to which a negative stereotype applies are likely to worry about confirming that stereotype and thus perform worse on a given task. For example, women were found to negotiate less well than men when the stereotype that women are not effective negotiators was primed; however, there were no differences in negotiation performance when the stereotype was not

primed. Thus stereotypes can negatively impact work outcomes for individuals through their effect on biased evaluations of performance by others and through their effect on the actual performance of stereotyped individuals.

There has been a great deal of research examining how to minimize the impact of stereotyping on organizational decision making. People are capable of overriding automatically activated stereotypes and making careful decisions based on individual behavior when given the time, incentive, and information to do so. Research has identified factors that allow for this type of careful decision making. First, organizational decision makers are less likely to rely on stereotypes when they have access to job-relevant information about the individual. Research has demonstrated that people are less likely to rely on stereotypes when there is unambiguous information about how successful or qualified an individual is, when it is clear that it is the individual that is responsible for the success, and when there are no alternative explanations available as to why the individual was successful. Thus one way to minimize the impact of stereotypes is making success and failure information explicit. In addition, it is critical to ensure that decision makers have enough time available to make careful decisions. Research has demonstrated that decision makers are more likely to rely on stereotypes when they are busy and distracted by other work. Finally, another important factor that minimizes the extent to which decision makers will rely on stereotypes in making judgments is whether or not the decision maker is motivated to make an accurate decision. Thus organizations that hold people accountable for accurate decision making, provide sufficient time for decision making, and provide sufficient information to decision makers are less likely to have decision-making processes biased by stereotypes.

Another important factor in minimizing the impact of stereotypes of workers is to change the way that jobs are seen. One of the most important factors in determining who is seen as a good fit for a job is the characteristics of job incumbents. If job incumbents are mostly White and male, then White males will be seen as having matching characteristics for this type of job. If job incumbents vary in terms of social groups, then it is more likely that organizational decision makers will have to examine individual characteristics of workers, rather than rely on stereotypes to determine who is a match for a given job.

The effects of stereotyping workers in organizations are tenacious, because stereotypes come to mind automatically. Stereotypes influence both perceivers and the targets of the stereotype. One of the most important things that an organization can do is to simply acknowledge the effects of stereotypes so that individuals can actively work not to rely on them when making judgments.

STRATEGIC HUMAN RESOURCE MANAGEMENT (SHRM)

Organizational strategy refers to the overall positioning and competitive approach of an organization in the marketplace. Strategic management is the deliberate effort to align the organization's long-term direction with organizational strategy. Good strategic management integrates organizational functions into a strategic plan so that all organizational units operate in a coordinated fashion in support of the overall strategy. *Strategic human resource management (SHRM)*, then, is the process by which an organization's management integrates its human resource plans and programs with the strategic plan of the organization. SHRM stands in contrast to traditional human resource management (HRM), which contributes to an organization at the

operational level. For example, the traditional human resource (HR) concern of selecting job applicants who display skills that are predictive of good job performance may only be implicitly related to the strategic objectives of the organization.

A key feature of SHRM is the linkage formed between management and HR to align the functions of HR with the direction of the organization. SHRM links human resources vertically and horizontally as well as in present and future time frames. Vertical linkages entail connecting HR practices with the strategic management process of the organization, while horizontal linkages involve the coordination of various practices within HR through a patterned or planned action. HR strategies are linked to organizational plans, anticipated HR needs, and to HR programs that will be implemented to meet those needs. SHRM involves multiple HR processes, such as recruiting, selection, performance management, employee and career development, succession planning, retirement, and termination. Each of these can be linked to an organization's strategic objectives. For example, a planned business expansion into Eastern Europe could be supported by strategic employee development (e.g., providing language and cultural training to key employees to prepare them to meet business needs) or by strategic recruitment and selection (e.g., hiring Eastern European employees prior to the expansion).

STEPS IN SHRM

SHRM involves three steps: forecasting, strategy formulation, and implementation. Forecasting is the attempt to predict future events that will impact the organization and its needs through the analyses of the organization's internal and external environments (e.g., mission statement, goals, labor markets, opportunities, and threats). HR strategy formulation—that is, strategic human resource planning (SHRP)—involves the development of initiatives that are aligned with the organization's mission statement, strategic objectives, strengths and weaknesses, and opportunities and threats. Finally, HR strategy implementation involves putting the HR plan into action with HR programs that support the organization's overall strategy.

Forecasting

Predictability and control increase the precision of forecasting. Predictability is the degree to which one

can estimate the occurrence of an event, and control is the ability to orchestrate the likelihood of an event occurring. Greater control implies greater predictability, although some events over which one has little or no control are predictable. Predictability and control have important implications for how forecasting should be approached. Forecasting is more effective when forecasting techniques are compatible with levels of predictability and control. For simplicity, it is appropriate to distinguish among four levels of predictability and control. The first consists of events over which an organization has control, for example, closing outdated plants and scheduling layoffs. The second level involves events over which the organization has little control but which are nevertheless predictable. For example, in some countries, organizations can predict retirements with a high degree of certainty because of government-mandated retirement ages. The third level consists of events that are probabilistic. Although they can be anticipated by extrapolating from historical trends, they involve a low to moderate degree of certainty because extraneous factors often alter previous patterns and because the limits to human rationality constrain the degree to which such events can be predicted. An example would be predicting skill sets that could have strategic implications. The fourth level involves events that are unknown, unanticipated, or random. These can include, for example, the unexpected death of a CEO or the introduction of new technologies that dramatically change labor requirements.

To be most effective, forecasting techniques should be congruent with the degree of uncertainty in a system. The greater the predictability and control of events, the more specific predictions can be. Techniques that use productivity ratios (i.e., the ratio of labor to output) to forecast labor demands are appropriate for predictable situations because they are based on straightforward prediction equations and they forecast specific numbers of workers for given conditions. However, in situations with less predictability and control, it is not possible to make specific predictions, and therefore the most appropriate forecasting techniques are those that provide general information. Forecasting in less predictable situations might, for example, involve looking at historical cycles in workforce demand and supply or at trends in demand for skills sets. Finally, in situations where future events are unpredictable, planning for any particular outcome is unwise. When forecasting is not

possible, a diversity (or variation) strategy is the best approach. As financial analysts have known for years, a diverse investment portfolio is the best hedge against losing money due to the uncertainty of the stock market. Similarly, SHRM activities that focus on variation are the best insurance against uncertain futures. A diverse HR portfolio increases the probability that one of the variants may prove useful for unexpected contingencies. Examples of HR programs that foster variation include allowing employees to choose a certain proportion of their yearly training courses; randomly selecting job applicants from a generous short list of those who meet basic qualifications; formalizing structures that encourage frequent informal interaction; instituting more lenient performance management policies that do not punish employees who work in nontraditional ways and who think unconventionally.

HR Strategy Formulation

The HR strategy formulation phase is a complex process that involves making decisions about HR activities based on forecasts, organizational strategy, and the anticipated effects of HR programs on strategic objectives. An important process in SHRP is linking HR functions to other processes in the organization. The goal of linking is to establish a closer relationship between management and HR and therefore increasing the likelihood of developing HR policies that are congruent with the organization's strategic objectives. Linkage is related to the amount of contact among the organization's strategic planners, the HR department, and the managers who will be responsible for executing the plans. Linkages can range from minimal (groups working independently) to full integration (groups working interdependently), but they are typically blended. For instance, information pertaining to hiring may flow both ways, whereas information regarding funding of projects might be handed down from the top management to HR. The appropriate degree of linkage depends on the business climate, organizational needs, and corporate strategy; however, some linkage between HR and management is generally necessary. A disconnect between planners and managers can easily derail the planning and implementation processes.

The probability of successful SHRP can be enhanced by starting with a simple plan (for example, forecasting the number of anticipated hires needed the following year based on typical levels of attrition at a

given site). As leaders gain experience using simple forecasting models, and as those models provide useful data that integrate with and help guide strategic business planning, the level of sophistication of the SHRP may increase. In some cases, however, it may never progress beyond a basic attrition-based replacement model; that may be all that's required under the circumstances. In other cases, complex algorithms based on multiple data sources may generate the needed (and useful) data. The point for HR to keep in mind is to use only what works and is needed—not more, and not less.

Implementation

Strategy implementation involves the integration of the larger organizational strategy into the HR functions of the organization, and it is arguably as—or more—complex than strategy formulation. Employee recruitment and selection, training and development, performance management, and labor and employee relations may all have to be altered by HR in order to integrate with the organizational strategy. Unlike the formulation process, implementation is an organizational intervention; and organizational interventions require assistance—at the very least, cooperation—from members of the organization.

Unfortunately, resistance to the planning process and to the strategic HR plan is a common outcome of planning, and therefore it must be managed appropriately. Resistance on the part of any group can be detrimental for strategy implementation. Resistance may stem from internal organizational politics, and it may influence the accuracy of the data that managers provide in the forecasting and planning stages. For example, managers interested in protecting turf or enhancing their unit's power may inflate their estimate of the number of new employees they need. In other cases, managers may just not respond to requests from HR for planning because of heavy workloads, competing business priorities, and uncertainty about future needs. Managers may view the outcome of SHRP as being of little value—because they view it as providing insufficient information to guide policy or business decisions (e.g., number of hires is given for a region, rather than an individual location or country; the types of skills, experience, or education required are not described), or because they view it as so detailed that implementing it would be too burdensome (e.g., a plan calling for master's-level chemical engineers, with at least at a 3.27 grade point

average, who have worked in the United States doing polymer chemistry to be split evenly across five sites in Southeast Asia). In these cases, calls to implement the plan will probably be resisted or simply ignored.

Strong relationships with business leaders, a good understanding of the business, and a willingness to modify plans where necessary are helpful in implementing strategic HR plans. Given the possibility of pushback from business leaders and lack of utilization of SHRM processes and plans, HR must take an active role in ensuring that the SHRM process is relatively painless and provides truly useful data to assist in business planning. Understanding what information business leaders need, what is actionable, and what is realistic are keys to making SHRM work. A strategic HR plan that is not, or cannot be, implemented is of no use to the organization.

COSTS AND BENEFITS INHERENT IN SHRM

If the success of any type of strategic planning is measured by the accuracy with which actual plans and forecasts come to pass, then the success rate of strategic planning is rather dismal. In most situations, managers and HR professionals cannot accurately forecast how the environment will change in the future and what specific HR capabilities will be needed to perform effectively in future environments. Planning involves assumptions about the environment and about the future. As environments become more complex, uncertainty increases and assumptions are more tenuous, and most organizations typically operate in complex social, political, and economic environments.

Fortunately for practitioners, empirical studies show a positive relationship between the use of SHRM and bottom-line outcomes, such as stock share price and employee productivity. In contrast, there does not appear to be a relationship between competent performance of technical HR duties and organizational performance. This underscores the importance of strategic, rather than technical, human resource management. These successes of strategic planning may be due to a number of factors. One is that organizations may be tailoring their planning processes to uncertainty levels—planning more generally in more uncertain environments, which in turn produces adaptive outcomes (not all of which can be predicted). In addition, the planning process may be just as important, if not more important, than the plan itself. Organizations that engage in strategic HR planning are likely to have

processes that require frequent interaction among executives, managers, and HR professionals. This means that the right people are talking about the right things at the right time. Plans themselves inevitably need updating and modification as circumstances dictate. Processes that modify and update plans help to ensure that plans stay relevant and useful.

RECENT DEVELOPMENTS

Globalization, technology, and diversity are recent developments that have had a significant impact on the process and use of SHRM. Globalization has brought with it increased competition and uncertainty, making future planning critical but increasingly difficult. The movement of people between countries has increased because of free trade agreements and visa programs. No longer is an organization limited to local hiring programs. Organizations can (and often should) consider regional, or even global, talent pools. Multinational organizations must plan not only for the needs of one country but must consider the cumulative impact of events in all countries in which they operate. Recent discussions of offshoring highlight the need to think about a company's talent management and planning in global terms.

Technology has enabled instant, electronic collection of SHRM data and development of complex models to better predict human capital needs. However, it has also given rise to new forms of work (e.g., telecommuting, globally distributed teams, 24-hour operations) and new skills (e.g., computer literacy) that have added a layer of complexity to the SHRM process. The increasing importance of skilled human resources in information-age economies and diversity of employee populations are increasingly important issues in planning. Skilled employees are as important as capital and technology in high-tech and sophisticated service organizations. Acquiring, developing, and retaining high-talent employees cannot be done by seat-of-the-pants methods that use little or no planning and that do not integrate HR programs with strategic plans.

Diversity has become important because of equal opportunity and affirmative action laws, which are no longer limited to the United States but are becoming widespread internationally (e.g., Brazil, South Africa, India, Canada, Malaysia). In addition, matching employee demographics to the demographic makeup of the regions in which the company does business is

now a critical ingredient of successfully competing in a global marketplace. Diversity of thought, style, and experience is also a growing consideration in the planning and implementation processes based on the premise that greater diversity leads to greater innovation, productivity, and company value.

CONCLUSION

Organizations now operate in an increasingly global, technologically sophisticated, and interdependent world, which has intensified competition among organizations. This, in turn, increases the importance of human resources and makes viable SHRM processes all the more critical to organizational survival and effectiveness. Without processes to explore organizational needs, create and modify plans to meet those needs, and align human resource management practices with the strategic objectives, organizations will increasingly be at a competitive disadvantage.

STRESS AT WORK

Stress is an experience that disrupts a person's emotional and physical state, such as having too much work that causes someone to become overtired or getting into an argument with a coworker that results in anger. Life itself is inherently stressful, so it should be no surprise that stress is an integral part of the workplace, and in fact a great deal of a person's stress comes from work. Studies have shown that stress occurs often at work, with most people able to recall at least one stressful incident in the prior month, and 10 percent to 15 percent of employees saying they had experienced *stress at work* in the prior day.

Job stress researchers distinguish stressors (factors at work that disrupt a person's emotional and physical state) from strains (a person's reactions to stressors). Stressors can involve the nature of the job itself, interactions with other people, and rewards. Strains are classified into behavioral reactions (e.g., calling in sick when not ill or drinking alcohol), physical reactions (headache or heart disease), and psychological reactions (experiencing anger or anxiety). People vary in their ability to cope with stressors, and different people may react in different ways. For example, when assigned a difficult task, one person might work extra hours the next day to successfully complete it, whereas another might call in sick.

The basic job stress process involves the reaction of people to the work environment. During the day at work, people are aware of circumstances and events that are occurring. Some events will be perceived and interpreted by an individual as a stressor in that it will cause a disruption to the daily routine. The person might see the event as a challenge to be met or a threat to well-being. Most likely the disruption will first result in an emotional reaction such as getting angry at a rude customer or anxious over being asked to take on an unfamiliar task. The emotional response will be accompanied by physical changes to the body, which over time could result in physical symptoms such as a headache or stomach distress. Finally, the person might take some sort of action that might be constructive (e.g., seeking assistance for the unfamiliar task) or destructive (e.g., insulting the rude customer).

There are many additional factors that help determine whether a given event will be perceived as stressful and whether or not the stressor will lead to particular strains. Perhaps the most important element is an individual's control over the situation. If a person feels in

Table 1. Most Commonly Studied Stressors

<i>Stressor</i>	<i>Definition</i>
Interpersonal conflict	Getting into arguments and fights with others that might include insulting, nasty, and rude behavior
Organizational constraints	Conditions of work that interfere with people being able to do their job, such as defective materials or unreliable equipment
Role ambiguity	Uncertainty about what people's responsibilities are and what they are supposed to accomplish at work
Role conflict	Incompatible demands such as being asked to be in two different locations at the same time
Work overload	Either too much work or work that is too difficult for the person to do

control, an event is less likely to be perceived as a stressor, and a stressor is less likely to result in strains. The person's personality is also important, as some people are more prone to experience stressors and strains than others. Finally, assistance and emotional support from other people can reduce the impact of stressors.

STRESSORS AND STRAINS

Much of the scientific research on job stress has been devoted to determining the conditions and events at work that are perceived by employees to be stressors and how those stressors result in strains. A series of studies have been conducted in which people were asked to relate an incident at work that was stressful, and these incidents were analyzed to look for recurring patterns. These studies have been done not only in the United States but also in Asian countries (e.g., China and India) as well. What they show is that there are certain universally experienced stressors, some occupation-specific stressors, and some stressors that are culturally determined. For example, having conflicts with coworkers and supervisors and having too much work to do are universal stressors experienced by employees across different occupations and countries. Not having enough control at work is mainly an American issue not often mentioned by Asians. However, not being given enough direction by the supervisor is an issue for Asians but not Americans. In terms of occupational differences, engineers find having their time wasted to be particularly stressful, whereas nurses find dealing with patient death to be a problem for them.

Most research on job stress has used a survey approach, asking employees to indicate the level of stressors and strains they experience on the job. The

table above contains a list of the most commonly studied stressors and their definition.

Each of these stressors (to be discussed in detail below) has been linked to strains. Table 2 lists commonly studied job strains that have been linked to stressors, in the categories of behavioral, physical, and psychological. Most of these are immediate responses to stressors, although some such as heart disease can take many years of continual exposure to stressors.

INTERPERSONAL CONFLICT

As noted above, when asked about stressful incidents at work, interpersonal conflict is often mentioned. Getting along with coworkers, supervisors, and others at work is an important aspect of well-being. Working people spend a great deal of their waking hours at work, and so getting along at work is important. Individuals who find themselves isolated from others, in conflict with others, and the brunt of abusive and nasty acts will experience emotional reactions, such as anxiety and sadness that in some cases can be extreme, and they can in turn lead to both behavioral and physical strains such as headaches and stomach distress. This can lead employees to avoid work by calling in sick and taking overly long breaks.

Conflict with supervisors can be particularly problematic, because the supervisor has control over much of the employee's work life, such as rewards and work assignments. Furthermore, it can be difficult to avoid or ignore a supervisor, resulting in continual unpleasant encounters and possibly the experience of retaliation by the supervisor.

It is not uncommon in organizations for certain individuals to be singled out for bullying by one or

Table 2. Commonly Studied Job Strains That Have Been Linked to Stressors

<i>Category of Strain</i>	<i>Strains</i>
Behavioral	Avoiding work, e.g., calling in sick, taking long breaks Drinking alcohol or taking drugs Getting into fights Poor job performance Smoking Starting arguments
Physical	Dizziness Headache Heart pounding Stomach distress Heart disease
Psychological	Anger Anxiety Bad mood Frustration with job or people Poor job attitude

more coworkers and supervisors. This can include being the brunt of nasty comments and practical jokes, being excluded from positive social interactions such as going to lunch, and being given no assistance by others. Extreme cases of bullying have led to emotional breakdowns requiring hospitalization. This occurs often in European countries, where job mobility has prevented the individual from switching jobs.

Another possibility is that conflict among employees can escalate into physical violence. Most instances of employee-to-employee violence is mild, consisting of pushing and shoving, but extreme cases of assault with a weapon do occur. Rare cases of homicide are typically featured in the national news, such as the rather well-publicized multiple murders in the U.S. Postal Service. For example, after experiencing months of bullying and harassment by supervisors and then being fired for insubordination, Thomas McIlvane returned to work on November 14, 1991, and killed four supervisors and then himself.

ORGANIZATIONAL CONSTRAINTS

Constraints in the workplace are things that interfere with an employee's ability to perform the job well. This can include insufficient physical resources

such as equipment or supplies, inadequate training, missing information, or lack of time. It seems obvious that constraints would result in poor job performance, but they are also experienced as stressors. Most employees wish to perform their jobs well, and conditions of work that make this difficult will result in strain. Although not as severe as interpersonal conflict, constraints can lead to anger and frustration over the job being made unnecessarily difficult or the inability to perform well. This also can lead to poor job attitudes and avoidance of work.

ROLE AMBIGUITY AND ROLE CONFLICT

Although role ambiguity and role conflict are different kinds of stressors, most researchers have studied them together. Role ambiguity is the lack of clear direction and guidelines about an individual's responsibilities at work. It is not uncommon for an employee, particularly at professional or supervisory levels, to be given only ambiguous and vague directions about areas of responsibility. Thus within an office it might be unclear about who is to make decisions in some areas; for example, an assistant manager might not be certain whether the purchase of particular items needs to be cleared with his or her superior. Thus there might be anxiety produced over not being sure if he or she should ask permission and risk being seen as indecisive or place the order and risk being accused of exceeding authority.

Role conflict includes a variety of ways in which there can be conflict about responsibilities and tasks. Some conflicts can arise because of incompatible demands by the same supervisor, for example, to work faster but be more accurate. Other conflicts occur because of incompatible demands by two or more individuals; for example, two supervisors ask that their task be done by the end of the day when there is only time to complete one of them. Finally, work/family conflict occurs when there are incompatible demands made between work and non-work, such as having to take a sick child to the doctor on the day of an important work meeting. In the United States and other industrialized countries, there has been a trend toward more single-parent households, households with both parents working, and households with elderly dependents. Such circumstances have produced increased family demands on working people that can produce work/family conflict.

Both role ambiguity and role conflict have been linked to strains, although more to psychological than the other varieties. Both of these variables (with the

exception of work/family conflict) have not been found to be often mentioned by people when noting stressful incidents at work, and they have not been found to be as severe as other stressors. On the other hand, work/family conflict has been shown to be important, with links to both physical and psychological strains. For example, individuals experiencing high levels of work/family conflict will tend to experience physical symptoms, poor job attitudes, negative mood, and symptoms of depression.

WORK OVERLOAD

There are two types of work overload: being asked to do too much work and being asked to do work that is too difficult. Too much work can arise because of organizational constraints that prevent efficiency, insufficient numbers of staff members to share the load, or inequitable distribution of work, where some individuals have heavier workloads than others. It can also arise because an individual is unable or unwilling to handle what should be a reasonable workload, thus putting an extra load on others. An individual might not have the skill to perform the job efficiently or might have low motivation and waste a great deal of time making it difficult to complete tasks. Work that is too difficult can arise because the job is poorly designed, making it difficult for anyone to perform, or because the individual doesn't have the necessary skills. The solution for work overload depends on the cause and whether it resides in the organization or employee. On the organization side, reduction of overload might require redesign of the job, reduction of constraints, hiring of more employees, or reducing the amount of work to be done. On the employee side, it might require selection of individuals better able to handle the load, particularly if the work is too difficult, or training employees to increase their efficiency and skill.

Work overload is a stressor frequently noted by people across countries and occupations. It has been linked to a variety of behavioral, physical, and psychological strains, although reactions to work overload can be different than to other stressors. Whereas other stressors may produce high levels of emotional distress, overload produces fatigue that in the long run can have detrimental effects on health and well-being.

WORKING HOURS

Related to work overload is the number of hours a person works within a day and within a week. Often

working hours arise from heavy workloads, but it is possible that an organization produces work overload by requiring more work within the same amount of time. The standard 8 hours per day, five days per week is being increasingly replaced by longer work days (e.g., 10 hours per day) and longer workweeks that can exceed 50 hours. Long workweeks are a particular problem in organizations that have engaged in downsizing, where the survivors are expected to complete the work of those who have left the organization. Long workdays have not been shown to produce particular strains other than fatigue with some jobs. However, long workweeks have been linked to heart disease when people are required to work in excess of 48 hours per week and wish to work less and when they don't get extra compensation for extra work. In part this had led to working-hour restrictions in the European Union, but such restrictions have not been adopted elsewhere in the world.

CONTROL

A critical element in the connection between the environment, perceptions of stressors, and strain is the control employees have over their work situation. Certain environmental events, such as the assignment of a difficult task, are not automatically perceived as stressors, and stressors don't automatically result in strain. These connections are affected by the control the employee has over the situation. For example, if the individual is able to refuse the assignment without penalty, or influence how, when, and where the assignment will be completed, it is much more likely that the event will be seen favorably as a challenge to be met rather than unfavorably as work overload.

There are different ways in which employees can have control over workplace stressors. Employees may have control over tasks, being able to choose which ones are to be performed, the procedures by which they are performed, and the scheduling of tasks. This enables employees to regulate stressors by finding approaches to tasks to reduce strain, taking breaks to reduce strain, or avoiding stressful tasks entirely. They might have control over other people, for example, the ability to avoid working with a particularly quarrelsome individual. Employees might be able to choose their own work schedule or their own location. This helps eliminate role conflict as well as avoid individuals at work with whom the employee has conflicts.

For control to be effective, an individual must perceive that he or she has control over the stressor. Just

giving an employee control that the employee does not recognize is not effective. Although it might seem that control is clear cut, in many organizations employees are not certain how much control they are allowed to exert. This can be part of role ambiguity when organizational policies are ambiguous about how much latitude an employee is permitted.

Jobs differ considerably in the amount of control they allow. For example, an assembler working in a traditional factory is required to perform a particular operation, such as attaching the wheels to an automobile. There is relatively little latitude that can be allowed, as the speed of the line and the task demands specify what needs to be done and when. A middle-level manager, on the other hand, has a job with tasks that are much less defined, allowing a great deal of employee control.

Research on control has shown that it relates to both psychological and physical strains. Employees with low levels of control tend to have poor job attitudes and experience emotional distress at work. They also experience physical symptoms, and research has even linked low control to heart disease. However, the link between control and strain is complex, as will be discussed in the following discussion of the demand/control model.

DEMAND/CONTROL MODEL

The demand/control model states that control buffers the effects of stressors that are termed demands. Specifically, it suggests that when an employee has low control, a demand (stressor) is likely to lead to a strain. When control is high, demands will be seen more as challenges and not lead to strain. Put another way, when control is low, as demands increase in frequency and severity (e.g., arguments with others or workload), strain will increase as well. When control is high, increased demands will not lead to strain.

Jobs by their nature may tend to be high or low in both demands and control. Jobs that are of relatively low demand do not cause concerns about strains, and so for those sorts of jobs, control might not be important. However, other jobs by their nature may be high in demands, and for those jobs, low control can be a problem. Thus it is recommended that jobs with high levels of demands be given high control.

Research on this model has not been entirely supportive, suggesting that the interplay between control and demands is likely more complex than the model suggests. Nevertheless, there is evidence that control can serve as a buffer with a variety of physical and

psychological strains, some of which might be related to heart disease.

MACHINE PACING

Most jobs allow employees to pace their own tasks, although hovering supervisors might put pressure on individuals to maintain the workload. However, some tasks are regulated by machines, for example, with assembly lines or computer systems. Many traditional factories have products move down a conveyor belt with employees lined up to perform a series of assembly tasks. Since the tasks must be done in order, the conveyor belt controls the pace of work. Individuals have little latitude to control pacing, since new items appear at a fixed interval, for example every eight seconds. If the person leaves his or her station, the entire process breaks down, so breaks must be carefully scheduled. Some computer systems work similarly in that the employee is given a fixed amount of time to complete each task, with the system prompting the employee to move on to the next task at the required time. Still other systems track response time, for example, for a telephone operator, and will give feedback if the person is taking too long to answer or is spending too long on the phone with a customer.

Research on machine pacing has clearly shown that it can be stressful and that it is linked to strains. Studies that have compared machine pacing to self-pacing have found it to be associated with anxiety at work, poor job attitudes, and physical symptoms. A series of studies at the University of Stockholm have linked machine pacing to physiological responses of employees. In these studies, employees' urine samples were assessed for the presence of stress-related hormones. Machine pacing was found to be associated with elevated levels of adrenaline, noradrenaline, and cortisol. The first two hormones are associated with effort and likely reflect that it was a harder task to keep up with the machine. Cortisol is associated with distress, and these results suggest that employees found the machine pacing to be a strain. Of particular concern is that elevated levels of cortisol have been linked to heart disease, suggesting that long-term exposure to machine pacing might contribute to this serious illness.

COPING AND SOCIAL SUPPORT

Employees are not passive recipients of stressors, but rather they actively engage their environments,

adapting the workplace to themselves and themselves to the workplace. As noted earlier, control allows the individual to avoid and modify stressors, thereby regulating to some extent the frequency and severity of exposure. However, not all stressors can be controlled, so individuals may have to make personal adjustments to deal with them. Both the nature of the situation and the person determines how stressors are addressed.

Coping refers to the means by which employees deal with stressors, by either making adjustments to the workplace or to themselves. *Problem-focused coping* is an approach by which the individual attempts to change the stressful situation. For example, if the stressor is a heavy workload caused by an additional assignment, the person might work out a plan to increase efficiency to complete the work within the allotted time, ask a coworker for assistance, or negotiate the postponement of other tasks until the assignment is completed. If the stressor is a conflict with another employee, the person might attempt to reach a resolution, either by trying a different approach with the other employee or asking a supervisor to mediate the conflict. Problem-focused approaches are most likely when individuals perceive control over the situation and are confident that they can be successful in dealing with the stressor.

Emotion-focused coping, on the other hand, deals with the person's own strain reactions rather than the stressor itself. This might entail attempting to reduce the strain through distraction (e.g., playing a game of tennis after work), drinking alcohol or taking other substances that might reduce the emotional response, or talking things over with a family member or friend. Both means of coping can be effective in dealing with strain, but problem-focused coping is considered more effective. Furthermore, people are not limited to one or the other, and often both forms of coping are used. For example, an employee might successfully deal with a stressful situation at work (problem-focused) but then go the gym afterwards to work out the frustrations of the day.

Social support is the assistance people (e.g., coworkers, including supervisors, friends, or family members) give one another in dealing with stressors. Paralleling coping, social support can be material in helping the person deal with the stressor, or it can be emotional in helping the person deal with the strain. Material support consists of help with doing tasks or dealing with issues related to stressors. With workload, for example, a coworker might agree to help with some tasks. With work/family conflict, the supervisor

might agree to reschedule a meeting so that the employee can take a child to a doctor's appointment. Emotional support is lending a sympathetic ear to the person who wants to talk about their work problems, or spending time with the person doing activities (e.g., playing tennis) that help cope with work stress.

Although social support can be effective in helping an individual cope with stressors, the same individuals who provide support can also be a significant source of stressors. The coworker who today helps with a task might tomorrow expect the same help, and the family member who today is sympathetic might tomorrow be a source of conflict. However, social support in combination with control can be an effective means for employees to deal with stressors at work, either by helping to reduce them or by helping to reduce strain responses.

INDIVIDUAL DIFFERENCES

People differ tremendously in their responses to the workplace. Given the same situation, for example, a difficult job assignment, one person might perceive it as a stressor, whereas another will perceive it as a wanted challenge. If the former person is unsure of his or her abilities, the assignment might seem overwhelming and threatening. If the latter person is ambitious and anxious to show the boss what he or she can do, the assignment is a long-awaited opportunity. The former person might experience anxiety and frustration, whereas the latter person will be enthusiastic and excited.

Three personality variables are particularly relevant to stress, two because of their link to perceived control and one because of its link to emotions. Locus of control refers to people's belief about whether or not they can control rewards at work, and self-efficacy is people's belief in their own abilities. People with an internal locus of control believe they are in control. People with an external locus of control believe outside forces are in control, such as powerful others (e.g., supervisors) or luck and fate. Because they see the workplace as controllable, those with an internal locus of control are less likely to perceive stressors than their external counterparts. When they do see stressors, those with an internal locus of control will be likely to attempt problem-focused coping strategies to deal with them directly. Thus internals perceive fewer stressors and experience less strain.

Similarly, those who have high self-efficacy believe they have the capability to do their jobs effectively. Particularly when it comes to task-related stressors

(e.g., workload), those high in self-efficacy will be less likely to perceive stressors than those low in self-efficacy. Rather, they will see challenging situations they believe they can effectively address. If they do perceive stressors, they will be more likely to engage in problem-focused coping approaches to directly deal with them.

People differ in their tendencies to experience negative emotions, as reflected in their level of negative affectivity (NA). Those high in NA tend to frequently experience anxiety and other negative emotions and can be quite sensitive to the environment. Such individuals have been shown to be predisposed to perceive stressors and respond emotionally. They exhibit high levels of psychological strains and physical symptoms associated with strong emotions, such as headaches and stomach distress. By contrast, those low in NA will be less sensitive to both stressors and strains and will likely experience negative emotions far less frequently.

STRESS INTERVENTIONS

High levels of job stress can produce negative consequences for both individuals and their employing organizations. For the individual, it can adversely affect both physical and psychological health and well-being. For the organization, it can adversely affect employee attitudes and job performance. The management of job stress can have positive outcomes for both employees and employers.

There are three approaches one can take to the control of job stress. Primary approaches focus on the stressors themselves. Appropriate workloads, reasonable working hours, clear expectations, and coordination among managers to avoid conflict can all help reduce job stressors. However, even under ideal circumstances, job stressors cannot be completely avoided. They can be an inherent part of many jobs, such as a paramedic or police officer. This makes it essential to have additional strategies.

Secondary approaches are designed to assist employees in dealing with stressors, either through problem-focused or emotion-focused strategies. Most of these techniques involve training to either enhance job skills or stress management skills. Job skills can be helpful in dealing with stressors inherent in tasks. Greater job skills can help employees work faster and thus get their jobs done in less time. It can also reduce the effort required. Stress management training teaches employees strategies for dealing with stressors or

controlling strains. Stressor training concerns techniques for handling stressors, such as how to avoid conflicts with others. When strain is experienced, emotional reactions can be controlled through relaxation techniques, such as exercise, meditation, or yoga.

Tertiary approaches are used when the person has experienced sufficient levels of strains that they are causing significant problems that interfere with the ability to do the job. Employee assistance programs are available in most large organizations for employees who are having emotional or personal problems, which are often associated with stress both on and off the job. Clinical psychologists and other mental health professionals can provide treatment for individuals who are in need of this level of assistance.

SUMMARY

Job stress is an integral component of the workplace, as it comes with the territory in most occupations. The job stress process involves both job stressors in the environment and job strains experienced by employees. Common job stressors can reside in the job itself, such as workload, or in the social environment of work, such as conflict among employees. Strains that are responses to stressors can be physical, psychological, or behavioral, and often all three can occur together. In order to maintain both a healthy workforce and organization, job stress needs to be managed by both employees and their employers. Although it can't be eliminated, job stress can be kept at an acceptable level so that it doesn't distract employees from doing their jobs and doesn't adversely affect their health and well-being.

STRONG INTEREST INVENTORY

The *Strong Interest Inventory* (SII), typically referred to as the Strong, is a self-report measure of vocational interests and one of the most widely used psychological inventories in research and practice. Information obtained by the SII is used to inform important life decisions related to vocational choice and career development for individuals in educational, industrial or organizational, rehabilitation, and private practice settings. The SII has the longest history of any vocational interest inventory currently available, and the scores provided by the instrument are supported by strong evidence for reliability and validity.

HISTORY

The SII has been under continuous research and revision since first published by E. K. Strong Jr. in 1927. To select items for his inventory, first called the Strong Vocational Interest Blank (SVIB), Strong used

an innovative approach to scale construction now commonly referred to as the empirical method of contrast groups. This approach compared item responses provided by satisfied members of a particular occupation with those of an "in-general" group of employed individuals representing a wide range of occupations. Only items on which the two groups responded differently were retained for the scale that corresponded to that occupation. Thus, the resulting scores for each occupational scale measured the degree to which an individual's pattern of likes and dislikes was similar to that of happily employed members of that particular occupation. This approach assumed that members of a specific occupation have similar interests and that a person who shares those interests would likely find satisfaction if she or he entered that occupation. The original SVIB, developed using all-male criterion samples, consisted of 10 Occupational Scales (OSs). The first SVIB for women was published in 1933. Seven comprehensive revisions of the instrument—approximately one per decade—have been completed since then, each expanding the number of OSs. The most recent revision of the Strong provides scores for OSs representing 122 occupations.

The late 1960s saw the addition of the Basic Interest Scales (BISs) to the SII. The BISs were constructed using procedures to identify highly correlated items; they measure a single interest factor (e.g., athletics, science, and sales) per scale. In 1974, six General Occupational Theme (GOT) scales were added to the inventory. The GOTs measure the six broad areas of interests (Realistic, Investigative, Artistic, Social, Enterprising, and Conventional) in John L. Holland's theory of vocational types and also provide the organizational structure of the SII profile. The 1974 revision also introduced the first combined-gender form of the instrument. Since then, women and men have responded to the same items, although separate norms for women and men continue to be used because of clear differences in response patterns between genders. In 1994, the Personal Style Scales (PSSs) were added to the SII. These scales measure preferences for specific features of the work environment, such as working with people versus things or learning in a hands-on versus traditional academic manner. The additions of the BISs, GOTs, and PSSs helped clarify the interpretation of OS scores. They also significantly expanded the uses of the SII to include identifying leisure interests, preferences for being around different types of people, and comfort with working or living in a variety of environments.

The most recent revision of the Strong became available for use in 2004. Developers of this revision

(a) reduced the overall number of items by 10 percent and modified their response format, (b) added or relabeled scales to reflect changes in the world of work, (c) introduced an improved index for identifying inconsistent or atypical response patterns, and (d) reformatted the profile on which scores are displayed. However, the inventory remains fundamentally similar to earlier versions of the Strong.

ITEM BOOKLET AND PROFILE

The booklet for the 2004 revision of the SII contains 291 items, divided into six sections: (1) Occupations, (2) Subject Areas, (3) Activities, (4) Leisure Activities, (5) People, and (6) Your Characteristics. In the first five sections, respondents indicate their degree of interest in each item by responding to a five-point scale ranging from *Strongly Like* to *Strongly Dislike*. Items for the sixth section use a five-point scale ranging from *Strongly Like Me* to *Strongly Unlike Me*. The Strong item booklet can be administered online or in paper-and-pencil form.

The nine-page basic profile presents (a) descriptive information to introduce the instrument and each set of scales; (b) scores for the six GOTs, 30 BISs, 122 OSs normed using the respondent's gender, and five Personal Style scales; (c) administrative indices that include an item response summary and a scale to identify atypical response profiles; and (d) a summary page that highlights high scores on the profile. Other available profile options include an expanded interpretive report, profiles with added interpretive content targeting the developmental needs of college or high school students, and a profile that provides supplementary scales designed to measure skill estimates for the six Holland types.

GOTs

GOTs provide the most global view of interests on the Strong. The six homogenous scales contain items selected to represent each of Holland's six vocational types. The items for the GOTs were selected using statistical evidence such as their intercorrelations, their popularity among occupations representing designated Holland types, and their correlations with scale scores.

On the SII profile, GOT scores are represented using standard *T* scores, with a mean of 50 and a standard deviation of 10. These scores provide a comparison of the respondent's interest level for each of Holland's types to that of a large norm group of employed women and men. Scores are displayed in rank order using a bar

chart, and the first letters of the Holland types corresponding to the highest three GOT scores are used to assign a Theme Code to the individual. The Theme Code aids in the interpretation of other scale scores on the SII and helps integrate SII scores into Holland's theory of career choice and development.

Figure 2 displays the GOT scores for Amelia Sample Client, a 27-year-old female employed as a medical social worker for a large hospice organization. Her high scores are on the Artistic and Social scales, with her Conventional score above average but in the moderate range, and her other three scores below the mean for women and men in general. Her Theme Code of ASC is a shorthand classification of her interests. Holland's theory suggests that a work environment consisting of like-minded coworkers—that is, those with Artistic, Social and Conventional preferences—is likely to be experienced by Amelia as satisfying.

BISs

BISs were designed to measure 30 specific interest factors, representing a higher level of specificity compared to the GOTs in measuring interest domains. Similar to the GOTs, the BISs are constructed using homogenous item content, which makes them fairly straightforward to interpret. The names of the 30 BISs on the 2004 Strong were assigned to describe their item content and the interest factor measured by each scale (e.g., Protective Services, Medical Science, Performing Arts, Teaching and Education).

The BISs are organized on the SII profile based on their respective Holland types, which were assigned by identifying the GOT with which each BIS has its highest correlation. This gives the BISs the appearance of measuring subdivisions within the GOTs. The BISs also are presented using standard *T* scores (mean of 50, standard deviation of 10) but are computed using separate-gender norms, such that female respondents receive a profile with scores normed on a women-in-general sample and male respondents receive a profile with scores normed on a men-in-general sample.

As Figure 3 depicts, all four of Amelia's BISs under the Artistic theme are one standard deviation or higher above the mean. Under the Social theme, Religion & Spirituality (72), Counseling & Helping (63), and Teaching & Education (60) are high scores, while Office Management (65) and Nature & Agriculture (61) represent Amelia's high scores under the Conventional and Realistic themes respectively. These scores were consistent with Amelia's self-perceptions and also are

YOUR HIGHEST THEMES	YOUR THEME CODE
Artistic, Social, Conventional	ASC

illustrative of the ability of the BISs to measure leisure interests as well as career-related interests. For example, her Counseling & Helping and Teaching & Education scores clearly fit Amelia's career interests as a social worker, while other elevated scores are consistent with her enjoyment of singing in her church choir, cooking for her family and guests, and maintaining a plot in her community garden.

OSs

OSs on the SII provide the highest level of specificity among scales on the instrument. The OSs on the 2004 Strong were constructed using the empirical method of contrast groups, essentially the same procedure that E. K. Strong Jr. used to construct the earliest SVIB. Specifically, for the 2004 SII, a set of occupations was first selected for possible inclusion among available OSs. After this, occupational criterion samples were formed, with each sample consisting of employees who were recruited and screened to represent an accurate characterization of their respective occupation. Contrast samples of people-in-general containing members of a large number of occupations were then formed for each gender; these consisted of 1,125 women and 1,125 men respectively. Response percentages for each item were then calculated for both the occupational criterion samples and the women- and men-in-general samples. Comparisons were made between percentages for a

particular criterion sample and each "in-general" sample to identify items (on average, 28 per occupation) that differentiated the two. The last step involved obtaining raw scores for each occupational criterion sample on its own OS and using these scores to establish *T* scores for that OS. The resulting OS scores represent the degree to which the pattern of interests expressed by the individual respondent is similar to the likes and dislikes of workers representing 122 different occupations.

The SII profile displays the OS scores in bar chart form across three pages, with scores presented in descending order and clustered under the GOT on which each occupation's criterion group scored highest. The OSs also are assigned a Theme Code with one, two, or three Holland types based on the pattern of GOT elevations for each occupation's criterion group.

Figure 4 displays the OS scores under the Artistic and Social Holland Themes for Amelia. The interpretive rule-of-thumb described on the profile suggests that scores of 40 or higher indicate shared interests with satisfied employees in those occupations. (An OS score of 40, at one standard deviation below the mean, indicates similarity to 84 percent of the occupational criterion sample used to construct that particular scale.) Amelia's scores of 68 on the Social Worker scale and 61 on the Musician scale suggest that she shares many likes and dislikes with satisfied female employees in these occupations. This level of similarity, it is assumed, suggests that Amelia would find satisfaction if she entered these

The Basic Interest Scales represent specific interest areas that often point to work activities, projects, course work, and leisure activities that are personally motivating and rewarding. As with the General Occupational Themes, your interest levels (Very Little, Little, Moderate, High, Very High) were determined by comparing your scores against the average scores for your gender.

As you review your results in the charts below, note your top interest areas and your areas of least interest, and think about how they relate to your work, educational, and leisure activities. Take time to consider any top interest areas that are not currently part of your work or lifestyle and think about how you might be able to incorporate them into your plans.

occupations. The fact that she currently is a social worker—and is largely satisfied with her work (even if not with her employer)—demonstrates anecdotally the validity of the scale scores. In contrast, her low score on the female Architect scale suggests that her pattern of interests differs considerably from that of female architects. It is likely that if Amelia had the necessary ability to pursue a career in this field and had chosen to do so,

she would describe herself as an atypical architect in terms of interests and may report correspondingly low levels of satisfaction.

work environment itself. The Work Style and Learning Environment scales were developed using the empirical method of contrast groups, similar to the OSs. The Leadership Style, Risk Taking, and Team Orientation scales were developed using item inter-correlations, similar to the BISs.

The Work Style scale measures the degree to which respondents prefer working with ideas, data, and things (low scores) or people (high scores). The Learning Environment scale measures the extent to which the respondent prefers applied, hands-on training (low scores) versus traditional academic learning environments (high scores). Scores on the Leadership Style scale indicate the extent to which respondents prefer leading quietly by example (low scores) or assuming leadership of others (high scores). The Risk Taking scale measures comfort level for taking emotional, financial, and physical risks. Finally, the Team Orientation scale measures preferences for accomplishing tasks independently versus collectively. As Figure 5 displays, Amelia's scores on the Personal Style scales suggest clear preferences for working with and helping people (Work Style score of 60) and for making careful decisions and playing it safe (Risk Taking score of 40). Her other scores are closer to the mean for working women and men, and indicate moderate preferences for being an independent contributor, learning in traditional academic fashion, and leading by example rather than taking charge of others.

USES OF THE SII

Practice

The Strong is commonly used in career-counseling contexts to inform client decisions related to educational (e.g., college major) and career (e.g., occupational field) pursuits. Often, scale scores are used to steer clients toward career fields in which they express high levels of interests, although practitioners may also use SII scores to identify areas of interests that are less familiar to clients and that could be explored further. The SII can be used with individuals as young as 13 or 14 years old to introduce them to the process of career decision making, and is commonly used with young adults preparing to choose a career. However, the Strong also is useful in promoting the career development of adults after they enter the workforce. In some cases, SII data may provide adults

with ideas for new career paths, but others benefit from using interest scores to identify possibilities for modifying their current jobs to make them "a better fit" and thus more satisfying. Still other individuals find that their scores on the SII confirm that the career choice they made initially was in fact a good one for them. Adults in the workforce who might benefit from the SII include those who are looking for more challenging positions, who are questioning their initial career choices, who are experiencing career plateaus, who are anticipating layoffs and outplacement, or who are preparing for retirement.

Organizations typically use the SII along with measures of personality, abilities, and work history data to inform selection, classification, and placement decisions. The assumption guiding the use of the Strong in this context is that for individuals with the appropriate personality characteristics and ability profile, high levels of interest in a particular job area serve as intrinsic motivation to perform that job at a high level. Many organizations provide the SII or other interest assessments through employee assistance programs (EAP), human resource (HR) services, or occupational health psychology (OHP) programs.

Research

Establishing evidence for the reliability and validity of scale scores on the SII has been a major priority in the field of interest measurement and is a legacy of the Strong tradition. Reliability evidence for the 2004 SII suggests that the homogeneous scales on the instrument have high levels of internal consistency and that respondents tend to obtain similar scores on the various SII scales upon retesting at intervals of up to 23 months. This is testament to the stability of SII scales but also to the stability of the construct of interests over time. Evidence for validity has been investigated using multiple approaches and is generally strong. For example, scale scores tend to be highly correlated with scores on other inventories designed to measure the same constructs, and homogeneous scales (e.g., GOTs, BISs, PSSs) tend to separate occupational groups in predictable ways (e.g., elected public officials and school administrators tend to score high on the Leadership Style scale, while foresters and production workers tend to score low). For the Occupational Scales, considerable evidence exists to suggest that scores are effective predictors of satisfied occupational membership. For example, between 54

The Personal Style Scales describe different ways of approaching people, learning, leading, making decisions, and participating in terms. Personal Style Scales help you think about your preferences for factors that can be important in your career, enabling you to more effectively narrow your choices and examine your opportunities. Each scale includes descriptions at both of the continuum, with scores indicating your preferences for one style versus the other.

Your scores on the Personal Style Scales were determined by comparing your responses to those of a combined group of working men and women.

YOUR PERSONAL STYLE SCALES PREFERENCES

1. You are likely to prefer working with people
2. You seem to prefer to learn through lectures and books
3. You probably prefer to lead by example
4. You may dislike taking risks
5. You probably enjoy the role of independent contributor

Clear Scores (Below 46 and above 54)
 You indicated a clear preference for one style versus the other.

Midrange Scores (46-54)
 You indicated that some of the descriptors on both sides apply to you.

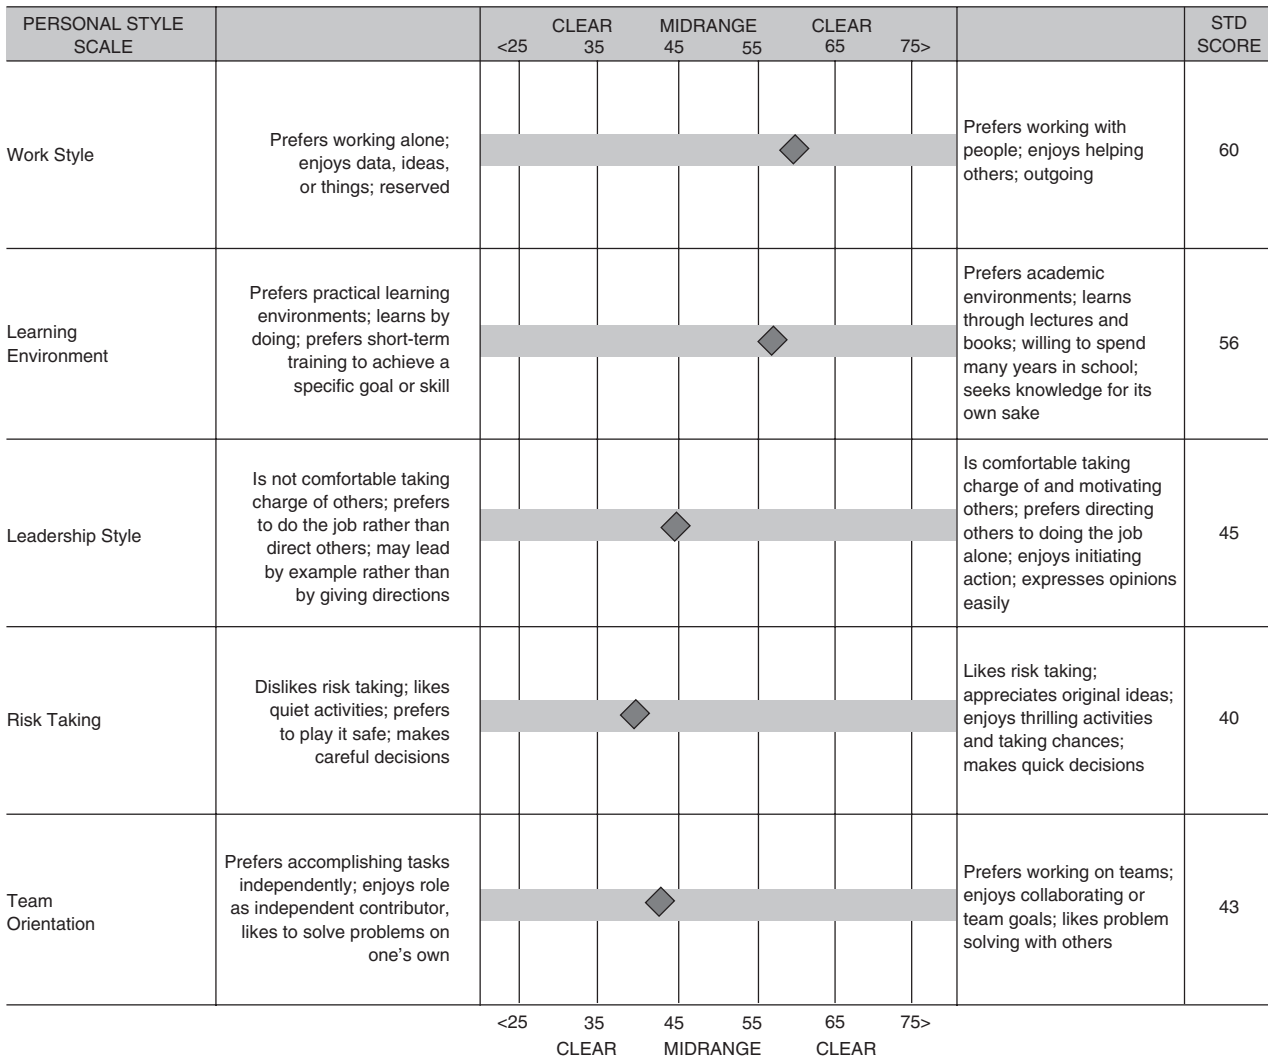

Figure 5. Personal Style Scales

percent and 74 percent of respondents across studies enter occupations predictable from earlier OS scores, even at intervals of longer than a decade.

Effective use and interpretation of any test requires an understanding of its validity across gender, age, and diverse racial, ethnic, and cultural groups. Studies of gender differences reveal that women and men do report differing levels of interests in some areas (e.g., women generally express higher Artistic and Social interests, whereas men generally express higher Realistic and Investigative interests). Evidence suggests that these differences are stable and robust at the item and scale score level over periods as long as 50 years, indicating consistency even through considerable societal change. For this reason, the SII continues to use separate-gender norms for most of its scales. Most investigations of the appropriateness of the SII across age have focused on differences between adolescents and adults. In general, evidence suggests that the level of interest scores tends to increase slightly as teenagers progress toward adulthood and that interests tend to be transitory until roughly age 17 or 18 for most individuals. Investigations of cultural differences on the SII have commonly examined mean differences in interest scores and differences in relationships among GOT and BIS scores across racial and ethnic groups. Results from such studies suggest that Strong scores have comparable validity across diverse groups. It is also notable that on the 2004 Strong, the standardized scores are computed using a normative sample of employed adults of which nonmajority groups comprise approximately 30 percent. Of course, effective use of the SII requires careful consideration of societal stereotypes and prejudices, language barriers, level of acculturation, assumptions about testing, family influences, and developmental needs of respondents.

Finally, the SII has been instrumental in basic research on the construct of interests and the role that interests play in career choice and development. For example, the Strong has been used to build the knowledge base related to the development of interests, the stability of interests, the structure of interests, the relationship of interests to other constructs (e.g., ability, personality, values, self-efficacy), and the degree to which interests predict important work-related outcomes.

CONCLUSION

The SII, carefully constructed at its origin with substantial attention to generating evidence for reliability

and validity, has been continuously refined over its long history. Currently, the Strong is the standard for sophisticated, empirically grounded, and practically useful interest measurement. Whether used for career counseling or for selection and placement, the Strong provides information that is useful in helping respondents make informed choices to develop their potential.

SUCCESSION PLANNING

Succession planning refers to an effort by organizations to select and develop future leaders who are prepared to replace current leaders. As such, a literature search will typically include articles that refer to analogous terms, such as the following:

- Replacement planning—to plan who will replace which key leaders in the firm

- High potential management—to select and develop persons who have the potential to replace the top 50 to 150 leaders
- Management and leadership—to put in place programs that develop future development leaders, not only for specific positions but, also, as a general talent pool. Sometimes succession planning refers to top-level leaders, whereas leadership and management development refer to lower level leaders
- Career and individual—to have a process and program for helping future leaders manage their own careers so that they qualify for key leadership positions

SUCCESSOR SELECTION

Personal traits that are often considered in potential appraisals are

- Good interpersonal skills
- Oral and written communication skills
- High intelligence
- Client orientation
- Achievement motivation or drive
- Results orientation
- Dealing successfully with adversity and hardship
- Operational effectiveness or resource management
- Ability to relate issues to business strategies
- Ability to get things done without being overbearing or disrupting the organization (political skills)
- Ability to organize, plan, and be efficient
- Ability to select and develop key staff
- Stress management

Jack Zenger and Joseph Folkman maintain, based on their leadership skills studies, that a future leader must have the minimal acceptable amount of each of these characteristics: an ability to learn from mistakes and develop new skills, interpersonal competency, being open to new ideas, taking personal responsibility for results, and an ability to take initiative. To not have an adequate amount of even one of these is to have a “fatal flaw.” Researchers agree that some very bright people have fatal flaws that, unless they are corrected, disqualify them for future leadership positions, what Morgan McCall has called “derailers.”

Beyond this, say Zenger and Folkman, it is important for leaders to build on and develop combinations of strengths in the following areas: leading change, having excellent people skills, being competent in your area of expertise, driving for results, and displaying high integrity and ethical character. Other

researchers agree that those choosing successors must consider a full range of leadership criteria, including “soft” skills and integrity, not just the ability to work hard, produce results, and be brilliant. Being able to accept risk and learn, and not only perform, is a foundational idea.

There is also a literature on the efficacy of various methods for selecting successors based on organizational criteria. Some of these methods include performance appraisals, boss recommendations, assessment centers, 360-degree feedback, psychological tests, competency profiles, kind of educational degree, place where the degree was received, and difficulty of the job assignments.

One critical problem is how to select a future successor (or leader). Some characteristics looked for in succession planning profiles are known to be stable for a long period of time (e.g. intelligence); however, the practice of identifying a future leader for an unknown business environment based purely on currently acceptable skill sets and current performance ratings may be flawed. As observed by Jon Briscoe and Douglas T. Hall, some metacompetencies that are sometimes cited as future-oriented are ability to work across boundaries, flexibility and willingness to change, team effectiveness, technical competency, and global mind-set.

Finally, it can be argued that what successful managers and professionals do at one career stage is not comparable to the knowledge and skills needed at higher level leadership stages. One must be able to acquire the advanced knowledge and skills at each relevant level or career stage to be considered a future leader.

SUCCESSOR DEVELOPMENT

Another critical issue in succession planning is how to train, develop, evaluate, and fine-tune future successors. As with selection, each industry and company has its own specific set of requirements.

In general, four models for the leadership development of successors have emerged, and while some companies use only one of these, many employ an amalgamation of them.

Model 1: Job Rotation

Numerous organizations believe that there exists an ideal portfolio of job experiences that future leaders

need before assuming top-level positions. They develop successors by transferring them, every 18 to 36 months, across a variety of positions: working in different functions (e.g. marketing, supply chain), working for a key people developer or mentor, working in a significant line or decision-making capacity working globally.

There are numerous problems with this approach. First, the average tenure of a talented person is much shorter today than it was in the past, so future leaders must be developed quicker and there is less time for extensive job rotation. Second, some of the most talented people are geographically bound and cannot easily accept job transfers. Third, it is unclear if occupying current jobs is good training for unknown future work or even if the position one occupies today will exist 5-10 years later.

Model 2: Talent Pool

Another option is to train future leaders more generally as part of a talent pool from which to draw successors as needed. Using this approach, the organization encourages its talent to accept various projects, enroll in courses, and take advantage of various opportunities that develop metacompetencies. Any assignments that include cross-boundary teams, “stretch” jobs, cutting-edge technology, key networking opportunities, or unusual personal growth are encouraged to prepare an individual for an unknown future leadership opportunity.

The problem with this approach is that it is difficult to retain upwardly mobile and talented future leaders when there are no visible paths or concrete signals leading toward upward mobility. Conversely, it is easy to raid another organization’s underutilized talent pool.

Some companies have found ways to integrate succession planning and leadership training so that future leaders are more generally developed but still able to understand the variety of future opportunities and what is necessary to be a candidate for each position.

Model 3: Buy Talent From the Market

Some advocate that it is more efficient to seek key talent from the labor market, where they have already been trained and developed by others. This is different from recognizing that it is impossible to promote from within for all leadership positions, because it is impossible to always find the best person within the

organization. Or as Kees Krombeen, former director of management development at Philips Electronics, told the author, “We grow our own trees but sometimes a job calls for a rare wood that we just don’t have.”

Boris Groysberg, Ashish Nanda, and Nitin Nohria argue that many “stars” from the outside are more like sputtering comets in their new jobs. The authors believe that the best successors have demonstrated inside the organization’s own culture how to be an effective business leader. They conclude that companies should raise their own stars and then take sufficient actions to retain them.

Model 4: Smaller Is Better

One of the surprising recent findings of Jon Briscoe and Brooklyn Derr is that numerous Fortune 200 companies now carefully develop their future successors using a mix of Models 1 and 2 above. However, they plan to shrink their successor pools and include only those who have both the talent to become high-level future leaders and who appear that they will remain with the company, if treated well, long enough to make a leadership contribution. This means that instead of a future leader talent pool of 800-1,000, the new successor pools are 200-300.

Methods used to develop talent for future leadership are internal and external coaching, mentoring programs, internal and external courses, assessment centers, project task forces, cross-boundary teams, international assignments, hardship assignments, and turnaround assignments.

Some researchers have also pointed out that different cultures have different paradigms and assumptions about successor profiles and how to develop future leaders. It is important to note here that this entry is discussing the models used by large multinational corporations and by organizations in the United States.

SYSTEMS PERSPECTIVE

Succession planning is managed in a variety of ways. One approach to succession planning asks the human resources or management development departments to develop procedures for selecting and developing future leaders at various levels and to then propose to top management at least two possible successors for every key position. This is a kind of replacement planning. Another succession planning system ensures that

there are two to three people from the general talent pool who are being developed and could be candidates, along with outsiders, for the key leadership posts.

Robert Guenther points out that after 172 corporate vice presidents perished in the World Trade Center disaster of September 11, 2001, many firms began taking their succession planning more seriously. The current population demographics, where lots of the leadership population is now over 55 years of age in the economically advanced nations and where there is scarcity in the under-30 age group, only seem to accelerate this felt need. Many companies are experiencing high turnover among senior leaders.

Most companies have a system to ensure that talented future leaders are recognized, selected, trained, developed, evaluated, and either eliminated or advanced at various critical stages. Whether formal or informal, open or secret, focusing only at the top, or going further down the hierarchy, there is normally some recognition that it is important to have “a leadership pipeline” and “leadership bench strength.”

A variety of models of succession planning have been suggested in the literature. One is the Inverted Funnel model, which looks at succession as selection, development, and fine-tuning over time. Another approach is the Rotary Model, which focuses on shorter tenure and on more fluid and faster in-and-out talent pool movement relevant to the new world of work. The Manager-Once-Removed (MOR) system focuses on developing an individual to move up two levels, whereas the Four Stages Model describes developmental issues for professionals and managers at four periods in the career based on learning competencies appropriate to each experience level or career stage.

CRITICAL ISSUES

Some critical issues have been highlighted in succession planning:

- What are the new leadership criteria for the twenty-first century? Subsequently, what are the necessary key competencies?
- How do we prevent top leadership from selecting successors who are their clones? The future may require very different leaders from the present.
- How do we ensure that the best people reach the top, not only those who have arranged their lives to perform continuously, move whenever necessary, and demonstrate company loyalty? Having motivation and stamina may not be the same as having talent.
- A related concern: How do we prevent burnout in the future leader group as they go from stretch to stretch assignments? How do we keep them from self-selecting off the succession track?
- Also related: How can talented women (and men), concerned about having and rearing children or being involved in elder care, take time-outs for caretaking without completely losing their opportunities?
- Another critical issue in succession planning is how to make selection competency based (not just cronyism, traits, and style).
- How do we prevent the “Hawthorne Effect” on designated successors moving along under the limelight but not adequately challenged or questioned?
- How can we focus not only on short-term performance but also on learning? Some very developmental assignments (e.g., global assignments) may be fraught with cultural frustrations and performance failures but high in learning potential.
- How do we keep managers from hoarding their best talent and preventing them from undertaking developmental assignments or job rotations? If these high potentials are allowed to leave, the managers are likely to be judged less productive.
- With the change in organizational structures in so many industries, how do we give greater emphasis to nonmanagerial leadership development (e.g., becoming a key team leader)?

CONCLUSION

Succession planning is currently one of the top five topics in human resource management. This may be due, in large measure, to the unique demographics (explained above) at this moment in time. Another perspective, however, is that preparing future leaders to succeed current leaders is one of the major responsibilities of any top management group.

SUPER'S CAREER DEVELOPMENT THEORY

Donald E. Super's (1910-1994) *career development theory* is perhaps the most widely known life-span view of career development. Developmental theories recognize the changes that people go through as they mature, and they emphasize a life-span approach to career choice and adaptation. These theories usually partition working life into stages, and they try to specify the typical vocational behaviors at each stage.

In the 1950s, when Super began to formulate his theoretical conceptions, differential psychology and the trait-and-factor theory permeated vocational counseling. The dominant assumption was that differing abilities and interests were crucial in determining occupational choice and success. For this reason, vocational counseling was seen primarily as a process of helping individuals match their abilities and other traits with those required by accessible occupations. By applying the matching model, practitioners of vocational guidance assisted their clients in choosing the "right" vocation, that is, the one that is well matched or congruent with an individual's abilities, interests, and personality traits. Super recognized the valuable contribution of the trait-and-factor theory and the matching model to vocational theory and guidance practice. But he also

believed that they were too static and insufficient in explaining the complexities of vocational behavior. Super proclaimed that occupational choice should be seen as an *unfolding process*, not a point-in-time decision. Therefore, he proceeded to supplement the trait-and-factor approach by constructing a comprehensive career theory in which (a) career development is seen as a lifelong process unfolding in a series of developmental stages and (b) career selection is not a one-shot decision but the cumulative outcome of a series of decisions.

In his attempts to shape a comprehensive career theory in the 1950s through the mid-1990s, Super complemented the traditional individual-difference approach to vocational guidance with three additional perspectives: (1) developmental perspective focusing on the life course of vocational behavior and stressing continuity in career development, (2) phenomenological perspective emphasizing the role of self-concept in the development of an individual's career, and (3) contextual perspective bringing forward the importance of multiple social roles and their interaction across the life span.

DEVELOPMENTAL PERSPECTIVE: UNDERSTANDING CAREERS IN THE LIFE SPAN

While traditional vocational guidance focused on occupational choice and the prediction of occupational success at some later point in time, Super stressed the need to understand and predict a *career*. He defined a career as a sequence of occupations, jobs, and positions held during the course of a lifetime, including also prevocational and postvocational activities. Super asserted that what was actually needed in vocational guidance was a *career model*, which takes into account the sequence of positions that an individual occupies during her or his working life. Interest in understanding careers led Super to look into peoples' *career patterns*, which portray one aspect of vocational development—the sequence of changes in occupational level and field over a period of time. Although initially "set out" by the individual's parental socioeconomic level, patterns are also determined by individuals' abilities, personality traits, and the opportunities to which they are exposed. The analysis of career patterns supported the view that the life cycle imposes different vocational tasks on people at various times of their lives. Drawing on the work of developmental psychologists and sociologists who

independently studied stages of life and work, Super and his colleagues outlined five major *stages of career development*, with each one characterized by three or four appropriate *developmental tasks*:

Growth (roughly age 4 to 13), the first life stage, the period when children develop their capacities, attitudes, interests, socialize their needs, and form a general understanding of the world of work. This stage includes four major career developmental tasks: becoming concerned about the future, increasing personal control over one's own life, convincing oneself to achieve in school and at work, and acquiring competent work habits and attitudes.

Exploration (Ages 14-24) is the period when individuals attempt to understand themselves and find their place in the world of work. Through classes, work experience, and hobbies, they try to identify their interests and capabilities and figure out how they fit with various occupations. They make tentative occupational choices and eventually obtain an occupation. This stage involves three career development tasks. The first one, the crystallization of a career preference, is to develop and plan a tentative vocational goal. The next task, the specification of a career preference, is to convert generalized preferences into a specific choice, a firm vocational goal. The third vocational task is implementation of a career preference by completing appropriate training and securing a position in the chosen occupation.

Establishment stage (25-44 years) is the period when the individual, having gained an appropriate position in the chosen field of work, strives to secure the initial position and pursue chances for further advancement. This stage involves three developmental tasks. The first task is stabilizing or securing one place in the organization by adapting to the organization's requirements and performing job duties satisfactorily. The next task is the consolidation of one's position by manifesting positive work attitudes and productive habits along with building favorable coworker relations. The third task is to obtain advancement to new levels of responsibility.

Maintenance (45-65) is the period of continual adjustment, which includes the career development tasks of holding on, keeping up, and innovating. The individuals strive to maintain what they have achieved, and for this reason they update their competencies and find innovative ways of performing their job routines. They try also to find new challenges, but usually little new ground is broken in this period.

Disengagement (over 65) is the final stage, the period of transition out of the workforce. In this stage,

individuals encounter the developmental tasks of deceleration, retirement planning, and retirement living. With a declined energy and interest in an occupation, people gradually disengage from their occupational activities and concentrate on retirement planning. In due course, they make a transition to retirement living by facing the challenges of organizing new life patterns.

Super's model demarcates the stages both with age bounds and task markers. Originally, Super viewed the stages as chronological, but later he also acknowledged an age-independent, task-centered view of stages. For example, individuals embarking on a new career in their middle adulthood might go through exploration and establishment stages. Thus the five stages spreading across one's entire life span, or the "maxicycle," might also be experienced as "minicycles" within each of the maxicycle stages. Individuals cycle and recycle throughout their life span as they adapt to their own internal changes or to changed opportunities to which they are exposed.

Super assumed that not everyone progresses through these stages at fixed ages or in the same manner. This notion led him to develop and elaborate on the construct of *career maturity* (initially called vocational maturity), which denotes the readiness of the individual to make career decisions. Operationally, it is defined as the extent to which an individual has completed stage-appropriate career developmental tasks in comparison with other people of the same age. Super and his colleagues devoted much effort to define this construct and develop appropriate measures. They identified five primary dimensions of vocational maturity: "planfulness" or awareness of the need to plan ahead, readiness for exploration, informational competence (comprising knowledge about work, occupations, and life career roles), decision-making skills, and reality orientation. Super believed that a young person should be mature enough to benefit from career assessment and counseling. In adults, where recycling through career stages is less dependent on age, Super suggested that readiness for career decision making should be referred to as *career adaptability*.

PHENOMENOLOGICAL PERSPECTIVE: THE NOTION OF OCCUPATIONAL SELF-CONCEPT

In his account of vocational behavior, Super incorporated in his developmental perspective the idea that people base their career decision on beliefs about their own abilities and other self-attributes. He saw career

choice as the process of implementation of self-concepts, work role as a manifestation of selfhood, and career development as an active process of improving the match between one's self-concept and the occupational environment. Self-concept can be defined as the way the person sees herself or himself. For example, a young woman might believe that she is bright and creative, self-confident, spontaneous in behavior, and unwilling to assume responsibility. This composite of her beliefs about her own abilities, traits, and values make up her self-concept. Since the self-concept is a subjective phenomenon or an appearance in experience, this perspective is often denoted as phenomenological.

Super accepted the view that self-concept is central for understanding a person's behavior. It is the product of the interaction of a person's inherited characteristics, neural and endocrine makeup, opportunity to play various roles, and resulting outcomes of role-playing success. Formation of self-concept begins in infancy when a sense of identity is developed. As they grow, individuals develop a personal image of their own abilities, personality traits, values, and roles. They then compare this subjective picture of themselves with what they get to know about the world's occupations, and they then try to translate their self-concept into an occupational perspective. The outcome is the occupational self-concept, defined by Super as a constellation of self-attributes that are vocationally relevant for the individual. The occupational self-concept eventually may transform into a vocational preference. Super believed that the career development process can be guided, among others, by aiding subjects to develop and accept their occupational self-concepts.

Thus the process of career choosing and development is basically that of developing and implementing a self-concept. The degree of satisfaction people attain from the work role is, according to Super, proportional to the degree to which they have been successful in their endeavor to implement self-concepts. This endeavor, however, requires a continuous personal adjustment; self-concepts develop and change throughout people's lives as does also their living and working environments. This makes the career choice and adjustment a continuous process.

CONTEXTUAL PERSPECTIVE: SOCIAL ROLES AND THEIR INTERACTION ACROSS THE LIFE SPAN

The third segment of Super's theory brings forward a contextual perspective, that is, the view of career

development in the context of all life roles enacted by an individual. The work role, albeit of central importance for many people in our culture, is only one among many life roles that an individual occupies in his or her life. None of the roles can be properly understood without taking into account the whole constellation of roles.

Already in his early theoretical writings, Super referred to work as a way of life and noted that satisfactory vocational adjustment is possible only when both the nature of work and the way of life complement an individual's aptitudes, interests, and values. However, this interdependency of various spheres of life is more completely addressed in Super's later writings, when he developed his life-span, life-space view to career development and portrayed it graphically in his popular Life-Career Rainbow.

Super conceives life space as a constellation of social functions arranged in a pattern of core and peripheral roles. People play a variety of roles during their life. Some of them begin early in the life course (e.g., that of child), others later (e.g., that of student), or still later (e.g., that of pensioner). At some life stages, a number of simultaneous roles (e.g., that of worker, spouse, homemaker, parent, and citizen) may constitute an individual's life structure. However, usually two or three roles are salient or relatively more important than others. The salient life roles constitute the core of a person; they are fundamental for the person's identity and essential for life satisfaction. The fact that people play several simultaneous roles means that roles interact and impact one another. The interaction among the roles can be supportive, supplementary, compensatory, or neutral. It can also be conflicting if some of the roles absorb too much of the available time and energy. As a matter of fact, for most people the interpenetration of different spheres of life is inevitable in some life stages. By combining the life space with the life-span or developmental perspective, the Rainbow model shows how the role constellation changes with life stages. As Super noted, life roles wax and wane over time.

This simple account was indeed needed to clearly emphasize an all-too-often forgotten point—that peoples' careers cannot be understood outside of their social context. To fully understand an individual's career, it is necessary to explore the whole web of his or her life roles. After all, according to a more recent view of Super's, it is the constellation of role interactions that constitutes the career.

CONCLUSION

Perhaps the most important single idea of Super was his tenet that occupational choice should be seen as an unfolding process. Interestingly enough, his theory building was also an unfolding process; he continued to augment and refine his theory throughout his life. Thus his theory also evolved through various stages that can be traced in their name modifications: from the original Career Development Theory to Developmental Self-Concept Theory, and then to the currently prevailing Life-Span, Life-Space Theory.

Super incorporated the ideas of many predecessors in his attempt to compile an integrative body of knowledge that comprises various perspectives on career development. The result was a comprehensive but also fragmental theoretical account. Super himself admitted that disparate segments of his theory need to be cemented together more thoroughly. He hoped that this task will be eventually accomplished by future theorists. However, in spite of his reluctance to present a more parsimonious and coherent theoretical statement, his theorizing was most appealing. Together with his followers, he has had, and continues to have, a major impact upon career development research and counseling.

SWEATSHOP LABOR

Sweatshop labor describes work performed under conditions that violate normal standards of minimum wage, employment, worker treatment, and workplace health or safety. It is an issue of great concern to human resource professionals charged with implementing employment laws and policies. While the term is most often associated with globalization and the movement of relatively low-technology jobs offshore by U.S. apparel manufacturers, sweatshop conditions can exist anywhere, including somewhat higher-technology firms or even in service industries. It can involve domestic operations hiring the unskilled, agricultural migrants, recent immigrants, or undocumented aliens. Particularly since the mid-1990s, controversy exists on many fronts regarding whether sweatshops assist or restrain the economic development and welfare of citizens where they are present. At the individual level, important ethical issues still remain for human resource professionals.

A good early example of sweatshops, at least by current standards, is the 1911 Triangle Shirtwaist Factory fire, where 146 mainly women and girls working in deplorable conditions died on the lower east side of Manhattan. This fire still ranks as one of the worst losses of life in U.S. workplace history. While the Triangle fire resulted in public outrage and passage of several antisweatshop laws, it was not until 1938 that President Franklin Roosevelt signed the Fair Labor Standards Act, which, at least on paper, outlawed

sweatshop production. Yet in September 1991, 25 workers died and 56 were injured in a Hamlet, South Carolina, chicken-processing plant fire. And Homeland Security checks following the September 11, 2001, tragedy in New York revealed several cases of Chinese immigrant workers still enduring sweatshop conditions in Manhattan garment district factories.

Sweatshops provide cost advantages in cases where labor wage differentials exist or can be created; these may involve immigrants (such as Triangle and post-September 11, 2001, garment district), women and girls (Triangle again, and current Vietnamese and Chinese export market garment and textile factories), and lower wage, less-developed countries. Legal restrictions on sweatshops make the practice more difficult but not impossible; but weaker legal frameworks often are involved. The practice is often easier to accomplish in areas where labor unions are either weak or nonexistent. The cost advantages from labor cost reductions become more important in cases of manufacturers of branded products, which typically require very high marketing expenses. As an example, Nike exhibits all types of wage differentials, with its branded sports and sportswear products manufactured by close to 500,000 people in 35 countries. An alternate example involves call centers in Bangalore, India, where almost universal literacy among the populace provides a labor pool that will work answering customer service phone calls for a fraction of the wage it would be necessary to pay in the United States or Western Europe.

In the late 1990s, public opinion began to mobilize against sweatshops. One example is the Clean Clothes Campaign, begun in Holland in 1989, which is a broad-based coalition of unions, consumer organizations, solidarity groups, and world shops in nine European countries. A more recent example is the United Students Against Sweatshops (USAS), formed in 1998, which links student activists at over 200 university campuses. The USAS succeeded in forcing Nike in October of 2000 to disclose the locations of 42 plants in 11 countries that make its college apparel. This same group campaigned in fall of 2003 to oppose discussion of the Free Trade Area of the Americas (FTAA), a potential expansion of the North American Free Trade Area (NAFTA). A group of student activists was also successful in forcing Nike in April of 2000 to make public its audit of labor practices at

600 related global manufacturing locations and in 2001 helped uncover the use of child labor by sports equipment manufacturers contracted by Nike.

International trade groups have also joined the sweatshops issue. The Japanese Federation of Economic Organizations adopted an updated Keidanren Charter for Good Corporate Behavior on December 17, 1996. In 1997, the Apparel Industry Partnership, created by the Clinton administration and including such well-known apparel companies such as Nike, Liz Claiborne, and Patagonia, publicized its Code of Conduct. As a result, many multinationals, including Nike, produced updated codes of conduct requiring contractors to fix harsh or abusive worker conditions. The International Labor Organization (ILO) Declaration on Fundamental Principles and Rights at Work was adopted in 1998, covering most major abuses of sweatshop-type operations. The Organization for Economic Cooperation and Development (OECD) adopted Guidelines for Multinational Enterprises at its Ministerial Meeting in 2000. More recently, Adidas-Salomon, Eddie Bauer, GEAR for Sports, Liz Claiborne, Reebok, Nordstrom, Nike, Patagonia, Phillips Van-Heusen, and Zephyr Graf-X all agreed to independently monitor and submit to external audits of their factories under the Fair Labor Association program. In April 2004, Reebok became the first apparel and footwear manufacturer accredited by the Fair Labor Association after establishing a compliance program that included both internal and external monitoring visits.

Other than the obvious ethical issues inherent in proper treatment of workers, economists and public policy researchers disagree about the overall impact of sweatshops on the economic development and welfare of the areas where they operate. Some say that no one is better off when workers receive only a minuscule share of the price for which these manufactured products retail and that consumers must unite to demand higher prices to allow for paying living wages to factory workers. Others argue that the antisweatshop movement is mistaken in its assessments. This group presents data that indicates that the comparatively higher economic proceeds earned by sweatshop workers allow them to found their own businesses and become independent contributors to the local economy. An example of this controversy is the economic participation of women and girls in Vietnamese export manufacture.

T

TEAM-BASED WORK

For an increasing number of jobs, the future belongs to teams. Due to the complexity of tasks, the need to integrate multiple perspectives and disciplines into work products and services, and/or the sheer volume of work, more people than ever will find themselves working in teams. For the many who have not been well trained for collaborative effort, the thought of this future can be unsettling. The United States, in particular, is a highly individualistic society where the traditional value of independence in thought and action may clash with the reality of a future of work in interdependent teams.

The research literature often differentiates between work groups and teams. Simply defined, a *team* is any group of people who engage in interdependent actions in the service of task accomplishment. This definition suggests a number of important points.

First, not all groups are teams. Collectives in which people can work independently with minimal coordination, or with coordination provided outside of themselves through management or other individuals, are not teams. Organizational departments are work groups but are rarely true teams. The need for interdependent effort defines a team and creates boundaries for team membership. Those who need to coordinate their efforts know who is part of their team and who is not. Vendors, suppliers, and contractors can support teams by providing resources or even by doing discrete parts of the work, but if they function independently, they are not part of the team.

Second, teams have a mission or goal that channels their efforts toward an outcome or outcomes. People

idly chatting around the coffeepot are not teams, nor are colleagues within the same work unit who work on different projects without the need for significant integration. Third, teams exist apart from organizations as well as within them. Preparation for team-based professional careers may take place through experiences with teams in educational or community settings.

All teams are not alike. Some teams are composed of peers doing similar work that needs to be integrated effectively to create value. They might be peers assigned to a project team on a particular assignment at work or to reach a decision, such as a jury. Other teams are cross-functional, where members have been trained in different disciplines or specialties and come together with others of different specialties to produce a unified product or service. Orchestras, or organizational decision-making teams composed of individuals from different professional specialties such as finance, sales, and human resources, are examples of such teams. As technology expands and organizations become more global in scope, virtual teams are becoming more common. In a pure virtual team, interaction may be conducted entirely through electronic means, including e-mail, teleconferences, and videoconferences, with a total absence of face-to-face contact. The work still requires interdependence, but coordination must be accomplished at a physical distance, which creates additional challenges.

Each of the types of teams described above may be short- or long-term in duration, comprising all or part of a person's work program. Although each type of team may require different skills for successful performance, two general sets of competencies are important for team members. First, they need competency in

their own area(s) of responsibility, whatever that may be, as do others engaged in individually based work. However, in team contexts, a second set of competencies involving the ability to work effectively with others rise in value. Models of team effectiveness typically include a component dealing with team process, that is, how a team combines their individual resources into a product through means of effective coordination, communication, decision making, and conflict management. Though the best of team processes may not be able to overcome a lack of requisite individual member skills, most models suggest that teams may fail to reach their potential if those skills are not effectively integrated through good process.

Effective team processes may be affected by characteristics and behaviors of individual members. In terms of the classic psychological Big Five personality characteristics, the importance of both agreeableness and conscientiousness might be expected to be more prominent in team settings. The ability to get along with others, and for others to be able to depend on you, is critical to the development of trust and cohesion in teams. For characteristics such as extraversion, however, the distribution of a trait across the members may be most important to success. It is good to have at least some people willing to talk, but too many voices actively vying for airtime might be counterproductive. Organizational citizenship behaviors such as pitching in as needed or contributing to non-work-related activities that promote social harmony and liking can also be valued team behaviors. The willingness to not only do one's own job but to look out for the team's needs and back up other members can make the difference between success and failure for a team effort.

Team members can also benefit from learning to handle conflict constructively. Coordination with others should produce differences in views that lead to better and more informed decisions. Yet to achieve these superior results, destructive conflict and turmoil within a team needs to be minimized. Individuals need to learn different ways to manage conflict and, where appropriate, to learn to seek integrated, so-called win-win, decisions that address the needs of all parties considered. Team members need to listen to others and be willing to extend themselves to understand the perspectives of diverse others for mutual benefit. In addition, as electronically mediated communication increases in both co-located and virtual teams, the importance of being able to write clearly and succinctly also increases.

Preparation for team-based work can include analyzing one's own success in team environments and modifying one's behavior as needed. Prior or in addition to organizational experiences with teams, people can experiment with their own behavior in teams. Getting opportunities to lead teams, to serve as members of effectively performing teams, and even to participate in ineffective teams can all help people better understand the requirements of team-based work as well as their own team skills. Fortunately, schools are increasingly aware of the need to develop team skills and are incorporating team projects into classroom activities, and opportunities to learn better team skills through volunteer work in the community are plentiful.

Even in individualistic cultures, working in teams like these can bring great satisfaction. Anyone who has ever watched a winning sports team celebrate has seen the intense joy and fulfillment that can emerge from collective success. With some additional thought and experience, even those who have been taught to seek and value independent effort and achievement can learn strategies to be successful in team-based work.

TECHNOLOGY AND CAREERS

Over four decades ago, Alvin Toffler predicted that our society would be affected by the Information Revolution due to technology provided by the computer. Clearly, this has occurred. We have moved from

an agricultural society to a factory/assembly line/manufacturing society, to an automated/knowledge-based society. There are few occupations that are untouched by technology. Whether an individual is involved with producing tangible goods or providing a service, technical advances have reshaped work and lifestyles. Today, employees' primary activities are gathering, creating, manipulating, storing, and distributing information related to products, services, and customer needs.

Technology has had a powerful effect on the nature of work and what jobs are currently in demand. In fact, jobs that were never even imagined 20 years ago are being created today. In the past, there were stable, clearly classifiable jobs (blue collar, white collar), while today there are many rapidly changing types of jobs (multitiered, technical, professional, executive jobs). Career preparation, choices, and objectives are different now than they were years ago. For example, today many individuals are targeting smaller firms, skill-contracting agencies, or starting their own businesses rather than working for larger firms. In addition, career objectives have changed from simply climbing prescribed organizational ladders to more personal development in areas of expertise. Individuals are less likely to work their entire careers at the same firm and instead are employed at various firms and by contracting agencies.

Almost all aspects of an employee's career are influenced by technology. From the time they are hired and selected (via Web site applications), trained (using online learning), mentored (via e-mentoring), evaluated (by computerized performance appraisals), as well as the type of work they do and where they do it (e.g., telework, virtual teams), they are exposed to some form of technology. Thus technology has also impacted how individuals apply for jobs, strategies used by employers to find employees and train them, and services provided by career counselors. Technology has also impacted vocational psychology and career guidance services. Counselors can provide future workers with a skills approach to their careers, thus enabling individuals to be transformed from powerless victims into knowledgeable, creative, self-initiated workers who can anticipate career shifts and plan for new career directions.

HOW TECHNOLOGY HAS CHANGED THE NATURE OF WORK AND SKILLS REQUIRED OF WORKERS

Changing Skills

Technology is considered to be one of the most widely recognized forces affecting work and how it is

changing. The technology of microelectronics, robotics, and computer-integrated manufacturing along with the explosion of digital telecommunications due to the growth of the Internet and the World Wide Web have brought the world to the verge of a transformation similar to an industrial revolution. It is expected that the Big Four information technologies—computer networks, imaging technology, massive data storage, and artificial intelligence—will continue to have revolutionary effects on shaping today's occupations.

Computerization and the emerging information highway are transforming the American economy. Computers are changing the composition and distribution of labor, improving labor efficiency, and creating new markets and new forms of organizations. Technology shapes what people do and how they do it. Technological change often creates new occupations (e.g., computer scientists, programmers) and reduces or eliminates some existing occupations (e.g., telephone operators). In addition, digitization has changed the types of skills needed on jobs. It has increased the analytic and information-processing skills required on some jobs and decreased the manual and sensory-based skills of others.

Today, brainpower is replacing manual labor, and future workers must continually educate themselves and increase their skills to maintain their value in the workplace. Technology has reduced the number of workers required to maintain and operate high-tech factories and workplaces, has given rise to the need for "knowledge workers," and has elevated the general education required for work. Few emerging occupations exist for people who cannot read, write, and do basic mathematics. Thus people who have weak educational backgrounds are likely to be increasingly vulnerable to unemployment. In fact, the growth of computer use is associated with increased employment of college graduates and decreased employment of high school graduates. In some industries, advanced technology has eliminated the need for some unskilled and semiskilled jobs and even some middle management jobs that tended to be the positions that collected and analyzed data for decision making. For future jobs, greater emphasis will be placed on cognitive, communications, and interactive skills.

With 76 million baby boomers heading toward retirement over the next three decades and only 46 million Generation Xers waiting in the wings, corporate America is facing a potentially large talent crunch. Labor-saving technology and immigration may help fill the gap, but by 2010 there may be a

shortage of 4 to 6 million workers. Not enough Americans are trained for these jobs, since they lack computer literacy, leadership, critical thinking skills, and communication skills.

Technology has also made workplaces more information dependent in order to operate machines (e.g., robots, aircraft) for quality control and for decision making about inventory management and tracking distribution of products shipped. Employees at all levels of the organization have greater access to information and greater opportunities to make work decisions. For some jobs, computers have given employees more autonomy in their work. For others, the need for continuous data entry to computers and monitoring them to meet customers' needs has imposed a new form of assembly line. In some cases, employees have greater concerns about invasion of privacy as managers use more sophisticated surveillance techniques to monitor productivity.

24/7 Work

With the increasing technological advances, workers are able to do their jobs almost anywhere. Laptops, fax machines, cellular phones, networks, e-mail, and voice mail have made it possible for workers to essentially work 24 hours, seven days a week. Work can now be done without regard to space, time, or political boundaries. Americans, as a group, now work harder and longer than almost any other people on earth. Some studies have indicated that people have less free time and feel more pressed for time as compared to those in the past. Information technology (IT) is now used in 64 percent of women's jobs, and by 2000, women using IT in their jobs worked 3.4 hours per week longer than nonusers. The economy, globalization, and 24-hour demand for goods and services have busted capacity in the 40-hour work week. Now, no longer are just police officers, nurses, taxi drivers, delivery personnel, factory employees, and security guards working at night. Today, all types of employees (e.g., stock brokers, building contractors, account reps, software fixers) are working at night. In fact, according to the Bureau of Labor Statistics, in 2000 it was estimated that 23 million people worked night, evening, or split shifts, up from 3.5 million working the night shift in 1997.

Changing Workplaces and Telework

Today, more workers are telecommuting. In fact, the innovations of telework and virtual teams are

experiencing an annual growth rate of 5 percent to 10 percent. Telecommuting is the use of computers and telecommunications equipment to work at home or in other locations away from a conventional, centralized office. Careers and jobs are increasingly being seen as boundaryless, flexible, and virtual.

Telework has the benefits of allowing people to work from home (saving commuting time and costs as well as office space costs) and is purported to help employees better balance their home and work lives. However, some workers feel isolated and are worried that less visibility might negatively impact their career progression. In addition, work and home roles often become blurred, which can lead to greater role conflict and stress among workers. Given the 24/7 nature of many jobs, it becomes increasingly more important for employers to work with individuals to create jobs that meet the life needs of employees as well as the organization's needs.

HOW TECHNOLOGY HAS CHANGED VARIOUS TYPES OF JOBS

Technology has altered the nature of various types of jobs and the mix of skills that are required to do them. The cognitive complexity of work appears to be increasing for blue-collar and service workers. A major effect of information technology on blue-collar work has been to replace physical activity with mental and more abstract forms of analysis. The predominant trends in blue-collar work are for computer-integrated manufacturing technologies and team-based work, which increases the degree of control and task scope and requires higher cognitive and interactive skills and activities. It is estimated that one-third of the blue-collar workforce is changing in this way. Some of the blue-collar jobs that have undergone the greatest transformations have been the steel industry, auto industry, and the apparel industry. It should be noted that what is most important, however, is the combination of computer usage by blue-collar workers with innovative work practices and cooperative labor-management relations (i.e., computers alone do not improve productivity).

Service work (e.g., personal service, clerical and administrative support, sales) has also changed due to technology. Automation and routinization of work has expanded from the back office (typists, data processors, operators) to the front office (customer service and sales employees). Call centers now exist for

telemarketing operations, banking, telecommunications, and insurance. There is also evidence of an overall increase in technical skill requirements, computer usage, and cognitive complexity of service jobs.

Managerial workers consist of managers, executives, and administrators. It is expected that increased computer power may lead to a fall in managerial employment, since expert systems have reduced the need for some types of managers. Managers are more likely to be project managers than functional managers. Thus they manage the process and flow of work, rather than people. This means that they need greater skills in coordinating tasks and working horizontally across the internal and external boundaries of organizations.

Professional and technical workers (e.g., engineers, scientists, computer occupations, social scientists, lawyers, religious workers, teachers, counselors, health occupations, writers, artists, entertainers) continue to expand in the labor force. This is due to corporate growth, technological changes, demographic changes, and the commercialization of scientific knowledge. Technological changes have shifted the workforce by creating new occupations (e.g., computer operators, analysts, programmers, air traffic controllers, nuclear technicians). In addition, some occupations are experiencing greater autonomy, while at the same time, some are experiencing bureaucratic controls (e.g., health care physicians who are subject to restrictions by managed care firms). Technical and professional work has always entailed high cognitive content, but interpersonal interactions (e.g., communications, problem solving, negotiation skills) are becoming more important in many of these jobs.

JOBS FOR THE FUTURE

The Bureau of Labor Statistics projects that 8 of the 10 fastest-growing occupations between 2000 and 2010 will be computer related. These include jobs such as computer and information systems managers, computer programmers, computer and information scientists, computer system analysts, computer hardware and software engineers, computer support specialists, database administrators, network and computer systems administrators, and data communications analysts. Jobs requiring information technology skills are in high demand for the future, especially for the military, aerospace, and federal agencies. One important consideration is that because the skills in

these jobs can become obsolete much faster than in other jobs, it is increasingly important for employers and government agencies to make it easier for IT professionals and those in computer-related fields to keep their skills current by lifelong learning efforts. In addition, some have suggested that soft skills such as communication and presentation skills are increasingly more important for IT professionals due to the greater need for them to explain technical issues to nontechnical people. It is also important for schools to attract more women to IT and computer-related fields, since traditionally few women express interest in IT or pursue these degrees. In addition, it is well documented that women often face barriers when pursuing academic careers in science, math, engineering, or technology.

TECHNOLOGY AND HEALTH IN CAREERS

The technological evolution of the office environment has produced many benefits, yet it has also brought with it some negative outcomes. These include both physical health concerns as well as psychological concerns. Employers will need to continue to examine the impact of technological advances on the physical and psychological health of their employees and to make adjustments as needed.

The most commonly reported physical issues are byproducts of increasing technological sophistication (increased work pace, noise, mental demands, repetitive movements), which can lead to musculoskeletal disorders (e.g., carpal tunnel syndrome, tendonitis, back injuries). According to the U.S. Department of Labor, approximately 1.8 million people report work-related musculoskeletal disorders. These disorders are costly and long term. According to the U.S. Department of Labor, musculoskeletal disorder costs total more than \$50 billion a year and are the third most frequent reason for disability and early retirement. In addition, they can lead to job loss, depression, and family disruption.

In addition to physical problems associated with increased technology in workplaces, there are also psychological health concerns. These come from office noise, changing work demands, a lack of control on the job (e.g., technological equipment breakdowns that they do not know how to fix), isolation from others, and reductions in privacy (e.g., increased electronic monitoring by supervisors). Research has linked most of these technology-related variables to psychological stress, which can then lead to other

negative outcomes (strains, negative attitudes, anxiety, depression, low job satisfaction, mood disturbances).

THE IMPACT OF TECHNOLOGY ON CAREER AND DEVELOPMENTAL PRACTICES

Today employers note that finding, attracting, and developing quality workers has become a top priority as they try to combat labor shortages, meet changing worker expectations, upgrade their workforce, and build innovation and creativity into internationally competitive organizations. Employers and applicants are increasingly relying on the Internet as part of the job search process.

Individual Job Search Strategies

With the advent of the Internet and computer-assisted career systems, individuals have greater control over their own career search strategies and progress. According to applicants, the use of the Internet for job searching is seen as a less effective strategy than personal networking but far superior to using newspaper ads and cold-calling to find jobs. In fact, most new college graduates view the Internet as a major source for help in locating job opportunities. Popular career sites such as Monster.com, Hotjobs.com, Headhunter.net, and Dice.com are busy not only at their peak times on Monday and Tuesday afternoons but also during off hours (between 1 and 2 a.m.). College students, in particular, are known for pulling all-nighters to hunt for jobs online. Individuals often use these sites to view job listings and apply for jobs.

Despite the popularity of the Internet, there are some reported problems associated with using it to search for jobs. These include less personal contact, less accuracy with regard to the job's description, difficulties finding companies' Web pages or navigating through them, problems submitting résumés according to specific Web specifications and receiving an acknowledgment or follow-up call from company representatives once a résumé is submitted.

Employers' Use of the Internet to Hire Employees

Employers are increasingly relying on career and job Web sites to recruit and select employees. In fact, the job of the recruiter has changed such that candidates can be identified, screened, and recruited all

online. Given the intense competition among employers for qualified employees, many recruiters are working late at night to look for potential résumés. Nocturnal Web surfing is now common practice among recruiters. Determined headhunters snap up hot résumés before dawn, contacting candidates by e-mail and sometimes even by phone. Many recruiters stay up past 2 a.m. examining job sites, surfing chat rooms, digging out fresh résumés on personal Web pages, posting help-wanted ads and sending e-mails. This is particularly true when recruiters are trying to hire overseas workers due to the time differences. Candidates with technical skills that are in high demand find themselves bombarded with calls and e-mail within minutes of posting a résumé online. Thus from an employer's perspective, online recruiting has tremendous potential benefits for corporations. These include reducing the time needed to hire someone, less costs relative to using headhunters and external search firms, reduced costs on mailings, brochures, and on-site interviews, and the ability to reach a more diverse applicant pool.

THE IMPACT OF TECHNOLOGY ON EMPLOYEE LEARNING AND DEVELOPMENT

Due to the dynamic quality of work and work organizations, people will likely engage in seven or more jobs in their work lives. They will also have to frequently be retrained in order to remain competitive and manage their own career development. Some workers may become "world workers," moving among nations in pursuit of suitable work. Thus there is a shift from developing "career maturity" and toward "career adaptability" (that is, being able to change to fit new or changed circumstances).

The corporation of the future will have accumulated knowledge and innovative potential of its workers as its single greatest asset. Thus training and continual learning is in demand as employees need greater skills to move more rapidly across jobs. Employees also need technical training and must learn how to operate with discretion in an open information environment. Retraining is increasingly important due to obsolescence of knowledge and skills among technical and professional workers. That is, as a result of the fast pace of technological advances, many workers lack the up-to-date knowledge and skills needed to maintain effective performance in their current or future work roles. This problem may intensify with an increasingly aging

workforce. Thus retraining the expanding older technical workforce is a major challenge facing the country. In addition, as firms downsize or restructure their workforces, they will need to retrain current employees to do other jobs or provide outplacement counseling so that those employees can find jobs in other organizations. For retraining efforts to be successful, it is important that there is top management support for retraining programs and that retraining is voluntary. It is also helpful if specific jobs are assigned to the employee prior to retraining so he or she can see the relevance of learning new skills.

Technology has not only impacted the importance of retraining or continual learning, but it has also influenced the type of training that can be used with employees. The methodologies used to train employees have changed due to advances in computer-based training and online methods. E-learning is gaining in popularity, since it allows individuals to continue their learning in a self-paced fashion. Thus it is immediately available to them and is not limited by travel time or costs (to attend training sessions). Likewise, distance learning programs are in great demand in firms. Some organizations (e.g., Federal Express) have implemented a corporate-wide computer system that handles most of the human resource functions of the firm (e.g., recording training completed for employees, posting job descriptions for hirings) as well as online training programs to help employees develop on their jobs.

WEB-BASED OR E-MENTORING

Advances in technology have created new opportunities for how the mentoring of individuals is conducted. Traditionally, mentors and protégés rely on face-to-face meetings to discuss issues and build a relationship. E-mentoring refers to the process of using electronic means as the primary channel of communication between mentors and protégés. The key distinction between electronic mentoring and traditional mentoring is reflected in the face-time between mentors and protégés. E-mentoring takes advantage of technology to broaden the definition of mentoring relationships by relaxing the constraints of geographical location and time. Thus individuals with alternative work schedules (telecommuters, flextime workers) may still access mentors without altering their work arrangements. In addition, those who have traditionally had less access to mentoring relationships

(e.g., women, minorities) may have greater opportunities to get mentored with e-mentoring.

THE IMPACT OF TECHNOLOGY ON THE ROLE AND SERVICES PROVIDED BY CAREER COUNSELORS

History of Technology and Career Counseling

Vocational psychology faces a number of challenges in the next century from the globalization of economies to the changing nature of work and the workforce. Many of the changes come from the explosion of communication technologies in the last 20 years. The increased use of computers and the Internet in vocational psychology has been a major development for practitioners. It has led to the availability of more systems and approaches to career guidance and has essentially changed the job and role of the career counselor. In particular, with the larger number of jobs that people are expected to have over their lifetime due to advanced technology and longer life spans, counselors will be in more demand to provide career assistance. Vocational counselors will need to be prepared to deal with the changing needs and demands of both individuals and employers. For example, with the aging of the baby boomers, counselors will need to assist them in changing careers and updating skills.

The use of technology to assist individuals with career planning had its genesis in the late sixties, when early developers first used the computer to assist with career planning. The early systems that were used stored a personal record for each user in order to monitor a person's progress through the career planning process. The results from the assessment were then linked to occupational options for the user. Some of the early systems were precursors of later systems such as SIGI PLUS and DISCOVER, which are described below and are still prominent in schools and other settings today.

In the 1970s, career information systems were developed due to the National Occupational Information Coordinating Committee. These systems were comprised of search strategies through databases of occupations, schools, financial aid, and military programs. From the early seventies until 1999, there was a steady growth of customized versions of commercial career information systems in the states. With the advent of common access to the Internet in the early 1990s, career planning changed dramatically.

Several of the computer-based career information systems moved from stand-alone delivery to delivery via the Internet. Web sites devoted to career information or planning began to proliferate at an astounding rate and with a wide range of quality.

Today, individuals can take a more active role in their own career progress, since the Internet provides a rich source of career and job information that is accessible to almost anyone. This means that the counselor's role/job has changed. Today, often the counselor's primary role is to help clients access information on the Internet and other computer-assisted programs in an efficient and helpful manner. Of course, it is still important for counselors to meet with clients and provide career guidance. The best combination is using computers for assessment and then offering counseling with a vocational practitioner. Interestingly, cybercounseling has emerged, that is, the provision of face-to-face counseling via the Internet.

As noted, a number of different tools are used by career counselors today. These include computer-assisted career guidance systems (e.g., DISCOVER, SIGI (or the System of Interactive and Guidance Information), CHOICES, CDSS (or Career Decisions Software Solutions) and online information systems (Internet).

Computer-Assisted Career Guidance Systems

Computer-assisted career guidance (CACG) systems are often designed to help high school or college students make informed and educated decisions about their future. For example, CHOICES offers information about vocational technical schools, education and training, state and local information, and financial aid. Most computer-assisted career guidance systems offer occupational information, information about postsecondary institutions and technical/specialized schools, financial aid information, interest inventories, and decision-making skills. They might also include ability measures, value inventories, job search strategies, information on job interviewing, and local job information files. O*NET, or the Occupational Information Network, was recently developed as a replacement for the Dictionary of Occupational Titles. It is a comprehensive system that describes occupations based on at least 60 years of research and knowledge on the nature of jobs and work.

Two commonly used CACG systems are DISCOVER and SIGI PLUS. Both systems provide multiple online

assessment devices to assist users in establishing links between their interests, values, abilities, and skills and the occupations that should best meet their needs. Counselors should do the following when using computer-assisted career guidance systems:

- Assess needs—assess the client's needs to determine which parts of the career program to use.
- Orient the client—explain the purpose and goals of the program and the mechanics of the system.
- Offer assistance—provide individualized help when the client's needs are determined.
- Provide online assistance—provide help when different stages are explored during the process.
- Follow up—encourage, motivate, set goals, and interpret outcomes to the client.
- Evaluate—monitor the effectiveness of the computer-assisted system.

As noted by Nadene Peterson and Roberto C. Gonzalez, computers provide a number of benefits to career counselors as noted below:

- A more efficient use of time for practitioners
- Immediate access to assessment results
- Greater accuracy of administration and scoring
- More opportunities for research
- Popularity with clients, especially self-motivated clients

There are, however, some potential problems such as the following:

- Loss of client/practitioner interactions
- Assumption of a certain level of client cognitive functioning and self-motivation
- Potential loss of privacy

Regardless of which computer system is used, it is important for counselors to know the client's needs and tailor the technology to his or her needs. It is also desired that counseling assistance be provided in addition to using the computer system, since most computer systems were not designed to be stand-alone. Furthermore, it is critical that career counselors receive additional training to keep pace with changes in technology as well as changes in the needs of a more diverse client population.

Career Guidance and the Internet

Today, the fastest growing source of information about careers, jobs, and related areas is on the

Internet. The Internet is an international linkage of computers, telecommunications, graphics, and knowledge bases from sites around the world, making comprehensive information accessible to persons in any setting or geographic location. Some of the major sources of information about careers and jobs include the Web sites for

- Department of Labor (www.dol.gov)
- Career Counseling Resources (www.hawk.igs.net/employmentplanning/)
- Career Counselors Consortium (www.careercc.org)
- National Occupational Information Coordinating Committee (www.profiles.iastate.edu/idid/ncdc)

The Internet will continue to play an important role providing career services, because not everyone has the time or money to seek face-to-face assistance from career counselors. The primary ways in which the Internet assists individuals is by (a) administering career assessments, (b) providing information on a variety of career planning topics (e.g., occupational descriptions, job databases), (c) serving as a conduit for cybercounseling (where the client and counselor can see each other on computers to conduct their meeting), (d) serving as a forum for group communication or networking between clients and school alumni or employers or support group members, (e) enabling the creation of virtual career centers (Web sites that integrate skills or interest assessments with training required for various jobs and job openings), and (f) facilitating individual participation in virtual reality technology so that clients can explore potential work activities.

Some of the benefits of using the Internet for career services include the following:

- Service can be available to adults 24 hours a day 7 days a week, wherever they have access to the Internet.
- Multiple users can connect (alumni, employers, clients).
- Career services might be more accessible and affordable for some populations.

While online services can provide valuable information to individuals, there are a number of concerns, including the following:

- The accuracy, relevance, and timeliness of information
- The usefulness of the information
- Adequate preparation for the user to know how to process the information, since in some cases the information is disjointed or not integrated

- Opportunity for follow-up to correct or confirm the information
- Confidentiality and privacy
- Potential for violation of copyright law
- Ethical exchange of information between sites and users
- Lack of training of counselors with the technology
- Addressing issues of informed consent, trust, and protecting the identity of participants when conducting research

SUMMARY

Technology has had a dramatic impact on the nature of work itself, individual applicants and employees, employers, and career counselors. It has changed the nature of work and the types of jobs that people do today. It has altered the knowledge and skills individuals need to be effective workers. It has transformed how employers recruit, select, and train applicants and employees. It has also changed how individuals gather occupational information and how career counselors work with their clients. As a result, individuals, employers, and career counselors will need to keep pace with advancing technology and be adaptable and responsive to change in order to continue to be successful to meet the challenges of the next century.

TELECOMMUTING

Telecommuting is a flexible work arrangement in which organizational employees work from an alternate location, usually the home. This variant of flexible work has been growing at a tremendous rate, which may be attributed to demands from employees, organizations, and society. First, employee demands for flexible work arrangements have arisen from substantial changes to the family structure. The growth of dual-career and single-parent families and increasing elder care responsibilities have resulted in individuals trying to balance the demands of both work and family. Telecommuting allows employees to eliminate their commute and have more flexibility, allowing them to meet both work and personal demands. Organizations also benefit from flexible work options.

Due to demographic changes, organizations need to make accommodations to attract and retain employees. Providing an option to telecommute, even one day a week, is attractive to many employees. Since employees can continue to work at times when it is not possible for them to be physically located at the traditional work site, telecommuting provides the organization with a means to deal with disasters or to accommodate disabled employees. Finally, telecommuting benefits society by reducing the number of people commuting to work, which contributes to less traffic congestion and pollution.

The growing power, sophistication, and portability of technology have made telecommuting a viable

work option. Technological developments, such as portable hardware, high-speed Internet access, and collaborative software have contributed to making work less geographically dependent. Individuals are now able to share software, information, and ideas from remote locations. Yet there is the potential for negative outcomes to telecommuting. Employees who work out of the office may become isolated, which could have an adverse effect on their career advancement prospects. Some employees may find telecommuting to cause additional stress.

The flexibility afforded by telecommuting may allow employees to diminish some aspects of work-family conflict but may increase others. Flexibility allows an employee to deal with time-based work-family conflict. For example, when working from home, a parent could take a break to attend an event at school. There are, however, some aspects of work-family conflict that may actually increase by working within the home. Blurring the boundary between work and home may increase behavioral-based work-family conflict, because an employee is forced to change roles and behaviors quickly. Strain-based work-family conflict, the spillover of strain from one role into another, may also increase, because the employee no longer has the commute to psychologically adjust from home to work and vice versa.

The research that has been done on the work outcomes of telecommuting has many contradictions. A number of books and articles suggest that telecommuting will increase job satisfaction and productivity and reduce employee stress and absenteeism. Conversely, other authors have insinuated that telecommuting has negative outcomes for employees, including loneliness, isolation, exploitation, increased stress, and limited career advancement prospects. It is likely that these contradictions are a result of the various ways telecommuting has been defined and examined. The concept of telecommuting has been explored under a variety of names, including telework, flexiplace, and homework. Despite years of study, there is still no clear, inclusive, accepted definition of this work arrangement. Location, employment relationship, telecommuting structure, and level of participation are suggested as factors to be included in the formulation of a complete definition of telecommuting.

Although most researchers have considered telecommuting to take place only from the home, others have suggested it may occur from a variety of

locations, including a satellite work center, customer's office, hotel, or airport. Location is an important consideration, since the experiences of individuals who work alone at home could be very different from the work experiences of employees working at an alternative work location.

Distinctions between home-based employees and home-based self-employed contractors must be made consistently by state and federal agencies to protect employees from becoming exploited. It is also necessary to consider the employment relationship with the organization in developing a complete definition of telecommuting. Some researchers have included self-employed individuals working from home in their definition and samples. Work experiences that may be impacted by telecommuting, such as career advancement and autonomy, would be expected to differ for self-employed and organizational employees.

Telecommuters may be either substitutors or supplementors. Substitutors are organizational employees who spend part or all of the work week at a nontraditional site in lieu of the traditional workplace. Supplementors work additional "overtime" hours at home, often to be able to concentrate and catch up on extra work. The work experiences and outcomes for substitutors and supplementors may vary substantially. Supplementors have been found to work more hours yet still devote the same amount of time to family responsibilities, suggesting they sacrifice their personal time to do additional work. Not surprisingly, supplementors have been found to experience more role conflict and work-to-family spillover. Substitutors, by not being in the office during traditional hours, may be limiting their visibility. This may result in less positive perceptions from supervisors and a reduction in career advancement opportunities.

Most of the literature suggests there should be a balance between telecommuting and working in the traditional office environment. Productivity studies have shown that working at home three days per week is optimum, with working more or less at home resulting in lower productivity. Other research has found that telecommuting one day per week did not have an adverse impact on career advancement prospects. Higher levels of telecommuting may lead to more isolation and, consequently, less career advancement.

Although varied definitions of telecommuting make it difficult to compare the current literature, numerous pilot studies have proven that when properly structured, there are a number of benefits to this

flexible work arrangement. It is imperative that researchers continue to explore the potential effects of this work arrangement on the organization, the individual, and the family. Ultimately, this research should guide organizational policy so that the benefits of telecommuting are maximized and the limitations are minimized.

THEMATIC APPERCEPTION TESTS (TAT)

Although rarely used by career counselors and practitioners, traditional projective techniques are experiencing a renaissance because they provide a

long-tested method of assessing stories and narratives, which are becoming the focus of career and narrative practitioners. These approaches, long overshadowed by quantitative methods, are providing new ground for exploration and explanation of individuals' career trajectories and concerns.

The *Thematic Apperception test* (TAT) is one such established projective technique. The TAT was initially developed by Christiana Morgan and Henry Murray in 1935 as a performance measure of personality. The TAT uses a projective narrative technique to elicit stories from individuals and then provides practitioners with a wide variety of interpretive methods. The test uses ambiguous stimuli in the form of pictures of drawings or photographs to assist people in producing stories. Numerous scoring systems have been developed to measure specific variables of interest to researchers. The most famous scoring system developed by Murray in 1943 assesses for the needs of achievement, affiliation, and power. Research indicates that these TAT-based motive measures provide a valid prediction of real-world behaviors and life outcomes. Though various systematic scoring models have been developed and validated, the current interest of career counselors and practitioners focuses upon the narrative and thematic interpretation of the TAT stories.

Narratives or stories are currently viewed as the main vehicle individuals use to express who they are and how they see the world. Narratives give us insight into the intentional actions of a person and are the platform individuals use to translate events and impose structure on their experiences. Individuals often repeat story lines in multiple variations, and a careful listener or reader will be able to recognize a unity and consistency revealed across each of an individual's narratives. Narratives in this context are not important as historical truth, but because they express the way in which people explain their experiences and indicate how they may cope with experiences. Narratives commonly become an extension of the person or reflect a picture of how the person would like to be. Interpretation of the TAT, therefore, has to be approached with a narrative sensitivity that understands the tendency of narratives to represent an extension of the person. This reflection of the individual into the narrative also can be referred to as projection.

Projective narratives like the TAT often allow access to an individual's personality in a way that direct questionnaires and interviews cannot. When

individuals engage in telling stories about the self or others, subconscious material often slips out even when the individual does not want it to. Individuals taking the TAT frequently project onto the pictures their own anxieties, motives, and desires in the narratives that they produce. This unconscious projection is facilitated through the external focus of the TAT session. The TAT pictures and the instructions associated with the pictures are focused externally and tend to draw the attention of the individual away from personal concerns to focus on the creative task of developing a story. The externality of the TAT fosters narrative responses that are projective in nature and provides the context for their interpretation.

The TAT pictures serve as the primary context to produce these narratives. Different TAT cards have been shown to result in or pull out consistent themes. Within the traditional 16 TAT cards, 3 cards, including (1) boy with violin, (2) young woman with books, (3) older man and younger man, tend to foster stories related to occupation, aspirations, and family dynamics. Stories written in response to these cards tend to produce themes that influence career concerns and trajectory. The specific techniques and instructions of the TAT administration help to facilitate expression of these individual narratives.

In the administration of the TAT, individuals are usually instructed to write or orally share a story about each picture, being told to answer these general questions: What is happening in the picture? What happened before? How are people in the picture feeling? What are they thinking? How does everything turn out at the end? Written responses tend to produce stories that are more autobiographical in nature and provide a more accurate written record that can be reviewed later by the practitioner and respondent. The TAT picture is held up for 10 seconds, and then the individual is given 5 minutes to write a story for the picture before the next picture is held up. The process is repeated until all cards have been reviewed, and then the responses are collected. Every response to a TAT picture, therefore, produces a brief and complete narrative that can prove useful to career counselors.

A case study may be demonstrative of the current efforts and use of the TAT for identifying narrative themes that influence career. The individual responded to the three TAT cards reviewed above with the following stories. To the first card, of the boy with a violin, the individual wrote that the child hated practicing his instrument and wished to be outside with friends

playing baseball. The child, however, remained inside to practice but always hated playing the instrument. To the card showing a young woman with books, the story was about the girl and her love of school but how she was feeling torn between going to college and staying home on the family farm. The girl eventually chooses to stay home and works on the farm. The story of the third card indicated that the picture was of a father and his son. The father wanted the son to take over the family shoe store, while the son wanted to go to college to pursue law. The son gives in to the father's wishes but ends up feeling miserable. A consistent theme of family conflict over career expectations is found in all three stories. The practitioner would want to highlight, verify, and investigate this theme and others with the client. The TAT and other projective measures, therefore, can provide the opportunity to express and explore otherwise unspoken narratives that are active in an individual's life and facilitate more effective career counseling.

THREE-HUNDRED-SIXTY-DEGREE (360°) EVALUATION

The use of *360° feedback* (also called multirater or multisource feedback, full-circle appraisal, and group

performance review) became highly popular in the mid-1990s and is currently being used by organizations of all sizes. This type of feedback or appraisal is used to obtain performance information from sources "in a circle around" the individual being rated—thus the term *360° feedback*. Those who provide *360°* performance feedback on the individual being assessed can include customers, coworkers, team members, supervisors, subordinates, and the person being rated (this is called self-assessment or self-appraisal). Rather than the more typical method of top-down appraisal, *360°* evaluation provides focus on the customers, both internal and external.

The traditional method of performance appraisal, where a supervisor evaluates a subordinate's work, is primarily a one-way or one-sided system. The conventional performance appraisal may allow a supervisor to be overly (and therefore unfairly) subjective when evaluating the employee, which could lead to rater error. There are several types of rater errors that can occur when a manager alone assesses an employee's performance.

USEFULNESS OF 360° FEEDBACK

Obtaining feedback using the *360°* or multirater model is useful because it allows employees to see a bigger picture of their performance, and with more detail. It also centers attention on the internal and external customers of the individual being assessed. Companies have also found that multirater feedback allows for a greater focus on the organization's mission, goals, and strategic plan more effectively than traditional appraisal methods. It can further place attention on coworker relationships and team building and can promote individual initiative in a hierarchical corporate environment. It permits employees to participate more in decision making, allows greater self-reliance, and gives them personal responsibility for their interactions with others. Moreover, it contributes to employee career development and growth, since feedback can be used to create individual career development plans that help employees better understand their own strengths and weaknesses. Because the feedback comes from many sources, it lessens the probability of discrimination that may be present with only one rater, who is usually the immediate supervisor. The primary positive results are the creation of a high-involvement corporate culture and increased personal responsibility.

Another positive aspect of multirater feedback systems is that if the organization chooses a Web-based assessment tool, it is easier for employees to use (no paper and pencil), and it can compile the data for results on each employee. Web-based systems can also be customized based on organizational goals and individual employee competencies.

USE OF 360° FEEDBACK

In 1995, approximately 40 percent of organizations employed 360° feedback, and by 2000 it was up to 65 percent of companies and growing. Many experts and researchers of multirater systems find that there are several best practices in the field. Experts suggest that multisource feedback be used only for individual development of employees, not for succession planning or compensation purposes. A good system will assess knowledge of the job, the industry, and the organization and its goals; the skills needed to be proficient in the employee's specific role; and behaviors such as being positive or having energy. Experts recommend that the system should not be used to assess personality traits, only competencies for the job being performed.

Researchers recommend that 360° feedback be linked to the strategic goals and objectives of the business. All users of this system should be well trained, and the process monitored closely. It is further advised that the organization's leaders be used as role models for others using the system and that the company invests in the process. The results of the process should be acted upon by creating a plan for employee development. Experts also advocate ongoing evaluation of the process to ensure that it is adding value to the business.

Researchers also say that unless those participating in a multirater feedback program are trained in the art of giving and receiving this type of feedback, the process can lead to conflict among team members. Differences between raters and their interpretations of the assessment questions can lead to errors in validity and reliability of the instruments being used. That is why importance must be placed on proper use of the feedback system. Other problems cited by researchers are that 360° feedback takes more time and effort than traditional appraisals, that it can assess competencies unrelated to the business goals, and that there is a lack of follow-up with so many different appraisals to review and consolidate. Differences among the various

raters will obviously cause problems for the manager who is responsible for developing a cohesive performance plan.

Researchers have also found that a supervisor is the most accurate assessor of an employee's performance and that employees are the least accurate raters of their own performance. Employees tend to give themselves higher ratings than others in the feedback loop. Lower performers tend to rate themselves more highly, and the best performers tend to underestimate their performance in comparison to supervisory ratings.

Another issue with 360° feedback is confidentiality. Studies have shown that confidential feedback tends to be more honest and to provide a more realistic assessment when the employee being rated does not know the exact identity of the appraiser. In other words, raters worry about retribution from the employee, so they offer higher ratings if the appraisal is not anonymous. Experts contend that the best practice is to use confidential, anonymous feedback.

Multirater assessment tools can be costly, but organizations should purchase an instrument that has been professionally developed and validated. Feedback instruments should include well-researched items that are directly related to employee responsibilities and competencies. Experts further recommend that 360° feedback be used only for performance improvement and employee development—not for performance appraisal or pay considerations. Moreover, they contend that multirater feedback should be an organization-wide initiative, not just for some employees who need development, but for all employees, including the organization's leaders. So that managers will not be expected to deal with feedback on all employees at the same time, authorities on this topic also conclude that such a program should be ongoing throughout the year on a rotating basis. If a supervisor has a large number of reports, this initiative could be too large a time commitment over a short period like an annual performance cycle.

An organization considering 360° feedback should answer several questions before pursuing such a program: (a) Is it clear why the organization is going to use this system rather than the traditional appraisal format? (b) Is the company "mature" enough to correctly and effectively collect and use 360° feedback, that is, does the culture support this type of feedback, (c) Is there a commitment from the corporate leaders, (d) Are the managers going to use the data toward the development of individual employees? (e) Are the

employees going to utilize the feedback for their own development and performance improvement?

BASIC STEPS IN THE PROCESS

The steps in the 360° feedback process can seem daunting, so considerable thought and research before launching the initiative is recommended. First, the organization must determine whether it is ready for such a program. After reviewing the questions listed above, if the answer to these questions is yes, the next step is to conduct research and select the appropriate feedback tool and process to be used. This might also mean selecting a consulting firm or external subject matter expert to assist the organization with the initiative. Consideration should be given to who will create the assessment form and what it will include. For whatever tool is selected, the organization should confirm that the assessment tool has statistical validity and reliability and should ensure that the questionnaires are directly related to the employee's job and competencies and to the company goals. Once the process is formulated, the next step is to determine who will provide the feedback and how it will be obtained. Again, the organization should answer several questions: Will it be internal only? Will it include suppliers and external customers? Will computers be used in completing the assessment? Is the computer system secure?

After the feedback is obtained, the next step is to compile it into a useful report that the employee can review and understand and then use to create an individual development plan. Supervisors should be prepared to provide ongoing and consistent communication about the process and the follow-up plan. The organization should have a strategy for how the feedback results will be shared with staff. Following the creation of employee development plans, the entire process should be evaluated. This entire process should be renewed every 6 to 12 months for the employees. The company needs to also consider whether the feedback system met the organization's expectations and whether employee performance improved, based on the feedback obtained via the process.

There are several issues to consider before an organization makes a decision on whether to use 360° feedback. First, they need to assess the costs of the program, both from a financial and a staff time standpoint. Next, they should consider whether this method is going to provide more focus on the mission, goals, and strategic plan of the company than the current

appraisal or employee development system. Also, companies should keep in mind that an initiative like this must have top-down support where corporate leaders are willing to give 360° feedback their full backing. Ideally, use of the system should begin with the leaders. Once the leaders and managers have been part of the process, they will be better able to explain it to their direct reports. The leaders, having been through the process, will confirm for employees its importance to the organization.

Another consideration is training the users of the 360° feedback system. All employees, customers, suppliers, and any other users will need proper training on the correct and fair application of the feedback system. The organization needs to be prepared to create an individual development plan for each employee once the feedback is gathered. This part of the process is essential and should be taken seriously. And finally, the company should also be prepared to continuously evaluate and adjust the system based on problems or issues that arise.

CONCLUSION

An organization should consider all the pros and cons of 360° feedback before making the decision to use such a system. The organization must be prepared for such an initiative from the top down. They must also employ effective planning and implementation processes. By carefully applying the strategies and best practices recommended by the experts, an organization will be successful with its 360° feedback initiatives.

TOKENISM

Rosabeth Moss Kanter's 1977 book *Men and Women of the Corporation* contributed to filling the gap between broad sociological and individualistic psychological approaches to organizational theory and research by taking a social psychological look at interpersonal relations within work groups. Specifically, Kanter described the on-the-job experiences of "token" women working with a "dominant" group of male sales managers in a Fortune 500 company. She attributed the heightened visibility and resulting performance pressures, marginalization, and role entrapment these women reported to "numbers," that is, their proportional representation as less than 15 percent of their "skewed" work group. These three outcomes and the role of skewed proportions rest at the heart of what has become known as *tokenism* theory. Empirical support for Kanter's conclusions across case studies representing a wide array of occupations and manipulative experiments is strong for women tokens. For example, research with military cadets found that women were readily visible, even in uniform; that women in basic training scored even higher than men on tests measuring psychological stress; that women felt socially isolated and disapproved of by peers; and that women reported role conflicts between masculinized expectations for cadets (e.g., "command" voices) and stereotypes for themselves as women (e.g., fragile).

Subsequent research undermined tokenism theory's gender-neutral reliance on proportions alone. There is solid evidence that the negative consequences associated with proportional underrepresentation did

not extend to White male tokens in female-dominated occupations, including nurses, social workers, librarians, teachers, and flight attendants. Although the perceived masculinity and work attitudes of token men may be threatened, token White men were advantaged with pay and promotion. However, this presumed glass escalator may reflect universal male advantage rather than benefits associated with token status itself. What Kanter attributed to proportions alone really resulted from token proportions intertwined with a stigmatized status, most commonly operationalized as being female in a male-dominated and masculinized context. Indeed, token proportions themselves may be an indicator of lower status. Token women, whose lower status as women and tokens was intentionally elevated, held fewer negative expectations about their interactions with dominant men. Moreover, solo women leaders (that is, women who were not only a token minority of less than 15 percent but also the sole woman in the group) facilitated group performance successfully when their expertise was legitimated.

Research extending these patterns beyond gender to race/ethnicity is minimal and may be culturally specific. A study of African American elite leaders found evidence of depression and anxiety as well as loss of Black identity, multiple demands, felt isolation, and pressures to confirm one's competence. The subjective experience of distinctiveness is especially strong among African Americans who commonly find themselves in positions as solos, an extreme form of tokenism. Indeed, stigmatizing effects of distinctiveness are generally associated with solo status across many subordinated groups. Studies of women firefighters highlighted how role entrapment, drawing on different stereotypes for African American and White women, occurred for both groups but in qualitatively different ways that overburdened Black and underburdened White women. Given that the fundamental basis for tokenism effects is difference between tokens and dominants, further research exploring race/ethnicity and the intertwining of multiple identities is warranted.

Researchers have explored a wide range of outcomes of proportional underrepresentation beyond those originally documented by Kanter. On the one hand, men, whether tokens or not, were advantaged consistently over women in both wages and promotions, making the broader gendered subtext of favoring men more influential than tokenism's work group proportions. On the other hand, and consistent with tokenism theory, career aspirations, job satisfaction,

and organizational commitment were negatively impacted by women's token status. Laboratory research documents that women who anticipated being a token in an upcoming group sought reassignment to a nontoken group. Furthermore, vignette studies, which described token settings and recorded readers' expectations, paralleled actual tokens' experiences, suggesting that job choice may be affected by negative expectations for token women. Token women more commonly reported sexual and gender harassment, probably used by dominants as mechanisms for boundary heightening, that is, for simultaneously tightening bonds among in-group dominants and boundaries excluding out-group tokens. Subjective performance evaluations from dominants were more negative for token women compared to women in groups with both higher female representation and all men, with some of these differences disappearing when raters were held publicly accountable for their assessments.

Recent research on stereotype threat has clarified the impact of tokenism on actual individual performance. Stereotype threat occurs whenever a negative task-relevant stereotype is activated for a member of the stereotyped group who values performance in the tested domain. For example, simply being a high-achieving solo woman taking a math test in the presence of two men led to poorer performance, both when test results were public or private, than that of women randomly assigned to same-gender test groups. A strong, developing body of research on stereotype threat merges with tokenism research to argue that the effects of token status extend beyond performance pressures to actual performance decrements. These studies raise serious questions about what it takes to level the playing field of work group interactions.

Another strand of research moved away from the simple documentation of negative impact to explore ways to facilitate tokens' success. Given Kanter's emphasis on proportions, the most obvious panacea became increasing numbers themselves. The benefits of numbers remain unclear, with some research reporting more favorable outcomes when proportions exceed 15 percent and with contrasting research highlighting intensified boundary heightening in the face of intrusive numerical increases. The inconclusiveness in this literature may well rest in the clearly established understanding that tokenism effects themselves are produced by more than skewed proportions.

Another line of research has followed successful tokens, comparing them to both less successful tokens

and similarly successful dominants. Successful tokens drew on good records of accomplishment, nurturing relationships, proactive management of their own career, mentoring, and developmental job assignments. Successful tokens typically were co-opted into the higher status group, declining to support and identify with their still disadvantaged out-group of origin. These findings are not surprising, given that such individual boundary crossing fails to challenge the core structure of tokenism.

The promise of tokenism theory when it was first introduced came from its focus on social context and situational barriers rather than on individual accountability with its potential for victim blaming. Individual tokens may persist and succeed, further directing attention away from the core tenet of tokenism theory, that is, that social context involving work group composition and its intersection with sexism, racism, and other forms of social oppression matters.

TOLERANCE FOR AMBIGUITY

Tolerance for ambiguity can be defined as the degree to which an individual is comfortable with uncertainty, unpredictability, conflicting directions, and multiple

demands. In essence, tolerance for ambiguity is manifest in a person's ability to operate effectively in an uncertain environment. The extent of ambiguity may vary greatly and is generally linked to the underlying cause for uncertainty. Some people may be born with a natural predilection toward tolerance for ambiguity, while for others it develops over time through education and experience. And there are some who strive daily to simply eliminate ambiguity in their lives. However, ambiguity exists in different degrees and for varying periods of time within corporations and organizations around the world. It may arise when questions are posed that have no single answer or that generate a number of new questions. Perhaps the initial question was ambiguous. Occasionally there is ethical uncertainty, and the line between right and wrong becomes blurred. How one deals with uncertainty and the stress of an ambiguous situation is an important consideration in the world of work.

Tolerance for ambiguity was first recognized as a personality variable in the early 1960s. Since then, psychologists, sociologists, project managers, human resource development professionals, software developers, business consultants, educators, and others have examined tolerance for ambiguity to better understand how people deal with uncertainty in their lives, whether in family situations, in the workplace, or in social settings. In general, people who have a high degree of tolerance for ambiguity tend to be able to see and appreciate multiple perspectives and thus are not so quick to rush to judgment. They ask more questions and look at more possibilities when trying to solve complex problems. Thus, tolerance for ambiguity often indicates a person's ability to be creative and to think critically.

The American Council on Education cites the ability to function effectively in an ambiguous, complex, and rapidly changing environment as a critical skill corporate recruiters look for in a pool of applicants. The job interview might include questions to determine whether the applicant simply copes with uncertainty, tolerates ambiguity, or embraces it as an exciting element of the world in which we live and work. For example, a job applicant may be asked to cite an instance in which he or she had to deal with an unexpected event or abrupt structural change at work. Where one's propensity for dealing with uncertainty falls along the continuum may be seen as an indicator of other attributes, such as a tendency toward flexible thinking, a preference for swift and independent decision making, or a positive attitude toward risk taking.

Business leaders highlight some of the talents they look for that go beyond the technical expertise needed in any particular field. These include excellent communication skills, successful teamwork, flexible and creative thinking, ease working with people of diverse backgrounds, understanding of implications associated with the global nature of business today, high ethical standards, and ability to deal with ambiguity in the work environment. One can readily see the connection among several elements in the forgoing list. For example, it is difficult to truly understand people from another culture if communication efforts are hampered by impatience derived from low tolerance for ambiguity. This in turn influences open-mindedness and the possibility of discovering creative solutions to complex issues.

Sources of ambiguity in the workplace vary. In the current milieu of international corporations and global organizations, it is likely that there will be multiple cultural perspectives to be considered. Studies indicate general cultural traits (sometimes referred to as sociotypes) within large ethnic communities. Eastern, African, and Iberio-American cultures tend to be more cooperative, while the Western orientation is more competitive. Similarly, the Western communication style is generally more direct than that of other cultures. In some instances, what is acceptable in one culture might be entirely inappropriate in another. Thus, a high level of tolerance for ambiguity is advantageous in multicultural settings.

At times, a business may experience rapid change that borders on the chaotic. Indeed, slow and steady improvement as a mechanism for organizational change is uncommon. Agility is important in today's fluid business climate as well as in the public sector. In times of rapid change, the way one deals with uncertainty becomes critical to individual success, thus influencing the success of the organization. In the frenzy associated with change and upheaval, those who are able to navigate the ambiguity are often seen as management material and have advancement potential within the organization.

Another source of uncertainty in the workplace may be a lack of clarity in expectations and in the long-term goals of the organization. This is usually due to ineffective management and may be a contributing factor to the type of chaotic change just described. Senior officers of the organization might be sending mixed signals to employees, or there may be dissension among those in upper management. When

faced with a high degree of uncertainty, individuals can simply try to cope with the situation, or they can try to maintain a low profile to “stay out of the way” of management ambiguity. A person who is adept at tolerating ambiguity and can still maintain a high level of productivity in the unstable climate is likely to continue to be an effective contributor in the work setting. Although they are probably few in number, there are those who fully embrace ambiguity, who see it as an opportunity for personal development and creative organizational change.

The world of work continues to grow increasingly complex. In businesses and organizations, those who are called upon to solve complicated problems and make good decisions must rely on more than factual knowledge. Dealing with uncertainty may evoke feelings of ambivalence or, in the extreme, paralysis and helplessness. Moving too quickly to decisive action, however, can lead to disaster. Employees and senior officers alike need to recognize uncertainty as a source of creative energy and therefore encourage a tolerance for ambiguity.

TOXIC LEADERSHIP

Toxic leadership exists in virtually every arena of social life. It takes a special toll, however, in the workplace, where workers frequently feel particularly constrained to acquiesce to employers and managers

whom they perceive as controlling their professional and economic destinies.

Toxic leaders in the workplace inflict serious and lasting harm on their employees, their colleagues, their organizations, and stockholders, even their customers and clients. They do so by virtue of their destructive behaviors and dysfunctional personal qualities. The garden variety “difficult boss” does not qualify as a toxic leader. Only those leaders who leave their followers and organizations measurably worse off than they found them—sometimes even totally destroying them—fall within this definition of toxic leaders.

Toxic leadership represents a social/psychological phenomenon, whose complexity is reflected in the fact that the same individual may be viewed as noxious by some and heroic by others, as toxic in certain situations and nontoxic in others, as intentionally damaging in particular circumstances but unintentionally harmful in still others. Consequently, understanding and defending oneself and others against various forms of toxic leadership require a multidimensional framework, one that takes into account both toxic leaders as well as their intended and unintended victims.

THE TOXIC LEADER'S SIDE OF THE EQUATION

At least six dimensions of the *leader's* decisions and actions need to be considered. These include *intentionality*; *intensity* and *duration* of the harm; nature and number of *destructive behaviors* and *dysfunctional personal characteristics*; and significance and impact of the *outcomes*.

In terms of *intentionality*, leaders who deliberately injure others or knowingly enhance themselves at great cost to others we consider intentionally toxic. Leaders who inadvertently cause substantial harm to others by careless or reckless behavior or faulty character structure, including incompetence and cowardice, we categorize as unintentionally toxic. *Intensity* of the leader's toxicity may vary considerably, as may the *duration* of harm; however, both intensity and duration must have a sufficiently significant *impact* to warrant the diagnosis of toxicity.

Behaviors of Toxic Leaders

Space limitations permit only an abbreviated list of *destructive behaviors* that qualify for inclusion in the

toxic leader's repertoire. Among the most destructive behaviors that toxic leaders use are the following:

- Violating human rights, by eliminating or destroying individuals through undermining, incapacitating, humiliating, intimidating, demoralizing, seducing, isolating, disenfranchising, and/or firing them without just cause
- Stifling constructive criticism and enforcing compliance with the leader's decisions through inappropriate means
- Weakening and/or destroying the organizational systems intended to promote truth, excellence, and equity, and otherwise engaging in deceitful, unethical, illegal, and/or criminal behavior
- Setting followers against one another, identifying scapegoats, and/or inciting disdain or other mistreatment of those the leader perceives as his or her opponents
- Deliberately creating the illusion that the leader is the only one through whose special gifts the followers can succeed, thereby increasing the leader's power and decreasing the followers' self-confidence. This behavioral strategy may involve stimulating the followers' most primitive fears and needs, including those for safety, material well-being, self-esteem, and meaningfulness
- Ensuring that the cost of unseating the toxic leader simultaneously destroys the organization.

This necessarily incomplete list of destructive behaviors combines with various character flaws to define toxic leaders.

Character Flaws of Toxic Leaders

Toxic leaders frequently exhibit a variety of dysfunctional personal qualities or character flaws, from lack of integrity to cowardice. Here too the following qualities represent only a partial catalogue:

- Deficient integrity that renders the leader untrustworthy
- Excessive ambition, lust for power, and/or greed that result in ruthless self-aggrandizement
- Outsized ego, disproportionate narcissism, and/or arrogance that blind toxic leaders to their own shortcomings, thereby limiting any capacity for self-correction and positive growth
- Amoral behavior that limits the toxic leader's capacity to differentiate between right and wrong
- Inadequate empathy and compassion that prevents toxic leaders from grasping the actual impact of their actions

- Lack of intellectual and other relevant competencies that leads to misdiagnosing problems and failing to create appropriate solutions
- Cowardice that inhibits toxic leaders from taking necessary difficult decisions and actions.

THE FOLLOWERS' SIDE OF THE EQUATION

An adequate conceptual framework for toxic leadership also requires a complex understanding of those whose lives the toxic leader affects. In the workplace, this refers primarily, but not exclusively, to those individuals who work under the direction or authority of the leader. Although most followers, or in this case employees, would deny it, we often tolerate, prefer, and sometimes even create toxic leaders. As targets of toxic leaders, we followers respond in terms of three major components: our *psychological and existential needs and fears*; the *sociohistorical context* in which we exist; and the *interaction* between our *individual capacities and experiences*, on the one hand, and the *environment* in which we live and work, on the other.

Psychological and Existential Needs

Employees bring to the workplace the *psychological* needs and fears that stem from their individual psyches, as well as *existential* concerns that emanate from their common experience as human beings. Psychological forces that predispose individuals to seek out leaders include the need for reassuring authority figures to provide parental direction; the need for certainty, physical safety, and economic security in an uncertain and turbulent world; the need for approval and inclusion in some human group; the need to feel chosen and special, which may provide access to important centers of action; and the fear of one's personal inability to challenge a toxic leader. Toxic leaders manipulate these needs and fears to bend followers to their will.

The circumstances of our human existence heighten our vulnerability to toxic leaders. Perhaps the most critical *existential* force is our awareness that we inevitably shall die under conditions we currently cannot foresee. The suppressed angst, or existential anxiety, that such awareness provokes sends us on an endless search for safety, certainty, and the meaning of our lives. This existential dread initiates our quest to escape death, at least symbolically, by achieving immortality through heroic deeds. Toxic leaders

attract us with promises of security, certainty, noble enterprises, and heroic opportunities for immortality.

Our External Environment: The Sociohistorical Moment

The external environment pummels us with incessant change, turbulence, and uncertainty. Natural disasters, scientific and technological catastrophes, as well as social and political crises, unsettle followers. While uncertainty and change open the door to previously unavailable freedom, they also stimulate followers to reach for reassurance from the nearest source. In such perturbing circumstances, followers accept leaders who offer to restore order and safety.

Each culture also inculcates clear social norms and behavioral expectations. It articulates what constitutes outstanding achievement, a standard that sets the stage for heroic action. Moreover, each historical moment offers new challenges, from walking in space to discovering the cure for some dreaded disease.

The Individual's Experience in the External World: Psychosocial Forces

We measure ourselves against the achievement standards set by society and its various institutions, including work organizations. When, by dint of our own capacities and opportunities, we meet society's norms for achievement, our self-esteem rises. When we exceed those norms, we find ourselves acclaimed as heroes and leaders (since the culture rarely distinguishes carefully between the two). When we fall short, however, we often seek alternative routes to bolster our self-esteem. One common path entails joining the ranks of those already acknowledged as leaders so that we may share vicariously in their status.

Our perception that the leader (or the "boss" in the workplace) has special gifts, greater than our own, plays an important role in maintaining our acquiescence. This belief enforces our acceptance, even when the leader's behavior crosses the toxic line. When the corporate culture reinforces the external culture's criteria for leadership, we increasingly believe that employers or managers who meet or exceed those standards are worthy recipients of our respect and support. Such circumstances also undermine our personal confidence to challenge their decisions and actions. When leaders use toxic means—such as

unwarranted threats to our employment—to ensure compliance, we are intimidated all the more.

Toxic leaders in the workplace rarely need to expend much effort or resources controlling those individuals who work under their authority. Rather, those in the grip of toxic leaders tend to keep themselves under control. Individuals daunted by toxic leaders convince themselves through a set of *rationalizations* that they *cannot* resist because they lack the skills and talents to do so successfully. Eventually, these rationalizations harden into a web of *control myths* that persuade the followers they *should not* defy the toxic leader, because that individual deserves to be in control by virtue of his or her strengths and the followers' needs.

DEALING WITH TOXIC LEADERS

Although many employees who work under the aegis of toxic leaders silently endure their suffering, certain circumstances may induce resistance. For example, individuals tend to speak out against a toxic leader when they are sufficiently close to the toxic action to be aware of the serious harm being caused. When they identify with the individual or group being injured, followers are more likely to feel motivated to challenge the toxic leader. Moreover, when the costs of not speaking out outweigh the benefits, followers may feel compelled to oppose the leader, either privately or publicly. Occasionally, the emergence of a protestor and/or a critical event can galvanize previously silent sufferers and/or onlookers.

Various strategies can be used to control or unseat a toxic leader, although the risks can be substantial. All strategies for deposing a toxic leader require careful planning. Such planning includes gathering relevant intelligence not only about the toxic leader but also concerning others who might assist or undermine the effort. Keeping an evidentiary journal or log of the leader's toxic behavior is essential, since such documentation will help to induce others to act. Additional steps include identifying and collaborating with associates who not only recognize the harm being done but who also are willing and able to take measures to curtail the damage. Consulting trustworthy, experienced colleagues and opinion makers within the organization, as well as the toxic leader's peers or advisers, can assist challengers in developing an effective operational plan.

Personal Strategies and Policy Options

Personal strategies and *policy options* exist for dealing with toxic leaders. At the individual level, *personal* strategies involve taking action on one's own or in collaboration with like-minded colleagues. Acting alone is fraught with risks to the follower. Coalitions tend to be more successful than lone rangers in confronting toxic leaders.

Low-key approaches tend to work best when there is reason to believe the leader is both able and willing to change his or her toxic ways. Offering to counsel the leader, aided by a positive action plan with specific guidelines and benchmarks for change, can be a useful first step. If the leader responds positively, a schedule for future discussions and progress evaluations can be developed. "Keeping one's cool" at every stage in the process is imperative to a successful outcome.

When toxic leaders are unable or unwilling to change their behavior and/or control their character flaws, then employees may work quietly to limit, offset, or, if possible, undo the damage caused by the leader. If that option fails, followers may take action to undermine the leader; however, this strategy presents serious moral dilemmas that must be carefully weighed.

If the harm to the organization warrants removing the toxic leader, resisters should join with others, particularly the most senior and respected members of the organization, to undertake this mission. The participation of the board is critical, but since the board usually was responsible for selecting the leader, opening the board's collective eyes to the leader's shortcomings often proves to be a delicate undertaking. One strategy involves individually approaching key board members either directly or through their trusted associates. Once a sufficient number of board members perceives the need for collective action, a meeting of the executive committee or the full board is in order.

If the board refuses to act, then informing the media offers another recourse. Since the media frequently face their own organizational and political constraints, this strategy must be undertaken in an informed and cautious manner. Finally, when it is evident that none of these strategies will work, or if the harm is limited to you, then leaving the organization may be the most realistic way for an individual to deal with a toxic leader.

At the organizational level, *policy options* can be developed for preventing the emergence and/or limiting

the damage wreaked by toxic leaders. The selection process is key to spotting potentially toxic leaders. The selection process should identify the largest possible cohort of qualified candidates, who then must be screened by multiple layers of reviewers from various sectors of the organization. Intensive due diligence should weed out toxic candidates. The selection process should be as transparent as possible. Once they have been selected, leaders at every level should be reviewed regularly with input from the total role set with whom they interact.

Followers should insist upon selecting leaders who do not offer them illusions of safety and grandeur. Leaders who expect them to participate in the governance and conduct of the organization are less likely to require submissive followers. Followers, for their part, must confront their own anxieties and fears to ensure that candidates cannot manipulate them through proffering unrealistic visions for the organization and its members.

Maintaining open and democratic policies and practices throughout the organization provides a bulwark against toxic leadership. The requirement for leaders to conduct periodic accountability sessions with large segments of the organization to explain critical decisions that they have taken is another useful policy option for keeping toxic leadership at bay. Term limits tend to prevent or reduce toxicity by reminding leaders of their future return to the ranks of followers or their timed exit from the organization. Finally, in organizations that create respectable departure options, such as a transition period with organizational support, leaders are less likely to cling to power beyond their reasonable usefulness to the organization.

TRAINING AND DEVELOPMENT

Training and development (T&D) activities identify and ensure, through planned learning programs, the development of key competencies that enable individuals to perform to the best of their ability, aptitude, and attitude on the job. The T&D functions have evolved to contend with and respond to social and economic events, as well as being highly influenced by changes in management trends and philosophies. Effective training provides opportunities for people to perform in new functions and to be promoted into new situations.

Training should be distinguished from education. Education is instruction in more general knowledge such as history, philosophy, economics, or mathematics. Training teaches the learner how to do a specific task or function (i.e., manage their time, change a behavior, or run a machine). Being more technically oriented, training is more applicable to the adult learner who brings different experiences and psychological predispositions to the workplace.

T&D has evolved from simple apprenticeship programs to a blend of instruments, including classroom-based instruction, systematic job instruction, team building, simulation, Web-based individualized instruction, and many others. Before industrialization,

training focused primarily on direct instruction and apprenticeships. Initially, as factories began to emerge in the Industrial Revolution, the first-line supervisor was normally assigned responsibility for training the workforce. Rationalization of work, division of labor, and routinized production created workers who became the keepers of the machinery. Due to this specialization, apprenticeships and on-the-job training were the training methods employed.

As the Industrial Revolution gained momentum, the number of factories increased and grew larger, and it became necessary to hire more employees directly from the farming communities who had little or no manufacturing experience. Unable to keep pace through one-on-one apprenticeships or on-the-job assignments, training moved into the classroom with assigned "trainers," enabling several people to be trained simultaneously with minimal disruptions to the production line. "Vestibule" training was developed for jobs requiring skill development on particular equipment away from the pressures of a production schedule.

By the first decade of the twentieth century, the United States had become a fully industrialized society with modern management, higher wages, and low unemployment. America's involvement in World War I created a widespread labor shortage, especially in skilled worker categories, because of the sudden need for production of wartime armaments, draft to government service and the military, and restrictions on immigration. Training departments were established in many companies to answer the call for faster and more efficient training methodology. A just-in-time method was developed, consisting of a four-step process that enhanced the teaching of repetitive, manipulative skills in a fast-advancing, automated world.

In the four decades after World War I, especially after World War II, the United States experienced unparalleled economic growth. While the industrial world was in full development mode, philosophers and psychologists were in the wings analyzing group dynamics and the learning processes. In the training arena, it was quickly recognized that not all workers were equal in their ability to learn and retain information. Given the numbers to be trained, the classroom was still the training site of choice, although it became necessary to rethink the way training was delivered, to incorporate techniques that would allow for the disparity of abilities and not hold back the more advanced learners. Self-paced learning and individualized training programs were developed to meet these needs.

The three decades between 1960 and 1990 brought continuing prosperity, an increased demand for services, a growing use of information technology, and an opening of global markets and competition. This was an equally tumultuous time for training departments as they tried to stay on top of the computer age while realizing that service jobs are labor intensive and not particularly amenable to automation. Moreover, the skill sets needed in a service society were less mechanical and more intellectual and behavioral, hence more difficult to define in precise training terms.

One answer in an ever-changing work environment was the development of a training system called job support, which did not require the employee to learn every process step by step, instead, to know where to find the information. Second, communication issues and interpersonal concerns in a more diverse workplace became prime issues. A third development was the incorporation of behavioral role modeling, which stressed the use of observation, modeling, and vicarious reinforcements to change human behavior. Multi-million-dollar training facilities endowed with computer-based training and technological innovations were built to meet these challenges.

Business theorists recognized that employees represented a vital resource as important as capital and thus should be managed and developed to facilitate competitive advantages. Gaining a competitive edge by managing people more effectively became increasingly important, thus leading researchers to rethink old training theories and reframe them in a modern context. However, a diverse workforce facing more complex problems made this a difficult task. Teams—their size, composition, dynamics, diversity, and processes—became the central focus of training initiatives. The *22nd Annual Training Industry Report* published by *Training* magazine indicated that the market was utilizing a cross array of training tools from the traditional classroom to computer-delivered instruction. The single largest growing training method was self-paced Web-based courses. The fluidity of the environment and the workforce created a challenge to increase the offerings of effective and intensive T&D programs.

Technology-based training will be the means of the future, that is, Web-based training (Internet, intranet, extranet), computerized self-study (CD-ROM, DVD, diskette), and satellite/broadcast TV (videoconferencing, audioconferencing, teleconferencing). An integrated

approach of the many techniques that have been successful with new modern twists will be applied to training venues. The growing complexity of global markets and an ever-escalating number of “virtual organizations” will lead to an increased need for negotiation and interpersonal communication skills as diverse employees at all levels need to learn how to interact across organizational boundaries and treat each other with greater respect and sensitivity.

Since the beginning of time, training has been a primary way to reproduce knowledge and skills. As societies evolve and become more complex, the instructional paradigms and the skills needed by those trained must also change. Furthermore, as the pace of change accelerates, efficiency (speed and cost) must join effectiveness as criteria for successful training. T&D helps individuals and organizations meet the increasing demands of the global business arena. Successful companies in the future will be those that preserve and develop their human capital by providing high-value training and development activities within a challenging learning environment.

TUITION REIMBURSEMENT

Tuition reimbursement is a popular benefit in which employers pay all or part of an employee's tuition for college courses or degree programs. Educational benefits taking the form of scholarships and grants are tax-exempt benefits under Section 117 of the Internal Revenue Code if the employee is a degree candidate and the course work is job related. Tuition reimbursements are classified as a working condition fringe benefit under Section 132 of the code and do count as gross income if the education maintains or improves job skills. In addition, educational assistance programs (EAPs), as defined under Section 127, permit companies to provide up to \$5,250 toward educational expenses without employees incurring tax liability. An EAP requires a written plan that is open to everyone but does not require the employee to be enrolled in a degree program or the content to be job related.

Surveys of both students and firms indicate that educational assistance and tuition reimbursement programs are widespread. A 1996 national survey found that 75 percent of U.S. establishments with more than 20 employees and almost all large employers offer some type of tuition reimbursement benefit. Other estimates come from surveys conducted by professional associations. These range from 67 percent of members of the Society for Human Resource Management (SHRM), who offered graduate assistance in 2005 to 89 percent of members in the International Foundation of Employee Benefit Plans (IFEBP), who report having at least one education benefit program. Surveys of students also find extensive use of employer tuition aid. A National Center for Educational Statistics (NCES) survey in 1996 found that 6 percent of all undergraduates and 13 percent of all graduate students received financial aid from their employers. For students who identified themselves as working, 25 percent of undergraduates and 42 percent of graduate students received employer aid. Tuition aid was strongly related to course of study; approximately one-third of all undergraduate students enrolled in business, engineering, and computer science programs received financial aid from their employers.

Although tuition reimbursement programs are common and nearly universal among large employers, the costs and structure of the programs vary widely. A 1998 Hewitt Associates survey of 460 tuition

reimbursement programs found that 77 percent reimbursed educational expenses (such as books and fees) in addition to tuition and that 14 percent placed no limits on the amount of tuition that could be reimbursed. A 2000 IFEBP survey found that the most common restrictions placed on tuition reimbursement programs were reimbursements contingent on grades, annual dollar limits, and length of service requirements before an employee becomes eligible to participate.

From the firm's perspective, tuition reimbursement programs are appealing, since they are widely seen as a good benefit by employees regardless of whether they actually take advantage of the programs. For example, *Fortune* magazine uses educational benefits in their assessment of the "Best Places to Work." In addition, costs are only incurred when employees actually enroll, and typically a much smaller portion of those employees who are eligible actually use the programs. Although there are no broad-based estimates of program participation, an IFEBP survey of 26 programs found that slightly more than half had participation rates of less than 5 percent and three-quarters reported less than 10 percent of employees. A RAND study of tuition assistance in the military found participation rates between 9 percent and 13 percent.

Company expenditures on tuition reimbursement follow the prevailing notion in the popular business press that employee development helps in recruiting and retaining quality employees. This substantial investment in employee education raises interesting questions, however, because it appears to contradict classic human capital theory as originally formulated by Gary Becker and others. This is because college classes develop "general" skills that are broadly marketable and should therefore make employees more likely to turn over. Human capital theory predicts that a firm would only invest in general skills if an employee were willing to bear the cost by accepting lower wages before or during the training. Since studies have shown that employees do not receive lower wages during training, a question is raised as to whether college educations create job opportunities and lead to turnover.

Of all the forms of company-sponsored development, college courses covered by tuition reimbursement are the most likely to be seen by employees as providing marketable skills because of the broad content and qualifications that they offer. Some organizations have recognized this potential for turnover and instituted policies that require the employee to stay for

a certain length of time or repay the cost of the classes. However, the proportion of firms that use contractual “handcuffs” to keep employees is still relatively low, with estimates ranging from 16 percent to 23 percent. This leaves open the question of why employers would provide educational assistance when the new skills would theoretically create an incentive for employees to leave.

Two recent studies have examined this question specifically and found that retention of employees while they are in school, as well as the ability to recruit better employees in general, justifies the widespread use of tuition reimbursement even though it provides employees with more marketable skills. A study of salaried employees from a manufacturing firm found that employees are less likely to turn over while enrolled in school and taking tuition reimbursement benefits. Employees who graduated with advanced degrees were then more likely to leave the company than those who were still in school, but the incentive to leave was alleviated if the employee was promoted after earning a degree. A second study found that firms with tuition reimbursement programs paid higher wages and had lower turnover than other employers using a large sample of establishments. Taken together, this research suggests that tuition reimbursement programs help to attract and retain high-quality employees despite the fact that employees gain new and marketable skills.

TURNOVER

Turnover is the separation of a member from an organization. Turnover can be categorized as voluntary (e.g., an employee voluntarily quits working at Firm A to start a new job at Firm B) or involuntary (e.g., an employee is laid off, downsized, or fired). Though in both cases the organization has one less member, the causes and consequences are highly likely to be different. In the case of voluntary turnover, most organizations are concerned about the many costs associated with the loss of needed personnel. In the case of involuntary turnover, most organizations are pleased to obtain the cost savings associated with the reduction in personnel. From the employee perspective, both voluntary and involuntary turnover have important implications for career development.

Because employers initiate involuntary turnover, it is generally assumed to be in the organization’s best interest. At the same time, this action has a major impact on the individual asked to leave. In the long term, organizational separation will likely alter an individual’s career path. After experiencing involuntary turnover, an individual may seek work in the same field and move up, stay at the same level, or move back on the same career track. However, many individuals reevaluate their career path at critical junctures, such as organizational separation, and decide to change careers.

In contrast, voluntary turnover is generally initiated by an employee and is generally assumed to be in the employee’s best interest. Many employees quit to start new jobs, to commence new careers, or to pursue personal interests. Evidence indicates that nearly all of these people expect the value of the new opportunity to be greater than the one they are leaving behind. At the same time, most organizations find voluntary turnover to be extremely expensive. They experience separation costs (e.g., exit interviews, administration costs, separation benefits, productivity declines, overtime and temporary help expense, lost revenues from turning away clients), replacement costs (e.g., recruitment, entrance interviews, testing, applicant selection, moving expenses), and incremental training costs (e.g., orientation, formal job training, off-site training, on-the-job training, inefficiency). Estimates of these costs vary by industry, position, and geography. They range from a few thousand dollars for low-skill positions to hundreds of thousands of dollars for high-skill positions.

However, not all of the consequences of voluntary turnover are bad. Resources formerly allocated to departed employees may be used to enable increased advancement opportunities for remaining employees. New employees may also bring new ideas, technology, or enthusiasm when they join the organization. Furthermore, when marginal or overpaid performers leave, employers may be advantaged, as they expect to replace them with better performers at lower wages. However, in the aggregate, research suggests that organizations that experience high exit rates underperform relative to their industry peers.

Because organizations and managers would like to have greater control over voluntary turnover, researchers have devoted a considerable amount of attention to the topic. Many theories that seek to understand the causes or antecedents of turnover have been advanced. Among the leading theories are job characteristics theory, met expectation theory, organizational demography, leader-member exchange, person-organization fit, the unfolding model, and job embeddedness. The most widely studied model of turnover is based on James March and Herbert Simon's pioneering work. They conceptualized employee turnover as a reflection of an employee's decision to participate in the activities of the organization. They explain the participation decision through the perceived desirability of movement and perceived ease of movement. Over the past five decades, the perceived desirability of movement has evolved to be defined as work attitudes like job satisfaction or organizational commitment, whereas the perceived ease of movement has come to mean perceived job alternatives or actual unemployment rates. In sum, this model posits that people leave if they are unhappy with their job and if job alternatives are available. Although valid, this model has had modest success in predicting turnover, with the variables seldom explaining more than 10 percent of the variance in turnover.

More recently, others have focused on why people stay rather than why they leave. Reflecting this different approach, researchers have drawn attention to the reasons people stay through a concept called *job embeddedness*. This concept reflects a sense of being "situated or connected in a social web." Its key considerations are (a) the extent to which people have links to other people or activities, (b) the extent to which their job and community fit with the other aspects in their life space, and (c) the ease with which links can be broken—what they would give up if they left. These dimensions are important both on and off

the job. After controlling for job satisfaction, organizational commitment, job alternatives, and job search behavior, job embeddedness explains a significant amount of turnover behavior. In sum, job embeddedness with its focus on why people stay represents an important complement to the job dissatisfaction approach that focuses on the reasons why people leave.

Many meta-analytic studies are available to help organizations understand the correlates of turnover. As would be expected, job satisfaction, organizational commitment, leader-member exchange, met expectations, and person/job fit all exhibit modest negative correlations with turnover. Important career variables also exhibit modest negative correlations with turnover, including promotions, promotion satisfaction, promotional opportunity, pay satisfaction, and performance. Turnover is positively correlated with similarly dysfunctional organizational outcomes such as lateness and absenteeism.

Because of its significant organizational consequences, turnover has received a great deal of research attention over the past 50 years. To date, the research still only explains a fraction of the variance in turnover behavior. Therefore, it is highly likely that additional work will be done in this area. Some of the most interesting areas have profound career development implications (e.g., alternative work arrangements, outsourcing, and retention of women and minorities).

TWO-CAREER RELATIONSHIPS

Two-career relationships, also referred to as *dual-career families*, represent a unique variation of the larger category of two-wage relationships or dual-earner families. This entry begins with a definition of two-career relationships and how this family form differs from the larger category of dual-earner families. Described next are factors related to its emergence and increased prevalence as a family form, characteristics of two-career relationships, challenges faced by partners in these kinds of relationships, and factors associated with successful career development and family life for individuals and partners. Because changing views about gender are central to the emergence of this family form, and to its ongoing evolution, special attention is given to this factor. Finally, it should be noted that the focus is on two-career heterosexual relationships; relatively little information is included on important distinctions associated with race, ethnicity, and sexual orientation.

DEFINITION OF TWO-CAREER RELATIONSHIPS

The term *two-career relationships* has primarily been used to describe a unique and enduring form of heterosexual marriage. In 1969, Rhona and Robert Rapoport first used the term “dual-career family” to describe what they considered to be an unusual and “revolutionary” type of dual-wage heterosexual family that emerged as the result of complex social changes. Revolutionary from their perspective was the dual-career family’s apparent inconsistency with respect to traditional notions of gender in marriage. In contrast to traditional marriage, in a dual-career marriage both partners pursued a lifelong career, relatively uninterrupted, and also established and developed a family life together that often included children.

The emergence of the heterosexual two-career family represented dramatic changes in conceptions of love, enduring relationships, and social structures in our society. Foremost among these were changes associated with assumptions of male superiority and male authority over women, and assumptions of female destiny being tethered to fertility and caregiving roles. Social changes had brought about an evolution in normative roles for adult women who married and broadened these roles to include occupational

pursuits. Traditionally, heterosexual women, even those who had prepared for lifelong careers, were expected to put careers secondary to marriage and caring for husbands and children. Husbands’ careers were viewed as primary and were to be interrupted minimally by family demands; women’s were not. Today, some 50 years later, the situation is quite different. Many women and men prepare themselves for careers with the expectation that their partner will support their career pursuits and that they and their partner will integrate occupational work with family life. This in turn has brought about changes in men’s roles and in societal views about what is needed to support the normative life roles of women and men.

TWO-CAREER, SAME-SEX RELATIONSHIPS

Two-career homosexual families also challenge assumptions about love and enduring relationships, but these are largely associated with attitudes and values about individuals of the same sex entering into a committed relationship. As is described later, occupational and family roles converge in many of the same ways for same-sex and heterosexual couples, and both experience similar stresses and challenges associated with their combining occupational work and family life, but there are also important differences. Some of these differences are described later in this entry.

TWO-CAREER RELATIONSHIPS AS COMPARED TO THE LARGER CATEGORY OF DUAL-WAGE RELATIONSHIPS

Two-career relationships are quite prevalent today, but two-earner families are far more numerous and in fact are the norm in the United States. Two factors are generally thought to distinguish the two-career family from the larger category of two-earner families: (1) the meaning of career and the opportunity for career development and (2) views of gender within a committed relationship.

In two-earner families, one or both partners are employed full or part time in jobs for which special education and training may not be needed. Historically, in comparison to careers, jobs involved less commitment to the work involved, required less training, paid less, and lacked clear developmental stages and accumulation of experience. This contrasts to partners in two-career families who are employed in positions requiring special education and training

and undertaken or engaged in as a lifework. Typically such positions require a high degree of commitment and provide the person with a sense of consecutive, progressive achievement, be it through promotions or other recognition of one's accomplishments and skills. In recent years, the distinction between what constitutes jobs and careers also includes whether an individual views involvement in full-time occupational work as reflecting that person's self-concept and life goals as a career. For example, some individuals view teaching, administrative positions, or practicing law as careers, and others consider these positions as nine-to-five jobs.

With regard to gender, on average, there is less gender-role specialization and less traditional authority differences between partners in two-career families than in two-earner families. Individuals enter two-career relationships with the expectation that both partners will pursue careers relatively uninterrupted and be involved in family life. Male partners appear less defined by the traditional "good provider role" long associated with male privilege and power and enter into marriages that view women and men as partners in love and work. This arrangement differs from more traditional relationships in which occupational work is viewed as the purview of men and considered separate from women's home and family responsibilities, even when female spouses are employed.

FACTORS ASSOCIATED WITH THE EMERGENCE AND INCREASED PREVALENCE OF TWO-CAREER RELATIONSHIPS

Historically, careers and occupational work defined men socially and economically but not women who worked only to benefit the family. Women were defined socially by their husband's (or father's) occupation and socioeconomic standing. This situation began to change after World War II. The women's movement of the 1960s largely concentrated on how to provide increased and more equitable educational and career opportunities for women in comparison to men. By the 1980s, the women's movement had expanded its focus to include the culture of work and changes needed to accommodate occupational work and family life. Another important change had to do with men as partners. By the 1990s, national time-surveys began to document a significant shift toward

more sharing of housework and child care between spouses.

Thus, contemporary two-career relationships are built on very different assumptions than were traditional relationships. The single most important factor bringing about this difference is women's increased access to education, good career opportunities, laws to protect them from discriminatory practices, and a status and meaning separate from their affiliations with men. Currently, women and men graduate from high school and college in about the same proportion. Approximately 84 percent of both women and men are high school graduates, and 28 percent are college graduates. Women are entering and graduating with advanced degrees from fields such as law, medicine, the life sciences, and business administration at a rate similar to men. Forty percent of college-educated women earn as much or more than their spouses, and married women on average provide 40 percent of their families' income. Finally, for both women and men, the age of first marriage is increasing, and the number of children in families is decreasing. The fact that more women view occupational work in professional fields as central to their self-identity increases the number of families with partners who both consider themselves in careers, as opposed to women moving in and out of the workforce depending on family needs. This is the larger context of two-career relationships today.

GENERAL CHARACTERISTICS OF TWO-CAREER RELATIONSHIPS

The emergence of the two-career relationships marks a significant shift in views of women's roles. This family form not only recognizes women as engaging in influential occupational positions that had historically only been open to men but also acknowledges women as participating in careers as well as marriage. Because the dual-career family form signaled profound social change, a good deal of research has focused on this family form. The following characteristics describe the variations as well as the commonalities among two-career relationships.

Patterns of integrating career and family vary from quite egalitarian to quite traditional. These variations and patterns depend to a large degree on partners' attitudes and values, relative incomes, availability of child care, employers' views and policies, and their current employment situation. Women, more than men, who prepare for careers assume and push for the

“revolutionary” two-career family envisioned by the Rapoport. Although women on average still do more of the family work, men are increasingly involving themselves in home roles and parenting. Studies indicate that at least one-third of heterosexual two-career families and most lesbian and gay partners have established egalitarian role-sharing arrangements, although many families who are not role sharing describe their situation as equitable in the context of their work and family situation.

Career-family issues are adult life issues. Women and men both experience conflict between their career and family roles and desire more flexibility in their work schedules and more time with their families. Although household work and parenting remain unevenly divided in many two-career marriages, the distribution of income and participation in family roles is much more equitable than in past decades. Husbands’ participation in housework increases when wives earn more of the family income and when husbands participate more in the care and nurturing of their children.

Partners engage in their various roles within the context of workplace policies and practices. Both the implicit and actual practices of employers and what is required for career success in particular fields significantly influence how partners live out their lives despite their individual or family preferences. For example, if success in a field requires a great deal of travel, or if using flextime or paternity leave to spend time with children is viewed negatively for career advancement, the choices of individuals in two-career relationships are impacted.

Career and family are mutually enhancing. Research findings are clear that under most circumstances, engaging in both family and occupational roles is beneficial to women and men, as reflected in indices of physical health, mental health, and relational health. Many studies support this conclusion. In contrast, research findings provide scant support for theories that assume marital stability is derived from women and men engaging in specialized, sex-segregated roles.

Career and family issues differ along dimensions of sexual orientation, race, and ethnicity. The cultural histories of various groups within our society and past or current discriminatory practices among various groups bring still another dimension to the career and family issues in two-career relationships. Partners in same-sex families and the biological children of

same-sex partners, for example, often are not entitled to the same health benefits as heterosexual partners. Similarly, societal views of male economic success and power have extended less to men of color than to White men.

Gender matters. The personal lives of individuals are always played out within the constraints of societal norms and values and social institutions, and these remain influenced by conventional notions of sex and gender. Indeed, if any one factor potentially affects women’s and men’s careers and their ability to satisfactorily and successfully integrate their careers and their family life, it is assumptions and processes associated with sex and gender.

CHALLENGES FOR TWO-CAREER RELATIONSHIPS

Men’s and women’s lives are very much linked. Significant changes in women’s lives bring about significant changes in men’s lives and vice versa. As already mentioned, the revolutionary aspects of two-career relationships had to do with fundamental changes in views of women’s roles and abilities. Thus many of the specific challenges being faced by two-career relationships are associated with assumptions about gender. Change can be difficult under the best of conditions, but contemporary society in many ways remains rigid in its assumptions of male prerogative and female accommodation, making change perhaps more complicated than the Rapoport may have anticipated in 1969.

SEX, GENDER, AND GENDER PROCESSES

Gender refers to the psychological, social, and cultural features and characteristics that have become strongly associated with the biological categories of female and male. Individuals are not born with gender but rather learn to be women or men within the context of their historical and cultural circumstances, including race, ethnicity, and other sources of social identities. That is, their gender identities are negotiated and developed over time. According to gender theory, many of the traits and behaviors assumed to be determined by biological sex have become constructed by the social reality of the lives of individual women and men. Thus women who are socialized to build their lives around the romantic experience of being with a man and being taken care of by a man,

and have few other choices, act in accordance with this social reality, regardless of their personal interests, personalities, and abilities.

Gender theories and processes provide an important framework for considerations of two-career relationships and how partners manage their lives. Participation in a culture involves participation in its cultural stories about what it means to be a man or a woman in that culture. Traditional patriarchal power rests on the social meanings given to biological sex differences and to their reproduction as cultural stories. These cultural stories take many forms, from the sexual division of labor depicted in fairy tales, novels, and traditional marriage, to internalized norms of femininity and masculinity. These cultural stories are central to the visions women and men develop about their adult roles—what is thinkable, what is possible, and what is doable.

Several salient sociopsychological factors and external structural factors associated with gender ideology are important to recognize.

Sociopsychological Factors

Male entitlement, prerogative, and assumed superiority. Historically, careers were viewed as important for men, and women were expected to accommodate any occupational aspirations to their husbands' careers. Such views continue today to some extent and become manifest as women consciously or unconsciously defer to the careers of their husbands. For example, women in two-career relationships may work fewer hours or accept less demanding positions in order to accommodate the man's career. She may also assume more of the family responsibilities.

The privileging of the male career is cultural. Still today, relatively few men consciously plan their occupational aspirations to fit with their future views of family life. In contrast, many women pursue fields of study or career paths they view as consistent with their future responsibilities as parents and spouses. This is generally true across fields. For example, women more than men pursuing fields in the sciences and engineering feel a pressure to choose tracks that will allow them greater flexibility to balance work and family responsibilities.

Female nurturance and care. Despite men's participation in fields such as pediatric medicine and child psychology and the greater involvement of men in parenting since the 1980s, nurturing is still linked

almost exclusively to women. Increasing numbers of men actively participate in parenting, and a significant proportion of men are the primary caretakers of young children. Nonetheless, women more than men are culturally expected to be actively involved with and available to their children and responsible for their care. In addition, cultural pressures that give greater importance to mothering than to fathering may increase barriers to men's involvement in parenting.

The prioritization of a man's career over a woman's often occurs after the birth of the first or second child and the associated changes in the career-family balance established by partners. It is important to note that while some men and women make these choices, these decisions are not made in a vacuum. Subtle gender processes within the family and society may define the ways in which women, but not men, are expected to accommodate their occupational aspirations to their spouse's career and to responsibilities for children.

Views of women's and men's abilities. Central to assumptions about male superiority and female nurturance are stereotypic and inaccurate notions about inherent differences between the sexes. Despite the large volume of evidence that women and men are more similar in their abilities and personal characteristics than they are different, these inaccurate beliefs continue to be perpetuated through various socialization mechanisms.

Early socialization, for example, emphasizing the superiority of men's or women's abilities in certain areas can result in girls or boys internalizing the belief that they are less capable and less likely to succeed in that area than their other sex counterparts. A case in point is math ability. Compared to men, on average women have less confidence in their math abilities. Recent studies provided evidence that internalized gendered beliefs about mathematics achievement influenced the performance of girls and boys on math tests.

Structural Factors

Women pursuing careers still face discriminatory practices at work, both in subtle and blatant ways. These can take the form of lower salaries, invisible glass ceilings, and sexual harassment. In addition, partners in same-sex relationships may face discrimination based on their sexual orientation. Being "out" on the job can have negative repercussions for career advancement.

Occupational sex segregation and glass ceilings. Although increasing numbers of women are entering professional fields such as law and medicine, overall women and men are still found in quite different occupations, with many women still concentrated in occupations that were historically female dominated. Research also indicates that a significant percentage of women experience a glass ceiling that limits their career opportunities.

Today the highest proportion of women with a college education are primary and secondary schoolteachers and registered nurses; neither of these occupations appears among the 10 most common occupations for college-educated men. Overall, men have a wider base of power and still predominantly hold more positions of power and leadership in business organizations, government, and academic institutions. Current employment benefits and policies enable women more than men to ask for and receive the accommodations necessary for combining work and family responsibilities (e.g., maternity leaves, flexible schedules); this practice contributes to their sex segregation within their professional fields.

Gender gaps in salary. Women on average continue to earn significantly less than men, although a significant proportion of women today earn more than their spouses. Earning differences for women and men have decreased from the 59 cents for every dollar men earned in the period from 1960 to 1980, but they still persist. Women and men between the ages of 16 and 24 tend to have similar earnings, with a wage gap occurring for older women and men. The reasons for this gap are complex, but subtle discrimination is considered to be a significant contributor. A case in point concerns the status of women faculty at major research universities. Recent research reports concluded that gender discrimination in the 1990s is subtle but pervasive and stems largely from unconscious ways of thinking that have been socialized into men and women alike. The report noted that the consequences of these more subtle forms of discrimination are as demoralizing to women as were the blatant inequities and intimidation of former decades. Among other indices of inequity, women faculty earned less than what men earned in comparable positions.

Sexual harassment. Sexual harassment remains a pervasive problem in the workplace, as evidenced by research findings and the settlement of highly publicized class action lawsuits. More women than men experience sexual harassment. Sexual harassment is

an abuse of power that can demoralize women and men in careers, cause professional and psychological distress, and affect career outcomes. Individuals who experience harassment may lose out on promotions, change positions to avoid harassers, and experience reprisal for reporting their harassment.

SUCCEEDING AS A TWO-CAREER RELATIONSHIP

While partners in two-career relationships face a number of unique challenges, research has provided useful information about how these families can succeed and flourish. A number of factors have been identified as important to the success of dual-earner families. Family factors are associated with partner behaviors within the family and include fairness, communication, and mutuality between partners, and career-family balance. Particularly important to effectively managing a two-career relationship is commitment to this lifestyle, the capacity to be flexible, compromising, and realistic. Spousal or partner support and sensitivity also play a key role. Shared values and expectations as well as feelings of fairness enhance the ability of spouses to be supportive. Factors residing outside the family are also crucial and include social support and family friendly work environments.

Family Factors

Fairness. Views of fairness are central to partners' abilities to successfully combine work and family life. Both men and women must be able to move outside traditional gender role norms and become comfortable with creating norms for themselves that both partners view as fair. For example, men may need to become accustomed to preparing lunches and managing carpools and women to earning a higher income than their spouse. Partners use this sense of fairness to create adaptive strategies in accommodating the family and home responsibilities and the emotional work required to create a partnership based in equality and role sharing. This balance will most likely be achieved if partners commit to frequent times together focused on communication about such issues.

Communication, mutuality, and spousal support. The quality of the communication between partners and an ability to communicate in areas central to the relationship are very important. The importance of

partners making time for one another for communication and mutual support is well documented. Valuing time with one another and striving to keep that time a priority gives partners the opportunity to show their mutual respect and appreciation for the different ways in which each partner is supporting the other and the family. In addition, making time to express appreciation as well as to communicate about problem areas helps build a stronger foundation for the family as a whole. Communication also involves expressing interest in each other's professional activities and acknowledging each other's family involvement and support.

Discussions during courtship about how partners envision integrating their career and family roles are associated with marital stability. Particularly important areas of communication then and after marriage are whether or not to have a child, when to have a first child, and whether or when to have additional children. Partners need to discuss how having a child will affect their relationship and their careers and how they will address these changes. The timing of the first child can also influence the timeline for having a larger family. Relevant to these discussions is the availability of flexibility at both partners' places of employment and parenting-leave policies.

Communication about household and parenting responsibilities is another important area. Day-to-day tasks must be discussed, including who will do the grocery shopping and prepare meals, wake up for early morning feedings, and take off work to take the children to the doctor when they are ill. Also critical is the discussion of future issues such as options for child care. Is an extended leave possible for father or mother during the first year? Does the budget allow for in-home care of the infant? Is child care available at either partner's workplace?

Communication is also useful when things feel out of balance. Research indicates that it is not the particular division of labor and time that affects marital quality but whether both partners feel they had a say in the arrangements and feel satisfied with the outcomes.

Career-family balance. Too much time at work can cause harm to either personal or family welfare, while too little time dedicated to one's work may endanger a family's economic security. Many studies have shown the benefits of integrating career and family roles. At the same time, it is important to identify when role demands at home or at work have become

excessive and unhealthy to the relationship. Greater relationship stability occurs when partners uphold boundaries around their career demands and take responsibility to not work excessive hours, which negatively impact their home lives.

As mentioned earlier, the extent to which partners in two-career families hold similar attitudes regarding roles within the family, and act in accordance with these attitudes, moderates the career-family balance achieved. A husband who is an involved father but leaves household duties to his spouse will create stress, resentment, and a lack of balance if his wife expects egalitarian participation.

FACTORS RESIDING OUTSIDE THE FAMILY

More effective coping and greater satisfaction among partners, especially those with children in the home, invariably are associated with flexibility of work schedules, family-supportive employers and benefit policies consistent with this supportive attitude, and suitable child care.

Areas typically receiving attention from companies are dependent care, including infants, adolescents, and the elderly; conditions of work such as greater flexibility in the organization, hours, and location of work; and corporate mission or the validation of family issues as an organizational concern. Currently, for example, nearly all companies offer flexible scheduling in the form of flextime, part-time employment, job sharing, compressed work schedules, or work at home. Of the Fortune 500 companies, 86 percent have work/family programs.

Many employers offer dependent care assistance programs that help employees pay for child care with pretax dollars. Under the Family and Medical Leave Act of 1993, companies with 50 or more employees are required to provide 12 weeks of unpaid leave for childbirth, adoption, and other family related situations. Research findings support the fact that supportive family friendly workplaces are associated with higher levels of career satisfaction among employees and more commitment to company success. Nonetheless, fewer men than women use family benefits. Should men in two-career relationships be reluctant to use these benefits, even when they are available at their places of work, it would place greater family responsibilities on their female partners and also potentially negatively affect their partners' early and mid-career development.

CONCLUSION

To conclude, succeeding as a two-career relationship is generally associated with the following conditions:

- Partners holding less traditional views of gender
- Partners discussing during courtship their plans for integrating careers and family life
- Partners affirming each other's career pursuits and aspirations
- Partners being happy in their occupational work
- Partners viewing each other's involvement in home roles as fair
- Employers of both partners having benefit policies that are family responsive
- If children are involved, both partners being actively participating in parenting and
 - Feeling comfortable sharing parenting with child care personnel
 - Being satisfied with the child care they are using.

Certain realities and accommodations come with two-career relational patterns, and partners need to be prepared for the kinds of choices they may necessitate. At the same time, what emerges from the extensive research on two-career relationships is the successful convergence of occupational and family norms for women and men who chose this family form. Two-career relationships represent an enduring family form, and their increased prevalence underscores the importance of the societal changes that have allowed the coming together of relational love and meaningful career pursuits for both partners.

TYPE A BEHAVIOR PATTERN

The *Type A behavior pattern* (TABP) was introduced almost 40 years ago by Meyer Friedman and Ray Rosenman as a risk factor in explaining coronary heart disease (CHD). TABP is a stable individual difference characteristic that has captured considerable attention in medical and psychological research circles. An important series of studies has strongly implicated TABP in the pathogenesis of CHD independent of standard risk factors such as age, hypertension, diet, and heredity, generally associated with the condition.

Certain identifying elements of TABP include exaggerated expressions of achievement striving, a strong sense of time urgency and competitiveness, and an aggressive demeanor. The Type A individual is described as an unrelenting worker, dominated by the success ethic, eager to outperform others and to constantly better his or her productivity. A psychological vigilance, hurried and restless movements, polyphasic behavior, and overtones of free-floating hostility are other Type A features. Type B's are characterized as individuals displaying opposing behavioral characteristics and having a more relaxed, calmer approach to life in general. Research evidence finds that Type A individuals' risk of developing CHD and of having fatal heart attacks is approximately twice that of Type B's in the population.

It has been reported that more than 50 percent of a workforce in a large urban city would be classified as Type A. In a study of managers from 12 different companies, John Howard, David Cunningham, and Peter Rechnittzer found that 61 percent were Type A's, 44 percent of whom exhibited the highest levels of TABP. TABP has also been shown to be higher among those at higher socioeconomic status and education. TABP is likely promoted by one's work environment. It has been found, for example, to be higher in fast-growing companies, and individuals at higher levels of TABP describe their jobs as more demanding and stressful.

A number of researchers have tried to identify specific components within the Type A constellation that were particularly critical in the development of CHD. Anger, hostility, and aggression have emerged as important Type A elements in the development of CHD. Several of the Type A components encompass achievement-oriented motivations and behaviors such as ambition, competitiveness, and time urgency. These Type A components have been found to be associated with superior academic and professional performance. It seemed unlikely that the same Type A components would be related to both stronger academic and professional performance and to CHD and other health problems. That is, some components of Type A are more likely to be related to performance, while others are more likely to be related to health problems.

Analyses of the measures most frequently used to assess TABP bear this out. For example, Janet Spence, Robert Helmreich, and Robert Pred report the results of factor analyses of the Jenkins Activity Survey, the most widely used paper-and-pencil assessment of TABP. They identified two factors: Achievement Striving (AS) and Impatience-Irritability (II). In a study of university students, they found that AS and II were relatively independent; AS was associated with academic grade point average but not physical complaints, while II was associated with physical complaints but not grade point average. These findings suggest that considering the two TABP components separately has merit.

The TABP is also reflected in the workplace. As opposed to their Type B counterparts, Type A's work more hours per week, travel more days per year, take less vacation and sick time off work, and are more job involved and organizationally committed. Type A's are also more likely to experience high self-esteem at work. This encourages Type A's to be more invested and committed to their work than their Type B

counterparts. Type A's are not necessarily more satisfied in their jobs, however. Type A behavior has typically been found to bear no relationship to job satisfaction. Two questions still remain unanswered: (1) Are Type A's more productive or effective in their jobs than Type B's? and (2) Are Type A's more likely to be promoted and found at the top of organizations? The limited data that is available suggest that Type A's were in fact more likely to receive greater organizational rewards than were Type B's. In addition, Type A's were more likely to be promoted and to have higher performance ratings than were Type B's.

Ronald Burke and Eugene Deszca reported that Type A's were more likely to report mid-career experiences of personal and social alienation and pessimism, which has been referred to as career success and personal failure, than Type B's. Thus, although Type A's invest more of themselves in their work role and report greater occupational self-esteem, they are not necessarily more satisfied in their jobs and run the risk of increased feelings of personal failure later in their careers.

Type A's report less marital satisfaction and a more adverse effect of their job demands on personal, home, and family lives. Spouses of male Type A job incumbents agree with their husbands, and also report less marital satisfaction and a more adverse effect of their partner's job demands on personal, home, and family lives. Thus there probably is a link between Type A behavior and marital distress and ultimately marital dissolution. It is also likely that Type A individuals are less involved with their children. Friedman and Rosenman provide anecdotal information that is consistent with the research conclusions that Type A individuals and their partners report a less satisfying home and family life.

Most TABP research considers its effects on individuals and only sometimes on their partners. In addition, relatively little attention has been paid to the possible role of TABP in the satisfaction and performance of groups. Can Type A's and Type B's work productively together, given the stress, anger, and issues of control? How will Type A's and Type B's deal with the intragroup conflict?

Giora Keinan and Miri Koren examined TABP and the performance and satisfaction of members of work groups. They considered group performance and mutual satisfaction of Type A's and Type B's assigned to homogeneous and heterogeneous three-member work teams working on competitive and noncompetitive tasks.

Teams consisting primarily of Type A's were more productive than teams consisting primarily of Type B's, and this difference was greater on competitive tasks. In addition, both Type A's and Type B's were generally more satisfied when working with same type members.

Others have examined the effects of Type A/Type B group composition on interpersonal relationships. It has been found that Type A's promoted their own positions and attacked antagonistic positions more than Type B's; Type A's engaged in more proself and anti-other behaviors than did Type B's. In addition, Type A's prefer to work alone and doubt their partner's ability to be of help to them. Type A's also react with irritation and irritability when others interrupt or distract them. Type A's also exhibit aggressive and competitive communications and interactions and are unwilling to relinquish control to a partner even when the partner could contribute positively to successful task accomplishment and provide a benefit to both.

Given the increased use of work teams in organizations, TABP now becomes more important. And though there is some evidence that TABP is positively related to job performance, the increasing use of work teams and the importance of trust in relationships within and outside the organization may increasingly make TABP a job performance and career liability.

The research on TABP and group functioning has some practical applications. First, assigning people to teams of like individuals based on TABP scores would increase team performance. Second, assigning teams of high TABP scorers the most difficult and challenging tasks would increase team performance. Third, training individuals with high and low TABP scores to increase mutual understanding and tolerance of the two types and improve their conflict resolutions skills will reduce levels of intragroup conflict.

TABP has several direct implications for careers in organizations. Individuals scoring high on TABP run the risk of premature death from CHD. This raises issues of succession planning and the development of managerial bench strength to replace individuals dying from CHD. Individuals who survive a heart attack are also likely to require considerable time for recuperation, raising issues of job performance, organizational continuity, and temporary replacement.

In addition, TABP also affects the way individuals pursue their jobs and their careers. On the positive side, competitiveness, involvement, and energy are likely to be rewarded. On the negative side, anger,

impatience, irritation, and aggravation are likely to interfere with relationships in the workplace. These emotions and behaviors are likely to be flaws or character deficits that limit career advancement. Finally, the negative effects of TABP on marital relationships and family functioning are likely to add to the heightened levels of stress experienced by individuals exhibiting TABP.

TREATING TABP

Friedman and Diane Ulmer have shown that TABP can be changed (reduced), and those reducing their levels of TABP also reduced the onset of clinical CHD. They carried out a longitudinal experiment in which a control group received standard cardiovascular counseling while an experimental group received the same cardiovascular counseling as well as TABP counseling. All participants were postinfarction patients under the age of 65 who are nonsmokers or reformed smokers. A third group was given only an annual examination (the comparison group). Counselors received training in understanding and managing their own TABP.

Individuals receiving TABP counseling initially met on a monthly basis in small groups with a trained counselor. Efforts were made in group discussion and practice outside these group sessions to alleviate time urgency and free-floating hostility—two central and overt components of TABP. This involved drills to be completed on particular days (e.g., every Monday in June, walk, talk, and eat more slowly; every Monday in July, leave your watch off, buy a small but thoughtfully chosen gift for your spouse/partner or some other family member). In addition, individuals received feedback from their fellow group members on their TABP and support in embarking on the difficult task of changing harmful habits learned over one's lifetime. This counseling program lasted three years. TABP, as reflected in self-report questionnaires and coded interviews, dropped in the TABP counseling groups, as did recurrent heart attacks.

Type A behavior poses a threat to careers, personality, and life itself. Type A behavior threatens careers through impatience, anger, and burnout. Type A tendencies threaten personality by increasing interpersonal conflict and narrowing the possibilities for joy (limiting oneself to things that can be counted—becoming boring and dull). Finally, Type A threatens life by fostering the development of CHD. It is possible,

though challenging, to preserve the achievement-oriented components of TABP (AS) while reducing the destructive components (II).

U

UNBIASED HIRING SYSTEMS

Employment practices are *biased* or unfair when employment decisions (e.g., hiring, promotion, job transfer) are based on factors (e.g., race, gender, age, disability, religion, and physical attractiveness) that are unrelated to a person's ability to succeed on the job. Biased employment practices are a very important issue, because selection systems control access to jobs and such other valued outcomes as opportunities for advancement and training.

Biased employment practices result in *unfair discrimination* in that individuals who have equal probabilities of succeeding on a job have unequal probabilities of being selected for it. Viewed in terms of selection decision errors, unfair discrimination results in a disproportionate number of individuals who are the targets of bias being classified as false negatives. These are individuals who would have succeeded on the job but were not hired.

Unfair discrimination is always a concern in cases of *disparate treatment*, that is, the deliberate exclusion of individuals from jobs on the basis of their membership in targeted groups (e.g., Blacks, women). In such cases, there are overt and intentional expressions of bias or prejudice against job applicants. However, unfair discrimination may also occur in instances of *adverse impact*. In such instances, the hiring rates for members of groups differ from one another. Adverse impact is an operational, legal, and ethical concern when group differences in hiring rates are a function of factors that are unrelated to the job. Note, however, that adverse impact is not always a sign of unfair discrimination.

The employment process in the typical organization involves the five sequential steps that are listed below. Biases can arise in one or more of them.

1. *Job analysis phase.* A job analysis is performed to identify task requirements and the knowledge, skills, abilities, and other requirements (KSAOs) of job incumbents. Although its results need only reflect minimally acceptable KSAO levels, the results often serve as a basis for specifying the KSAOs of the ideal incumbent. This can introduce bias, because conceptions of the ideal incumbent are typically affected by the beliefs of dominant groups in organizations. As a result, subsequent phases of the selection process will be affected by the biases introduced at the job analysis phase.
2. *Recruitment phase.* A variety of strategies are used in the recruitment phase to advertise the job opening and attract potential applicants, including listings in newspapers, trade publications, and online recruiting. Bias can be an issue when such strategies leave potential applicants unaware of job openings, precluding them from applying. One way in which this may occur is through stereotypes of ideal job incumbents influencing where organizations search for applicants. For instance, such stereotypes may lead them to recruit at private universities that are dominated by relatively affluent White students rather than universities with ethnically and socioeconomically diverse students. Bias can also be a problem if an organization's reputation and past employment practices (e.g., a history of unfair discrimination against women and ethnic minorities) have a chilling effect on potential applicants, reducing their motivation to apply for jobs. Finally, bias can arise if recruiting strategies or materials lead potential applicants to believe that they will not fit in the organization.

3. *Job application phase.* At the application phase, job applicants submit such materials as résumés and applications. Employers screen these materials to make initial judgments about applicant suitability. This phase is particularly susceptible to biases, because there is only a limited amount of information about applicants, and decision makers may base their suitability judgments on stereotypes about and/or affective reactions to members of various groups. This may lead to negative beliefs and feelings about applicants who are the targets of bias.
4. *Testing phase.* In the testing phase, the applicant completes measures of predictors (e.g., cognitive ability tests, interviews, personality inventories, work samples) designed to assess his or her KSAOs. A key issue with such measures is their criterion-related validity. This is typically indexed by the degree of correlation between (a) the predictors and (b) job performance or other important criteria (e.g., absenteeism, turnover). Regrettably, criterion-related evidence does not guarantee that predictor measures lack bias. This is suggested by strong evidence of the adverse impact of many types of predictors (e.g., cognitive ability measures) against various groups. For example, research has shown that Blacks and Hispanics score lower on cognitive ability tests than Whites. Bias would be an issue if the test performance of targets of bias were an artifact of cultural biases in such tests rather than actual differences in their cognitive ability. Unfortunately, the existing evidence does not allow for well-founded conclusions about the degree to which cultural biases in tests are responsible for adverse impact. However, inferences about cultural bias are much clearer for certain types of predictors (e.g., personality). For instance, research shows that individuals from collective cultures (e.g., Asians, American Indians) have different personalities (e.g., as reflected in measures of values) than individuals from individualistic cultures (e.g., Anglo-Americans). In addition, as a result of differential exposure to stressors, Blacks have higher levels of neuroticism than Whites. Research also demonstrates that predictor measures that are based on subjective assessments of the attributes of applicants are highly subject to bias. For example, unstructured interviews are prone to such problems as first impression effects, contrast errors, and similarity errors. In addition, subjective assessments can be biased by an observer's stereotypes (e.g., based on the applicant's race, sex, age, disability, unattractiveness). Thus it may be better to base inferences about job suitability for many types of jobs on measures such as work samples than on measures that have high levels of subjectivity.
5. *Decision phase.* Using predictor information, the decision maker makes judgments about the relative suitability of applicants and then selects one or more individuals to be the recipients of a job offer. Although selection procedures are typically top down, they may rely on banding. In the case of *top-down* selection, individuals are rank-ordered on the basis of their standing on the predictor (single or composite), and job offers are made sequentially to those with the lowest ranks. With *banding*, individuals who have scores on the predictor that are within given score ranges (bands) are considered to be equivalent to one another, and job offers are made sequentially to those within the bands that have the highest scores.

In summary, biases may affect many phases of the selection process, resulting in unfair discrimination. However, it is vital that such biases be minimized or eliminated in the interest of providing fair employment opportunities to all qualified individuals.

UNDEREMPLOYMENT

Underemployment is a multidimensional concept that refers to the underutilization of labor. The broadest conceptualization of underemployment refers to all dimensions of wasted ability of the eligible workforce. While this conceptualization would classify some of those not pursuing higher education as “underemployed” on the basis of wasted talents, most researchers adopt a narrower focus, taking the amount of human capital in the labor force as a given. Underemployment involves any combination of three related dimensions: (1) a time dimension, (2) a skills or qualifications dimension, and (3) a utilization or effort dimension. It should be noted that underemployment as referred to in this entry does not include unemployment, which could be considered the extreme underutilization of labor, where the individual is working zero hours but actively seeking employment.

TIME DIMENSIONS OF UNDEREMPLOYMENT

The time dimensions of underemployment involve different aspects of work time. First, this category includes individuals involuntarily working *fewer hours* than they would prefer to work. In general, this involuntary part-time employment refers to individuals working less than 30 hours per week, although an individual’s preference for working more hours can occur anywhere in the work time spectrum. Second, it includes involuntary *temporary or intermittent employment* that occurs generally over part of a year, as is often the case with seasonal work or limited-term contracts. Third, the time-related dimension can include *involuntary retirement* as reflected in those cases where such individuals would prefer to continue working but are inhibited from doing so perhaps because of a mandatory retirement policy in their organization.

The common aspect of these forms of underemployment is that the underemployed would prefer to work longer hours or longer periods during a given year or over their life cycle yet are not able to do so.

SKILL-RELATED OR QUALIFICATION-RELATED DIMENSION OF UNDEREMPLOYMENT

The common aspect of the skill or qualification-related dimension of underemployment is that the individual’s *skills* are underutilized. This can occur for

persons who possess surplus educational qualifications or credentials and are thus labeled as “overqualified” or “overeducated.” This terminology has been used both in relation to what is necessary in order to be hired and what is necessary for adequate job performance.

While some instances of overeducation clearly imply that a worker’s skills are underutilized, in other cases the issue is more ambiguous. For example, higher levels of formal education may serve to compensate for education of inferior quality or other human capital deficiencies such as lower literacy, ability, or work experience.

UTILIZATION OR EFFORT DIMENSION

The utilization or effort dimension of underemployment involves the underutilization of labor in general, not just of their skills or qualifications. This can occur if firms engage in labor hoarding whereby redundant workers are retained rather than laid off. The underutilization may also occur with respect to the effort dimension more generally, if workers do not have the incentive or motivation to put forth effort and they effectively shirk.

CAUSES AND IMPACTS OF UNDEREMPLOYMENT

Time-related Underemployment

Time-related underemployment generally occurs when the preferences of workers to work longer hours or longer periods during the year or over the life cycle do not correspond with the constraints imposed by employers. The extent of such underemployment may change over time, reflecting changes in the preferences of employees and the constraints of employers. For example, the growing number of dual-earner families may want shorter hours for one or both parents, in which case underemployment may dissipate if they prefer the shorter hours. In contrast, if employers increasingly want more part-time workers or limited-term contracts as part of the shift toward nonstandard employment, and this does not match the preferences of employees for such shorter work time, then underemployment will increase.

Skill-related Underemployment

Explaining skills mismatch is somewhat challenging when firms and individuals are assumed to be

optimizing agents that make full use of investments in training and education. One reconciliation of this disparity is that underemployment is a temporary phenomenon eliminated by market forces, with mismatches reflecting imperfect labor market information and job search costs. Underemployment may also be a short-term situation consistent with optimizing behavior when individuals voluntarily accept “inferior” positions under the impression that imminent promotions are likely.

Underemployment may be longer lasting, however, in the presence of labor market constraints or rigidities. For example, in the process of maximizing total family income, labor market choices of married women are often constrained by the decisions of their (generally more highly paid) husbands. Underemployment is often a long-term phenomenon for immigrant workers whose foreign credentials remain unrecognized by domestic licensing bodies.

According to job competition theory, individuals compete for scarce jobs on the basis of their educational credentials. Thus it could be rational for individuals to become “overeducated,” since those with the highest schooling are assumed to go to the front of the queue for the job openings. Furthermore, since wages are assumed to depend upon the job, rather than the forces of labor market demand and supply, there is no mechanism (i.e., changing wages) to eliminate underemployment.

From a worker’s perspective, underemployment can lead to reduced earnings, reduced job satisfaction, increased turnover, and the erosion or atrophy of skills. Some even define and measure underemployment in terms of reduced earnings relative to some reference group. Even low-skilled workers can suffer from underutilization of skills if their wages and job opportunities are adversely affected by a “bumping down” process. That is, when relatively skilled workers occupy jobs below their educational background, they “take away” jobs that could be adequately performed by less skilled workers, who are subsequently either forced into low-paying jobs or out of the working population.

Utilization or Effort Dimension

The underutilization of labor in general can occur during economic downturns when firms engage in labor hoarding whereby redundant workers are retained rather than laid off. The rationale for this is

that when the cycle reverses, the workers are available and their human capital is not lost. When they are retained as redundant workers, however, they are likely underutilized and not working at maximal effort or efficiency in order to produce the desired output. This can contribute to the productivity decline that occurs during economic downturns.

Underemployment with respect to the effort dimension may occur, for example, if the compensation system is poorly designed or if employee involvement and commitment is low. Organizational productivity may decline as a result.

MEASURING UNDEREMPLOYMENT

The measurement of some forms of time-related *underemployment* is fairly straightforward. For instance, in Canada’s monthly *Labour Force Survey* (LFS), “involuntary part-time” workers are identified. Other surveys like the *General Social Survey* (GSS) periodically ask individuals if they are involuntarily retired due to mandatory retirement. The extent of underemployment due to involuntary temporary or intermittent employment (e.g., seasonal work, limited-term contracts) does not appear to be commonly measured.

Four measures of *skill-related underemployment* are most common: (1) comparison of a worker’s educational attainment to the educational requirements for the occupation (as specified by job analysts), (2) comparison of a worker’s educational attainment with the education level that the worker believes to be necessary for either job entry or satisfactory job performance, (3) the respondent’s perception of mismatch, and (4) deviation from the average level of educational attainment within a narrowly defined occupation.

There is considerable debate as to which measurement approach is preferable. Some equate external assessment of job requirements with objectivity and hence view them as superior. On the other hand, so-called subjective measures relying on worker’s perceptions may incorporate the most accurate information about the job situation as well as the worker’s skills and credentials. Measures of underemployment due to *labor hoarding* in recessions or due to worker shirking or *lack of effort* are not done by conventional surveys. Rather, they tend to be done in periodic ad hoc studies.

UNEMPLOYMENT

The "misery index" of an economy refers to the sum of the *unemployment* rate and inflation rate. The inflation rate might hit zero or turn negative, but the unemployment rate will always be positive. Regardless of how rich a country is and how well the economy is doing, there will always be people out of work. The way in which unemployment affects the jobless depends upon several factors.

First, unemployment can be voluntary such as that resulting from people simply quitting their jobs, and these people may feel content with their joblessness. However, voluntary unemployment is not very common, accounting for less than 15 percent of the unemployed in the United States. Second, the duration of unemployment is relevant; the longer the period of unemployment, the greater the accrued distress and misery. Third, if the period of unemployment is transitory, such as in the case of laid-off automobile workers waiting for recall or United Airlines pilots on furlough, the prospect of reemployment reduces anxiety. Fourth, environmental factors may play a role; the more people are out of work in the neighborhood, the more bearable it is to be unemployed.

The economic cost of unemployment can be approached at both the macro and micro levels. At the macro level, the economic cost is measured by the loss of aggregate output. According to Arthur Okun's Law, each percentage point that the actual unemployment rate exceeds the natural rate of unemployment leads to a 2.5 percent gross domestic product (GDP) gap, the difference between the potential and actual GDP. The resulting waste of human resources is one form of the economic inefficiency caused by unemployment. Other problems include (a) raising the

fiscal burden leading to public budget deficits and possibly monetary instability and (b) increasing social costs caused by rising poverty, poor health, family and community breakdown, and crime.

At the micro level, the cost of unemployment is reflected in lost income, medical insurance, and other fringe benefits for those now unemployed. In addition, there are psychological costs for the unemployed as well as some negative externalities. While the former is the focus of this entry, the latter refers to the financial and psychological stress plus the pathological behavior (including child abuse) that the family members have to endure. The community at large might also feel the psychological pain of the unemployed, for example, in the threat from economic uncertainty and the prospect of crime and social unrest.

This entry focuses on how unemployment affects health (physical and mental), a vital element of the worker's productivity over the worker's career. The next section describes various sources and types of unemployment and explains the factors behind lengthy periods of high unemployment, known as *hysteresis*. The third section discusses how unemployment affects mortality/morbidity and mental health. The fourth section reviews selective economic and social psychological theories of how unemployment affects health. The last session presents the conclusions.

SOURCES AND TYPES OF UNEMPLOYMENT AND HYSTERESIS

Unemployment arises from four sources: job loss and the end of temporary assignments (42 percent), quitting jobs (14 percent), reentrants to the labor force (36 percent), and new entrants to the labor force (8 percent). The percentages indicated in the parentheses refer to the relative importance of these individual sources in the United States in 1999. The causes of unemployment can be classified into three basic types: frictional, structural, and cyclical factors. Frictional unemployment, also called search unemployment, refers to people who are between jobs or just entering or reentering the labor market. Structural unemployment is joblessness due to the mismatch between workers' skills and employers' needs or to workers' unwillingness to relocate. Cyclical unemployment arises from reductions in production over the business cycle.

While frictional employment may be voluntary and short term, structural unemployment tends to be involuntary and lasts longer due to the time involved in retraining. Cyclical unemployment reflects the extent of economic recessions and so is driven in the short term by the business cycle. The sum of frictional and structural unemployment is known as the natural rate of unemployment, which is determined primarily by long-term factors such as changes in demographics and economic structural and institutional variables.

Normally, the actual unemployment rate fluctuates around the natural rate over time. Sometimes a high level of unemployment may persist for a lengthy period (hysteresis) which, for example, Europe has experienced since the mid-1970s and which has eased off in some countries only recently. For instance, in 1994 the official unemployment rate of the European Union was 12 percent. Since 1981 the rate of unemployment has been at least 8 percent and on average 2 percent higher than the OECD average for all developed industrial countries.

The major causes of hysteresis include mismanagement of macroeconomic policies and lack of institutional flexibility. The former affects the extent of cyclical unemployment, while the latter influences the natural rate of unemployment. Valerie Symes claimed that tight monetary and fiscal contractions in the 1980s in most European Community countries rendered any expansionary strategy by individual economies impotent. The resulting demand shock reduced investor confidence and incapacitated the effective functioning of the labor markets. The institutional factors that contributed to the high natural rate of unemployment in Europe include duration of unemployment benefits, replacement ratio, expenditures on national manpower policies, union coverage, and bargaining by unions and employers.

The replacement ratio refers to gross benefits as a percentage of the most relevant gross wage. In 1985, the ratio was at least 70 percent in Denmark, Netherlands, Spain, Finland, Sweden, and Switzerland, as compared with 50 percent in the United States. The duration of unemployment benefits was indefinite in Belgium, Germany, Ireland, Netherlands, United Kingdom, Austria, and Finland, as compared with six months in the United States. Expenditure on manpower policies is money spent on placement and counseling, training, direct job creation, and recruitment subsidies. The expenditure per unemployed person as a percentage of output per person in 1987 was 2.4 percent in the United States as compared to a range of 2.7 percent-34.6

percent for European countries (with the exception of Italy and Spain).

Apparently the unemployed in most of Europe obtain much more generous unemployment benefits and other public support and for a longer duration than those in the United States. Furthermore, their powerful unions also provide strong protection for their members (so-called insiders) that results in wage rigidity and the insensitivity of wages to unemployment levels.

UNEMPLOYMENT, MORTALITY, AND MENTAL HEALTH

Over the past three decades, much of the work on unemployment and health has used two empirical methodologies: aggregate time-series data and panel or micro-level data. The time-series studies built on research by M. Harvey Brenner, which documented that increases in unemployment were associated with sizable increases in mortality (including suicide), mental health admissions, and crime. However, these aggregate studies have methodological pitfalls. Because of the long time span, it is necessary to control for possible improvements in health technology and health care that have taken place over the period. If this is not done properly, the uncontrolled variables can bias the results. Furthermore, the results can also be sensitive to the particular lag structure selected to explore the effects of unemployment.

Panel data, on the other hand, avoid the pitfall of the role of some uncontrolled variables. The technique analyzes changes in the dependent variable (e.g., mental health), thereby eliminating the potential bias from uncontrolled variables that are constant over time. For example, when examining cross-sectional data on labor force participants, Anders Bjorklund found that the unemployed have poorer mental health than the employed, even though the differences are rather small. He then used panel data to show that joblessness caused deterioration of mental health.

The association between unemployment and health (mental and physical) has long been recognized, but the critical question is whether the unemployment causes ill health or whether the ill health leads to unemployment. In general, the empirical findings about the causal relationship between unemployment and health are inconsistent. Overall there are three major qualifications that should be noted about the causal relationship between unemployment and health:

1. *Overestimation of the impact of unemployment on health.* Even though individual-level surveys have shown that the employed are healthier than the unemployed, there is a possibility that people who are in poor health may be more prone to become unemployed. I. P. Spruit reported that, before becoming unemployed, the unemployed had more often been sick on the job, more inclined to have work accidents, and more often changed jobs due to their health problems. In addition, individuals with poorer health may be more likely to remain unemployed. This selection problem may lead to overestimation of the impact of unemployment on social costs.
2. *Job insecurity and health.* In analyzing the effect of unemployment on psychological health, Brendan Burchell claimed that job insecurity rather than unemployment per se causes psychological stress. This conclusion was based on his empirical studies of the General Health Questionnaire (GHQ) scores of the employed and unemployed. One employed group, labeled as "male descenders," had all experienced a job change in the past to a lower type job. They were more likely to have been unemployed, lacked job security, and were dissatisfied with their jobs. These male descenders had similar GHQ scores as those of the unemployed.
3. *Recessions may be good for health.* Recent empirical findings have claimed that some public health indices improve during recessions. Using longitudinal data from 50 states plus the District of Columbia for 1972-1991, Christopher Ruhm reported that state unemployment rates were *negatively* related to total mortality and 8 of 10 specific causes of fatalities, with suicide representing an important exception. Ruhm also employed microdata to show that consistently higher joblessness was associated with reduced smoking and obesity, increased physical activity, and improved diet.

ECONOMIC APPROACHES AND SOCIAL PSYCHOLOGICAL THEORIES OF MENTAL HEALTH AND UNEMPLOYMENT

The mechanism by which unemployment affects health has been explored using two approaches: economic and social psychological.

ECONOMIC APPROACH TO UNEMPLOYMENT AND HEALTH

While economists have recognized health as one component of human capital and have documented

the link between human capital and individual earning capacity, the specific impact of unemployment on health has been somewhat neglected. However, the determination of health in home production may shed some light on the link between unemployment and health.

The idea is based on Michael Grossman's formulation of the demand for health, which is derived from the way in which an individual consumer's satisfaction with consuming health services and other commodities changes over time. As employment generates income, it facilitates the home production of gross investment in health, which in turn produces health services that give rise to the individual consumer's satisfaction over time. Joblessness, on the other hand, reduces or interrupts the capacity of the unemployed to undertake gross investment in health. Thus, as a lesser amount of health services is produced from home production, the consumer's satisfaction diminishes over time.

SOCIAL PSYCHOLOGICAL THEORIES OF UNEMPLOYMENT AND MENTAL HEALTH

After the dire experiences during the Great Depression in the 1930s, several social psychological theories were proposed to illuminate the way in which unemployment influences the mental health of individuals, including (1) the stages model, (2) Jahoda's functional model, (3) Warr's vitamin model, (4) agency theory, and (5) the status passage model.

1. *The stages model.* When becoming unemployed, in response to such a stressful event, people go through a progression of specific psychological stages. For instance, based on a large British survey of unemployed youth, J. Hill identified three stages in their response to joblessness: a period of optimism, followed by increasing stress, and finally a state of tolerance and depression.
2. *Jahoda's functional model.* Marie Jahoda proposed that unemployment deprives an individual of the benefits associated with employment such as structured time, shared experiences with coworkers, provision of goals and purposes for life, personal status and identity, and enforcement of activity.
3. *Warr's vitamin model.* Peter Warr proposed nine environmental factors analogous to vitamins that influence mental health, including opportunity for control, opportunity for skill use, externally generated goals, variety, environmental clarity, availability of money, physical security, opportunity for interpersonal contact, and valued social position. The central

theme of this model is that a reduced level of these environmental vitamins results in a lower level of mental health. Unemployment will affect negatively these environmental vitamins and therefore the mental health of individuals.

4. *Agency theory.* Both Jahoda's and Warr's models focus on the benefits of work for the employed and fail to explore the link from the perspective of the unemployed. In agency theory, Burchell argues that the negative psychological consequence of joblessness is caused by its abrupt disruption to the individual's plans and strategies rather than anything intrinsic to the work itself.
5. *Status passage model.* Status passage refers to individuals' movement into different social structures that reflects changes in their identity, their social status with respect to one's influence or power, and thereby their behavior. Applying this concept to interpret the impact of unemployment on the individual, Douglas Ezzy suggested that job loss leading to unemployment is a divestment passage that emphasizes separation from a status. The unemployed often face an extended transitional phase of uncertain duration, and the effects of this divestment passage result partly from the inability to maintain a consistent positive image about themselves, which is at the root of the eventual psychological disturbance observed in some studies.

Stage theory shows descriptively how the unemployed go through different psychological stages, but it does not explain why the emotions arise. Both Jahoda's functional model and Warr's vitamin model focus on the connection of work and the individual by emphasizing the social support and institutional setup that employment can provide, in addition to financial remuneration to individuals. However, there is lack of focus in both on the perspective of the unemployed.

Agency and status passage models share a basic theme that it is the interruption by unemployment of the strategies or plans that the unemployed have that causes the psychological distress. The major difference between the two models is that agency theory focuses on the impact of unemployment at a single point in time, while status passage emphasizes the dynamic transition experiences triggered by the shock of joblessness. Thus the status passage model offers an additional perspective on the connection between the individual and the external community.

CONCLUSION

Unemployment is always greater than zero in an economy, a reflection of the natural rate of unemployment. Thus there is always some segment of the population that is unemployed and faces unemployment problems. The impact of unemployment has been well researched since the Great Depression. Brenner was the first to document the direct association between unemployment and mortality, mental health admissions and crime. Later, both time-series and panel data were used to explore the causal link between unemployment and health. The major qualifications of link are the following: (a) the selection issue may cause an overestimation of social costs of unemployment, (b) the core of the causal relationship may lie in job insecurity rather than unemployment, and (c) recessions reduce mortality, especially certain types of fatalities.

While economics has recognized the economic cost of unemployment in the loss of aggregate output, it has rarely explored the effects of unemployment on mental health. The only theoretical framework that may shed light on the issue is the demand for health in which income is a means of purchasing inputs for the consumer's home production of gross investment in health. Thus, unemployment results in less gross investment in health, thereby diminishing the consumer's satisfaction over time.

Over the years, social psychologists have developed several theories explaining the path by which unemployment affects the mental health of the unemployed. These theories offer insights into the perspective of the unemployed and also how individuals are psychologically connected to work and the external environment. These insights should be taken into account when economists venture into this field to explore further how unemployment affects physical and mental health so that macroeconomic policy can be proposed, with supportive public programs that ease the financial, physical, and psychological stress that the unemployed, their families, and their communities experience.

V

VALUES

Values constitute a pervasive and comprehensive concept, variously defined and elusive to comprehend. Philosophers and social and behavioral scientists have long considered values across the broad spectrum of human experience as overarching life goals and guiding principles for determining what constitutes desirable outcomes and modes of behavior. Together with attitudes, needs, norms, interests, and traits, values reside within a constellation of psychological constructs posited to affect individual adjustment to the social world. Applied psychologists in the early part of the twentieth century turned to studying values as a primary element motivating human behavior and developed psychometric instruments to operationally define the construct.

Beginning with the efforts of developmental vocational psychologists in the 1950s, notably Donald E. Super, and fueled by advances in work adjustment theory led by René Dawis and Lloyd Lofquist, general human values have been examined within the specific domain of occupations in the form of *work values*. Values in this regard have been promoted as principal guideposts of vocational behavior and career development, as well as one of the four preeminent individual differences variables involved in work motivation, along with the “big three” of abilities, interests, and personality traits. The present analysis considers the nature of values and their use in career development, assessment, and counseling.

THE NATURE OF VALUES

Broadly construed, values represent beliefs about qualities of human life or modes of behavior that individuals deem important and worthy of attaining, upholding, and pursuing. As evaluative beliefs, values indirectly guide selection and appraisal of behaviors and events. Narrower in conceptual reach and fewer in number than beliefs and attitudes, values relate to a wide array of (a) cognitive processes, such as decision making, and career choice beliefs; (b) emotional states, including satisfaction, happiness, anger, or detachment; and (c) behaviors such as relational style, vocational choice, and work adjustment. Reflecting the utility and range of the concept, researchers and theorists have considered values across multiple levels of human experience in terms of personal, family, societal, and cultural values and across multiple domains, including environmental, economic, and political.

Job satisfaction research prompted conceptualizing values specific to the work domain. Work values constitute particular aspects of jobs and occupational life, such as income, hours, advancement, relationships, and security, which proffer and relate to satisfaction because they hold substantial meaning for the individual worker. As guideposts of vocational behavior, values are thought to influence *how* an individual practices an occupational choice rather than *what* occupation an individual chooses. For example, one person makes the occupational choice of physician to realize altruistic values, whereas another does so to realize lifestyle values. The importance individuals

ascribe to the worker role relative to roles in other domains such as family, leisure, and community reflects in large measure the values they maintain.

Values are widely purported to endure with stability across context and time, although little research supports this claim. Constructed hierarchically, people prioritize values in order of relative importance and use them to explain, coordinate, and justify behavior. Typically, values remain outside an individual's conscious awareness. Only when conflict ensues between or among highly prized values, such as personal success versus promoting the welfare of others, do they become activated, enter consciousness, and guide behavior. Considered within the context of career development, values figure prominently in outcomes related to occupational choice, job satisfaction, work style, conflict-of-interest management, career commitment, lifestyle, and workplace structure.

VALUES, NEEDS, AND INTERESTS

Values have been equated with needs and interests, which are closely interrelated concepts. Yet values differ from needs and interests in that values represent beliefs about desired goals to be achieved, ideals to be upheld, or courses of action to be taken rather than thoughts, feelings, or behaviors to be expressed or satisfied. Needs denote wants that activate or energize individual movement. Interests serve as links between personal preferences and environmentally situated activities or social roles that guide movement. Values signify goals or desired outcomes of movement. In this way, for example, a need for recognition prompts an individual to develop interest in the occupation of lawyer to realize a value of social status. Needs, construed in terms of what is necessary or unnecessary, come closest to human desires for growth and survival. Interests, a narrower concept than values construed relative to liking or disliking, most nearly approximate actual behaviors. Values, considered in terms of importance or unimportance, reside closest to beliefs about what constitutes personally or socially preferable ends or means to ends and thereby approximate a philosophy of life.

Whereas needs may be construed as innate and objective, values constitute subjective, learned adaptations transmitted within cultures and across generations. Milton Rokeach's argument that humans and animals differ to the extent that both may be said to have needs, whereas only humans have values, perhaps

most clearly illuminates the distinction between these concepts. Values likewise differ from personality traits, including interests, which accumulating evidence suggests are largely endogenous and fixed. Grounding values firmly in a social context underscores the view that values are negotiated and expressed through relationship and interaction with the social world and provide frameworks for decision making.

VALUE TYPES

Two commonly construed categories differentiate fundamental value types. One category comprises terminal, social, or extrinsic values that reflect desired goals sought from an activity. A second category, termed *instrumental, personal, or intrinsic values*, signal preferred ways of achieving desired goals. Stated simply, extrinsic values represent preferred outcomes of an activity, whereas intrinsic values constitute means of satisfaction inherent in an activity itself. Job security, compensation, and social status exemplify extrinsic work values, whereas service, creativity, and variety typify intrinsic work values.

At the level of culture, cross-cultural social psychology distinguishes individualistic and collectivistic (IC) value orientations as broad social patterns of beliefs, norms, attitudes, and behaviors. Individualism promotes personal goals over those of the group, whereas collectivism gives priority to group goals. Research indicates that IC predicts social behavior and relates to specific personal attributes. IC provides a useful construct for elaborating the cultural dimensions of values in career development, especially with regard to diverse groups. For example, IC likely relates differentially to specific work values such that significantly stronger positive associations might be expected between collectivism and extrinsic work values that stress relationship to others (e.g., altruism, associates, and supervisory relations). Similarly, significantly stronger positive associations might be expected between individualism and intrinsic work values that emphasize personal gain (e.g., achievement, independence, and lifestyle).

VALUES STRUCTURE

Theory and empirical research has considered the structure of values generally and within the context of work. In their work on values, Gordon Allport, Philip

Vernon, and Gardner Lindzey built upon six personal value dimensions termed theoretical, economic, aesthetic, social, political, and religious. Rokeach identified 18 terminal values, such as salvation and world at peace, and 18 instrumental values, including honest and imaginative. The theory of integrated value systems advanced by Shalom Schwartz offers a general values model of increasing contemporary predominance and ambitiously researched to support a comprehensive set of different motivational values types identified across 41 countries. Arranged in a circular structure and encompassing representative goals and single values, the model includes the following 10 value types, which have been considered within the work domain:

Power: Social status and prestige, control or dominance over people and resources

Achievement: Personal success through demonstrating competence according to social standards

Hedonism: Pleasure and sensuous gratification for oneself

Stimulation: Excitement, novelty, and challenge in life

Self-direction: Independent thought and action—choosing, creating, exploring

Universalism: Understanding, appreciation, tolerance, and protection for the welfare of all people and for nature

Benevolence: Preservation and enhancement of the welfare of people with whom one is in frequent personal contact

Tradition: Respect, commitment, and acceptance of the customs and ideas that traditional culture or religion provide the self

Conformity: Restraint of actions, inclinations, and impulses likely to upset or harm others and violate social expectations or norms

Security: Safety, harmony, and stability of society, relationships, and self

In addition to considering the structure of personal values, theorists and researchers have also specified the structure of work values. The momentous multinational Work Importance Study led by Donald Super identified five main work value orientations—Utilitarian, Individualistic, Self-Actualization, Social, and Adventurous—with specific underlying work values ranging from prestige and lifestyle to ability utilization and risk. The theory of work adjustment

proffers and empirically supports six broad value orientations of Achievement, Comfort, Status, Altruism, Safety, and Autonomy derived from factor analyses of psychometric data. Underlying these 6 broad work values are 14 second-order work values ranging from accomplishments and variety to associates and job security.

VALUES IN CAREER ASSESSMENT AND COUNSELING

Values assessment has long been conducted within career development and counseling contexts to appraise work importance. Researchers and practitioners use psychometric scales to operationally define and measure values globally, with scales such as the Rokeach Value Survey and the Study of Values. Instruments such as the Work Values Inventory, which scales 15 values, the Minnesota Importance Questionnaire, which scales 6 primary and 15 secondary values, and the Values Scale, which assesses 21 values, measure values specific to the work domain. The Salience Inventory measures value expectations of work and other life roles. Values appraisals also exist within various computer-assisted career guidance programs such as DISCOVER and SIGI. Qualitative assessments, particularly in the form of card sorts, permit subjective evaluations of work values. Considering values as both an important individual differences or person variable and an emerging cultural context or environment variable enhances the usefulness of values in career assessment and counseling contexts to promote occupational exploration, choice, and adjustment.

VALUES AS A PERSON VARIABLE

Career choice and development theories and counseling approaches converge on values as an important person variable that influences vocational choice, job satisfaction, and work adjustment. Values rest at the core of career construction and other developmentally grounded theories, as well as work adjustment theory, and the values-based model of career choice and development. The RIASEC model of vocational personality types holds that particular personality styles maintain specific values. For example, Artistic types are thought to more highly value beauty and creativity, whereas Conventional types presumably more highly value security and comfortable work surroundings. The learning theory of career counseling proposes

that learning events shape values, which in turn guide individual behavior. Social cognitive career theory characterizes values within the notion of outcome expectations. The cognitive information processing approach to career problem solving and decision making includes valuing as a central component of the theory.

Typically, counselors appraise and consider values within various theoretical contexts as a person variable, in the mode of abilities, interests, and personality traits. As such, values lend readily to both psychometric assessment to promote person-occupation matching and qualitative assessment to foster personal meaning making of work and career. In the classic matching paradigm, counselors appraise work values to help individuals identify occupations that may best allow them to realize their values, clarify what outcomes they seek from the work role, and how they wish to practice in a chosen occupation. For match-making, counselors may use both global and work-domain-specific values scales, which have proven useful for general life design, values clarification, and initial occupational decision making. By eliciting personal stories, counselors may assist individuals to identify and contextualize the personally construed meaning of their values as they construct their life careers. Considering values in service of meaning making concerns assisting individuals to elaborate on the significance of the role of work in their lives and offers an area ripe for theory development, research investigation, and counseling practice.

VALUES AS A CONTEXT VARIABLE

Considered as an environment variable, values take on added relevance in career assessment and counseling contexts. Values represent a prominent contextual variable having inherent cultural dimensions. Cross-cultural psychology articulates values as a fundamental element of subjective culture, which constitutes the meaning, beliefs, norms, and values within a society. A theme that surfaces in the multicultural career literature concerns values as a culturally situated variable crucial for fully comprehending the meaning of work and career in the contexts of people's lives. Placing attention more squarely on value sets and IC dimensions is particularly of potential use in cross-cultural career assessment and counseling because it helps to comprehend how broader cultural value orientations may shape specific work values.

CONCLUSION

Long overshadowed by abilities, interests, and personality, in part because of their seemingly nebulous nature, values hold particular promise for the long-term future of career development, both as an individual differences variable and an environment variable. Broadening the construct of values as conceived in career development to incorporate its cultural dimensions might enrich values as a context variable that can be considered relative to individual career exploration, choice, and adjustment. Values have been examined broadly across national, group, and individual levels of human experience. Yet values remain incompletely understood and have received relative research inattention compared to the big three constructs of abilities, interests, and personality. Values remain understudied despite the fact that principal career development theorists and researchers have long articulated a central role for values in explaining and predicting vocational behavior—particularly vocational choice satisfaction—and supported such a role with, albeit modest, empirical data. Because career commitment is a function of values and not interests, values may offer a more valid and reliable predictor of how an individual enacts an occupational choice or role. Contemporary streams in science and practice increasingly recognize the importance of values in career development contexts and bode well for the prospects of values in career theory, assessment, and counseling.

VIRTUAL EXPATRIATES

A "traditional" expatriate is an executive or employee of a company who relocates—often with his or her family or significant other—to the country in which the expatriate assignment is located. In contrast, a *virtual expatriate* does not physically relocate to the host country. Instead, the virtual expatriate manages the responsibilities of the assignment through frequent business trips and the use of teleconferences and electronic communication. A virtual expatriate assignment differs from a traditional expatriate assignment not only in the physical location of the expatriate but also in the cost and the duration of the assignment.

The concept of a virtual expatriate is new and offers logistical flexibility that a traditional expatriate assignment does not provide. Perhaps the most significant benefit of the virtual expatriate assignment is that the partner and/or children of the expatriate are not uprooted from their jobs and schools. This concern is becoming more relevant with the increased prevalence of dual-career families. Another significant cause of stress in the traditional expatriate arrangement is the adjustment of the expatriate's family to the new country's culture. Some employees have refused expatriate assignments because they prefer not to move their families. The virtual expatriate assignment allows the significant other or family member to remain in the home country while the expatriate travels to the assignment location.

Traditional expatriate assignments are costly to organizations. They typically include cost of living allowances and housing allowances in addition to compensation that would be competitive in the home country. Generally, it costs a company two to four times more to place an expatriate in a role than it would cost to place a host country employee in the role. Despite the extensive travel required to manage the responsibilities of virtual expatriate assignments, they tend to be less expensive for employers compared to traditional expatriate assignments.

Virtual expatriate assignments also tend to be shorter in duration than traditional expatriate assignments. Virtual expatriate assignments often last between two and four years, whereas traditional assignments often last up to five years.

Because the virtual expatriate is not on location in the host country on a continuing basis, a potential drawback of this approach is that the expatriate may have difficulties becoming integrated with his or her work team. This situation could lead to relationship-building issues with the host country employees.

The concept of a virtual expatriate is relatively new. Moreover, there is little theoretical or empirical research on virtual expatriates. As a result, the long-term benefits and drawbacks of the virtual expatriate assignment for companies and employees are yet to be determined.

VOCATIONAL EDUCATION

Vocational education in its broadest sense prepares individuals for their primary adult activity, usually paid employment. Preparation for entry into an established

occupation such as the law, nursing, construction, or teaching usually presupposes a sustained engagement with it over a period of years. Vocational education will have, as one of its primary objectives, preparation for an occupational career. In a sense, anyone who is educated and wishes to use their education as a preparation for employment undertakes education for vocational aims, even if they are not specifically inscribed in the educational program. Thus, to the extent that one needs to be literate and numerate at work, elementary education involves a vocational element. However, the vocational element of education usually grows more explicit and specialized as schooling progresses. This entry examines vocational education in the high school or secondary school, the home, the college, and the workplace.

VOCATIONAL EDUCATION AT SCHOOL AND HOME: PREVOCATIONAL EDUCATION

One of the aims of school education is to promote young people's knowledge of their interests, what they are good at and what they find most worthwhile. Without such self-knowledge, it is difficult for them to choose an occupation that is suitable for them in adult life. School and home must play an important role in promoting self-knowledge through general education but also through introducing young people to the kinds of knowledge, skills, and character attributes that they may expect to need in the workplace. If they do not know what is expected of them, it is difficult to know whether they can meet those expectations. Since one of the major options that young people wish for is to establish whether practical activities in the workplace are what they are most suited to, schools need to provide a range of such practical activities. On the other hand, it is not the role of schools to provide preparation for particular jobs. Their role, rather, is to give young people a good basis on which to make their choices. Thus, they need to know the general skills needed for work in an industry, whether they are capable of developing the necessary skills and whether they have the temperament and interest to succeed in it. In other words, they need to be able to make meaningful choices about their employment futures. Essentially, this is the job of prevocational education: for a young person to find out in general terms what they are suited to and what interests them. In order to do this, though, they need specialist staff, buildings, and equipment; this does not come cheap.

VOCATIONAL EDUCATION AT COLLEGE OR IN THE WORKPLACE

Postschool, the issues are different. Unless students are moving to higher education or on to further academic study, they are going into a form of education that is a direct preparation for work at a particular job or occupation. This type of training is properly called *vocational education*, and is properly so-called. Some of this vocational education can take place directly in the workplace, through a form of on-the-job training or instruction. This is usually most suitable for jobs with fairly low levels of required skills, responsibility, or theoretical knowledge. When the job requires a higher level of skill and knowledge, however, such work-based training is unlikely to be sufficient. The necessary knowledge to be applied will need to be taught in tranquil and safe surroundings and will have to be taught and practiced in safe conditions. Thus vocational education involves the acquisition of skills through classroom learning, exposure to a simulated work environment (so that skills are practiced safely), and often probationary practice, where skills are practiced under operational conditions but with supervision and occasional advice when necessary. Such complex educational processes need good organization, clear curricula, and robust and reliable assessment procedures if they are to work effectively. In many countries, such systems are formally regulated, often by the state.

APPRENTICESHIP AND ALTERNANCE

The relationship between instruction and work is central to vocational education. The traditional way of educating craftspeople has been through apprenticeship, where young people are employed as junior workers at a low wage, which reflects their current low productivity. In return, the apprentice receives instruction and training. The employer is compensated for training the apprentice by paying low wages and by obtaining a skilled worker at the end of the process; the apprentice is compensated for low wages through skill acquisition. Traditionally, apprenticeship took place within self-regulating occupational institutions called guilds, which also socialized the apprentice into the values, traditions, and ways of dealing with society and customers that formed the core of the guilds' place in society.

Some version of the institution of apprenticeship still exists in some countries, notably the

German-speaking ones, but it is at least as common to find a different approach to managing the work-classroom interface, known as *alternance*. Here trainees are students rather than cadet workers and spend part of their time under instruction and supervision in the workplace. On completing the program of study, the student enters the labor market, usually with a qualification.

CONTINGENT VOCATIONAL PREPARATION

Such systems are to be distinguished from cases where classroom instruction or workplace training takes place for a very specific need. All workers undergo such contingent preparation at some point in their working lives, and it is clearly an important aspect of job preparation. It should, however, be distinguished from the longer term educational processes described above.

OCCUPATIONAL ENTRY AND THE DEVELOPMENT OF A CAREER

Apprenticeship and alternance-based systems of vocational education usually prepare young people for a career within an occupation, which will consist of a series of jobs. Occupational mobility is much less common than job mobility and is often confused with it. Both alternance- and apprenticeship-based systems usually provide the novice with a wide-ranging set of occupational as well as job-specific knowledge and skill. This poses a problem for employer-based systems of vocational education, as it is certain that occupational knowledge will help to make apprentices employable in other firms within that occupational structure. Any form of vocational education that involves direct expense by the employer and includes an element of occupational and not merely job preparation runs this risk. Such systems therefore either require a degree of employer solidarity or some compulsory pooling of resources, so that training does not become an insoluble coordination problem for employers. Vocational education as opposed to job training is therefore more a matter of occupational and industrial preparation than it is preparation for a specific job and is, in that sense, preparation for a career.

VOCATIONAL PREFERENCE INVENTORY (VPI)

The *Vocational Preference Inventory* (VPI) is one of two inventories operationalizing John L. Holland's person-environment fit theory. The other inventory, the *Self-Directed Search*, is intended to simulate the vocational guidance experience, whereas the VPI is intended to be a personality-interest inventory. The item content of the VPI consists of 160 occupational titles. Respondents choose either "like" or "dislike" to each of the occupations. A fundamental assumption that guided the construction of the VPI is that occupational preference is an expression of a person's motivation, personality, knowledge, and ability. Furthermore, it is assumed that occupational preferences also indicate the favored methods of coping with interpersonal and environmental problems.

The purpose of the inventory is fourfold. First, it can be used as a brief assessment of personality with high school and college students as well as employed adults. Second, it can be a useful complement to other personality assessment instruments. Third, it provides a means of assessing vocational interests. Fourth, it can be used to assess the vocational behavior in the context of Holland's theory.

The inventory can be used with people at least 14 years old and of normal intelligence. Generally, most people complete the inventory in 15 to 30 minutes, and hand scoring takes about a minute. The VPI has been used with diverse populations, including high school and college students, prison populations, employed adults, and psychiatric patients.

The VPI contains 11 scales that provide information regarding the test taker's interests, self-conceptions, interpersonal relationships, and coping behaviors. Six

of the scales represent Holland's conceptualization of vocational personality types: Realistic, Investigative, Artistic, Social, Enterprising, and Conventional. These six scales make up what is commonly referred to as the RIASEC hexagonal dimensional model of personality and environments that is central to Holland's theory. While the VPI is primarily used as a personality inventory, scores from the aforementioned scales can be used to derive a person's vocational personality profile and hence used to identify potentially suitable occupations. This is accomplished by examining the three highest scores among the scales and matching them against occupational codes found in the *Dictionary of Holland Occupational Codes* or the Self-Directed Search Form R *Occupations Finder*.

The five other scales tap into other aspects of personality that career counselors would find helpful in interpreting results: Self-Control, Masculinity-Femininity, Status, Infrequency, and Acquiescence. On each scale it is assumed that high scorers have the traits associated with each scale and that low scorers possess the opposite of the traits associated with each scale. Brief conceptual definitions of each scale are offered below.

1. Realistic scale: This scale represents traits associated with being pragmatic and conventional. Those with high scores tend to be described as being mechanically or technically inclined, interpersonally reserved, candid, and obstinate and are lacking social skills.
2. Investigative scale: This scale represents traits associated with being rational and intellectual. High scorers tend to be scientifically inclined and are scholarly, curious, shy, and independent.
3. Artistic scale: This scale represents traits associated with expressiveness and creativity. High scorers tend to be inclined toward artistic endeavors, and are sensitive, imaginative, emotional, open to new ideas, and unconventional.
4. Social scale: This scale represents traits associated with friendliness and social responsibility. High scorers tend to be inclined to help others, and are extroverted, amiable, and dependent.
5. Enterprising scale: This scale represents traits associated with social dominance and adventurousness. High scorers tend to be inclined to lead or persuade others, and are energetic, extroverted, and enthusiastic.
6. Conventional scale: This scale represents traits associated with conformity and orderliness. High scorers tend to be inclined toward organizational or computational activities, and are practical, cautious, and traditional.
7. Self-Control scale: This scale represents traits associated with impulse control and responsibility. High scorers are inclined to be inhibited, insecure, cautious, and passive.
8. Masculinity-Femininity scale: This scale represents identification with stereotypical male and female roles. High scorers typically prefer traditionally male occupations, whereas low scorers prefer traditionally female occupations. High scorers are also typically characterized as being asocial, competitive, and shrewd.
9. Status scale: This scale represents a person's concern with prestige. High scorers generally prefer occupations that are high in social status and reflect a degree of self-confidence or desire for upward mobility.
10. Infrequency scale: This scale represents a person's preference for unpopular occupations. High scorers may have unsuccessful work histories and may view themselves in disparaging terms.
11. Acquiescence scale: This scale represents a person's degree of yea saying. High scorers tend to report liking many occupations. Extremely high scorers may represent lack of self-knowledge or someone with multiple interests and abilities.

The scales of the VPI generally have good internal consistency reliability estimates, with a few notable exceptions being the Masculinity-Femininity, Status, and Infrequency scales, which are quite low and should be interpreted with some caution. The scales that represent the RIASEC typology have demonstrated a moderate degree of predictive validity with high school and college students in terms of selection of an academic major and choice of occupation. The remaining scales show a moderate degree of convergence with similar scales on other personality inventories.

Users of the VPI should consider the person's age, education, area of vocational training, and occupational status. For the purposes of vocational guidance, the RIASEC scales should be examined for their degree of differentiation and consistency. Differentiation refers to the magnitude of difference between the highest and lowest scores on the RIASEC scales. The greater the difference, the more clearly a person resembles one type and less like the others and hence should be more predictable in terms of appropriate

vocational choice. Consistency refers to the degree of relatedness between personality types as represented in the hexagonal model. The closer the types on the hexagon, the greater the degree of overlap in terms of interests and traits. The other scales may provide additional information that can either reaffirm or elucidate score meaning of the RIASEC scales and may serve as additional information to help clarify a person's self-concept and how it relates to choice of an occupation.

VOCATIONAL PSYCHOLOGY

Vocational psychology, a specialty within applied psychology, is the study of vocational behavior and its development across the life cycle. Emerging in the first decade of the twentieth century as America became heavily industrialized, vocational psychology originally concentrated on the fit between a worker's abilities and interests and a job's requirements and rewards. The outcome of a good match between a person and position is job success and satisfaction, with failure and frustration being expected from a poor fit. This paradigm, once called trait-and-factor, is now called person-environment fit. It rests on the contributions of differential psychology, that is, the measurement and study of individual differences in personality traits and cognitive abilities.

Vocational psychology crystallized as a specialty in the second decade of the twentieth century, promulgated in 1916 by Hollingworth's book titled *Vocational Psychology*. Until World War II, vocational psychology concentrated on two functions. The first functioned applied the matching model in vocational guidance to help individuals choose jobs. The second function applied the matching model in personnel selection to help companies choose

workers. The same person, a personnel and guidance psychologist who counseled individuals and consulted with companies, performed both functions. Following World War II, personnel psychologists began to concentrate on either guidance or selection, with guidance becoming the hub for counseling psychology and selection becoming the hub for industrial psychology. While today they are distinct, both disciplines remain interested in vocational behavior. Vocational psychologists study vocational behavior from the perspective of the worker, while industrial/organizational psychologists study vocational behavior from the perspective of the employer. Because of its concern with the individual rather than the organization, vocational psychology research serves as the basic science for the profession of career counseling.

Contemporary vocational psychology encompasses two domains, one sphere of activity is concerned with vocational choice by high school and college students and the other sphere of activity is concerned with work adjustment by adults. Spanning both choice and adjustment, a second model to augment that of person-environment fit became popular during the middle of the twentieth century. It was called the *vocational development model*. This paradigm popularized the term *career*. For example, *career development* replaced *vocational development* as a rubric. Viewed objectively, career is the series of positions that an individual occupies from school through retirement. Viewed subjectively, career is the imposition of meaning on vocational behavior. Individuals construct their careers by using subjective meanings both to guide their selection of occupational positions and to make their work roles matter to themselves and others.

Vocational psychology's unique contribution to psychology continues to be the conceptualization and measurement of vocational interests. Other important topics include vocational choice, career indecision, career intervention, school-to-work transition, organizational commitment, work adjustment, mentoring, and work-family balance. Research on these topics can be found in vocational psychology's three main journals: *Journal of Vocational Behavior*, *Journal of Applied Psychology*, and *Journal of Counseling Psychology*. Regular updates about research and reflection on vocational behavior appear in the serial volumes of the *Handbook of Vocational Psychology*.

W

WECHSLER INTELLIGENCE SCALES

The *Wechsler Intelligence Scales* consist of the Wechsler Preschool and Primary Scale of Intelligence (WPPSI), the Wechsler Intelligence Scale for Children (WISC), and the Wechsler Adult Intelligence Scale (WAIS). These are the most widely taught, used, and researched contemporary measures of human intelligence. Each Wechsler test consists of extensive interaction between a test taker and an administrator who assesses various cognitive abilities through a diverse array of standardized exercises. Because adult intelligence is of greatest direct relevance to career development, and because all three Wechsler scales possess a similar overall structure, the present discussion is limited to the WAIS. Research concerning the adult scale—currently in its third edition (WAIS-III)—supports its value as an indicator of intellectual ability and potential. However, decisions concerning the use of the WAIS in career assessment will depend on situational needs and constraints.

The WAIS-III conceptualizes intelligence as a general capacity for effective reasoning and behavior. This capacity is measured by performance on 11 to 14 subtests administered by a trained proctor, who adheres to a highly structured testing protocol. These tests vary considerably: some are timed, others not; some are strictly oral, others involve visual stimuli; and still others require physical manipulation of objects. The WAIS measures a person's general intelligence level, along with more specific capacities, such as verbal and performance ability. Verbal intelligence involves verbal memory, general fund of factual

knowledge, and capacity to reason with words, numbers, and other abstract symbols. Performance intelligence is visual-spatial-motor ability, including the capacity to process, integrate, manipulate, and discriminate among objects and visual stimuli (i.e., shapes, patterns, and pictures). Various WAIS subtests also measure other specific mental abilities, such as working memory and processing speed.

Because of the WAIS's long history and widespread contemporary use in psychological assessment, scholars have produced a substantial body of supporting research. Evidence from these studies indicates that (a) there is such a thing as general intelligence, (b) intelligence is an effective if imperfect predictor of academic and job performance, and (c) the WAIS-III is a reliable and valid measure of this mental property. WAIS research has also supported its value in the assessment of specific cognitive problems, such as memory loss, attention disorders, and cognitive developmental disabilities. Particularly in career-development-related cases where such cognitive disorders are suspected, the WAIS-III is of great potential use.

Nevertheless, despite the WAIS's obvious rigor and validity, some scholars question the sensibility of using it in career assessment of nonclinical populations. Past grades, standardized achievement test scores (e.g., the ACT), and related information can often be used in career guidance to make reasonable predictions about one's capability of acquiring job-related skills. Similarly, in employment selection, grades and demonstrated job-related skills may be a fair indicator of potential. To the extent that these alternative sources of information are available, the

added benefit of a formal intelligence score may not justify the cost and effort of administering the WAIS. Moreover, when a formal measure of general intelligence is desired, there are other available research-based assessments that are sufficiently valid and significantly more cost and time efficient.

WELFARE-TO-WORK PROGRAMS

Welfare clients are highly aware of the stigma attached to welfare reliance and express a strong commitment to self-sufficiency. Employers need a productive and reliable workforce, and many employers recognize that former welfare clients may help them meet this need. The transition of former welfare clients into the workforce is a critical issue that affects not only former welfare clients and employers but also customers, taxpayers, and society in general. Employers provide a key to the success of this transition and, through their human resource management practices, can make a difference in the job retention of former welfare clients.

Welfare reform in the 1990s has increased the urgency of the transition from welfare to work by attaching work requirements to the receipt of welfare payments. In the United States, the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 abolished the Aid to Families with Dependent Children (AFDC) program and established Temporary Assistance to Needy Families (TANF) in its place. TANF included work requirements for welfare clients deemed able to work and provided funds for support services such as child care and transportation. In addition, TANF imposed a five-year lifetime limit on the receipt of welfare benefits. As governments around the world have embraced capitalist globalization and

implemented policies of deregulation, privatization, and social austerity, assistance to persons living in poverty has increasingly become linked to work requirements. These policy changes have increased pressure on welfare clients to make the transition to work.

But how able are welfare clients to achieve self-sufficiency through work? To answer this question requires examining the population of welfare clients and their life circumstances. In the United States, Black and Hispanic individuals historically have been more than twice as likely as Asians or Whites to live below the poverty level. In 2003, Blacks and Hispanics constituted about 13 percent and 14 percent of the U.S. population respectively, and 1,376,000 Whites, 618,000 Blacks, and 505,000 Hispanics aged 15 years and older were on TANF. In the United States, welfare clients are predominantly women with children. Being less educated, being unemployed, and having a work-related disability are all positively associated with using welfare assistance.

Many clients go off welfare on their own, but for many others, TANF supports for training, child care, and transportation assistance are critical for easing the transition from welfare to work. Job skills training, job readiness training, and other supports for helping welfare clients enter paid employment are generally not provided directly by the government in the United States. Rather, consistent with the philosophy of privatization, private for-profit and nonprofit agencies contract with the states to provide such services to welfare clients. One study of welfare clients receiving these services in Philadelphia, Pennsylvania, showed that the average client was a 32-year-old, non-White woman with between three and four children who had been on welfare for 32 months with skills equivalent to an eighth-grade level in reading and a sixth-grade level in math.

Given the importance of human capital endowments for escaping poverty and avoiding reliance on welfare, the profile of the average welfare client receiving job readiness assistance indicates important challenges. The jobs available to someone whose skills are below that of a high school graduate are unlikely to pay a sufficient wage to support a family of three or more. When TANF-related child care benefits end, wages must cover day care and afterschool care expenses. In addition, demonstrated differences in earnings between White and non-White women when skill levels are controlled indicate possible

employer discrimination and reluctance to hire women of color. The relatively low wages associated with jobs likely to be available to women, combined with substantial family care responsibilities, low skills, and possible employer discrimination, create a formidable set of barriers to self-sufficiency for women on welfare.

These challenges mean that employers play a critical role in the transition from welfare to work. Some employers choose not to hire former welfare clients because of concerns about productivity. However, numerous employers have successfully employed former welfare clients and gained competitive advantage through this source of labor. Former welfare clients are generally in ample supply, enabling a firm to better handle periods of tight labor markets. The jobs that former welfare clients hold, in occupations such as food service and child care, often involve front-line interaction with the firm's customers, and continuity of service and care may critically affect revenue and reputation. The employment of former welfare clients can also be an image boost for an employer, further impacting the bottom line.

Job retention is the critical indicator of a successful transition. If the experience of employers and former welfare clients is a revolving door, then neither benefits. Research has identified several employer human resource management practices that contribute to retention. Perhaps foremost are good wages and financial and health benefits. While it may be possible for an employer to hire former welfare clients at low levels of compensation, paying more than necessary may be a good investment that pays off in future retention and productivity. Development opportunities are also important. Research indicates that practices such as mentoring and career coaching enhance retention even during the first six months of employment. This period of the transition to work may be the most difficult. Even good wages may not make ends meet, and child care and other challenges can lead to discouragement. Development plans may provide the hope necessary to survive this period. Family-friendly benefits, such as paid time off and subsidized child care, also can contribute to retention by accommodating the needs of former welfare clients during this transition.

Numerous societal stakeholders, including employers, their customers, taxpayers, and welfare clients themselves, have an interest in making the transition from welfare to work successful. Governments, non-profit agencies, and researchers need to continue to

find ways to support welfare clients and employers in this transition.

WELLNESS AND FITNESS PROGRAMS

Wellness and fitness programs sponsored by and conducted in organizations have historically aimed at enhancing individual health, providing health risk screenings, avoiding the burden of suffering associated with distress, health, and safety problems, and reducing the organizational costs of distress at work. Because cardiovascular disease continues as the leading cause of death for men and women in the American workforce, many wellness and fitness programs have been designed around aerobic or cardiovascular fitness. However, in the workplace itself, the greatest health risks for men are industrial accidents and for women are incidents of homicide. This has been true through much of the twentieth century. Therefore, early health promotion programs in industry focused on workplace safety and later gave way to ergonomic programs that focused on worker-environment fit. These two early health initiatives were followed by the advent of wellness and occupational health promotion

programs, many based on an allopathic medical model. This medical model gave way to a preventive medicine one as used, for example, in the Duke Executive Health program.

To examine the current state of the practice and science of wellness and fitness programs, we look first at the early foundations for wellness and fitness programs. Second, we turn to positive health versus health-risk management. Third, we consider a three-level typology of wellness and fitness programs. Fourth, we examine the impact of these programs. Finally, we identify success factors for wellness and fitness programs.

EARLY FOUNDATIONS OF WELLNESS AND FITNESS PROGRAMS

The health of a workforce is of concern for both humanitarian and utilitarian reasons, and there is interdependence between the health of the employee and the health of the organization. Hugo Munsterberg's turn of the twentieth-century research on industrial accidents brought attention to the importance of workplace safety in America. Throughout the century, workplace safety was a concern in manufacturing and industrial work environments. The Occupational Health and Safety Act (OSHA) of 1970 brought forth a wide variety of regulations and practices that advanced safety practices in the workplace. The focus in these programs was problem avoidance as opposed to health enhancement and was very compatible with the broadly accepted allopathic medical model that is symptom and disease oriented. Thus early wellness and fitness programs that grew up during the 1970s and 1980s often emphasized addressing unhealthy behaviors, such as smoking, substance abuse, poor diet, and lack of exercise. In addition, the emphasis was on individual behavior in contrast to characteristics of the workplace. With the advent of Kenneth Cooper's preventive approach through aerobic exercise in the 1970s, the broader increasing emphasis on preventive medicine at the same time, and the impact of the osteopathic medical model, the early approaches to wellness and fitness promotion gave way to new ideas, approaches, and practices in health, wellness, and fitness.

POSITIVE HEALTH VERSUS HEALTH-RISK MANAGEMENT

Wellness and fitness programs typically focus on the promotion of positive health and/or the prevention and resolution of health risks. Inherent in these

themes are the perspectives of health as the presence of positive states or health as the absence of illness. Both psychology and medicine have historically focused primarily on preventing health risks and healing disease and illness, and consequently, early wellness and fitness interventions followed within this tradition. Recent calls have been made, in contrast, for a focus on health defined as the presence of the positive in both mind and body. The positive psychology movement, pioneered by Martin Seligman and colleagues, emphasizes psychology as a science of human strengths, some of which lead to flourishing and others that act as buffers against illness.

Reflecting this movement toward a more positive view of both physical and mental health, wellness and fitness programs are increasingly including components that promote resilience and positive health as well as the management and identification of health risk factors. Thus the content of these programs includes both health-enhancing activities as well as health risk management activities that encompass health in its broadest definition. Among the goods that are essential to positive human health are having a purpose in life, quality connections to others, and positive self-regard. Aristotle long ago proposed that the highest of all human goods was the realization of the individual's true potential, which he described as eudaemonia. Wellness and fitness programs thus belong squarely within the realm of career development, as the career facilitates all of these goods. Development of these goods requires the effort of both individuals and organizations.

In addition, the emphasis on health has grown to include not only individual health but also organizational health, as articulated in the preceding section. Healthy organizations consider multiple levels of health (individual, group, and organization). They promote organizational congruence, or fitness, between the organization and its external environment, and between components within the organization.

In summary, a broader, more positive view of health has evolved. This comprehensive view emphasizes positive health, along with health-risk management, and encompasses both healthy individuals and healthy organizations.

TYPES OF WELLNESS AND FITNESS PROGRAMS

As the broader conceptions of health and wellness have evolved, so too have the typologies of interventions

offered by organizations. An early typology offered by several researchers proposed three levels of health programs:

Level I: Awareness programs, including newsletters, health fairs, screening sessions, education classes, and other activities that raise individual awareness of the consequences of unhealthy behaviors

Level II: Specific programs for lifestyle modification, including fitness programs, back exercises, and the like, characterized by active employee involvement in adopting health-promoting behaviors

Level III: Programs that create environments in which individuals can sustain healthy lifestyles over the long term, including the provision of fitness centers at the workplace, making healthy food available, and removing unhealthy food from the workplace.

From these three levels, fourth-generation programs evolved, variously referred to as total health programs, comprehensive health promotion programs, or health and productivity management programs. Johnson & Johnson's Live for Life program represents one of the earliest comprehensive wellness programs. Three key components of the J&J program are health risk assessment, creative educational units, and physical fitness training. Health risk assessments may include analyses of stress management, fitness, nutrition, safety, and ergonomics, and the assessments are used to identify the individual's strengths and weaknesses. In the educational units, a wide variety of media is used to deliver education on such topics as weight management, smoking cessation, women's health issues, and blood pressure management, among other health-related subjects. In J&J's physical fitness training, programs are tailored specifically to individual needs. Evaluations of the Live for Life program have indicated positive effects on exercise, health behaviors, and employee work attitudes.

Kimberly-Clark Corporation's Health Management program is also a benchmark comprehensive program, initiated in 1977. The program reflects the company's culture and its belief that well-informed, healthy employees are happier, safer, more productive, and have better attendance records, and that these factors produce lower health care costs for the organization. Integrated, multidisciplinary teams provide health screening, primary care, exercise programs, nursing care, and employee assistance programs at Kimberly-Clark's various locations. Fitness facilities include indoor running tracks, Olympic-size pools, nature

trails, weights, and aerobic equipment. Preventive and educational services are provided, which include family wellness, nutrition education, CPR training, and sport-specific workshops, among other programs.

Health and productivity management programs (HPM) have three basic goals: (1) to provide integrative services that promote employee health or assist with injury, illness, or work-life balance, (2) to increase productivity and morale, and (3) to manage medical benefits, risk management, employee assistance programs, and other services such that they promote health and productivity. Keys to the success of HPM programs include health promotion and wellness staff who serve as models of healthy lifestyles, employee empowerment, and self-responsibility. The distinguishing factor of HPM programs is the tie to the mission of the business and articulation of the links between individual health and business operations.

POSITIVE IMPACTS ON INDIVIDUALS, CAREERS, AND ORGANIZATIONS

There are five positive impacts that proceed from wellness and fitness programs in organizations that have effects on individuals, careers, and organizations: (1) employee physical and psychological health, (2) employee engagement and involvement, (3) health care cost avoidance, (4) reduction in absenteeism, turnover, and injury, and (5) high performance on the job and morale at work.

Physical exercise programs that address the employee's cardiovascular fitness, muscular flexibility, and muscular strength lead to improvements in employee physical health and well-being with a number of associated improvements in psychological health. The latest research suggests that the most positive physical effects of exercise occur at the low-impact, low-intensity level rather than at the high-impact, high-intensity level. The aerobically fit employee has a lower resting heart rate, lower blood pressure, lowered stress-reactivity, and, when combined with flexibility and weight training, improved muscular flexibility and tone. Psychologically, exercise lowers anxiety, helps to metabolize anger and other potentially toxic emotions, and improves mental acuity. Thus employees' overall physical and psychological health improves.

Jim Loehr and Tony Schwartz have found that adopting some of the lessons from high-performance athletes by corporate executives and employees can enhance health, well-being, and performance. A central tenet in their approach is the management of

energy in contrast to the management of time. Thus employee engagement in work and nonwork activities is balanced by strategic disengagement, during which time energy recovery occurs. Balancing energy expenditure in productive activities, on or off the job, with energy recovery through personal renewal activities, leads to both improved health and improved performance. These benefit both the individual and the organization while contributing to sustained energy for longer term career progress and success.

Wellness and fitness programs have been shown to lead to health care cost avoidance. Johnson & Johnson pioneered the approach to health care cost reduction through their health and fitness programs in the J&J family of companies. Because wellness and fitness programs take a systemic view of health, they can lead to overall health improvements in employees, thus reducing a range of health costs for physical, psychological, and behavioral disorders and problems.

Wellness and fitness programs have broad, positive effects throughout a workforce even for the nonparticipating employees. This appears to be due to an osmotic effect that occurs as some nonparticipating employees begin to model the positive health attitudes, behaviors, and actions of the wellness and fitness program participants. This overall improvement in workforce health has positive effects on work attendance and retention while leading to reduced absenteeism and turnover. In addition, overall physical and psychological fitness has been associated with reduced injury rates on the job, which continues as a serious workplace problem for both men and women.

Finally, the net effect of wellness and fitness programs can lead to high performance on the job, coupled with high morale on the part of employees. This is good for individual employees, for their careers, and for the organization as a whole. Thus improved individual employee health has positive effects on organizational health and vitality. The caveat is that wellness and fitness programs should not be aimed at improving employee health and well-being as an intermediate step to increasing work pressures and demands on employees. As stated earlier, in addition to the utilitarian reasons for health concerns at work are humanitarian reasons.

EMPLOYER-SPONSORED PROGRAM SUCCESS FACTORS

If employer-sponsored wellness and fitness programs are to be successful, a number of factors should

be considered by management. These program success factors include, but are not necessarily limited to, (a) top management commitment, (b) program goals and objectives, (c) a quality staff of wellness and fitness professionals, (d) appropriate recruitment of participants, and (e) a feedback and evaluation strategy for the program.

Top management commitment to wellness and fitness is essential to the success of any program, as is the case for almost all employer-sponsored programs of any kind. This may mean that senior executives actively participate in the program, as is the case for PepsiCo Chairman and CEO Steven Reinemund, who considers wellness and fitness essential components of leadership development. Alternatively, senior executives provide the resources and other support elements to ensure the success of the program.

Because employees, supervisors, professional staff, and senior management may have different motivations, agendas, and perspectives on wellness and fitness, it is important to use a multidisciplinary approach to the articulation of program goals and objectives. This planning component of the program serves as an important element of feedback and evaluation of the program.

A quality staff of professionals is a third program success factor. This staff may well need to be multidisciplinary in nature so as to include professional expertise in exercise science, behavioral psychology, medical health, risk management, and even social work.

The recruitment of appropriate program participants is a fourth key to success. Early program participants are the leading edge of embedding the program successfully within the organization. *Thus influence leaders* in the company, to include senior executives, can be very influential in both attracting other participants as well as effecting positive health behaviors more broadly throughout the organization.

Finally, yet critically, it is important to have a systematic feedback and evaluation strategy for the wellness and fitness program. This strategy begins in the planning stage of the program with a clear statement of program goals and objectives. The strategy should include the systematic collection and evaluation of both quantitative data (e.g., percentage of workforce participating) and qualitative data (e.g., participant description of benefits, such as personally, professionally, and for career enhancement).

WHITE-COLLAR WORK

White-collar work is perceived as being corporate level or business-oriented and is performed in an office setting or at a desk using technical and electronic resources such as computers. Whereas some organizations may be solely composed of positions defined as white-collar work, others have a variety of work to include white-collar, blue-collar, and service-level positions. Every industry is different, and organizations within industries may find that there is a need for a combination of workers. However, industries saturated with organizations performing white-collar work are more likely to have workers who have strong intellectual capabilities and are paid a salary

based on their level of intelligence and ability to perform complex or complicated work. More than likely, white-collar work is not paid on an hourly basis. Consequently, organizations pay white-collar workers a high salary for the performance of work that is indefinite in quantity and quality. White-collar work brings to mind work performed by an employee who has an advanced degree acquired after years of study at a college or other educational institution.

Employees at the white-collar level include professional, administrative, technical, and clerical staff. While managers and supervisors are not always included in this category, they can be technical managers and supervisors, performing the work in addition to giving oversight to the work being performed by others. This grouping (professional, administrative, technical, and clerical) is referred to as PATC by the Bureau of Labor Statistics.

The concept of white-collar work was derived from the studies of criminologist Edward Sutherland, who coined the term "white-collar crime." The crimes committed by white-collar workers are defined as nonviolent crimes. The crimes generally take place within a corporation by professional, administrative, technical, or clerical workers in the course of performing their business duties. Sutherland's studies introduced a different thought process or direction of criminal activity in which crime is performed at a higher level. Some of the criminal activity identified includes tax evasion, insider trading, computer fraud, forgery, unfair labor practices, bribery, embezzlement, false advertising, financial theft, and/or fraud (as in securities dealing).

White collar is indicative of white-collar, button-down shirts worn by workers performing less physical work; they perform desk work. Workers have the flexibility to wear professional clothing because they do not perform hard labor—work requiring a significant amount of movement or that would cause them to exert much energy. The work is not dirty work or work that would get their clothing soiled. The work performed is nonmanual in nature, not laborious. White-collar work requires practical knowledge, the use of learned experience, thought process, mental engagement, problem solving, analysis, and task orientation. Another perspective would be that white-collar work requires advanced knowledge and the ability to perform work that is principally intellectual in context, requiring consistent exercise of discretion and judgment. The advanced knowledge is customarily

acquired by an extended course of specialized intellectual instruction.

White-collar work is viewed as nonroutine mental operations or processes based on particular information or on dealings with individuals. Due to the nature of white-collar work, it is almost impossible to track, observe, and evaluate the work. For example, white-collar workers apply their knowledge of management, health care, or human resource management to a variety of individual situations such as dealing with workflow processes, assessing the health of a patient, performance management and other forms of employee relations, interpreting or applying relevant laws and regulations, and supervising and evaluating employees. The ability to do this type of work is learned through experience and acquired education. Some organizations may also offer training in the workplace to support the performance of effective white-collar work. White-collar work requires intellectual ability to learn such skills. Organizations traditionally assume academic ability and education to affirm a worker's ability to learn and perform white-collar work. Organizations rely on this experience as a valid premise to recruit and allocate workers to perform white-collar work.

White-collar work is sought after by individuals as an entry or starting point to their career development. This inroad would lead to opportunities for personal growth and development in a professional field of work. As employees thrive in the performance of white-collar work, they are able to take on more expansive levels of white-collar work. If there were degrees of white-collar work, one could gauge or chart a path of progression by degree. For example, this potential could occur through advancement within an organization from grade level to grade level—denoting an upward progression. Advancement could also come in the form of lateral progression in that white-collar work hones skills that are transferable in nature. For example, professional skills such as analysis can be utilized in different departments or divisions within an organization. The skill level would offer the opportunity to move within the organization laterally from one white-collar position to another outside of the initial department or division. This level of achievement would come as an employee reaches an employer's expectation of preferred performance or feels the need to redeploy its intellectual capital. White-collar work can be achieved as a progressive or developmental process for individuals who may not have secured an educational background to support direct entry into white-collar work.

The benefit of white-collar work as a form of career development draws on an employee's intellectual knowledge base, viewed by organizations as intellectual capital. Also, it sets employees apart and distinguishes their capabilities within the workforce. Its challenging level of work pushes employees to draw on their past experience, educational background, ability to discern, analyze, assess, measure, and derive answers in order to respond to work issues. White-collar work is perceived as work that challenges the intellect of employees who are capable of handling advanced-level work.

WONDERLIC PERSONNEL TEST

The *Wonderlic Personnel Test* (WPT) is one of the most widely used tests of general cognitive ability (g). A recent search of an automated database located over 1,000 references to the WPT. The current form is the result of more than 60 years of research and development. Wonderlic Inc., the WPT's publisher located in Libertyville, Illinois, states that the test is used by business and government organizations for evaluation of applicants for employment and training. Both paper-and-pencil and computer-administered versions of the test are available. Equivalence of the administration methods has been substantiated by research. There are also large print, Braille, and audio versions for special needs populations.

There is a well-written test user's manual with documentation that contains important criteria used to judge the merits of the test. Wonderlic acknowledges

the more than ample research on the efficacy of general cognitive ability as a predictor of important occupational criteria. The user's manual also notes that the WPT does not measure noncognitive constructs such as interests, motivation, or personality.

The WPT forms have 50 questions constituting a wide variety of content areas, including verbal, numerical, and spatial. In keeping with good professional practice, the questions are arranged in order of increasing difficulty, and the publisher states that a sixth-grade reading level is sufficient for test comprehension and completion. Knowledge of basic mathematics, U.S. monetary units and currency, and frequently used units of measurement (e.g., foot, yard) are required. Administration of the paper-and-pencil version takes about 20 minutes. The exact testing time is 12 minutes; the other 8 minutes are for administrative procedures such as distributing forms, answering questions, providing instructions, and collecting the forms. There are guides for the proper administration, age adjustment, and retesting on an alternate form. Complete scoring instructions and a single overall score are provided. The publisher can provide scoring, if desired.

Reliability

Several measures of reliability are reported. The publisher has been careful to identify the type of reliability such as test-retest, KR-20, or alternate forms. Depending on the study cited, the reliability has ranged from 0.73 to 0.95. The publisher also addresses the question of test score differences by reference to the Probable Error of Measurement (PEM), also called the standard error of measurement. PEM estimates for the WPT are given as between 1.3 to 1.8, and interpretations of differences are provided.

Fairness

The WPT user's manual presents a thorough discussion of the fair use of tests and the WPT in particular. It is recognized that assessment of test fairness and fair use of tests is a complex and statistically sophisticated issue. External researchers are cited as having found the WPT, as a professionally developed cognitive ability test, to be free of bias.

Score Tables

Numerous tables are provided, including population norms. The 1992 normative population includes

118,549 participants and is available as number-right scores. Among the useful tables is one showing the score distribution in the adult working population, high school graduates from 16 to 30, and college graduates aged 20-30. Number-right scores and their cumulative percentiles are provided. Tables are included that show the effects of sex, age, and education on test scores. Tables also show score distributions and effects for ethnicity for Whites, African Americans, and Hispanics. There are interpretive guidelines for various classes of occupations as well as scores achieved by samples of applicants for numerous occupations ranging from "packer" to "attorney." In addition, there is a table with suggested minimum test scores for selected occupations. However, the knowledgeable counselor or human resources specialist will remember that these are just suggestions, and both legal and scientific rigor requires the development of appropriate minimum scores for the situation.

Validity

The WPT user's manual shows the results of numerous validation studies. Construct validity is addressed by providing correlations with other tests. The manual includes information on tests the WPT has been correlated with, the citation of source studies, and the provision of information about sample size. Tests with which the WPT shows a high correlation are well characterized as tests of general cognitive ability such as IQ tests and achievement tests. The WPT shows an especially high correlation with the Wechsler individually administered IQ tests. Adding to the construct validity, there are low correlations reported with measures of personality, social judgment, interest inventories, and emotional adjustment. This provides a proper nexus of correlations for a construct validation.

Empirical validations also are reported, and the sample size is shown for each study. For each of the validity coefficients, the business occupational category such as General Office, Blue Collar, or Supervision is provided. Specific positions are reported, ranging from bank tellers to utility crew, and from first-line production supervisors to bake shop managers. Validity studies are also cited for the non-business categories, including Decision Processing, Engineering, and Professional. Validity coefficients also are provided for Vocational Training Programs.

Criteria, validity coefficients, and a citation are given for each study. Criteria range from annual pay

increase to the supervisor's rating of performance. Validity coefficients are reported in the form of correlations. The validity coefficients tabled in the user's manual are consistent with studies of other similar tests and are in the expected range in the many meta-analyses of general cognitive ability as a predictor of training and job performance.

LANGUAGE VERSIONS

The WPT has been translated into several languages. The most useful may be the Spanish language version, which has gone through translation from English and other development activities. The publisher has conducted research and development activities so that the Spanish version has evolved into a measure equivalent to the English version.

The WPT is a well-documented, widely used measure of general cognitive ability. It is available in both electronic and paper-and-pencil forms in several languages. The WPT is appropriate for both theoretical and practical applications. Furthermore, the WPT has demonstrated that solid psychometric properties (reliability, validity, fairness) and norms are available for many subgroups.

WORK ETHIC

Members of the business community often express concerns that the *work ethic* among employees has diminished. This perceived decline is often linked to lower levels of job performance and increases in turnover, absenteeism, and counterproductive behavior in the form of unauthorized breaks and theft on the job. Others, however, maintain that the work ethic is not in decline but that what it means to be committed to the value and importance of hard work has simply changed over the years. Regardless of one's point of

view on this issue, the work ethic is still clearly important to employers. For instance, in one survey of 150 managers, it was found that nearly 60 percent ranked work ethic as the most valued characteristic to consider when hiring an employee for an administrative position, assuming that the applicant had the requisite skills necessary to perform the job. Indeed, work ethic was viewed as being more important than intelligence, enthusiasm, and education. In another research survey, it was discovered that more than 50 percent of hiring managers expressed greater concern for a job candidate's attitude than aptitude.

HISTORY OF THE WORK ETHIC

While contemporary views toward the work ethic are quite favorable, such was not the case throughout the history of civilization. For instance, the ancient Greeks and Romans disdained manual labor and held individuals that engaged in this activity in low regard. It was not until the Protestant Reformation, led chiefly by religious leaders Martin Luther and John Calvin in the sixteenth century, that attitudes toward manual labor changed greatly. Luther espoused the belief that all vocations, no matter how menial, served God and were therefore useful. Individuals were encouraged to apply themselves diligently in their given profession (known as their "calling") to which they were placed by birth and society. To attempt to change one's calling in pursuit of higher goals was considered a transgression against God, as he alone determined one's place in the world.

Extending Luther's doctrines, the French theologian John Calvin introduced the concept of predestination—the belief that one's ability to attain eternal life was predetermined by God. The selected few, known as the elect, would find their place with God, whereas others would be damned for eternity. What made the concept of predestination most disconcerting was that there was no way to tell for sure if one was a member of the elect. People reconciled this fact by subscribing to the belief that economic success was evidence of being chosen by God for eternal salvation. Thus hard work was a vehicle toward economic success, and economic success was a sign of salvation.

DEFINITION OF WORK ETHIC

Modern formulations of the work ethic construct stem from Max Weber's two-part essay "The Protestant Ethic and the Spirit of Capitalism" written

in 1904 and 1905. Weber argued that capitalism's introduction and rapid expansion in Western Europe and North America was greatly influenced by the Puritan value of asceticism (i.e., scrupulous use of time and strict self-denial to achieve personal discipline) and the belief in a calling from God. He argued that other Protestant faiths shared common theological underpinnings that stressed the value and importance of work for its own sake; thus the term *Protestant work ethic* came into being.

Despite being originally conceived as a religiously oriented concept, research in the area has failed to find differences in work ethic beliefs among members of differing faiths. This is not surprising, given that all major religions have espoused the importance of work. Thus it is more appropriate to refer to the work ethic without its original religious connotation.

Aligned with Weber's position, current conceptualizations tend to view work ethic as an attitudinal construct pertaining to work-oriented values. An individual espousing a high work ethic would place great value on hard work, independence, fairness, wise and efficient use of time, delay of gratification, leisure activities that serve a rejuvenating function, and the intrinsic value of work.

THE FUTURE OF WORK ETHIC

While what is viewed as the traditional work ethic has been highly valued in the United States, the argument may be made that the meaning people hold of this construct should be revisited due to the influence of factors such as workforce diversity, unscrupulous corporate behavior, and corporate downsizing.

The attitudes and beliefs that one adopts about work, as well as a host of other issues, are clearly impacted by one's cultural upbringing and generational cohort. Given the vast diversity represented in our nation's workforce, it is likely the case that there is not a universally accepted work ethic. Specifically, the work-related values held by one group may differ from that of another. This has important implications when one seeks to understand not only the meaning of work ethic to different people but also how it is reflected in behaviors in the workplace.

The recent spate of corporate misdeeds, fraud, and unethical activities has caused people to have a diminished trust in employers. This lack of trust has likely affected the levels of commitment and devotion employees feel toward their place of work, which in

turn influences their job-related behavior. Furthermore, corporate restructurings, mergers, and downsizings have led to a large percentage of the workforce being laid off at one time or another—often to remain unemployed for considerable periods of time. Associated with these activities is the rise of jobs that are part time or nonpermanent in nature. Notwithstanding the obvious financial challenges with which many people have been confronted, individuals also must deal with the psychological effects of having one's work role arbitrarily taken away and the impact of being unemployed or underemployed. Such events would likely impact levels of dedication, commitment, and loyalty to future employers.

In summary, while interest in the work ethic has withstood the test of time, it should not be assumed that its meaning has ceased to evolve. Future research and discussion should address the impact, if any, that the aforementioned variables have on the meaning of work ethic in our society. An understanding of these issues will serve to advance knowledge of the work ethic construct and its implications in the workplace.

WORK VALUES

In career development theory and counseling, vocational fitness is generally accepted to be the result of

congruence between the characteristics of occupations and the individual differences among people. Abilities, skills, and interests were the individual differences traditionally thought to be most salient. Recently, a third set of personal variables has been entered into career theory: *work values*, or preferences for aspects of a job, occupation, or career. Many other kinds of values are of interest, tapping such constructs as respect for others, the primacy of family, honesty, living frugally, and the like.

ASSESSING WORK VALUES

Over the years, there have been many inquiries into the nature of work values in counseling and industrial psychology. The concept of work values harkens back to the early studies of job satisfaction, in which it was found that job characteristics such as pay, safety, or working hours could be valued differentially and summed into a single index of satisfaction. It followed naturally to inquire into differential valuing of various attributes of an occupation or a career.

Two lines of conceptualization and research on work values are currently prominent: Rene Dawis and Lloyd Lofquist's Theory of Work Adjustment (TWA) and Donald Super's multinational Work Importance Study (WIS). Dawis and Lofquist assembled a measure of 21 "needs" to which diverse attributes of jobs or work are responsive. They are all positive in tone, such as achievement, variety, and creativity. The developers' extensive research with workers at many levels of the employment strata found that values are robust predictors of job satisfaction and that different jobs and occupations offer satisfaction to different combinations of needs.

Factor analysis of the 21 needs yielded six combinations, which they labeled as values. They are as follows:

1. Achievement: feeling of accomplishment, using one's abilities
2. Comfort: comfort on the job, absence of stress
3. Status: recognition, dominance over others
4. Altruism: helping others, doing good
5. Safety: structure in the job, predictability
6. Autonomy: independence, being in command

Satisfaction, derived from the correspondence of workers' values and job reinforcers, combined with

"satisfactoriness" derived from the correspondence of workers' skills and abilities and job performance requirements, result in workers' tenure, being retained, promoted, or terminated.

The parallelism of the terms *need* and *value* in the two lines of research led Super to attempt to differentiate them. He viewed the two concepts as two sides of the same coin—needs representing something lacking and seeking satisfaction, and values representing the satisfactions that are sought. He believed that both lead to the activities in which needs or values are satisfied, which is to say, interests.

In a multinational study, the WIS team of researchers formulated 18 values adaptable to any work role. Having been derived from some of the same sources, 12 are identical or very similar to those of the TWA. Of interest is their inclusion of "risk," which is not in the same positive frame of reference as the remainder of their list and is not of the TWA set. Factor analysis reduced the 18 values to five factors, which were identified as follows:

1. Utilitarian: achievement, prestige, ability utilization
2. Self-actualization: personal development, ability utilization
3. Individualistic: autonomy, lifestyle
4. Social: social interaction, social relations
5. Adventurous: risk, authority

The WIS found a remarkable degree of consistency for these factors in the value set across the 11 countries on five continents included in their study. Of more importance was the finding that the most prevalent values across all nationalities were personal development, ability utilization, and achievement, or in sum, self-actualization. Super and Branimir Sverko are careful to point out that all of their subjects had attained some degree of education, which in many of the countries they studied would be indicative of valuing self-actualization. On the other hand, willingness to take risks, as well as valuing prestige and authority, were of little importance.

ASSESSING WORK VALUES IN CAREER DEVELOPMENT

The two streams of research on work values have fostered two career development applications of their two assessments. The values survey used in the Super

and Sverko study was published for use in career counseling, but has unfortunately gone out of print. A precursor, Super's Work Values Inventory (SWVI-R) has been revised by dropping three scales thought to be redundant with interest constructs and lengthening the remainder. It is available for use in career applications. Donald Zytowski cautions that occupations are not as homogenous for value orientation as they are for interests, so a work value profile should not be applied exclusively to select an occupational objective. At middle and secondary school levels, the inventory is probably best used to illustrate the utility of developing a concept of one's values and to help individuals identify attributes of work and occupations that might be of greatest importance to them. With college students and adults, value assessment might be profitably applied to prioritizing or selecting among several "interesting" possibilities.

The WIS values assessment has been adapted for counseling use as the Work Importance Locator (WIL). It uses a card-sorting procedure with 20 of the original needs to rank-order the importance of six values. One is hand scored and includes a list of occupations that are responsive to each value orientation. The other version is administered online and scored automatically. Users of both the WVI and the WIL can access the master list of occupations that are responsive to their value orientations in an O*NET Occupations Master List. This online document lists 15 to 20 O*NET occupations at five educational levels for each value orientation. The instructions for application of the list cautions that it should not be used for hiring or employment decisions but is most appropriate for career exploration and counseling purposes.

WORK VALUES INVENTORY

Competent career planning is generally understood to rest on a tripod of interests, skills or abilities, and values. Interests and skills or abilities have a long assessment history; assessment of work values has only recently emerged. One of the original assessment tools is Donald Super's *Work Values Inventory* (WVI).

Generally speaking, work values can be defined as the qualities that people seek in their work, occupation, or career. In contrast, interests may be defined as the *activities* through which valued qualities are realized. For example, valuing independence may call for one to be interested in managerial activities.

Super's inventory was devised originally as a research tool in the Career Pattern Study of the late 1940s. After extensive further development, the inventory was made available to the profession in 1970, though by 2000 it was virtually out of print. It assessed 15 values, such as achievement, prestige, esthetics, and economic returns, using a five-point scale to rate the importance of each to the respondent.

THE REVISED EDITION

Super's Work Values Inventory-Revised (SWVI-R) is currently published exclusively online as part of a comprehensive career planning system at www.ncasi.com. In this edition, three scales, Altruism, Esthetics, and Management, were dropped owing to their conceptual similarity to scales on its accompanying interest assessment. Scales were lengthened to five items each, but the five-point rating scale was retained. New norms were created from samples of 5,000 each of male and female inventory takers from middle and high schools and postsecondary institutions distributed among 21 states in the United States. Scale reliabilities and intercorrelations were found to be similar to those of the original edition, although factor analysis revealed only two factors, "intrinsic," such as independence, and "social validation," such as lifestyle.

Applications

Super stated the WVI was to be used to assist in the choice of an occupation as well as a work setting. The revised edition does not fully endorse this position, on the grounds that a single occupational family may not be homogeneous with regard to a single type of work.

For example, there are strong rewards for an individual who highly values a high income in an assortment of contrasting occupations. For example, high income and rewards can be achieved in such occupations as rancher, pharmaceutical researcher, advertising executive, university president, business executive, or comptroller, but these occupations vary significantly in their job content.

With individuals who are about to enter the workforce in their chosen interest, the SWVI-R would be effectively employed to help evaluate the potential of a given job or employment opportunity

A resource for exploring occupations in the framework of work value orientation is the O*NET Work Importance Locator Master List. It contains from 75 to 100 jobs and occupations at five educational levels that are a response to each of six general values that correspond to certain clusters of SWVI-R scales.

WORK-FAMILY BALANCE

There are two general perspectives on what *work-family balance* is, both of which are rooted in role theory. The traditional view comes from theory on interrole conflict and defines work-family balance as an absence of conflict between work and family roles. Role conflict occurs when the demands of the two roles are incompatible, such that participation in one role makes it difficult or impossible to fulfill the obligations of the other role. The view of work-family balance being the absence of work-family conflict recently was augmented to include the extent to which one role (work or family) provides skills and experiences that are helpful in carrying out the demands of the other role. This is referred to as facilitation, enrichment, enhancement, or positive spillover. According to this perspective, work-family balance exists when there is

low work-family conflict and high work-family facilitation. Imbalance, then, is characterized by high conflict and low facilitation. Both conflict and facilitation can occur in two directions: when work role demands interfere with or enhance family role demands (work-to-family conflict/facilitation) and when family role demands interfere with or enhance work role demands (family-to-work conflict/facilitation).

Most research on work-family balance—indeed, most research on the work-family interface—has focused on work-family conflict, with facilitation processes and outcomes only recently being investigated. Also, like most work-family research, a great deal of the studies conducted have been atheoretical in nature, relying instead on the empirical findings of prior research to inform new hypotheses. Only recently has work-family balance been conceptualized affirmatively rather than as something that it is not (i.e., conflict).

This second perspective is grounded in theory on role balance and defines work-family balance as the extent to which a person is equally engaged in and satisfied with his or her work and family roles. Work-family role balance has three components: time, involvement, and satisfaction balance. People achieve balance when they spend equal amounts of time in each role, are psychologically involved to the same extent with each role, and are equally satisfied with each role. This perspective conceptualizes work-family balance as existing along a continuum, ranging from extreme role imbalance that heavily favors work or family over the other, to perfect balance that puts the two roles on equal footing. Two types of balance are possible: positive balance and negative balance. Positive balance occurs when the amount of time, involvement, and satisfaction are *equivalent and high* for both the work and family roles. Negative balance occurs when the amount of time, involvement, and satisfaction are *equivalent and low* for both the work and family roles. For example, a person who spends little time in both the work and family roles, is psychologically withdrawn from both roles, and is dissatisfied with both roles has achieved negative balance in all three dimensions. This distinction highlights the idea that not all balance is necessarily helpful or adaptive.

This understanding of work-family balance differentiates it from work-family conflict and from other conceptualizations that are used to understand how the work and family domains are connected to each other. For instance, these two life domains have been

thought of as accommodating each other; draining resources from each other; and compensating for, spilling over to, and enriching each other. In each case, something that happens in one sphere of life (work or family) then affects the other sphere of life, sometimes positively and sometimes negatively. Rather than concentrating on how the two roles iteratively affect each other, this second conceptualization of work-life balance focuses on the equivalence of engagement and satisfaction across roles.

Research using this formulation of work-life balance is sparse but has indicated that when people spend a large amount of their total time and total psychological investment in their work and family roles, and when they are imbalanced in favor of the family role, people experience the least stress and work-to-family conflict and, in turn, the highest quality of life. Those who are imbalanced in favor of the work role experience the most stress and work-to-family conflict and, in turn, the lowest quality of life. Those who are balanced fall in between. Similar results were found with respect to satisfaction with life roles. The least work-to-family conflict and stress and, in turn, the highest quality of life were found for those with greater family than work role satisfaction, followed by those who were equally satisfied with their roles, then by those who were more satisfied by their work roles.

When people invest little time, involvement, or satisfaction in their work and family roles, balance does not predict quality of life. Specifically, individuals who are generally disengaged and dissatisfied with both their work and family roles tend to report a low quality of life, regardless of the degree of role balance or imbalance they have achieved. This supports the idea that negative balance may not be desirable. Overall, this research indicates that imbalances favoring work over family roles tend to result in lower quality of life because they create greater work-to-family conflict and more stress.

Such results call into question the assumption that has been made in most work-family research that balance is desirable. From an individual outcome point of view, this may not be the case. Research is needed that investigates how the three components of work-life balance are related to organizational outcomes, such as organizational commitment, productivity, and performance quality.

There remains an intuitive appeal to the idea of achieving balance between work and family roles, perhaps because moving toward balance would, for

many people, involve moving away from the problematic imbalances favoring work over family roles. Many organizations now offer employee-friendly benefits designed to help people negotiate the conflicting demands of their work and family roles more successfully. For instance, companies provide child care programs, elder care assistance, telecommuting options, and flexible work hours. The extent to which employees perceive their organizations as being responsive to their work-family issues has been associated with greater job satisfaction, organizational commitment, work functioning, and family functioning, as well as less work-family conflict and lower turnover intentions. Researchers have not yet determined how well such offerings help employees reduce the problematic life role imbalances that favor work over family.

WORK-FAMILY CONFLICT

Work-family conflict refers to a situation where the demands and responsibilities from work roles and family roles are mutually incompatible in some respect. In other words, participation in the work role is made more difficult by virtue of participation in the family role, and participation in the family role is

made more difficult by virtue of participation in the work role. According to this definition, work-family conflict can occur in two directions: family life can interfere with work life (*family-to-work conflict*) and work life can interfere with family life (*work-to-family conflict*). For example, parents might experience family-to-work conflict when a deadline is missed because they need to take time off from work to stay home with a sick child. Alternately, a spouse or parent might experience work-to-family conflict when his or her work schedule makes it impossible to attend a family function or complete household chores. Work-family conflict also has been referred to as work-family interference, work-family tension, and negative work-family spillover.

A number of societal changes occurred over the latter half of the twentieth century that have made the issue of work-family conflict salient to employers, employees, and policymakers. The most important societal change has been growth in the proportion of households, especially those with children, that have two wage earners. Another change has been an increase in the proportion of single-parent households, and especially an increase in the proportion of single parents who are employed. A third change, due to the aging of society, is the growing proportion of working adults who are responsible for the care of elderly family members.

Although the result of these societal changes is that many working adults have more to do, does this mean that they actually experience conflict between their work and family lives? Results from several national studies conducted in the United States during the 1990s suggest that they do. Among adults between the ages of 25 and 54 who work at least 20 hours per week and have some form of immediate family (i.e., a spouse, live-in partner, or at least one child under 18 years old), roughly 40 percent report experiencing work-to-family conflict, and about 12 percent report experiencing family-to-work-conflict. A consistent finding is that work-to-family conflict is more prevalent than family-to-work conflict. Said differently, family roles appear to encounter higher levels of cross-role interference than work roles. In general, research fails to show robust and consistent differences between men and women in exposure to either type of work-family conflict or in the predictors and outcomes of work-family conflict.

The predictors of work-family conflict can be grouped into three general categories: work environment, family environment, and person characteristics.

Research shows that the two categories of environmental predictors have differential relations to the two types of work-family conflict. In other words, characteristics of the work environment are causes of work-to-family conflict, whereas characteristics of the family environment are causes of family-to-work conflict. For example, higher levels of time devoted to family responsibilities, higher levels of psychological importance attributed to family, and the experience of family stressors (e.g., parental demands, marital problems) are associated with higher levels of family-to-work conflict. Also, higher levels of family-related social support are related to lower levels of family-to-work conflict. In contrast, higher levels of time devoted to work responsibilities, higher levels of psychological importance attributed to work, and the experience of work stressors (e.g., work overload, conflicting demands at work) are associated with higher levels of work-to-family conflict. Also, higher levels of work-related social support are related to lower levels of work-to-family conflict. Person characteristics are generally related to both types of work-family conflict. For example, negative affectivity, which represents a general predisposition to experience negative moods, is positively related to both work-to-family conflict and family-to-work conflict. Time-management preferences, such as the tendency to set priorities and be organized, are negatively related to both types of work-family conflict. The fact that person characteristics are common predictors of both types of work-family conflict is not surprising when one considers that they represent intrinsic characteristics that are brought with the person into both work and family settings.

The outcomes of work-family conflict can be grouped into three general categories: work outcomes, family outcomes, and personal outcomes. Research shows that work and family outcomes have differential relations with the two types of work-family conflict. In other words, work-to-family conflict is predictive of adverse family outcomes, such as lower levels of family satisfaction, family work performance, and family participation. Family-to-work conflict is predictive of adverse work outcomes, such as lower levels of job satisfaction, work performance, and work attendance. Although family-to-work conflict is generally related to poorer behavioral outcomes at work, research shows that it is work-to-family conflict that is associated with intentions to quit a job or career and actual job or career turnover. This makes sense if one views turnover as a

coping mechanism. Changing jobs or careers may eliminate or reduce the extent to which work interferes with family life (i.e., work-to-family conflict). However, because one's family situation remains unchanged, changing jobs or careers is unlikely to reduce the extent to which family interferes with work life (i.e., family-to-work conflict). Finally, because both types of work-family conflict represent stressors, they each have been predictive of adverse personal outcomes, such as poor psychological health (e.g., depression), poor physical health (e.g., somatic symptoms), and poor behavioral health (e.g., heavy alcohol use, smoking).

The management of work-family conflict can be approached through personal initiatives and organizational initiatives. The personal initiatives that individuals can invoke to manage work-family conflict include seeking out and developing appropriate social support at work and at home, reducing or reorganizing the time devoted to work or family demands, reducing the psychological importance of work or family roles, and developing strategies to reduce or better cope with the sources of stress at work and at home. However, work organizations also can help. As many as 30 to 40 organizational initiatives have been discussed in the literature, which can be classified into several general groups: flexible work arrangements, paid and unpaid leaves, dependent-care assistance, and general resource services. Although many personal and organizational initiatives can be identified, little evaluation research has attempted to determine which personal and organizational initiatives, and which combinations of them, actually reduce conflict between work and family life.

It is useful to point out that work-family conflict is a source of stress that affects more people than implied by overall prevalence rates. In other words, work-family conflict affects more than just the individuals experiencing it. It also may directly or indirectly affect family members, coworkers, supervisors, organizations, and communities. Work-family conflict often has been viewed as a problem to be resolved by the affected employees. However, given the potentially severe consequences and the broad impact of work-family conflict, it represents a social issue best tackled with collaboration from employers, employees, and governments.

WORK-FAMILY ENRICHMENT

Although work-family research has typically focused on the difficulties of participating in both work and family roles (i.e., work-family conflict), there is a growing awareness that there are also beneficial effects of combining work and family roles. These beneficial effects have been referred to as *work-family enrichment* and may have positive implications for career development, which is a function of one's work and nonwork experiences.

Work-family enrichment and work-family conflict are conceptually distinct constructs. Thus it is possible that an individual can experience high (or low) levels of both conflict and enrichment at the same time or high levels of one and low levels of the other. Similar to work-family conflict, researchers have conceptualized work-family enrichment as consisting of two directions: work-to-family enrichment (where one's work experiences benefit his or her family life) and family-to-work enrichment (where one's family experiences benefit his or her work life). Each direction

of work-family enrichment may be associated with unique antecedents and outcomes.

The dominant theoretical perspective used to explain the linkages between work and family has been role theory. The two predominant perspectives within role theory for describing the relationships between work and family roles are the scarcity hypothesis and the enhancement hypothesis. The scarcity hypothesis suggests that a person has a limited amount of time and energy and that strain is normal and inevitable, given the overdemanding nature of engaging in multiple roles. This hypothesis forms the basis for much of the research on work-family conflict. In contrast, the enhancement hypothesis proposes that occupying multiple roles can result in a variety of benefits such as the development of new skills, increased self-complexity, a larger social network, and increased monetary resources. This hypothesis forms the basis for research on work-family enrichment. It is believed that the net effect of these benefits facilitates the integration and management of work and family roles, leading to fewer negative outcomes and more positive outcomes.

Although ideas about the benefits of combining multiple roles have been around for decades, there remains a need for construct clarification, theory building, and measurement tool development. Recently, constructs such as work-family positive spillover, work-family facilitation, and work-family enrichment have been introduced to describe the theoretical relationships and associated mechanisms that enable work and family to benefit one another. Because the distinctions among these constructs are not well understood, all of them are categorized under the general rubric of work-family enrichment. The following is a brief discussion of the differences and similarities between these various constructs.

The term *positive spillover* has been used in the literature since the early 1980s. Spillover refers to the transfer of affect (i.e., emotion), skills, behaviors, and values from one domain to the other, such that there is a positive relationship between experiences in the two domains. Spillover has been broken down further into positive (i.e., beneficial) spillover and negative (i.e., problematic) spillover.

A term that has been used more recently to describe the benefits of combining work and family roles is *work-family facilitation*. Work-family facilitation has been defined as the extent to which an individual's participation in one role enhances functioning

in another role. Although both positive spillover and facilitation are concerned with how individual participation in one domain (e.g., work) is beneficial for the second domain (e.g., family), positive spillover involves the transfer of characteristics (or personal gains) of a person such as affect, skills, behaviors, and values from one domain to another, thereby benefiting the second domain. In contrast, facilitation is proposed to occur not just through personal gains but through capital gains as well (e.g., money, benefits, and social contacts). Therefore, positive spillover may be considered one mechanism by which facilitation may occur.

Work-family enrichment is a recent term used to refer to the process by which experiences in one role improve the quality of life in the other role. Given this definition, constructs such as work-family positive spillover, and even work-family facilitation (at times), can be broadly categorized under the rubric of work-family enrichment. The process of work-family enrichment begins when resources are generated in the originating role (e.g., work) that can potentially be utilized in the receiving role (e.g., family). Examples of resources that may drive enrichment include skills (e.g., interpersonal skills), perspectives (e.g., respecting individual differences), psychological resources (e.g., self-efficacy), physical health, social capital, and material assets.

These resources may improve the quality of life in the receiving role through one of two paths: the instrumental path or the affective path. The instrumental path describes a situation in which resources are transferred directly from the originating domain to the receiving domain, resulting in a direct increase in performance in the receiving domain. For example, an individual may apply a skill learned in the family role (e.g., listening attentively to one's child or spouse) to his or her role as a supervisor at work, thereby boosting his or her performance at work. The affective path occurs when resources gained in the originating role promote positive affect or emotion in that role, which then produces increased performance in the other role. The direct transfer of resources through the instrumental path may occur either intentionally or unintentionally, whereas the affective path is believed to be predominantly unintentional.

Factors that produce family-to-work enrichment include both personal and family-level characteristics. Personal characteristics such as extraversion, agreeableness, conscientiousness, and use of constructive

coping mechanisms have been linked to high levels of family-to-work enrichment. Family-related characteristics such as marital quality, lack of family conflict, and high levels of family support have also been associated with increased family-to-work enrichment.

Factors that produce work-to-family enrichment include both personal and work characteristics. Personalities high in desire for growth, extraversion, and openness and low in neuroticism have been linked to high levels of work-to-family enrichment. The work-related factors of job complexity and autonomy are also related to high levels of work-to-family enrichment.

To date, very little research has examined the outcomes of work-family enrichment. The research that does exist has linked enrichment to better mental and physical health and decreased problem drinking. Increased levels of work-family enrichment are also related to both greater job satisfaction and effort and greater family satisfaction and effort.

In addition, research has found significant crossover relationships between work-family enrichment experienced by a spouse and a decrease in his or her partner's depressive symptoms one year later. This finding demonstrates that not only does work-family enrichment benefit individuals, but the benefits may extend to other family members. Furthermore, these benefits are posited to impact individuals' career development over time.

WORK/LIFE LITIGATION

Work/life litigation refers to legal action taken against employers for discriminating against a worker or workers due to their family responsibilities. Among the most common types of work/life litigation are cases charging employers with pregnancy discrimination, creating a hostile work environment, unequal pay, disparate treatment, disparate impact, violations of the Family and Medical Leave Act, and violations of the Americans with Disabilities Act. The majority of cases are filed by women, but men are increasingly becoming plaintiffs as well.

When careers of parents derail for reasons seemingly unrelated to performance, the culprit may be a form of gender bias and stereotyping against workers (men as well as women) who play the feminine role of primary caregiver. When women hit the "maternal wall," they suffer from job penalties once they become mothers. The maternal wall typically is triggered at three points: when a woman gets pregnant, returns from maternity leave, or adopts a flexible work arrangement to accommodate family demands. Men too have sued successfully when denied leaves that are routinely granted to women. Though most suits involve child care, some large judgments have emerged from cases involving workers caring for elders or ill partners.

Women have won maternal wall cases in which, once motherhood becomes salient, their performance reviews drop precipitously, they are held to higher standards than their coworkers, or (often as a result of these practices) they are denied or not considered for promotions or are terminated.

Several different kinds of gender stereotyping emerge in maternal wall cases. Hostile prescriptive stereotyping involves statements that mothers should not be employed. Hostile prescriptive stereotyping seems to be common: People seem to know that it is not appropriate to say "We don't hire women" but not that it is equally inappropriate to say that mothers belong at home. Also common is "benevolent stereotyping," which polices women into traditional gender roles in a kinder, gentler tone of voice, as when employers fail to consider a mother for a promotion

because they assume (without asking) that she will not want to relocate or travel.

The most common type of work/life litigation is a lawsuit brought under the basic federal antidiscrimination statute, Title VII. Among Title VII cases involving caregiving, the most common type is a disparate treatment suit in which a mother alleges that she has been treated worse than a similarly situated man or that she was penalized by gender stereotypes. In addition, plaintiffs often sue under state antidiscrimination statutes, many of which are more pro-plaintiff than the federal law. Government workers can sue under the equal protection clause of the U.S. Constitution.

Successful lawsuits also have been brought under Title VII disparate impact theories, alleging that a facially neutral employment practice, for example, disallowing use of sick leave to care for dependents, has a disparate impact on women not justified by business necessity. Additional Title VII theories include (a) when a plaintiff alleges a hostile work environment based on sex, (b) when an employee alleges that she was treated so poorly that she has no choice but to quit (*constructive discharge*), or (c) claims that an employer retaliated against the plaintiff for asserting her legal rights. Maternal wall cases also are filed under the Pregnancy Discrimination Act, the Family and Medical Leave Act, and the Americans with Disabilities Act, which prohibits discrimination against a worker caring for a disabled family member.

Many cases involve substantial damage awards. Most are not reported, because successful cases settle, and settlements are rarely disclosed. Yet more than a dozen awards over \$100,000 are public, most of them over \$400,000. These numbers dramatize the growing potential for liability if work/family issues are not handled well.

Flexible scheduling, a policy some companies adopt to respond to employees' work/family conflict, has been featured in several lawsuits. In *Lovell v. BBNT Solutions* (2003), the court held that an employer risked violating the Equal Pay Act when it paid a woman a lower pay rate than other predominantly male workers because she worked a 30-hour, instead of a 40-hour, week. Another case, which was settled, asserted that a systematic refusal to promote people on flexible work arrangements had an illegal disparate impact on women (*Goldstick v. The Hartford Inc.*, 2002). In another case not involving caregiving, a court allowed a suit to go forward when a woman sued over her employer's abolition of a job sharing arrangement (*Tessmer v. Nationwide Life Insurance Co.*, 1999). Specific types of stereotyping and bias tend

to occur in the context of flexible work arrangements. One, which social psychologists call *leniency bias*, occurs when the rules are applied leniently to members of the *in group* (usually career-focused employees without caregiving responsibilities) but rigidly to the *out group* (usually those on flexible work arrangements). A second form of attribution bias occurs when actors attribute their own behavior and that of in-group members to legitimate causes while making very different assumptions about the behavior of the out group. Thus a woman who works part time and is not in her office may be assumed to be tending to her children even when she is at a business meeting, whereas (predominantly male) full-timers may be assumed to be on business even if they are coaching a soccer game.

Work/life litigation is adding a new urgency to employers' need to handle work/life issues fairly and effectively. While progressive employer policies have been traditionally viewed as optional benefits that companies have discretion to use—or eliminate—at will, case law suggests that workplaces without well-managed work/life policies and practices may run a risk of litigation.

WORKAHOLISM

Although the popular press has paid considerable attention to *workaholism*, very little research has been undertaken to further our understanding of it. It should

come as no surprise, then, that opinions, observations, and conclusions about workaholism are both varied and conflicting. Some researchers, such as Marilyn Machlowitz, view workaholism positively from an organizational perspective, finding workaholics to be satisfied and productive. Others, such as Barbara Killinger and Gayle Porter, view workaholism negatively, equating workaholism with other addictions and depicting workaholics as unhappy, obsessive, tragic figures who are not performing their jobs well and are creating difficulties for their coworkers.

Wayne Oates, generally acknowledged as the first person to use the term *workaholic*, described a workaholic as someone with such an excessive need for work that it creates a disturbance with the workaholic's physical, psychological, and social well-being. Kimberly Scott, Keirsten Moore, and Marcia Miceli proposed three elements of workaholism: the extent to which an individual (1) spends discretionary time in work activities, (2) thinks about work when not working, and (3) works beyond organizational requirements. Finally, Janet Spence and Ann Robbins describe the workaholic as a person who is highly involved in work, feels "driven" to work because of internal pressures yet experiences relatively little enjoyment at work. Most writers view workaholism as a stable individual characteristic, and there have been suggestions that workaholism may be increasing.

Some researchers have proposed the existence of different types of workaholic behavior patterns, each having potentially different determinants and different effects on job performance and other work and life outcomes. Scott, Moore, and Miceli suggest three types of workaholic behavior patterns: compulsive-dependent, perfectionist, and achievement oriented. They propose that compulsive-dependent workaholism will be associated with high job performance, high job satisfaction, and high life satisfaction; that perfectionist workaholism will be associated with high stress, extensive physical and psychological problems, hostile interpersonal relationships, low job satisfaction, low job performance, and voluntary turnover and absenteeism; and that achievement-oriented workaholism will be associated with physical and psychological health, high job and life satisfaction, high job performance, low voluntary turnover, and pro-social (altruistic) behaviors.

Spence and Robbins found three workaholic patterns—Work Addicts, Work Enthusiasts, and Enthusiastic Addicts—based on their three workaholism components (work involvement, feeling driven

to work, and work enjoyment). Work Addicts were highly involved in work, felt driven to work, and were low on work enjoyment. Work Enthusiasts were high on work involvement and work enjoyment and low on feeling driven to work. Enthusiastic Addicts were high on all three components of workaholism. The existence of different types of workaholic patterns might help reconcile the conflicting observations and conclusions in the literature.

There has been considerable speculation regarding the work behaviors likely to be exhibited by workaholics. This list includes an extensive number of hours worked per week, a high level of job involvement, extensive job stress, nondelegation of job responsibilities to others, high levels of interpersonal conflict, and a lack of trust.

Most studies of workaholic behaviors have compared the three workaholism types identified by Spence and Robbins. In general, there are no differences between Work Addicts, Enthusiastic Addicts, and Work Enthusiasts in the number of hours worked per week (although the three workaholism types work more hours than nonworkaholics). Work Addicts report greater job stress than Enthusiastic Addicts, and both report greater job stress than Work Enthusiasts. Both Enthusiastic Addicts and Work Enthusiasts report greater job involvement than Work Addicts, and Work Addicts have a greater unwillingness to delegate than the other types. Enthusiastic Addicts not surprisingly are more perfectionist than Work Enthusiasts.

Three potential determinants of workaholism have received some conceptual and research attention. Two of these, family of origin and personal beliefs and fears, are the result of socialization practices within families and society at large. The third—organizational support for work-personal life balance—represents organizational values and priorities.

FAMILY OF ORIGIN

Bryan Robinson has written about work addiction as a symptom of a diseased family system. Work addiction, similar to other addictive behaviors, is intergenerational and passed on to future generations through family processes and dynamics. In this view, work addiction is seen as a learned addictive response to a dysfunctional family of origin system.

PERSONAL BELIEFS AND FEARS

Ronald Burke examined the relationship of personal beliefs and fears with workaholism. Beliefs and

fears are a reflection of values, thoughts, and interpersonal styles. He found that Work Addicts scored higher than Work Enthusiasts and Enthusiastic Addicts on this measure and concluded that workaholism emerges in response to feelings of low self-worth and insecurity.

ORGANIZATIONAL VALUES

Organizations differ in the extent to which their culture supports work-personal life balance. Burke compared perceptions of the supportiveness of organization culture across the three Spence and Robbins workaholism types. He found that Work Addicts saw their workplaces as less supportive of work-personal life balance than both Work Enthusiasts and Enthusiastic Addicts.

It is likely that different types of workaholics will report varying work and career satisfactions. In support of this, Scott and her colleagues found that Work Enthusiasts and Enthusiastic Addicts were more satisfied with their jobs than Work Addicts, and Work Enthusiasts perceived brighter career prospects than Work Addicts. Not surprisingly, Work Addicts had a stronger intention to quit their organization than Work Enthusiasts.

There is considerable consensus in the workaholism literature on the association between workaholism and poor psychological and physical well-being. Work Enthusiasts have fewer psychosomatic symptoms—and more positive lifestyle behaviors—than both types of Work Addicts, and Work Enthusiasts and Enthusiastic Addicts have more favorable emotional well-being than Work Addicts.

A number of writers have hypothesized that workaholism is likely to impact negatively on family functioning. The comparisons of the workaholism types on three measures of life or extrawork satisfactions have provided moderate support for the hypothesized relationships. First, Work Addicts were less satisfied with their family lives than the two other types. Second, Work Addicts were less satisfied with their relationships with friends than Work Enthusiasts. Third, Work Enthusiasts experienced greater satisfaction with their community than did Work Addicts and Enthusiastic Addicts.

The relationships between specific workaholism components (work enjoyment, work involvement, feeling driven to work) and various types of outcome variables are interesting and complex. Work enjoyment

was the only component related to all work outcomes. Employees reporting greater work enjoyment also experienced more job satisfaction, more optimistic future career prospects, more career satisfaction, and a lower intent to quit their organization. Moreover, both work enjoyment and feeling driven to work were related to indicators of psychological well-being but in opposite directions. Individuals reporting greater work enjoyment and lesser feelings of being driven to work reported higher levels of psychological health.

There is a large speculative literature suggesting ways to reduce levels of workaholism. One part of this work focuses on individual and family therapy, and a second part emphasizes organizational and managerial interventions.

INDIVIDUAL COUNSELING

Workaholics Anonymous chapters have sprung up in some North American cities. These groups, patterned after Alcoholics Anonymous self-help groups, endorse the 12-step approach common to the treatment of a variety of addictions. Killinger and Robinson include chapters outlining actions an individual might pursue to reduce levels of workaholism.

FAMILY THERAPY

Robinson, consistent with his clinical and consulting perspective, focuses on treatment, both individual and family. This is not surprising, given the central role he gives to both family of origin and current family functioning in the development, maintenance, and intergenerational transmission of workaholism. The treatment recommendations Robinson offers are similar to those offered to alcoholic families.

Denial is common among workaholics and their family members. Workaholics define their behavior and symptoms in a favorable light, and family members are reluctant to complain. Parental expectations of children, often unrealistic, should be addressed as should family members' collusion with the workaholic parent. Family members need help in expressing their negative feelings to the workaholic. Families also need to learn to set boundaries around the amount of time they work together and talk about work. Family members can set goals regarding communications, roles, and expressions of feelings to improve family dynamics.

WORKPLACE INTERVENTIONS

How can employers help workaholics and help workaholics help themselves? Employers should pay attention to the performance and work habits of employees and be alert to warning signs of workaholism. They should ensure that employees take vacation time away from work. Finally, job insecurity, work overload, limited career opportunities, and lack of control can make employees feel compelled to work longer. If these factors exist, employers should try to minimize their impact on the atmosphere within the organization.

Robinson also highlights the role that managers can play in assisting their workaholic employees to change. Workaholic employees should be referred to an employee assistance program or a recovery program to start treatment processes. Managers should help prioritize projects for employees as long-term and short-term assignments. Workaholics must be encouraged and helped to delegate their work. At the end of each day, the manager should meet with the employee to discuss what has been accomplished during that day and to plan (down to short intervals) for the following day. The employee should be given specific times to take breaks and to leave work. It may also be possible to reduce the negative effects of workaholism (particularly on impaired well-being and poor health) through stress management training. The development of workplace values that promote new, more balanced priorities and healthier lifestyles will support those workaholics who want to change their behaviors.

WORKER ADJUSTMENT AND RETRAINING NOTIFICATION ACT OF 1992 (WARN)

The *Worker Adjustment and Retraining Notification Act* (WARN) of 1992 was passed by the U.S. Congress in part to provide workers with an early warning of layoffs and plant closings so as to limit the amount of disruption in the workers' lives as much as possible. Given that so many companies continue to reorganize and lay off workers, this continues to be an important act for both employers and workers to understand.

In general, this law requires employers who have at least 100 employees to provide at least 60 days' notice to affected employees in the event of a mass layoff or plant closing. A mass layoff means a reduction in the workforce that results in an employment loss at a single site for any 30-day period for at least 33 percent of the active full-time employees and is equal to at least 50 full-time employees, or at least 500 full-time employees regardless of the percentage of employees affected. An employment loss is further defined as a termination of employment, a layoff of six months or more, or a decrease in work hours by more than half over a six-month period.

Notice to affected employees must include name and address of the plant closing location, the job(s) being terminated, the date of termination, any "bumping" rights that may exist, a telephone contact number, and a statement indicating if the layoff is temporary or permanent.

However, there are a number of conditions under which employers have no duty to provide notice to affected workers. These include waiver of one's rights, exemptions allowed under the law, a faltering company, unforeseeable business circumstances, natural disaster, independence of operations, sale of a

business, single-site issues, bankruptcy, bridge banks, and a statute of limitations.

WAIVERS

The courts have allowed employees to waive their WARN rights under various federal and state laws, so long as consideration is provided for the relinquishment of the right and the person(s) did not waive their rights under conditions of fraud or duress.

LEGAL EXEMPTIONS

Those employees who are hired with the knowledge that their employment is for a limited period have no notice rights under the WARN Act. In addition, employers are not expected to provide notice for any layoff or plant closing that occurs as a direct cause of a strike or a lockout.

Organizations can escape WARN provisions under the faltering company clause so long as it is actively seeking capital or new business that would prevent a layoff or plant shutdown. Firms must demonstrate that they were acting in good faith and actually seeking capital or additional business to qualify.

There are other adverse business conditions that occur from time to time that are unforeseeable. These are also excluded under the law. For example, despite prior warnings from the government, a prominent defense contractor was able to qualify for this exemption when the government suddenly cancelled one of its defense contracts.

Even a casino that was unexpectedly unable to renew its license was able to avoid complying with WARN provisions. Layoffs' and plant closings' notice requirements are also waived for natural disasters that might occur such as floods and hurricanes.

Businesses may also steer clear of WARN provisions under the independence of operations clause. In effect, this means that parent companies may avoid liability if they do not exercise control over day-to-day operations of subsidiaries or other companies that they own or to whom they have lent money. Other considerations in this determination include common ownership, common directors or officers, common personnel policies originating from a single source, and dependency of the operation(s) on the higher-level unit.

Whenever there is a sale of a business to another firm, the seller is only liable for any layoff prior to the date of sale. After that date, the buyer, even if the

seller's name is still on the lease, is liable for any failure to provide notice to workers in the event of a layoff or plant closing.

Single-site issues are the most complicated part of the WARN Act. Basically, buildings that are next to each other and owned by the same employer are not covered by WARN provided they have separate management, produce different products and services, and have separate workforces. Consideration is also given to employee rotation between sites and sharing of staff and equipment. The greater the distance between buildings or sites, then the less likely they are to be ruled to be a single site. Courts have found buildings as close as 20 yards apart to be separate sites when they were managed by independent management teams or had independent workforces.

Those businesses that have filed for bankruptcy are also excluded from WARN requirements. The courts have determined that companies in bankruptcy are not engaged in commercial activities, which is a fundamental requirement of having a business. In a related situation, banks that fail are often operated temporarily by the Federal Deposit Insurance Corporation (FDIC) through the use of bridge banks. The courts have also found these bridge banks to be excluded from WARN provisions.

STATUTE OF LIMITATIONS, PENALTIES, AND AWARDS

The WARN Act does not have a time limit for filing for any violations. However, the Supreme Court has ruled that when a law is silent on the period for filing a claim, then generally the most analogous state law is to be used. Victims can receive up to 60 days of back pay. Companies that fail to comply with the WARN Act can also be assessed up to \$500 a day.

CONCLUSION

The fundamental purpose of the WARN Act is to provide workers with notice of layoffs or a plant shutdown to minimize the impact on their families and lives, but achieving this objective has become quite complex in its application. While there are a variety of legal snares that may trap the most well-intentioned organization, there are also many ways to avoid the act's requirements. Studies have shown that many companies are able to steer clear of the act's legal demands. As a result, it appears that the WARN Act is generally failing to live up to its intended purpose.

Despite the relative ease of dodging its rules, many companies choose to provide workers with notice even if the layoff or plant closing is not covered by WARN. This practice is not only smart management, but it is also the humane thing to do.

WORKFORCE 2020

The workforce research of the Hudson Institute has consistently emphasized the role of "shaping forces." The research took its most influential form in the organization's high-selling volumes *Workforce 2000*, published in 1987, and *Workforce 2020*, published in 1997. In the Hudson Institute's treatment, their shaping forces determined the trends and challenges that would affect human resources planning and workforce development in the years ahead. Critically, the forces described in the research have had a futurist component, giving corporations and policymakers a measure of long-term perspective for their human resources and workforce development planning.

The shaping forces most frequently stressed in Hudson's research have been technological change and demographic transformation. The former has

typically been less detailed and of less impact. *Workforce 2020*, written in 1995 and 1996, largely disregarded or failed to predict the key technological changes that came in so many ways to define workforce change over the 1990s, for example.

The demographic analysis within the research received widespread attention, however, and continues to be quoted extensively despite the time since the last book's publication. The first volume focused heavily on the future of racial and ethnic diversification. *Workforce 2020* updated these projections and extended them, while adding a stronger focus on population and labor force aging.

As 2005 approached, Hudson Institute again decided to renew its workforce research. This included updating the trends in racial and ethnic diversification and aging covered by its earlier work. In addition, just as *Workforce 2020* had done relative to *Workforce 2000*, the research added new points of emphasis to account for the changes occurring in the world of work. Out of this has grown the concept of the global workforce.

THE GLOBAL WORKFORCE

As the 1990s drew to a close, the importance of immigrant labor to U.S. population and workforce growth had become obvious. U.S. universities and "knowledge industries" rely heavily on skilled or educated immigrants to compensate for shortfalls in the native population. Hispanic immigrant populations of varying skill and knowledge levels had spilled out of their traditional geographic targets in the East Coast and the West and Southwest and had come to drive significant shares of population growth in the South, Midwest, and Plains states. Moreover, rapid growth in these regions' Hispanic populations occurred in both urban and rural areas.

The strong labor markets of the mid- and late-1990s quelled much of the popular disaffection with high immigration levels that had surfaced in the 1992 elections. This somewhat marginalized immigration as a core explanation for change. Globalization, on the other hand, remained a central narrative. The role of globalization in job loss was, again, a focus of the 1992 election. This role received less attention as unemployment rates fell, but international trade and the dynamics of global financial markets seemed to become more frequent topics of media and popular discussion as both the United States and global economies continued to grow.

Yet labor markets are in truth found in the bedrock of even these changes to the global economy. The 1990s thus saw a rapid expansion of two workforce trends: increasing numbers of workers (immigrants) coming to the United States and increasing numbers of new jobs going to foreign locales, particularly in the less developed world. This two-way labor market exchange—increasing numbers of less developed world workers coming to the United States and increasing numbers of jobs going to the less developed world workers—is the expression of the global workforce. It has its roots in two shaping forces. The first is technological change that facilitates the international consumption and production of goods and information. The second is the accelerating collapse of the developed world as a contributor to global population and labor force growth.

TECHNOLOGICAL CHANGE AS A SHAPING FORCE

Workforce 2020, like much of the contemporary technological discussion, highlighted the geometric growth of microchip power or speed in its analysis of technological change and the effect on computer pricing. Moore's Law and the increase in optical storage density have certainly been important. When *Workforce 2020* was published, Intel's new Pentium promised clock speeds of 200 MHz. By mid-2004, the Pentium 4 offered clock speeds as high as 3,400 MHz. In the five years between 1997 and 2002, the number of personal computers in the United States had nearly doubled, from around 110 million to almost 200 million.

The manner in which these additional, more powerful computers communicate with each other turned out to have been the more important evolution, however. The ability of computers to exchange data has obviously changed the U.S. economy and culture. It has also created entirely new possibilities for the global organization of work.

The effect of technological change is best understood in terms of the growth of less developed world labor markets. However, it is not an unimportant aspect of immigration. The improving ability of migrants to communicate with the social networks they have left behind has reduced the opportunity cost of emigration. The role of information technology in expediting remittances, or the transfer of earned money to migrants' home countries, which totals over \$60 billion worldwide, cannot be denied.

Still, the effect of information technology on foreign workforces is larger than its role in migration. Far-flung multinationals can now organize global production far more effectively and cheaply as a result of the Internet. Businesses can coordinate the exchange of goods with lower transactions costs. Information itself has become an easily tradable commodity across national borders.

The networking of computers is the critical change to global work, but the growth in computers' power should not be ignored. The radically improved ability to bundle different types of data—qualitative, quantitative, graphical, and aural—lessens the importance of distance in international coordination, particularly within the operation of a single corporation. The importance of language barriers can also be reduced to a degree, and in an occasionally controversial effect, the barrier itself is disappearing in many instances as English increasingly dominates electronic communication.

The rise of foreign labor forces is typically discussed in terms of international wage differentials. The lower wages found in the less developed world are an important consideration. Yet less developed workforces have always worked for lower wages than are found in the wealthy nations. The key driver of change has been information technology that allows foreign workforces and firms to be more closely and cost-effectively integrated into the global economy.

As policymakers and corporate planners look to the future effect of IT in integrating global workforces, the emergence of wireless communication is of prime importance. In middle- and low-income countries, the ability of wireless communication to circumvent problems of infrastructure has favored the rapid adoption of wireless devices. The rate of adoption has been especially fast in middle income countries, where there are now more cellular phone subscriptions than telephone main lines. This suggests an accelerated expansion of global workforce integration.

In addition, the introduction of wireless connectivity and digital processing capability into a host of "everyday" goods promises to inject a new source of relative value that has virtually no mass that would incur transportation costs. Coupled with information technology's impact on trade in the form of miniaturization, improved logistics efficiency, and new categories of tradable economic goods such as information, the advantages of internationally dispersed work to the developed world should grow more rapidly in the future than they have even in the recent past.

DEMOGRAPHIC CHANGE AS A SHAPING FORCE

The effect of IT in realizing the potential of a global workforce comes at a historic turning point in global history. The present decades are witnessing the end of the developed world's responsibility for driving global population growth. The speed with which this is occurring is stunning. Between 1950 and 1970, the world's developed regions accounted for roughly one-fifth of the world's population increase. After 2020, the developed regions will effectively cease growing in population as a group and begin to decline.

The effect on the ratio between developed and less developed labor force growth follows the changes in population dynamics. Developed region labor force growth between 1980 and 1990 was approximately 9 percent. The forecast for the 2000 to 2010 period is 3 percent. As a result, the developed regions are projected to contribute just 4 percent of global labor force growth over this decade. The contribution will continue to drop as developed world population growth continues to decelerate or turn negative. The world's "new" workers will increasingly come from its less developed areas. The adjustments this change will require will cement the concept of the global workforce.

While this general conclusion about the widening gap between the developed and less developed worlds in driving global population and labor force increase is critical, there are important distinctions that should be noted. The increasing responsibility of the less developed world for population growth does not mean that the less developed world itself is growing more rapidly. The rate of change in Latin America, for example, is becoming much smaller. However, growth in Africa and the Middle East will remain fairly strong through mid-century.

Within the developed world, most of its larger nations face an eventual period of absolute population decline. The United States, on the other hand, will experience healthy growth in comparison to most of its wealthy peers. The population of Eastern Europe is projected to decline from 2005 to 2020, while Western Europe's is projected to increase by just 1 percent. U.S. population growth over the same time period is forecast to be 15 percent.

However, the relative strength of U.S. population growth is only that: relative. It will not escape the difficulties associated with a rapid slowdown in population and labor force growth. Moreover, projections of

positive population growth are no sign that the United States will not be reliant on an infusion of immigrant labor to augment workforce rolls. Instead, they are a result of U.S. reliance on immigrant labor in the past decades and the present. Immigration in recent years may be as high as three times their 1980s' levels. High immigration levels are a significant component of the comparably stronger U.S. outlook.

Absent even higher levels of immigration, there is no way to avoid a keen reduction in labor force growth. This is likely to become most noticeable as the present decade draws to a close, when baby boomers begin to retire in larger numbers. The problem will reach its nadir as the United States approaches 2020. The rate of labor force growth in the year 2000 was nearly as great as what is projected for the entire 10-year period between 2015 and 2025.

As stated, the historic U.S. response to tighter labor markets has been to tolerate increased immigration, both of the lower and higher skilled variety. The extent to which the United States dominates the global market for migrant labor is dramatic. Nearly half the annual flow of migrants from the less developed to developed regions is absorbed by the United States. The advantage appears to be even more pronounced among more educated migrant stocks. In a 1998 study of migration patterns to select OECD nations, the United States absorbed 57 percent of the total measured migration. It absorbed 76 percent of the migrants with tertiary education.

There are a variety of factors that account for U.S. immigration levels relative to their developed world peers, but it must be noted that these factors are by no means immutable. As other developed nations have begun to confront the demographic fate that awaits them, many have aggressively targeted immigration to meet the challenge. This is especially true of the more highly educated and skilled members of the global workforce. In addition, there are signs that changes to some aspects of U.S. policy vis-à-vis temporary immigrant status, as well as improving opportunities in less developed nations, are putting pressure on U.S. success in attracting the world's best and brightest. The data on these points are not yet conclusive, however. Increasing educational attainment could also potentially offset a lower propensity to migrate among less developed world populations.

The trends that make such issues critical—decreases in native population growth only partially offset by high levels of immigration—will create a

rapidly diversifying U.S. population and labor force. The White non-Hispanic share of the labor force will drop by 11 percentage points between 2005 and 2020. The Hispanic share will climb to 17 percent. By 2050, White non-Hispanics will comprise just 50 percent of the labor force, non-Hispanics of other races 25 percent, and Hispanics 25 percent. Hispanics will drive more than two-thirds of overall labor force growth between 2020 and 2050.

As the composition of the workforce changes, ensuring that it remains capable of responding to the need for greater skills, education becomes a major policy priority. There are wide gaps among races and ethnicities in both high school diploma and college degree attainment. Improving attainment and lifelong learning opportunities for groups that lag behind will be the only way for the United States to meet the historical superiority of its workforce relative to skills and education.

In both the public policy and corporate realms, this clearly brings up the role of diversity management and practice. Its scope and the rationale behind diversity policy will necessarily evolve in response to the far tighter labor markets now forecast. Diversity strategies that target only race and ethnicity will be insufficient. Notions of fairness will be coupled with the need to attract as wide a spectrum of the U.S. labor force as possible to survive in the face of a population that is changing in its growth rate and its composition.

Race and ethnicity will obviously remain important components of diversity policy in the years ahead. So will cultural background or preferences and nationality in the era of a global workforce that constantly transfers workers and jobs across national borders. So, very critically, will age be a factor in diversity.

A population that is growing more slowly is almost always one that is aging. The outlook in the developed world is stunning. Again, the United States will not bear the worst brunt of this change. Among the most challenging situations will be Japan's. By 2050, one in two members of its population will be over 50, one in three will be over 65, and one in six will be over 80. In the United States, only about one-third of the 2050 population will be over 50.

The relative growth of various U.S. age cohorts has important implications for work, however. Between 2000 and 2020, the population aged 50-74 will swell by 34 million. The population aged 25-49 will grow by roughly 1 million over that time period. The challenges that will confront policymakers and corporate

HR departments from these trends will be enormous. The population that has traditionally been the bedrock of the workforce will barely change in size. The population that has traditionally had a high propensity to retire will explode. Developing strategies to integrate these older workers into a work environment that is increasingly international in its concern and decreasingly tolerant of obsolete skills may well be the most important diversity challenge that lay ahead. The success or failure of these strategies will be an inescapable determinant of corporate and national prosperity.

WORKPLACE ROMANCE

The workplace has become a common and natural place for romantic relationships to evolve. It is where most employees spend the majority of their waking hours, and those who work closely together often have a lot in common—they are likely to have similar interests, values, educational and socioeconomic backgrounds, and job pressures. In addition, today's high interaction, team-based organizational structures are

particularly conducive to the formation of romantic relationships in the workplace. Thus researchers have become increasingly interested in *workplace romances*, or mutually desired romantic relationships between two members of the same organization. To date, researchers have explored (a) the antecedents of workplace romance, (b) how romances evolve, as well as the different types of romantic relationships in organizational settings, (c) the consequences of workplace romances, and (d) managerial responses to such relationships.

Antecedents to the formation of romantic relationships in the workplace include proximity, the intensity of the working relationship, organizational culture, work group norms, and autonomy. For example, employees who interact with each other more frequently, due to either the closeness of their work areas or longer work hours, are more likely to form romantic relationships. The development of workplace romances is also more likely when working relationships are intense or involve feelings of excitement that come from the pursuit of similar work goals or from completing tasks successfully. Conservative organizational cultures, which endorse traditional values, are less conducive to the formation of workplace romances, whereas organizational cultures characterized by creativity and innovation have more flexible norms regarding appropriate employee behavior and thus are more supportive of workplace romances. The level of independence or autonomy employees have in their work could also influence the development of romantic relationships. For example, those in tightly knit work groups could experience peer pressure as to the appropriateness of such behavior, possibly limiting their involvement in such relationships. However, those who hold jobs that are more autonomous may be more likely to participate in a workplace romance because they have more freedom with regard to making decisions about their work and interacting with others at work.

Research suggests that the three most common types of workplace romances are true love, a fling, and a utilitarian romance, each occurring with approximately equal frequency. True love is when each partner has a sincere love motive, whereas a fling is when each partner has an ego motive (e.g., excitement, ego satisfaction, sexual experience). A utilitarian romance is when a lower-rank employee has a job-related motive (e.g., advancement, security, power, financial rewards) and a higher-rank employee has an ego

motive. It should also be noted that participants' motives for being involved in a workplace romance may change over time, with each partner feeling more or less satisfied with or committed to the relationship than he or she was in earlier phases.

The consequences of a workplace romance can be positive, negative, or neutral (i.e., no impact). For instance, theorists have suggested that positive feelings experienced from a workplace romance can spill over into other aspects of work, increasing the romantic couple's level of job satisfaction. Other examples of positive changes include improvements in productivity, work motivation, and job involvement. However, research suggests that the consequences of a workplace romance are more often negative than positive. Examples of negative consequences include one or both participants having increases in absenteeism and tardiness, being more preoccupied, making more mistakes, missing meetings or other commitments, and having decreases in productivity. If one participant continues to pursue a romantic relationship that the other participant no longer desires, there may be complaints of sexual harassment, stalking, or physical violence.

Additional negative consequences are possible in hierarchical romances (those involving a superior and subordinate) such as ignoring complaints about the subordinate's performance or showing favoritism toward the subordinate in task assignments, pay raises, and promotions. If the romance sours, the subordinate may retaliate by claiming sexual harassment, or the supervisor may discriminate against the subordinate by blocking further rewards. Either situation could lead to litigation against the employer.

Since most couples who work together are unsuccessful at keeping their romance hidden, workplace romances also tend to have consequences for the work environment. Coworkers' reactions may vary from approval or tolerance to outright objection, complaints of favoritism or hostile work environment (especially if the participants involved in the romance exhibit public displays of affection), blackmail (e.g., threatening to tell a participant's spouse about the romance), ostracism of participants, decreases in work group morale and productivity, and turnover (coworkers leave what they feel is an intolerable work environment). At a minimum, workplace romances stimulate gossip among coworkers. Overall, romances that are hierarchical, extramarital, more visible, and job motivated (e.g., exploitation is perceived to have

occurred) are likely to elicit the most negative gossip from coworkers and have the most negative effect on group morale and productivity.

While it is legal in most states for a company to establish and enforce policies that prohibit dating (as long as the employees are forewarned and the policy is applied consistently), survey research suggests that few organizations have written or unwritten policies about workplace romances and that managerial inaction is the most common response. Most companies have realized that it is impossible to prevent people from being attracted to one another and that strict rules merely force employees to go underground with their relationship. Thus a common recommendation in the literature is that workplace romances should be managed or discouraged but not prohibited, and that management should intervene only when exploitation of one romantic partner has occurred or when there has been, or there is potential for, a workplace disruption.

The workplace romance literature has focused on three kinds of management interventions: no action, punitive action (e.g., reprimand, warning, transfer, demotion, termination), and positive action (e.g., open discussion, counseling). Another more recent intervention known as a "love contract" is being used as an alternative to the forced resignation or transfer of one or both employees involved in a supervisor-subordinate romance. These contracts state the voluntary nature of the relationship, affirm the existence of sexual harassment policies and procedures, and may also ask the parties to agree to resolve any differences that might occur using alternative dispute resolution rather than resorting to the courts.

Because of the sensitive nature of workplace romances, conducting rigorous empirical research has not been easy. Even though these relationships have become increasingly common and their potential for causing negative outcomes is great, there is still much that is unknown. Studies investigating the typical duration of workplace romances, the effects of a dissolved workplace romance on all parties, and the relative effectiveness of various managerial interventions would not only add to the academic literature but also help organizations in their efforts to better manage the impact of workplace romances.

WRONGFUL DISMISSAL

The term *wrongful dismissal* (or discharge) describes those instances where an employer illegally chooses to terminate (including a constructive discharge, forced resignation, elimination of the job, permanent layoff, or failure to recall or rehire) the employment of an employee. There are a number of factors to take into account in attempting to determine whether the dismissal of an employee is illegal. Many of the issues relating to wrongful dismissal depend on whether the employee is working under an employment contract or not. In situations where the employee has an employment contract, questions may arise as to what constitutes "good cause," "just cause," or simply "cause," under the terms of the contract. The law provides that an employment contract for a definite term may not be terminated without cause before the expiration of the term, unless the contract provides otherwise. Where a union is involved, collective bargaining agreements generally contain prohibitions on discharge except for just cause. However, courts in nonunion situations have generally ignored the extensive body of arbitration agreements that have addressed this situation in collective bargaining.

Generally speaking, just cause may be of two types: (1) economic reasons unrelated to the employee or (2) employee misconduct or inadequate performance. Just cause may be established for economic reasons if the employment agreement does not have a definite term and the reason for termination is a bona fide reduction in force, plant closing, or reorganization. If the agreement does have a definite term, these situations may not establish just cause, unless the contract defines it as such. The second type, employee-based reasons, may include inadequate performance or misconduct, such as providing fraudulent background

information, sexual harassment, or mistreatment of customers.

If the employee does not have an employment contract, the so-called at-will doctrine applies. Under the modern interpretation of this doctrine, absent an agreement to the contrary, the common law gives employers the legal right to dismiss employees without having a good cause, or any cause at all, except if one of the exceptions to the doctrine applies. These exceptions are (a) the termination was contrary to an important public policy, (b) the employer broke an implied contract of continued employment, or (c) the termination violated an implied covenant of good faith and fair dealing.

The roots of this doctrine can be traced back more than 100 years. In the nineteenth century, jobs were plentiful, labor was scarce, and national prosperity was thought to depend on the elimination of all barriers to the process of free exchange. This background led American courts, toward the latter part of that century, to adopt the at-will doctrine. Horace Wood, an author of legal textbooks, is generally regarded as the authority upon which courts relied for creation of this doctrine in 1877. In his *Treatise on the Law of Master and Servant*, he consolidated the legal presumption in the United States that an indefinite contract was terminable at will and without notice, for any reason or no reason at all. Gradually, the courts refined the doctrine to the modern understanding discussed above.

PUBLIC POLICY EXCEPTION

The major exception to the at-will doctrine is the public policy exception. Courts have typically held that it is illegal, even where employment is for an indefinite term, for an employer to discharge an employee when the employer's intent is to violate an important and clearly mandated public policy. The public policy exception is generally interpreted narrowly. So, for example, as set forth in *Stephenson v. Litton Sys., Inc.*, (646 N.E. 2d 259), an employee who was discharged for reporting to police that it was likely that his or her superior was going to be driving while intoxicated was illegally discharged in violation of the public policy exception, since the policy was sufficiently clear and compelling and the employee had a reasonable basis for their suspicion. The policy involved must be clearly defined and involve an important public purpose and not merely a private or proprietary interest. Courts try to balance the interests

of employers, employees, and public. Not all socially desirable duties are protected. A discharge is not illegal merely because an employee's conduct is praiseworthy or because the public may have derived some benefit from it. The infringement must be a substantial one on an important public policy.

Public policy may be found in state or federal constitutions, statutes, regulations, judicial decisions, and sometimes in ethical codes. The judge usually determines whether the plaintiff-employee has identified an important public policy. Once identified, it is up to the fact finder, usually a jury, to determine whether a discharge violates the particular policy. States vary in terms of permissible sources for public policy. For example, Illinois has a fairly broad interpretation of public policy and may include the state constitution, statutes, and some judicial decisions. By contrast, however, some states, such as California, limit their interpretation of public policy to statutes or constitution (see, for example, *Gantt v. Sentry Ins.*, 1 Cal. 4th 1083, 1992).

Although there are many types of public policy exceptions, most of the cases fall into four major categories: (1) refusal to perform unlawful acts, (2) reporting illegal activities, (3) exercising a right under state law, and (4) performance of a civic duty. Almost all states recognize an exception to the at-will doctrine when an employee is discharged for refusing to commit a criminal act. A seminal case, *Peterman v. International Brotherhood of Teamsters, Local 396*, illustrates this exception. In this case, the employer ordered an at-will employee to give false testimony at a legislative hearing, that is, perjure himself, and then fired the employee for refusing to do so. Notwithstanding the above delineation, the term *public policy* remains ill defined.

The second major category of public policy exception relates to employees who are discharged because they have reported illegal or improper activity (e.g., whistle-blowing). About three-fourths of states have some sort of statute protecting employee whistle-blowers. However, even where no statute exists, a number of states permit employee whistle-blowers to bring retaliatory charges against employers. In these cases, the courts seem to afford much more protection to so-called external whistle-blowers who report illegal employer activities to organizations outside the employer; courts are much more hesitant to protect employees who report employer wrongdoing only within the organization, so-called internal whistle-blowers.

The third type of public policy exception involves exercising a right provided to employees under state law. Generally, the courts interpret this right to relate specifically to the employee's right as an employee (and not as a right as a citizen). A frequent case of this type involves workers' compensation claims. Almost all states recognize protection for employees terminated for filing a proper claim under workers' compensation laws. A number of state statutes permit employees the specific right to file suit for retaliation if the employer terminates them for filing such a claim. Where such a statutory right does not exist, the courts in the remaining states almost always permit the employee to file a claim under the public policy exception. However, few states protect employees who claim that they were fired *in anticipation of* filing a workers' compensation claim.

The final type of public policy exception involves performance of a civic duty. When courts have found in favor of employees for employer violation of this type of public policy exception, it has generally been when the employee is involved in some sort of obligation with respect to a legal proceeding, including such particular examples as jury duty or obeying the terms of a subpoena.

IMPLIED CONTRACT EXCEPTION

A second exception to the at-will doctrine is triggered when an employer breaks an implied contract of continued employment. Sometimes, even in the absence of an express (written or verbal) employment contract, an employee is able to argue that the termination was in violation of a contract that should be "implied" because of the employer's conduct (words or actions that a reasonable person would rely upon). If such conduct exists, the legal issue then becomes whether those expectations can be enforced as an implied-in-fact promise. A number of cases in this area involve employer letters to employees strongly suggesting (i.e., implying) a specific term of employment, which is later violated when the employer terminates the employee. For example, in a classic case, the court held for the employee when the employer wrote a letter to the then prospective employee saying that the corporation would employ and compensate the employee for two years (*Hillman v. Hodag Chem. Corp.*, 96 Ill. App.2d 204, 206, 238 N.E. 2d 145, 147, 1968). Sometimes seemingly minor details can be construed by the courts to infer an implied contract.

As an example, a court held that a letter to a prospective employee indicating that half of his moving expenses were to be paid immediately and the other half one year later indicated an implied contract of at least one year (*Miller v. Community Discount*, 228 N.E. 2d 113, 1967).

GOOD FAITH AND FAIR DEALING

The final major exception to the at-will doctrine involves violation of an implied covenant of good faith and fair dealing during an employee dismissal. In these cases (which, by some accounts, about a fifth of states recognize), courts take the position that the employer should not be allowed to deprive employees of benefits already earned. For example, it has been used to prevent an employer from firing a 25-year at-will salesperson the day after it received a \$5 million order from a customer in that employee's sales territory. The court concluded that the dismissal was an attempt to avoid paying a commission to that employee (*Fortune v. National Cash Register Co.*, 364 N.E. 2d 1251, 1977). However, most states do not permit enforcement of this exception to the at-will doctrine under the theory that its adoption would impose a "just cause" standard for at-will employment, which would be an inconsistency.

STATUTORY PROTECTION

In addition to protection afforded directly by the courts (at-will protection), various legislative branches have provided protection for employees wrongfully dismissed for various reasons. Perhaps the most frequent protection claimed by employees in this regard is that provided by Title VII of the Civil Rights Act of 1964, as amended in 1991. If a worker believes they have been discriminated against (basically, treated differently) because of membership in a "protected group," they can file a charge with the federal Equal Employment Opportunity Commission (EEOC) or, in many cases, with similar state or local agencies. Generally, protected class membership is based on some demographic characteristic such as race, sex, national origin, or, in separate statutes, age and disabilities.

Certain dismissals for employee activities that a reasonable person would consider as involving a privacy interest may also be protected. For example, dismissals based on private items seized by an employer from areas the employee intends to keep private (such as a locked drawer in a locked office) may provide an

employee with a remedy. Moreover, dismissals based on false information that damages an employee's reputation might also lead to grounds for recovery under defamation.

REMEDIES

In terms of compensatory damages (basically, damages to compensate the injured employee for the damages sustained because of the injury), the remedy for wrongful discharge depends on whether the court infers there to be a contract between the employer and discharged employee. If the court determines there was an actual or implied contract, then they would likely award the employee with damages equivalent to those necessary to complete the contract. So, for example, if an employee were terminated after three months and the court determined there to be a one-year contract for \$40,000, the employee would get \$30,000 (plus perhaps some miscellaneous charges). However, if the basis for the court's award to the employee were not based on a contract claim (e.g., public policy), then it would award what is called "tort" remedies. Of states that recognize the implied covenant of good faith and fair dealing, most would permit only contract damages. Frequently, but not always, tort remedies can be greater than contract remedies. A major difference between contract and tort remedies is that contract remedies do not permit recovery for emotional distress and punitive damages (both of which can, at times, be substantial).

In either case, the employee can recover back pay to the extent that will put the employee in the same position her or she would have been in had the employer not engaged in the wrongful dismissal. Back pay would include compensation (wages, salary, commissions, or other payments, plus fringe benefits) the employee lost because of the wrongful dismissal. On the other hand, the employer has the right to have the amount of the back pay reduced (mitigated) by the amount of other compensation received by the terminated employee until the date of the trial. Plaintiff-employees often also seek compensation for future damages for periods beyond the trial date. Often this is based on inference of a "just cause" relationship based upon reasonable expectation of continued employment grounded in assurances in an employee handbook or other enforceable promises.

Occasionally, employees claim damages not directly based on their compensation but based on a

reasonable reliance on promises from the employer, which later hurt them. For example, an employee who sold his house, bought a new house, and took out a loan was awarded damages equal to the losses when the court held that he reasonably relied upon the employer's assurances of continued employment (*Pearson v. Simmonds Precision Products, Inc.*, 160 Vt. 168, 624 A.2d 1134, 1993).

As noted, for those legal grounds based on tort recovery, courts permit recovery for emotional distress and punitive damages. Emotional distress involves not merely employer conduct that hurt the employee's feeling or made them upset; it must involve intentional or reckless conduct by the employer that must also be extreme or outrageous. Punitive conduct, if awarded, can result in large amounts of money to a plaintiff-employee. In part, this is the case, because, at least in theory, it is not related to the harm the employee suffered but to the outrageousness of the conduct by the employer. It is intended to punish the wrongdoer-employer and to discourage such conduct in the future.

ORGANIZATIONAL CONSEQUENCES

Beyond the threat of employee reprisals and claims, wrongful dismissals have significant performance implications for organizations and the employees who remain. Social science researchers have identified the effects of employee distrust and organizational reputation on employee performance, recruitment, and well-being. Workers often react strongly to wrongful acts by employers, and these reactions may have long-term financial consequences for companies that engage in wrongful dismissal.

Any unjust act by an employer, and particularly one that strikes at the heart of the employee/employer relationship such as a dismissal, may be a violation of the psychological contract between the organization and worker. A psychological contract can be defined as an expectation of an organization to attend to the employee's psychological needs in return for meeting the organization's requirements. Employees invest time, effort, skills, and trust in an organization and expect compensation in addition to pay in the form of respect and fair treatment.

Psychological contract violations are related to decreased trust in an employer. Trust is forward looking and involves a willingness to be vulnerable, and once that trust is lost, employees no longer feel bound

to live up to their end of the psychological contract. Fundamental violations of trust by organizations have been shown to lead to negative expectations of future employer conduct and to employee cynicism. Moreover, researchers have found a consistent relationship between employee perceptions of unfair treatment (also known as injustice) and reprisals and claims by employees. This line of research has focused primarily on employee perceptions of three types of organizational justice: distributive justice, the fairness of outcomes; procedural justice, the fairness of procedures that lead to outcomes; and interactional justice, the fairness of interpersonal treatment.

Closely aligned with distrust and perceived injustice, cynicism has been defined as an attitude associated with disillusionment and negative feelings toward an organization. Psychological contract violation has been viewed as a primary determinant of employee cynicism. Cynicism develops through the failure of organizations to meet employee expectations and the subsequent disillusionment that results. Cynicism carries a host of attitudinal and behavioral consequences, including poor effort and performance, a lack of willingness to engage in organizational citizenship behaviors, resistance to change, emotional withdrawal, absenteeism, job hunting and turnover, worry, stress-related health problems, and possible future protests, retaliations, and claims against the employer. As well, research has shown that worrying about future job insecurity leads to negative work attitudes and lack of trust in organizations.

As wrongfully dismissed employees, and the surviving employees who witnessed such dismissals, communicate with or move on to other firms, an organization's reputation can be quickly tarnished with customers, suppliers, and potential applicants. Researchers have suggested that organizations that behave unethically may find themselves headed down a dangerous fiscal path, as damaged reputations are difficult to repair. Successful supply chain performance, for example, is based on trust between supply partners. An organization with a reputation of dealing with its own employees in an unfair or unlawful manner may find it difficult to persuade potential partners to enter into interdependent agreements.

A further casualty of damaged reputation is recruitment. Attracting highly skilled, qualified employees is an important component in an organization's competitive advantage. Many companies use their reputation for employee treatment and social responsibility to attract quality applicants. Researchers have demonstrated that there is a positive and significant relationship between corporate reputation and job seekers' intention to apply for positions and accept job offers in an organization. As well, firms with poor reputations for fairness may entice the wrong kind of employees: those who aren't concerned with organizational trust because they expect to have no allegiance to the organization and consider it simply a short-term source of income and experience.
