Sabbaticals	Tokenism	
School-to-work transition	Tolerance for ambiguity	

Reader's Guide

This guide is provided to help readers locate entries on related topics. It classifies entries into 10 themes: (1) theoretical perspectives on careers; (2) the social context of careers, including the contemporary workplace; cultural and international perspectives; ethnicity, gender, and diversity; organizational environment; social class and background; and work-life interface; (3) the evolution and development of careers; (4) decision making and career development; (5) variations in career patterns and career success; (6) career development initiatives; (7) legislative and regulatory mandates; (8) assessment areas and techniques; (9) job search and organizational recruiting; and (10) professional associations. Some entries appear in more than one category.

THEORETICAL PERSPECTIVES ON CAREERS

Career
Career construction theory
Circumscription and compromise
Cognitive information processing in career counseling
Erikson's theory of development
History of career studies
Holland's theory of vocational choice
Metaphors for careers
Minnesota Theory of Work Adjustment
Occupational choice
Person-environment fit (P-E fit)
Positive organizational scholarship
Reinforcement theory
Social cognitive career theory
Social constructionism
Social learning theory of career development
Super's career development theory
Vocational psychology

THE SOCIAL CONTEXT OF CAREERS

The Contemporary Workplace

Antisocial work behaviors
Boundaryless career
Churning of jobs

About the Editors

Jeffrey H. Greenhaus is Professor and William A. Mackie Chair in the Department of Management at Drexel University's LeBow College of Business. A Fellow of the American Psychological Society and the Society for Industrial and Organizational Psychology (SIOP), he received his PhD in Industrial/Organizational Psychology from New York University. Jeff's research, which focuses on career dynamics and work-family linkages, has appeared in journals such as the *Academy of Management Journal*, *Academy of Management Review*, *Journal of Applied Psychology*, *Journal of Management*, *Journal of Occupational Health Psychology*, *Journal of Organizational Behavior*, *Journal of Vocational Behavior*, and *Organizational Behavior and Human Decision Processes*. Former Associate Editor of the *Journal of Vocational Behavior*, Jeff is coeditor (with Saroj Parasuraman) of *Integrating Work and Family: Challenges and Choices for a Changing World* (1997); coauthor (with Stewart D. Friedman) of *Work and Family—Allies or Enemies? What Happens When Business Professionals Confront Life Choices* (2000); and coauthor (with Gerard A. Callanan and Veronica M. Godshalk) of *Career Management*, now in its third edition (2000).

Gerard A. Callanan is Associate Professor in the Management Department at West Chester University. He received a PhD in Organizational Behavior from Drexel University. Prior to his appointment at West Chester University in 2001, he was a Vice President with the Federal Reserve Bank of Philadelphia. During his 22 years at the Federal Reserve, Gerry held a number of senior posts, including responsibility for areas such as strategic planning, credit and risk management, and national currency management. A member of the Academy of Management, the American Psychological Association, and the Society for the Advancement of Management, he has done research that has appeared (or will appear) in scholarly publications such as the *Journal of Vocational Behavior*, *Career Development International*, *Journal of Psychology*, *Journal of Education for Business*, *Journal of Developmental Entrepreneurship*, *Education + Training*, and *Team Performance Management Journal*. In 2000, Gerry coauthored (with Jeffrey H. Greenhaus and Veronica M. Godshalk) the textbook *Career Management*, now in its third edition.

About the Editorial Board

Nancy E. Betz is Professor of Psychology at The Ohio State University and is also a Huber Fellow in the College of Social and Behavioral Sciences. She has been a Visiting Scholar at Stanford University and the University of California, Santa Barbara. She has authored or coauthored over 130 articles on the topics of career development, measurement, and applications of Bandura's self-efficacy theory to career decision making. She is the author of *Tests and Assessment*, with Bruce Walsh, now in its fourth edition, and of *The Career Psychology of Women*, with Louise Fitzgerald. Nancy served for six years as the Editor of the *Journal of Vocational Behavior* and has served on the Department of Defense Advisory Committee on Military Testing. She is a Fellow of the American Psychological Association and American Psychological Society. Nancy is a recipient of the John Holland Award for Research in Career and Personality and the Leona Tyler Award for Scholarly Contribution to the field of Counseling Psychology.

Douglas T. (Tim) Hall is the Morton H. and Charlotte Friedman Professor of Management in the School of Management at Boston University. He is also the Director of the Executive Development Roundtable and Faculty Director of the MBA Program. He has previously held faculty positions at Yale, York, Michigan State, and Northwestern universities, and visiting positions at Columbia and the U.S. Military Academy at West Point. Tim is the author of *Careers In and Out of Organizations* and numerous other books and articles on careers and management. He is a Fellow of the American Psychological Association, the Society for Industrial and Organizational Psychology, and the Academy of Management, where he served as a member of the Board of Governors and as Chair of the Organizational Behavior Division and

cofounder and Chair of the Careers Division. Tim is a recipient of the American Psychological Association's Ghiselli Award for research design, the American Society for Training and Development's Walter Storey Professional Practice Award, and the Academy of Management's Everett C. Hughes Award for Careers Research.

Kerr Inkson is Professor of Management at the University of Otago, New Zealand. He has a background in organizational psychology, organizational behavior, and management studies and has held positions at 10 universities in the United Kingdom, United States, and New Zealand. He has published over 60 refereed journal articles, 30 book chapters, and 10 books. In recent years, his research has focused on careers, including boundaryless careers and international careers, and his books include two Sage publications related to careers: *The New Careers* (1999), coauthored by Michael B. Arthur and Judith K. Pringle, and *Understanding Careers: The Metaphors of Working Lives* (2006). Other recent books are *Management: Perspectives for New Zealand* (2002), coauthored by Darl Kolb; and *Cultural Intelligence* (2004), coauthored by David C. Thomas. Kerr is a contributor to key professional and academic forums and was Chair of the Careers Division of the Academy of Management for 2005-2006.

Phyllis Moen holds the McKnight Presidential Chair in Sociology at the University of Minnesota. She also directs the Flexible Work and Well-Being Center, part of a larger NIH-funded research network initiative. Prior to coming to Minnesota in 2003, Dr. Moen spent many years as a faculty member in both sociology and human development at Cornell University, where she founded the Bronfenbrenner Life Course Center (an interdisciplinary cross-college initiative) and the Cornell Careers

Institute (supported by the Alfred P. Sloan Foundation). She studies and has published numerous books and articles on occupational careers, retirement, health, gender, policy, and families, as they intersect and play out over the life course. Her two most recent books are *It's About Time: Couples and Careers* (2003) and *The Career Mystique: Cracks in the American Dream* (2005, with Pat Roehling). Dr. Moen has been elected a Fellow of the American Association for the Advancement of Science, the Gerontological Society, and the National Council for Family Relations. She also is a member of the Conference Board's Work-Life Leadership Council, the Center on Aging & Work/Workplace Flexibility's Research Advisory Committee at Boston College, the National Academies of Science's Steering Committee for a Workshop on Decision Making Needs of Older People, and the National Institutes of Health study section on Social Psychology, Personality, and Interpersonal Processes.

Mark Savickas is Professor and Chair in the Behavioral Sciences Department at the Northeastern Ohio Universities College of Medicine and Adjunct Professor of Counselor Education at Kent State University. His 80 articles, 25 book chapters, and 500 presentations to professional groups have dealt with vocational behavior and career counseling. He has served as Editor of the *Career Development Quarterly* (1991-1998) and is currently Editor of the *Journal of Vocational Behavior* (1999-present). He also serves on editorial boards for the *Australian Journal of Career Development*, *British Journal of Guidance and Counselling*, *L'Orientation Scolaire et Professionnelle* (France), and *Educational Research Journal* (Hong Kong). In 1994, he received the John L. Holland Award

for Outstanding Achievement in Career and Personality Research from the Counseling Psychology Division (17) of the American Psychological Association. In 1996, he received the Eminent Career Award from the National Career Development Association.

Rosalie L. Tung is the Ming and Stella Wong Professor of International Business at Simon Fraser University. She was formerly a Wisconsin Distinguished Professor, Business Administration, with the University of Wisconsin system. She has been elected as a Fellow of the following associations: the Royal Society of Canada, the Academy of Management, the Academy of International Business, the British Academy of Management, and the International Academy for Intercultural Research. Besides serving on the Board of Governors of the Academy of Management in the 1980s, she was elected to a five-year term as a member of the Executive Committee of the Academy of Management, including the position of President of that association in 2003-2004. She has also served on the Executive Board of the Academy of International Business. Rosalie has published widely on the subjects of international management in publications such as the *Journal of World Business*, *Organizational Dynamics*, *Journal of International Business Studies*, *Academy of Management Executive*, and *Academy of Management Journal*. She is the author or editor of 11 books, including the *IEBM Handbook of International Business* and *Learning from World Class Companies*. She serves as Editor of International Human Resource Management for the *Journal of World Business* and is a Consulting Editor for the *Journal of International Business Studies*.

Acknowledgments

The publication of the *Encyclopedia of Career Development* represents the culmination of more than two years of work. Along the way, we were fortunate to be helped and guided by many people. To these individuals, we wish to express our deepest gratitude.

Our Editorial Advisory Board comprises six internationally renowned experts in career development, and we thank them for their willingness to share their expertise with us at every stage of the project and for their unswerving commitment to the highest level of excellence: Dr. Nancy Betz, Professor of Psychology at The Ohio State University; Dr. Douglas T. (Tim) Hall, Morton H. and Charlotte Friedman Professor of Management in the School of Management at Boston University; Dr. Kerr Inkson, Professor of Management at the University of Otago, New Zealand; Dr. Phyllis Moen, McKnight Presidential Chair in Sociology at the University of Minnesota; Dr. Mark Savickas, Professor and Chair in the Behavioral Sciences Department at the Northeastern Ohio Universities College of Medicine; and Dr. Rosalie L. Tung, Ming and Stella Wong Professor of International Business at Simon Fraser University.

We also thank a number of colleagues at our respective institutions for their assistance, emotional support, and expert advice. At Drexel University, we thank Dr. George Tsetsekos, Dean of the LeBow College of Business; Dr. Dona DeCarolis, Head of the Department of Management; and Emily Missner Devaney, Information Services Librarian for the LeBow School of Business. At West Chester University, we thank Dr. Christopher Fiorentino, Dean of the College of Business and Public Affairs; Dr. Cynthia Benzing, Professor in the Economics and Finance Department; Dr. Charles McGee, Chair of the

Management Department; and Dr. Stephen Marvin, Associate Professor and Reference Librarian.

We also offer our thanks to Dr. Stephen A. Stumpf, Professor of Management and Fred J. Springer Chair in Business Leadership at Villanova University. Steve's widespread knowledge of career development and his extensive network of relationships were instrumental in the selection of topics and authors.

Many highly dedicated and talented professionals at Sage Publications deserve our special thanks and gratitude. Rolf Janke, Vice President and Publisher, and Al Bruckner, Acquisitions Editor, were extraordinarily supportive from the beginning of the project, providing enthusiasm, advice, and friendship. Yvette Pollastrini and Paul Reis, Development Editors, and Leticia Gutierrez, Systems Coordinator, were very helpful in facilitating the submission and review of the entries. Thanks also to Beth Bernstein, Production Editor, and Barbara Coster and Carla Freeman, Copy Editors, who took well-written entries and made them even better.

We also express our deep appreciation to the more than 300 authors who contributed entries to the *Encyclopedia of Career Development*. They are the heart and soul of the encyclopedia, and we are forever grateful for their willingness to share their extensive knowledge with legions of fortunate readers.

Finally, we thank our families for their love and patience. Were it not for our families' continuing support and encouragement, this encyclopedia would have remained a pipe dream. We therefore dedicate the *Encyclopedia of Career Development* to Adele, Marge, Joanne, Tim, Riley, Michele, Jeff, Hallie, and Carly (JHG), as well as to Laura, Michael, Tim, Ryan, and the fat kid (GAC). Thank you for everything!

Introduction

Sweeping changes in the nature of work, shifts in the meaning of career success, the rise of global business and international careers, heightened concerns over social influences on careers, and emerging labor laws and regulations influence the ways in which individuals, organizations, and the broader society view career development. It is therefore an opportune time to present the *Encyclopedia of Career Development*, which provides a thorough treatment of these recent and emerging trends.

Our goal was to make the *Encyclopedia of Career Development* the premier reference tool for students, scholars, practitioners, and others interested in gaining knowledge or conducting research on career development-related topics. We have kept the entries concise, easy to read, and jargon free, while ensuring that the content reflects the most current thinking and research on the particular topic. We have provided entries that are directly related to the field of career development and have expressly avoided tangential topics or biographical profiles that add pages but do not improve the content. Most important, we sought authors who are recognized experts on their topics and who have demonstrated a history of contributing high-quality writing to the field of career development.

It is our firm belief that the *Encyclopedia of Career Development* represents an indispensable reference resource for college and university libraries and public libraries located throughout the United States and around the world. In addition, the encyclopedia can be an invaluable reference tool for corporations and consultants for use in their libraries and career centers.

In collaboration with our expert and prestigious Editorial Board, we identified the significant terms, concepts, and practices that represent the field of

career development. This intensive process resulted in an encyclopedia that spans two volumes; contains over 400 entries, arranged in A-to-Z format; and totals over 600,000 words. The entries were written by renowned researchers, scholars, and practitioners, who provided the most current definitions, information, theories, and applications relevant to their topics. The provision of relevant, up-to-date material on each entry is especially important from a reference standpoint because career development is a dynamic field of study.

THEMES AND PERSPECTIVES

When a person hears the term *career development*, several different perspectives may come to mind. For example, some people might be inclined to view career development strictly in personal terms, being more concerned with their own achievement and success. Others might view career development in terms of organizational programs or practices that assist employees in managing their careers. Still others could see career development from a work-life integration perspective or from a legal or societal viewpoint. Of course, there are many other vantage points from which career development can be seen.

Because of this wide variation in lenses through which career development can be viewed, the *Encyclopedia of Career Development* has a multidisciplinary focus that represents psychological, sociological, educational, counseling, organizational behavior, and human resource management perspectives on career development issues. As shown in the Reader's Guide, the entries in the encyclopedia collectively capture 10 significant career-development

themes or perspectives, each of which is briefly described below:

1. The *theoretical perspectives on careers* theme represents a variety of major theories and conceptual frameworks relevant to career development. Providing an excellent foundation for understanding career development, entries that reflect this theme include Career Construction Theory, Holland's Theory of Vocational Choice, Metaphors for Careers, Social Cognitive Career Theory, and Super's Career Development Theory.
2. The *social context of careers* theme recognizes that career development takes place in the larger society. Many entries reflect the social context by considering the characteristics of the contemporary workplace (for example, the Customized Careers entry); culture and international perspectives (e.g., Culture and Careers); ethnicity, gender, and diversity (e.g., Multi-cultural Organization); the organizational environment (e.g., Toxic Leadership); social class and background (e.g., Family Background and Careers); and the work-life interface (e.g., Two-career Relationships).
3. The *evolution of careers* theme recognizes that careers unfold over time. In this sense, career development can be viewed as a series of stages, patterns, and transitions. Entries that reflect this theme include Career Interruptions, Career Plateau, Job Loss, Midlife Crisis, and the Obsolescence of Knowledge and Skills.
4. The *decision-making* theme emphasizes the decisions and choices that individuals make throughout their lifetimes. These decisions are often evaluated in terms of whether they produce a fit or consistency between the individual and the environment within which that person works. The encyclopedia includes entries that highlight decision-making tasks and issues from a variety of vantage points, such as Career Decision-making Styles, Career Indecision, Career Strategy, and Individual Career Management.
5. *Variations in career patterns and career success* are the norm rather than the exception in contemporary society. Individuals are more likely than ever to follow their own values rather than those prescribed by society, as the entries on the Boundaryless Career and the Protean Career richly illustrate. Other entries that reflect individual variations in the meaning and pursuit of a career include Career as a Calling, Career Success, Entrepreneurship, and Lockstep Career Progression.
6. *Career development initiatives* are programs and practices that employers, counselors, universities, and society provide to promote successful career decision making and the effective development of students' and employees' careers. Entries representative of this theme include Academic Advising, Career Centers, Computer-based Career Support Systems, Mentoring, Three-Hundred-Sixty-Degree (360°) Evaluation, and Wellness and Fitness Programs.
7. *Legislative and regulatory mandates* are various legislative, regulatory, judicial, and labor relations decrees and mandates that influence career development and decision making from both an individual and an organizational perspective. A number of entries reflect this theme, including Domestic-partner Benefits, Family and Medical Leave Act (FMLA), Hostile Working Environment, and Wrongful Dismissal.
8. *Assessment areas and techniques* include the personal characteristics that influence career development as well as the instruments that assess these characteristics. Representative entries that reflect this theme include Abilities, Allport-Vernon-Lindzey Study of Values, Career Anchors, Career Development Inventory, Emotional Intelligence, Multiple Intelligences, and Personality and Careers.
9. *Job search and organizational recruiting* represent, respectively, the processes by which individuals select organizations and organizations select individuals. The job-search process is the focus of entries such as Informational Interview, Internet Career Assessment, Job Search, *Occupational Outlook Handbook*, and Networking. Handwriting Analysis in Hiring,

Organizational Staffing, Personnel Selection, and Recruitment are among the entries that center on organizational recruiting.

10. Information on *professional associations* can be useful to readers who want to explore educational or other developmental opportunities in different fields. Entries describing associations are the American Counseling Association, American Psychological Association, Center for Creative Leadership, and National Career Development Association.

IMPORTANT FEATURES

A number of features embodied within the *Encyclopedia of Career Development* make it a user-friendly reference tool. First, at the end of each entry, the “Further Readings and References” section

provides the reader with additional sources of information on the particular topic. These added references primarily represent either seminal works on the topic or the most current research.

Another important feature at the end of each entry are “See also” listings, which provide cross-references to other associated entries. This information is especially useful for students doing research because it provides linkages with other topics that they might wish to consult to broaden their research.

In addition to the A-to-Z listing of the entries, we have also included a Reader’s Guide, which presents the entries according to major themes or categories. The guide is a valuable tool that allows students and researchers to gain a broader understanding of a particular area of study based on how the entry is grouped with other entries representing a specific theme.

—Jeffrey H. Greenhaus and Gerard A. Callanan

A

ABILITIES

Abilities represent an individual's capacity to perform a wide range of tasks. They are believed to be somewhat stable traits or attributes but can be developed or refined over time. There are numerous types of abilities, which can be classified into four categories. Reasoning, judging, reading, writing, mathematical reasoning, and related capabilities reflect mental capacity or *cognitive ability*. Abilities related to muscular activities and bodily movement are labeled *psychomotor abilities*. Examples of psychomotor abilities are reaction time, reaction speed, precision, coordination, and dexterity. *Sensory* or *perceptual abilities*, such as visual and auditory abilities, relate to detecting and recognizing stimuli. *Physical abilities* refer to muscular strength, cardiovascular endurance, and movement quality. The abilities that are most useful in explaining career-related outcomes are cognitive abilities, which are thus the focus of this entry.

Interest in the human intellect and cognitive ability has existed since these concepts were first introduced by Alfred Binet and Charles Spearman around 1904. Some of the first applications of this knowledge took place in the U.S. Army, through tests that assessed cognitive ability. The Army Alpha and Army Beta tests of general cognitive ability were used during World War I to select army recruits. Cognitive ability tests evolved over the years to assess different dimensions of cognitive ability, such as verbal, spatial, and quantitative ability. These tests were used during World War II to select and classify aircrew. Subsequent years saw the application of cognitive ability

tests to civilian employment settings and guidance counseling in school settings.

One hundred years of interest in cognitive abilities have seen numerous issues arise related to the definition and measurement of cognitive ability. One issue that has received widespread attention is the way the different cognitive abilities are structured. There are competing viewpoints as to whether cognitive abilities are best represented by flat or hierarchical models. There is a general consensus that abilities have a hierarchical structure, although there is still some disagreement on the number of levels in the hierarchy. However, in all hierarchical models, general intelligence or general mental ability is the highest-order factor, often labeled the *general factor*. Different tests designed to assess cognitive ability share some common variance. The general factor forms the largest component of most tests of cognitive ability and explains the greatest common variance among these tests. Hence, most tests of cognitive ability assess general mental ability or the general factor. Second-order factors in the hierarchical structure of cognitive abilities have been labeled *quantitative* or *numerical abilities*, *spatial* or *mechanical abilities*, and *verbal* or *linguistic abilities*. A number of standardized tests used in educational settings assess these second-order ability factors. Third-order factors are defined by more specialized abilities. Examples of specialized abilities that reflect the verbal factor are oral and written comprehension and expression, deductive and inductive reasoning, and information gathering. Specialized abilities in the quantitative factor are mathematical reasoning and number facility. Specialized abilities of the spatial factor include spatial organization or visualization.

Given the hierarchical structure of cognitive ability, there has been an interest in understanding whether the more specialized abilities are more useful than general cognitive ability or the general factor in explaining important individual outcomes. Tests of specialized abilities have been used to determine whether these abilities are more effective than the general factor in predicting success in a given job. Although specialized abilities explain unique variation in an individual's performance in a job, the amount of unique variance explained by specialized abilities is minimal and rarely exceeds 3 percent over and above general mental ability. Thus, most tests of cognitive ability used for personnel selection are designed to assess general mental ability rather than specialized abilities.

Cognitive ability is an important and meaningful construct insofar as it satisfies criteria for scientific significance. One criterion is that the items in a test of cognitive ability demonstrate acceptable levels of internal consistency reliability. The second criterion is that cognitive ability be useful in explaining important individual outcomes. Numerous tests of cognitive ability demonstrate acceptable levels of internal consistency reliability, suggesting that the questions on these tests measure the same construct. Research overwhelmingly indicates that cognitive ability explains significant variation in numerous outcomes of life, including work. A full understanding of how cognitive ability influences life, work, and career outcomes first necessitates a discussion of its influence in skill acquisition and school settings.

Individuals' cognitive abilities impact their capacity to learn. Skill acquisition is an important first step in learning how to perform novel tasks. Skill acquisition involves three phases: cognitive, associative, and autonomous. Cognitive ability is most influential during the first phase (cognitive), which occurs when individuals are first confronted with the novel task. Other abilities are relevant during different phases of skill acquisition. The first phase places the greatest demands on the individual's cognitive resources. Performance on the task increases with practice and at a faster rate for individuals high in cognitive ability. However, the important role that cognitive ability plays in the process of skill acquisition depends on the type of task that an individual is trying to learn. Tasks can be either consistent or inconsistent. Consistent tasks can be learned and become automatic or routine with practice (e.g., fast and effortless). The correlation

between cognitive ability and performance decreases after practice on consistent tasks. In contrast, inconsistent tasks retain their novelty over time and do not become routine. The relationship between cognitive ability and performance remains positive and strong even after practice on inconsistent tasks. Thus, the degree of association between cognitive ability and performance depends on the consistency of the task and the phase of skill acquisition.

The school setting is one of the first settings in which individuals acquire basic skills and develop these skills to levels that permit them to function effectively in society. The early years of formal education are the most formative years, in which the basic skills of reading, writing, and arithmetic are acquired and developed. Subsequent education in high school, college, and graduate studies provides for the development of more specialized skills and the acquisition of specialized knowledge. General mental ability influences an individual's achievement in each of these stages of academic development. More specifically, general mental ability has been shown to explain approximately 36 percent to 49 percent of the variation in course grades in elementary school, 25 percent to 36 percent in high school, and 16 percent to 25 percent in college. Furthermore, general mental ability has been shown to explain significant variation in numerous indicators of success in graduate studies. For example, an individual's score on tests of general mental ability predicts attainment of the graduate degree, the time required to complete the degree, research productivity, scores on comprehensive examinations, and general performance ratings by faculty members.

Success in the academic arena equips individuals with the required knowledge and skills to function in society at large. General mental ability continues to explain variation in life outcomes even after school. The world of work is another setting in which general mental ability has proven its utility. Numerous years of research have demonstrated that general mental ability predicts job performance in both civilian and military settings. A full understanding of the extent to which cognitive ability relates to job performance requires knowledge of the different components or categories of job performance on which employees are measured. One category represents the core functions or duties of a job and has been labeled *task performance*. A second category, labeled *organizational citizenship, contextual, or extra-role performance*,

represents nontask behaviors that contribute in a positive way to the organization. A third category, labeled *counterproductive work behavior*, represents negative behaviors that detract from the goals of the organization. Cognitive ability is a stronger predictor of task performance than of organizational citizenship behavior or of counterproductive work performance. However, it is a significant predictor of all three categories of job performance. Furthermore, cognitive ability is a stronger predictor of objective measures of performance (e.g., dollar sales) than subjective measures (e.g., supervisory ratings) but is a significant predictor of both.

The predictive power or utility of cognitive ability also depends on the complexity of the job. Jobs at the highest level of complexity include professional, scientific, and upper-management jobs, which account for approximately 14 percent of the jobs in the economy of the United States. Cognitive ability explains the greatest percentage of variation in performance in these jobs, approximately 34 percent. Cognitive ability explains the smallest percentage of variation in job performance, approximately 5 percent, in jobs at the lowest level of complexity, which account for approximately 2.5 percent of the jobs in the U.S. economy. Thus, the utility of cognitive ability is directly related to the information-processing requirements of the job. Cognitive ability is more useful in predicting job performance for cognitively complex jobs.

An important consideration for any construct that is used to make decisions about selection into educational programs or occupational settings is that the construct, in this case cognitive ability, is fair or is not inadvertently biased against members of different racial, ethnic, or gender groups. Concerns about racial bias have haunted cognitive ability tests for years. These concerns focus on the language and structure of cognitive ability tests. One popular model for assessing predictive bias in employment tests is called the *regression model*. An application of this model requires data on cognitive ability test scores for minority and majority group members and ratings of job performance for these members. Regressions predicting job performance from ability test scores are computed separately for majority and minority group members. These regression lines are then tested for significant differences in their slopes, intercepts, and error variances. Predictive bias is said to occur if the slope is significantly smaller for minority group members relative to majority group members. Research

in which this technique has been used reports that ability tests do not underpredict the performance of minority group members even when the rater and ratee are matched on race.

An important component of an individual's career development is job training. As individuals acquire credentials and advanced degrees, they gain access to high-status occupational training programs. Individuals acquire job knowledge from training programs and experience on the job. Questions about the usefulness of cognitive ability have also focused on whether an individual's cognitive ability predicts his or her performance in job-training programs. Research indicates that cognitive ability explains anywhere from 25 percent to 58 percent of the variation in overall performance in job-training programs. Although the bulk of the research has been conducted in military settings, substantial evidence also exists for this relationship in nonmilitary settings. Furthermore, cognitive ability predicts training performance for jobs at all levels of complexity.

Theories of career development focus on the process of matching the person to a job. These theories rely on the assumption that each individual possesses a unique combination of interests, aptitudes, and personal characteristics that are ideally suited to a specific set of jobs. Cognitive ability plays an important role in the process of matching individuals to jobs. The second-order cognitive factors of mathematical reasoning, verbal aptitude, and spatial aptitude have been shown to influence the undergraduate and graduate degrees that students pursue. More specifically, individuals high in verbal aptitude tend to pursue careers in law and humanities, whereas individuals high in quantitative aptitude pursue careers in medicine and biological and social sciences, and individuals high in both quantitative and spatial aptitude pursue careers in engineering and the hard sciences. Beyond the discipline that individuals choose to pursue, cognitive ability also impacts the broader job strategies they choose. Jobs that are bureaucratic in nature emphasize low risk, job security, employment stability, job training, and pensions. Jobs that are entrepreneurial emphasize self-sufficiency, control and discretion at work, ambition, and the trade-off of risk for income maximization. Individuals high in cognitive ability express a preference for entrepreneurial job properties.

Skill acquisition early in life, achievement in the school setting, effective job performance, and success

in occupational training programs are important steps in the development of successful careers. Evidence indicates that cognitive ability continues to play a role in important work-related outcomes after success in these early stages. Cognitive ability impacts an individual's career satisfaction and job satisfaction. *Career satisfaction* refers to career progress, career advancement, and future career prospects. *Job satisfaction* refers to satisfaction with pay, coworkers, benefits, the work itself, and the supervisor. A negative and significant relationship between cognitive ability and career satisfaction (job satisfaction) is reported for individuals employed in hourly nonmanagerial jobs, whereas a positive and significant relationship is reported between cognitive ability and career satisfaction for individuals employed in salaried managerial jobs. A level of cognitive ability that is above the level required to learn and perform the job does not result in greater success on the job. Rather, it leads to lower levels of job and career satisfaction. Research also indicates that cognitive ability is related to extrinsic career success as measured by income and occupational status. Individuals high in cognitive ability earn higher incomes and obtain higher-status jobs. Furthermore, cognitive ability is related to vocational maturity. *Vocational maturity* is defined as having an adequate understanding of oneself and the world of work and adequate decision-making skills. Individuals high in cognitive ability score significantly higher on measures of vocational maturity than do individuals low in cognitive ability.

The impact of cognitive ability on individual outcomes is pervasive even in life outside of work. An individual's capacity to self-manage and to function effectively in society on a daily basis is largely influenced by their cognitive abilities. Numerous tasks that individuals must perform in daily life have high information-processing requirements. As with work, the more complex the task, the more important is cognitive ability in determining success. Our ability to comprehend our surroundings, read, and write influences our effectiveness in adapting and adjusting to life. The extent to which we can handle money, participate socially, and understand bank documents, medical information, and political issues is influenced by our cognitive abilities. The importance of cognitive ability at each stage in life and career development cumulates to produce greater odds of success for individuals high in cognitive ability and limited opportunities and less success for individuals low in cognitive ability.

However, it is also important to consider the mediating influence that individual-difference characteristics other than cognitive ability have on work and life outcomes. Characteristics such as personality, family background, and socioeconomic status are also known to influence success in educational and work settings and in daily life. It is important to consider how these variables interact with cognitive ability to impact individuals' work and life outcomes.

ACADEMIC ADVISING

Academic advising has been important to the success of undergraduates in colleges and universities since the beginning of American higher education. Developmental advising, which addresses the social and cultural acclimation of a student as well as academic success, is the most effective type of advising. Developmental advising makes it possible for advisor and student to develop and maintain a relationship based on mutual respect and inquiry, which allows students to explore and develop academic and career direction.

Academic advising has its origins in the close teaching and learning relationship between students and professors. The Greek Sophists developed close relationships with their students, shaping their development politically, culturally, and intellectually. This model for teaching and learning was imitated as colleges developed in colonial America. After the American Revolution, a university education broadened its scope beyond religious and classical studies to include more practical knowledge that benefited the personal and work-related goals of students.

As the American system of higher education evolved, there was great concern that faculty were losing their close relationships with students. As related by Susan Frost, as early as 1832, a Harvard student claimed that educators did not show enough regard and interest for students. Nearly 200 years later, this concern remains and influences how colleges and universities provide academic advising.

Most institutions rely on faculty in academic departments to provide academic advising; however, as student populations have grown and there has been

an increased emphasis in providing holistic support for students, many institutions have supplemented faculty advisors with "professional" advisors. Professional advisors have varied backgrounds, many being faculty members who continue to teach. Other professional advisors have expertise in counseling and related student service areas. Regardless of the configuration of faculty and professional advisors established by an institution, the most effective type of academic advising is developmental.

Developmental advising is a practice derived from theoretical positions about student growth and responsibility and the role of the advisor in facilitating this growth and responsibility. Developmental advising contrasts with *prescriptive advising*, in which the assumed role of the advisor is little more than to inform students about requirements, school policies, and course selection. In prescriptive advising, advisors do not emphasize issues of responsibility in the advising relationship. In developmental advising, advisors take into account the current level of maturity and experience of the student in deciding how to approach the issue of responsibility, with responsibility for the student's academic success being negotiated and shared. One goal in this practice is to assist the student in moving toward full responsibility. The developmental advisor is a teacher, mentor, informed authority, and competent referral agent in the advising relationship.

With developmental advising, the advisor is concerned with the intellectual and social growth of the student and is also involved in discussion about curriculum and its relationship to the individual student's strengths and career interests. The advisor interprets information, helps the student move toward integration and synthesis of ideas, and has a goal of assisting the student in becoming an independent learner. The advisor challenges the advisee but is also available for support and encouragement. The advisor does not coddle, but serves as a mentor. Developmental advising is consistent with a humane and caring learning environment and promotes the development of independent and responsible students.

Developmental advising is a process that students enter in different ways and at various times in their lives, but the process does have certain commonalities. While advisors need to be knowledgeable about various academic programs, the common human processes are what drive the advising situation, not the content discussed and studied. Burns Crookston and

Terry O'Banion, working independently of each other in 1972, based their concepts of developmental advising on the psychosocial theory developed by Arthur Chickering. Outcomes of developmental advising for the student are extracted from Chickering's theory: developing competence, or increasing the intellectual, physical, and social skills to master a range of tasks; developing autonomy, or confronting a series of issues leading ultimately to the recognition of independence; and developing purpose, or assessing and clarifying interests, educational goals, and career options.

Many students begin the college experience with uncertainty about the academic major they will select. The developmental advising process encourages students to play an active role in understanding the goals of a university education. For many, this is a process of understanding the difference between selecting an academic major and establishing a viable career path. The selection of the academic major is the critical building block for a lifetime of growth and continuous learning. Academic advisors must be able to articulate the competencies and skills developed in the pursuit of any college degree as well as the specific competencies and skills developed in specific academic majors.

For many students, a particular career interest is often the starting point for exploring a number of academic majors. The academic advisor plays a critical role in referring students to career counseling professionals and experts in various fields, so students can actively research and synthesize their ideas about careers. This exploration requires students to be independent learners; however, students are often overwhelmed by the responsibility involved in this process. Academic advisors need to coach and support students as they move through this process. Like the experience in the classroom, advisors and students need to remain actively engaged in the learning process to be successful at reaching academic and career goals.

AFFIRMATIVE ACTION

Affirmative action (AA) is a public policy designed to eliminate systemic bias against members of under-represented groups in employment and education. Although the use of AA is not limited to the United States, it can be argued that it is in the United States that AA has its greatest influence on business, education, and the employment practices of federal contractors. As a result, AA is the subject of considerable debate in the U.S. media. AA requires an organization to take proactive steps toward ensuring that the demographic characteristics of its workforce are consistent with the demographic characteristics of the labor markets in which it recruits. The extent of the controversy surrounding AA in employment and education is a direct function of the deeply felt differences of opinions about the policy's usefulness and fairness. The controversial nature of AA raises doubts about its future in the United States and in other countries as well.

In discussing its origins in the United States, many are unaware that AA did not originate through federal legislation approved by congressional vote. Rather, the roots of AA lie primarily in the executive branch of government. AA has evolved through a series of Executive Orders (EO) originating during Franklin Roosevelt's administration in the early 1940s. EOs are documents issued by the president of the United States to manage the federal government and are listed in the Code of Federal Regulations (CFR). Discrimination-related EOs initially targeted racial discrimination in the armed services and in organizations doing business with the federal government.

Perhaps the EO most influential in shaping today's AA is EO 11246. Issued in 1965 by President Lyndon Johnson, EO 11246 requires that federal contractors with 50 or more employees and contracts with the government of \$50,000 or more have written AA plans and track progress toward their employment goals throughout the year. It is important to note that while many U.S. business organizations develop voluntary AA plans, only organizations that conduct business with the federal government are required to have a formal AA plan and, as such, are regulated by EO 11246 (which has been amended since 1965).

ENFORCEMENT OF EO 11246 BY DEPARTMENT OF LABOR EMPLOYMENT STANDARDS

The administration's Office of Federal Contract Compliance Programs (OFCCP) investigates discrimination claims filed against employers and also conducts random compliance reviews of organizations under its jurisdiction. Another discrimination-related enforcement agency in the United States, the Equal Employment Opportunity Commission (EEOC), is charged with enforcing the various civil rights laws (most notably, Title VII of the Civil Rights Acts of 1964 and the Civil Rights Act of 1991) and is usually not involved in AA enforcement.

An AA plan must be completed annually by a federal contractor and is based on data collected from within and outside the organization. The first component of a plan is an *organizational profile* or *workforce analysis*. In this component, the organization's jobs are listed, and an inventory is created showing the composition (by gender and race) of the incumbents in these jobs. The workforce analysis lists the incumbents in each job according to gender and the five racial categories that are used for reporting purposes in AA: White (not of Hispanic origin), Black (not of Hispanic origin), Hispanic, Asian or Pacific Islander, and American Indian or Alaskan Native.

The second component of a plan is *job group analysis*. In this analysis, jobs are classified into categories in accordance with their level of responsibility, duties, and required skills and knowledge. The categories used may be the same listed on EEO-1 forms (documents for reporting purposes): officials and managers, professionals, technicians, sales workers, office and clerical, crafts workers (skilled), operatives (semiskilled), laborers (unskilled), and service workers. The job group

analysis lists the incumbents in each job according to gender and the five racial categories.

After completing the job group analysis, an availability analysis is then completed that identifies the percentage of women and minority group members in the organization's local labor market in each of the nine job groups, as well as the percentage of women and minorities in the organization who are promotable into each of the job categories. A comparison is then made between the race and gender composition of the organization's current workforce and the availability in the labor market for each job group. If this comparison indicates that significantly more women and/or minority group members are available in the labor market in any of the job groups, relative to the organization's incumbents in these groups, the organization is then required to develop an action plan to reduce this disparity. This plan must include specific steps the organization agrees to take, the goals and timetables that will be used to assess the firm's progress, and, finally, the assignment of responsibility for its implementation.

AA, then, does not require the establishment of hiring or promotion quotas by employers. Rather, it requires a federal contractor, based on current labor market and workforce data, to take proactive steps to ensure progress is made toward reaching a consistency between the demographic composition of its workforce and the composition of the labor markets from which it recruits. In its reviews and investigations, the OFCCP assesses the organization's good-faith efforts toward meeting its employment goals, not in imposing employment quotas.

Arguments against the need for AA in employment and education are often based on the notion that establishing goals and timetables forces employers or university admission officers to give preferential treatment on the basis of race or gender and that this practice is contrary to Title VII of the Civil Rights Act of 1964. Title VII made it illegal for employers to discriminate on the basis of race or sex (along with color, religion, and national origin). Opponents of AA also argue that preferential treatment based on race or gender violates the Equal Protection clause of the Fourteenth Amendment to the Constitution, which guarantees all citizens equal protection under the law. Finally, opponents also claim that AA is contrary to the meritocratic individualism on which the United States is based, as opportunities are allotted based not on merit, but on demographic characteristics.

Conversely, proponents of AA argue that such proactive steps are necessary to compensate for past discrimination and minimize the risk of its continuation in the future. At the extreme, proponents often claim that anti-AA attitudes are a manifestation of the continued presence of racism in the United States (thus proving the need for AA). Less extreme but equally passionate views in favor of AA claim that AA is needed to provide the same opportunities for members of protected classes as those that are available to majority group members. These opportunities may simply mean becoming aware of professional networks to which many minority group members have not had access in the past. In addition, those who favor AA also assert that illegal discrimination against women and minority group members still exists today but that it is not openly expressed. As such, a systematic, data-driven approach like AA is still needed to guard against the more prevalent, but equally insidious, covert forms of today's discrimination.

Since public opinion of AA in the United States is so clearly divided, it is not surprising that a significant body of research investigating AA has evolved since its inception. This research has focused on areas such as individual attitudes toward AA, the study of AA's effects on its targeted beneficiaries and nonbeneficiaries, and its influence on workforce diversity. Not surprisingly, research has generally found that members of minority groups (the intended beneficiaries of AA) express more favorable attitudes toward AA than do members of majority groups. Some researchers have speculated that majority group members are likely to hold negative attitudes toward AA since they are less likely than minority group members to believe that discrimination exists and, as such, do not see the need for practices that are intended to minimize discrimination. Interestingly, however, the research has also reported that some of the negative attitudes expressed by majority group members toward AA are attributable to misinformation about these programs. In fact, when questioned about their attitudes toward specific proactive employment practices that are consistent with an AA plan, majority group members are likely to express positive attitudes toward these practices. For example, while there is a strong consensus of public opinion against the use of preferential treatment of minorities and women in either employment or education, equally strong opinions are often expressed in favor of offering training programs to help disadvantaged individuals get ahead or be given equal access to

opportunities readily available to members of the majority.

In addition to studying attitudes toward AA, research has also explored AA's effects on its intended beneficiaries and nonbeneficiaries. Perhaps the most interesting studies of the effects of AA have focused on the change in the workforce participation of AA's intended beneficiaries. Studies have found, for example, that the employment share of Black males and females increased faster in federal contractor establishments than in noncontractor firms in the late 1970s, a trend that may be attributable to the stricter enforcement of AA policies by the OFCCP. However, perhaps indicative of AA's limitation as a public policy, during this same period of time, similar increases were not found in the employment share of Black males and females in skilled occupations.

Studies have also raised awareness of the potential for AA to negatively influence its targeted beneficiaries. For example, some evidence has shown a drop in a woman's self-esteem and/or self-confidence that is associated with her belief that she was chosen for a position due solely to a policy of preferential selection based on gender and not her qualifications for the job. Nonbeneficiaries of AA may also hold negative attitudes toward those who they feel benefit from AA. The stigma of believing an individual was hired or promoted due solely to meeting AA goals implies that the woman or minority group member is less qualified for the position than a man or member of a majority group. As such, AA beneficiaries are often thought of by majority group members as being incompetent. It is also likely, under these conditions, that stigmatization may become a self-fulfilling prophecy in the organization, resulting in the ultimate failure of many women or minority group members and a reinforcement of the majority's belief that AA forces contractors to hire unqualified employees, based solely on their race or gender.

For nonbeneficiaries, AA is also associated with claims of reverse discrimination from majority group members. However, it has been reported that these claims occur more frequently by Whites employed by companies that do not use AA in their employment practices than by Whites employed by companies that do. This phenomenon may be minimized by emphasizing the qualifications of the individuals who are hired or promoted, along with communicating the fairness of the selection procedures used by the organization.

Studies of AA programs have also focused on their relation to the degree of diversity in an organization's workforce. Evidence has been found that human resource practices that consciously focus on the demographic characteristics (gender and race) of employees, known as *identity-conscious practices*, are positively associated with the level of the highest-ranking woman in an organization and the percentage of minority employees in the management group. Conversely, human resource practices that do not focus on demographic characteristics of employees, *identity-blind practices*, are not related to the presence of women and minorities in these companies. Equally important, the number of the identity-conscious practices (not identity-blind) used by organizations was related to whether the company was regulated by the OFCCP, that is, whether it was an AA employer.

Other studies have distinguished having a formal AA plan from using AA in both recruitment and selection. These studies have shown that the use of AA in recruitment is positively associated with reaching a wider, more diverse range of job applicants and, probably as a result of this, the employment of more women and minorities compared with firms that do not use AA in their recruitment practices. Firms that use AA in staffing procedures also tend to use more recruitment practices and tend to examine their applicants more intensely than those that do not use AA in their hiring practices. These same studies showed that using AA in staffing is related to hiring more employees who do not meet the academic qualifications established for the positions but that members of minority groups and women hired who are educationally underqualified for their positions are just as likely to receive promotions and are paid comparatively more than employees who are academically qualified.

Although considered a U.S. policy, AA-type policies also exist outside the United States, but with one substantial difference. Governmental reservationist policies exist in India that are designed to protect the majority indigenous populations in some areas against more educated and more successful minority group members. Like India with its "sons of the soil" policies, the Malaysian government has mandated policies that impose quotas on admission to government educational institutions, qualification for public scholarships, positions in government, and business ownership for the *bumiputras*, the indigenous majority in Malaysia. Contrary to the U.S. experience, then, AA (or preferential selection) in both India and

Malaysia has been implemented to help members of the majority population. The future of these policies, particularly in Malaysia, is very uncertain.

The future of AA in the United States is also very uncertain. In 1996, 54 percent of the voters in the state of California approved Proposition 209, which made it illegal to discriminate against or grant preferential treatment to anyone based on race, sex, color, ethnicity, or national origin. One of the proposition's intentions was to prohibit the use of race as a criterion of admission by the University of California. Although the state of Washington passed a similar initiative (I-200) in 1998 and Florida has banned the use of race as a factor in college admission, the expected rush by other states to implement laws similar to California's has not materialized.

In addition to adverse public opinion leading to an election mandate, another threat to the continuation of AA lies in the judicial system, in particular with the U.S. Supreme Court. In many of its recent cases, the Court has often used a "strict scrutiny" standard in its decisions involving the legality of preferential treatment based on race or gender. In these cases, strict scrutiny implies that preferential treatment may be used only if there is clear evidence of past discrimination and preferential treatment is necessary to remedy the past injustice. However, it has often been claimed that the strict scrutiny standard is "strict in theory, but fatal in fact," which would imply that the continuation of AA and its use of preferential treatment based on race and/or gender may be problematic under these standards.

As a public policy, AA is often misunderstood and engenders deep-seated opinions, both for and against its continued use in education and employment. Its future in the United States depends on a number of individual-, organizational-, and societal-level factors. For individuals, it is important to ensure that their opinions toward AA are based on factual information about the policy's intent and requirements. For organizations and public policy makers, it is important that they continue to develop and implement practices that meet the objectives of AA, namely, that women and minority group members be given the same educational opportunities as those in the majority and be employed by organizations consistent with their presence in what is increasingly becoming a globally oriented and diverse workforce.

AGE DISCRIMINATION

Along with race and gender, people commonly use age to categorize and form stereotypes about others. Ageism consists of a negative bias or stereotypical attitudes toward aging and the aged. It is maintained by persistent, mostly negative stereotypes and myths concerning older individuals. *Age discrimination* itself is an action; however, it is a consequence of and is motivated by ageist attitudes, beliefs, and prejudices.

Age discrimination in the workplace occurs when an employer differentially treats employees on the basis of their age rather than on their individual merit. It affects various workplace functions, including hiring, training, promoting, and termination of employees. Underlying age discrimination at work are ageist attitudes and stereotypes about the abilities of older workers. These ageist stereotypes hold that age is a primary factor in determining individuals' abilities and that older workers are less mentally and physically able to perform their jobs than are younger workers. Based on these stereotypes, older workers are assumed to be less productive, less creative, less innovative, less willing or unable to learn, and more prone to sickness and accidents than are younger workers.

Stereotypes encourage age discrimination because they mask individuals' capabilities and therefore limit workers' opportunities and potential. Attitudes about appropriate social roles for older people and the assumption that all older workers would prefer and are able to afford to stop working also encourage age discrimination. Deeming some jobs unsuitable to workers over a certain age may disqualify entire groups of workers considered to be too old. Beliefs about the costs of employing older workers also further workplace discrimination. After longer employment tenures, older workers generally have higher earnings and are also assumed to have more health problems. Since employers are always searching for ways to reduce costs, older workers may be considered less desirable.

Age is only one criterion on which employers may discriminate among workers. Indeed, age discrimination can be intertwined with other types of discrimination, including race and gender. Some older workers may experience "double jeopardy" in the workplace due to their race, gender, or disability.

Nonetheless, age discrimination in employment is different from other types of discrimination because it is the one type of discrimination that all workers have the potential to experience during their lifetimes. Unlike other groups that are legally protected from discrimination, such as women, racial and ethnic minorities, and disabled workers, if they live out the normal life span, all employees will eventually be part of the legally protected group of workers over the age of 40. In addition, age discrimination is a unique form of bias, since it is likely that younger workers who benefit from ageist employment practices in their

youth will be negatively impacted by the same policies as they grow older.

SHIFTING TRENDS FOR OLDER WORKERS

Labor force participation rates of older workers have been on the rise since the mid-1980s. In 2002, workers over age 55 comprised approximately 14 percent of the labor force. Among people 55 and older, 35.7 percent were employed in 2003, and that number is expected to increase to 39.3 percent in 2014. Although men have higher labor force participation rates than women overall, rates for both women and men workers in all age categories over 55 are projected to increase by 2014 as well.

A central focus of discussions about age discrimination in employment is the impending impact of the “baby boom generation” (individuals born between 1946 and 1964). This large group of workers is expected to radically alter individual and societal expectations about aging and work. Future labor force participation and retirement patterns among baby boomers are important factors in determining the future age composition of the U.S. workforce. Because they constitute such a large and visible cohort, employment patterns of baby boomers will impact norms and assumptions about older workers. Furthermore, baby boomers are expected to retire at older ages (in part due to changes in the Social Security retirement age from 65 to 67) than previous cohorts of workers, and these trends are likely to impact the age structure of the labor force.

Researchers predict that due to slow growth and the aging of the workforce, older workers will become increasingly attractive to employers needing to fill jobs. In theory, this means that once the baby boomers retire, the number of open jobs will increase dramatically without enough younger workers to fill them. Thus, some researchers predict that the job market may become more accessible to older workers seeking employment. Others are not as optimistic about the shifting demand for older workers and caution that they will still experience disadvantages in the labor market.

Why do older people continue to work past the typical age of retirement? A primary reason for many is economic need. Many individuals must work past the typical retirement age to be better financially prepared to live out their later years. Also, many older workers continue working because they enjoy their jobs, take

pleasure in work relationships, and derive part of their self-identities from work. Furthermore, older workers also have the desire to remain independent, active, and involved in the world and to continue contributing to society.

DISPELLING STEREOTYPES ABOUT OLDER WORKERS

Older workers are an extremely heterogeneous group, which makes it difficult to formulate broad generalizations about them as a whole. Nonetheless, research on psychological and physical functioning and aging demonstrate that ageist stereotypes that inspire age discrimination are without merit. Indeed, most older workers are physically and intellectually able to perform their work roles far beyond the typical age of retirement and well into later years in life. Substantial empirical research finds no support for the assumption that age changes necessarily precipitate unavoidable declines in work performance. Nor does age lead to an increase in workplace accidents or absenteeism. In fact, according to the American Association of Retired Persons (AARP), many employers report that older workers are more loyal, have lower rates of absenteeism, and are generally more reliable than younger workers.

Studies also show that older workers are, in fact, willing and capable of changing with the times and learning new work methods and technologies. Some researchers argue that the type of work is an important determinant of older workers’ motivation and adaptability. They suggest that intellectually challenging and stimulating jobs have a positive impact on all workers’ morale, commitment, and ambitions on the job.

Although some older workers have higher earnings than younger workers due to longer job tenure, in terms of health care costs to employers, older workers are not more expensive than younger workers. Rather, employers report that younger workers with dependents are actually more expensive to employ. While the costs of some health benefits increase with age, the AARP reports that older workers use fewer medical benefits than do younger workers. Furthermore, since disability is one of the primary reasons for retirement, those who remain employed beyond the typical retirement age are likely to be a self-selected group of healthier, older workers. Presumably, these workers require less, rather than more, medical care.

PROTECTION AGAINST AGE DISCRIMINATION

Age discrimination has consequences for individuals, employers, and society at large. It can hurt individual workers and their retirement security, and it is costly to employers charged with discrimination. Finally, ageist attitudes potentially exclude a valuable pool of workers, which will become even more important as the younger workforce gets smaller with the aging of the baby boomers.

The Age Discrimination in Employment Act (ADEA) was first enacted in 1967 and was later expanded in 1978. Growing from the sentiments and momentum of the civil rights movement, the purpose of the ADEA was to challenge ageist assumptions about older workers' abilities and prohibit employers from discriminating against workers on the basis of age alone. As part of the 1964 act, Congress directed the U.S. Secretary of Labor to investigate the prevalence of age discrimination in the workplace. The report cited rampant age discrimination, finding that 50 percent of all job openings in the public market in 1965 were closed to applicants over age 65 and that 25 percent made the age 45 the cutoff. The Equal Employment Opportunity Commission (EEOC) is the government agency charged with enforcing the ADEA through investigating and litigating charges of age discrimination against employers. According to the EEOC, 12.8 percent of all discrimination charges filed in 2002 were based on age.

The ADEA prohibits discrimination against a person over 40 on the basis of age in every aspect of the employment relationship, including job advertisements, recruitment, interviewing, hiring, firing, compensation, assignments, classifications of employees, transfers, promotions, layoffs or recalls, testing, training and apprenticeship programs, medical examinations, fringe benefits, or other terms of employment. The ADEA also prohibits retaliation against an individual for asserting his or her right to file an age discrimination charge against an employer, participating in an investigation of the employer, or otherwise opposing discriminatory practices.

In addition, the ADEA prohibits discriminating between two individuals solely on the basis of age, even if both individuals are 40 or older. For example, in choosing between two potential employees for the same position, it is illegal to choose a younger worker instead of an older worker solely on the basis of their

ages. Also, if choosing between two potential employees both over 40, the employer may not turn down either on the basis of age, but must use some other criteria to decide. The ADEA applies to private employers with 20 or more employees employed for 20 consecutive weeks, as well as federal, state, and local governments. Labor organizations with 20 or more members and employment agencies must also comply with the act.

There remain a number of exceptions to the ADEA. The first one is the bona fide occupational qualification (BFOQ), which has been used to justify excluding older workers from certain public safety jobs. The BFOQ specifies that employers must prove that an age limit is necessary for performance of the job. Other exceptions to the ADEA include the Equal Benefit Rule, specifying that individuals cannot be denied the opportunity to participate in an employer benefit plan. Furthermore, age-based reductions in benefits are illegal unless the costs increase with age and the cost to the employer is the same for younger and older workers. Bona fide seniority systems are permissible as long as they do not attempt to subvert the purposes of the ADEA and the retirement decision is not coerced and voluntary. When employees receive severance benefits or accept early-retirement incentives, some employers use waivers and releases of ADEA rights and claims. For these to be valid, employees must agree to them both knowingly and voluntarily. The Older Workers Benefit Protection Act of 1990 amended the ADEA and sets strict guidelines for establishing the validity of these waivers.

INSTITUTIONAL AND INDIVIDUAL DISCRIMINATION: EFFECTIVENESS OF THE ADEA

The ADEA was intended to eliminate age discrimination at both individual and institutional levels. Many analysts argue that it has been more effective in reducing the latter than the former type of discrimination. At the institutional level, mandatory retirement laws are the most evident historical example of age discrimination. Historically and currently, social norms and the system of retirement either explicitly or implicitly limit the number of people holding or looking for jobs. Although mandatory retirement is illegal, several weaknesses in the ADEA allow employers to discriminate against older workers regarding retirement. Some economists argue that although mandatory

retirement was outlawed, it has essentially been replaced by lucrative financial incentives for retirement that are concurrent with the time mandatory retirement would occur. Early voluntary retirement programs, even if they are offered to reduce a firm's costs, do not violate the ADEA. Others have shown that the benefit calculation rules of Social Security as well as most defined-benefit employer pensions encourage retirement and discourage working beyond the typical retirement age because they reduce the value of workers' retirement income for those who stay on the job after age 65.

Outlawing mandatory retirement programs based on age has been effective at the institutional level. However, evidence of age discrimination in employment persists, including the length of time it takes older workers to become reemployed, the accompanying wage loss that many older workers experience upon reemployment, and the size of the compensations granted to victims of age discrimination. Some research shows that during economic downturns and episodes of downsizing, employers may subvert the ADEA by terminating workers across the age spectrum but rehiring only younger workers.

With economic changes and the decline in lifetime employment in recent decades, older workers are no longer as secure in their jobs as they once were. Although older workers are still less likely to lose their jobs than are younger workers, the consequences of unemployment for older workers can be severe. Once unemployed, older workers have greater difficulty finding jobs after spells of unemployment. In fact, being laid off and the ensuing job hunt can be particularly discouraging for older workers and can encourage them to retire even though they may prefer not to do so.

At the individual level, age discrimination is difficult to prove. Employers charged with hiring and firing make individual decisions about the capacities of older versus younger workers. These types of decisions may be influenced by blatant and overtly ageist attitudes or subtle and covert attitudes about aging. In legal terms, there are two discourses used to claim individual age discrimination: disparate treatment and disparate impact.

The majority of age discrimination cases use the *disparate-treatment* theory. Under this argument, the plaintiff must prove that the discrimination was intentional, providing evidence to prove that there was motivation to discriminate. Motivation is difficult to

establish, and courts often rely on a three-stage model of proof. The plaintiff must verify that he or she is part of the protected group, suffered adverse reactions due to the employer's behavior or policies, was successfully performing the work to the legitimate expectations of the employer prior to the discriminatory acts, and was subsequently replaced. The employer must then present nondiscriminatory reasons justifying the action taken against the employee. Finally, the plaintiff must establish that the reasons given by the employer were actually a pretext for discrimination.

Under a *disparate-impact* claim of age discrimination, the plaintiff must show that seemingly age-neutral employment practices or policies had a disproportionately negative effect on older workers. To refute the claim, the employer must demonstrate that the organization required the action or policy for "business reasons" or show that the negative effect was due to non-age-related factors.

In summary, although blatant age discrimination is no longer legal, age biases continue to operate in the workplace. Age discrimination remains an important concern for all workers. The aging of the baby boomers and their changing work and retirement patterns will certainly challenge cultural norms and expectations about aging and work. It remains to be seen what kinds of impact this cohort will have on stereotypes about older workers as well as employment practices.

—Jennifer Keene

AGE DISCRIMINATION IN EMPLOYMENT ACT OF 1967 (ADEA)

Age discrimination is one of the fastest-growing areas of employment law. The U.S. Equal Employment Opportunity Commission (EEOC), the federal agency charged with administering the law, has received upward of 19,000 claims of age discrimination per year over the past several years. This growth is most attributable to the increasing number of aging employees in the workplace, the overall economic conditions of the country, and resulting employment layoffs and plant closures, which many times disproportionately affect older Americans.

The *Age Discrimination in Employment Act of 1967* (ADEA), 29 U.S.C. § 623(a)(1)-(d), protects employees from discrimination in the workplace because of their age. The policy behind the ADEA is to protect older workers from stereotypes that they are inefficient or that because of their age, they can no longer perform at the same level as younger workers. The ADEA prohibits discrimination against employees in hiring, firing, or other terms and conditions of employment if they are 40 years of age or older. Individuals under 40 years old do not have a claim under the federal law.

However, many state laws allow for claims of age discrimination regardless of the individual’s age.

Private employers of 20 or more persons, state and local governments, employment agencies that serve covered employers, and labor unions with 25 or more members are required to comply with the terms of the ADEA. There are, however, several exemptions to the law, including some high-level managers and bona fide executive or high-policy-making positions; uniformed military personnel; public safety personnel (police, firefighters, and prison guards); and individuals appointed by elected officials who serve in a policy-making capacity. In those cases, depending on the circumstances, an employer may be permitted to base employment decisions on an employee’s age.

Generally, however, employers are prohibited from taking any adverse employment action against an individual “because of” his or her age. Adverse actions come in many forms and may include the following: firing, refusing to hire, pay cuts, demotions, transfer, discipline or reprimand, and undesirable reassignment. Employers are also prohibited from the following: limiting, segregating, or classifying employees in a way that would deprive the employee of job opportunities or adversely affect employee status; reducing the wage rate of an employee in order to comply with the ADEA; indicating any preference, limitation, specification, or discrimination based on age in a notice or advertisement for employment; or operating a seniority system or employee benefit plan that requires or permits involuntary retirement. A person who is unlawfully discriminated against because of his or her age is entitled to damages, including loss of income, emotional distress, and, potentially, attorneys’ fees. In addition, depending on the egregiousness of the violation, the court may double the damage award or even award triple damages.

In cases of alleged age discrimination, employees can meet a prima facie burden by using direct evidence of differential treatment based on age. This could be in the form of an admission on the part of a representative of the employer that the individual is “too old” to perform the job, though this kind of statement is rarely made. Sometimes individuals do make statements or deliver messages that suggest that the company would prefer a younger “face” to its workforce or a particular job or that the company needs a “fresh outlook” on a particular project. Many times, the court will look at these facts not as direct proof, but as circumstantial evidence of animus because of an individual’s age.

In the absence of direct evidence, an employee who files a suit claiming age discrimination may depend largely on statistics showing disparate treatment directed at older employees. However, merely replacing an older employee with a younger person does not establish age discrimination. Similarly, it is not necessarily illegal to replace an older employee with a high salary with a younger person earning a lower salary. However, these two factors weigh heavily in whether an employee is able to prove a claim of age discrimination under the act.

Employers have several defenses to age discrimination claims. An employer may be able to justify an adverse employment action because of some legitimate, nondiscriminatory reason. Many times, good cause, legitimate business decisions, and reasonable factors other than age are mentioned as reasons for an adverse employment action. Under the ADEA, if an employer is able to show that although age may have been a motivating factor in an employment decision, the employer would have made the same decision anyway, the employer can escape liability.

Much of the recent litigation in connection with age discrimination claims involves an amendment to the ADEA called the Older Workers Benefits Protection Act (OWBPA), 29 U.S.C. § 626(f). The OWBPA sets forth certain rules regarding the waiver of an employee's rights under ADEA. Under OWBPA, waivers of the right to sue for age discrimination must be knowing and voluntary and therefore must (a) be a part of a written, clearly understood agreement between the individual and the employer; (b) refer specifically to rights or claims arising under the ADEA; (c) exclude waiver of any rights and claims arising after the date of the waiver; (d) include the exchange for consideration, something of value to which the individual is not already entitled; (e) advise the individual to consult with an attorney; (f) provide 21 days for the individual to consider the waiver and allow 7 days for the individual to revoke the waiver. (If it is offered to a group or class as a part of a termination program or acts as an incentive, a waiver must allow 45 days for consideration and provide additional statistical information to the employee for a waiver of his or her ADEA rights to be affected.)

The purpose behind the OWBPA is to ensure that older workers are not taken advantage of when being laid off and/or terminated from employment by being rushed into severance agreements that require them to waive their rights to pursue age discrimination claims.

To meet this end, an employer must, among other things, allow for a sufficient amount of time for the individual to review the agreement and obtain advice from an attorney in connection with the terms of the agreement. Employers must be very careful in drafting releases so that they effectively waive claims under the ADEA, because under certain circumstances, employees may be permitted to execute such releases and ultimately sue and recover not only money entitled to them under the agreement, but any amount of damages rewarded in the age discrimination claim.

Age discrimination is often hard to prove unless there is some incontrovertible evidence that the employer acted "because of" age. No employer would admit that an employment decision was based on an individual's age. Laws prohibiting age discrimination are very effective as a deterrent to ensure that an employer does not use age as a factor in making employment decisions unless it is justified by a legitimate business reason recognized by the law.

ALLPORT-VERNON-LINDZEY STUDY OF VALUES

For decades after its initial development in 1931, the *Allport-Vernon-Lindzey Study of Values* (SOV) had a substantial impact on psychological practice and research. In terms of the metric of citation count, by 1970, the SOV was the third most popular nonprojective personality measure, after the Minnesota Multiphasic Personality Instrument (MMPI) and the Edwards Personal Preference Schedule (EPPS). Designed primarily for use with upper-level high school students, college students, and adults, it became

popular because it reflected a number of positive features, the most important being its multiplicity of applications. First, the SOV provided a vivid classroom demonstration pertinent to courses in psychology, social psychology, personality, organizational behavior, and education. In this regard, the 1970 test manual noted that students are always interested in their own scores and enjoy a discussion of the results. Second, the SOV was widely used in vocational and educational guidance (and even in marriage counseling). Third, it was integral to hundreds of research projects, such as those concerning group differences, changes in individual values over time (e.g., before and after divinity school training), and ascertaining patterns of value agreement among friends and family members.

By the late 1980s, though, the SOV was no longer in print. The reasons for the extraordinary 50-year popularity of the SOV and its subsequent fall into psychological oblivion are discussed below, after a brief description of the instrument itself, two illustrations of its practical utility, and past reviewers' evaluations.

Based on the seminal work of Eduard Spranger, the SOV identifies six value orientations, which, briefly, are as follows:

- Theoretical (the discovery of truth: empiricism, intellectualism)
- Economic (that which is useful: resourceful, practical affairs)
- Aesthetic (form and harmony: grace, artistry in life)
- Social (love of people: altruism, sympathy, caring)
- Political (power in all realms: influence, leadership)
- Religious (unity of life: comprehension of life's meaning, holiness)

Each individual receives a total score of 240 points, based on answers to questions describing a number of familiar situations, for instance, "If you had some time to spend in a waiting room and there were only two magazines to choose from, would you prefer (a) *Scientific Age* or (b) *Arts and Decorations*?" Consequently, the SOV measures the relative strength of each value orientation. The theoretical average for each value is 40 (240 points apportioned among six values), but individual profiles often demonstrate unique value patterns. Note that the SOV ascertains values indirectly through realistic behavioral scenarios; in contrast, two currently used values measures (Milton Rokeach's Value Survey and Shalom Schwartz's Value Scale) require respondents to directly rank and rate values, respectively—assuming that individuals can access and consciously process

this information and report it accurately. More specifically, the Rokeach scale requires respondents to rank order two sets of 18 relatively abstract values (e.g., freedom, loyalty, courage), and the Schwartz instrument requires the rating of 52 broad values (e.g., wisdom, inner harmony, unity with nature).

Pertinent to the psychometric adequacy of the SOV, internal consistency estimates for each value have ranged from .84 to .95, and averaged .90 (after Spearman-Brown prophecy adjustment). Indicative of the SOV's substantive validity, early normative data collected from more than 8,000 students were very consistent with a priori expectations. For 500 engineering students, the mean Theoretical value was 48; for 7,100 medical students, the mean Theoretical value was 50; among 800 business students, the mean Economic value was 46; among 400 art and design students, the mean Aesthetic value was 57; and among 100 divinity students, the mean Religious value was 55. The popularity of the SOV can be attributed in part to its solid psychometric properties. Further reflecting its demonstrated construct validity, scores on the SOV have been reliably related to types of professional education, occupational choice, and such vocationally relevant outcomes as job satisfaction and, to a lesser extent, job performance.

An interesting book-length study by Abraham Zaleznik, Gene Dalton, and Louis Barnes examined the careers of 174 scientists/engineers and engineering managers in a high-technology company. The organization employed a dual-track system of advancement, such that individuals could choose to stay on the technical (scientist/engineer) track or elect for a managerial progression. Scientists with higher Theoretical than Economic scores on the SOV and managers with higher Economic than Theoretical scores were deemed "oriented." In contrast, scientists with higher Economic than Theoretical scores and managers with higher Theoretical than Economic scores were deemed "conflicted." As hypothesized, job satisfaction, organizational satisfaction, career satisfaction, and (to a lesser extent) rated job performance levels were higher among the "oriented" than the "conflicted" employees. In addition, conflicted employees reported a greater incidence of fatigue at work.

Vocational and counseling psychologists have also used the SOV to assist in educational guidance. The utility of the SOV in assisting college students in selecting a field of graduate education was demonstrated in a recent study by Richard Kopelman, David Prottas, and Lawrence Tatum. Value profiles derived from four

measures of values were compared: the two Rokeach Value Surveys (Terminal and Instrumental), the Schwartz Value Scale, and the Study of Values. As predicted, the value categories of the SOV yielded distinct “ideal” profiles, as reported by deans and directors of graduate programs, in five of six different disciplines (business administration, fine arts, social work, divinity, and chemistry and physics). Deans of MBA programs saw the economic need as most salient; deans of MFA, MSW, M. Div., and M. Chem./M. Phys. viewed the aesthetic, social, religious, and theoretical needs as most salient, respectively. In contrast, the other three value measures yielded generic profiles with respect to fields of graduate study; that is, the same values were seen as important across disciplines (e.g., wisdom, self-respect, achievement). It might be noted that the provision of counseling in connection with graduate education is not a trivial matter. Ten years ago (1995-1996), there were 2.8 million individuals enrolled in postbaccalaureate programs, according to the U.S. Department of Education.

Over the years, several highly favorable reviews of the SOV have appeared in various editions of the *Mental Measurements Yearbook*. For example, Paul Meehl described the SOV as a remarkably good test; Harrison Gough concluded that the SOV possesses considerable merit and utility; and N. L. Gage opined that the SOV is a very good instrument for classroom demonstration, for counseling and vocational guidance, and for research on a wide variety of psychological questions. Robert Hogan noted that the SOV scale scores predict a variety of criteria in the theoretically expected manner and, furthermore, that when used with cooperative subjects, the SOV provides dependable and pertinent information concerning individual cases. Writing in 1951, the year of the SOV’s second and only substantive revision (prior to the 4th edition in 2003), Laurance Shaffer’s comments in the *Journal of Consulting Psychology* were prescient: He predicted that the Study of Values (in its “excellent” new format) seemed destined for several more decades of service as a tool for guidance and for research.

So why did the SOV go out of print and fall into psychological oblivion? It is likely that the SOV fell into disuse due to its increasingly archaic content (e.g., users did not know who Amundsen and Byrd were); a lack of religious inclusiveness (only churches were mentioned, no temples or mosques); dated cultural assumptions (especially concerning love and marriage); and obsolete linguistic terminology.

According to anecdotal reports of several experienced educators, whereas in the 1970s, students found the SOV “ quaint,” by the 1980s, they found it “ sexist” and “ outdated.” When one “ veteran” educator used the SOV with executive MBAs in the 1990s, he reported that “ the women students wanted to lynch me!”

In response to these complaints and to resuscitate, if not resurrect, the SOV, a new 4th edition of the SOV was recently constructed, and it was published in the *Journal of Vocational Behavior*. In large measure, the new edition of the SOV brought the instrument into the twenty-first century merely by “ tweaking” 15 of 45 items (e.g., substituting Bill Gates for Henry Ford). The psychometric properties of the new and earlier versions were found to be virtually identical. The 4th edition of the SOV is no longer characterized by sexist language or dated content.

In recent years, a number of researchers have lamented that existing values measures (not including the SOV) have demonstrated only limited evidence of validity, a phenomenon attributed to attempting to assess values directly. Furthermore, Kaipeng Peng, Richard Nisbett, and Nancy Wong have suggested that the low validities of commonly used value survey measures might be avoided by using a behavioral scenario methodology. Ironically, such a measurement method has long existed in the venerable SOV. Importantly, the SOV can again be successfully employed for research and practice in vocational psychology and to aid career development.

AMERICAN COUNSELING ASSOCIATION

The *American Counseling Association* (ACA) is the world's largest association exclusively representing professional counselors in all their various practice settings. Founded in 1952 as the American Personnel and Guidance Association (APGA), ACA changed its name to the American Association of Counseling and Development in 1983 and then to its current name, the American Counseling Association, in 1992. Each name change resulted from a further refinement of the mission and purpose of the association.

Headquartered in Alexandria, Virginia, just outside Washington, D.C., the ACA promotes public confidence and trust in the counseling profession so that professional counselors can further assist their clients and students in dealing with the challenges that life presents. The over 50,000 members of the ACA include professional counselors in the United States and in 50 other countries, including the Philippines and the Virgin Islands and in Europe and Latin America. In addition, the ACA is associated with a comprehensive network of 19 divisions representing the various specialties within professional counseling and 56 state, district, and international branches consisting of an additional 40,000 members. The mission of the ACA is to enhance the quality of life in society by promoting the development of professional counselors, advancing the counseling profession, and using the profession and practice of counseling to promote respect for human dignity and diversity.

The ACA has been instrumental in establishing professional and ethical standards for the counseling profession, and it has made considerable strides in accreditation, licensure, and national certification. The association established the National Board for Certified Counselors (NBCC) to provide a national certification body, the Council for Accreditation of Counseling and Related Educational Programs (CACREP) to provide a national accreditation body for counselor training programs, the American Counseling Association Foundation (ACAF) to provide

for support for the profession, the American Counseling Association Insurance Trust (ACAIT) to provide high-quality, low-cost professional liability insurance for members, and other organizations to support the profession. Professional counselors (mental health counselors or clinical counselors) are licensed in 48 states and the District of Columbia. ACA also represents the interests of the profession before Congress and federal agencies and strives to promote recognition of professional counselors to the public and in the media.

IMPACT OF VOCATIONAL GUIDANCE IN THE ACA

Vocational guidance and career counseling played a preeminent role in the founding of ACA, a role that continues to this day. The professional association representing vocational guidance, originally known as the National Vocational Guidance Association (NVGA) and now known as the National Career Development Association (NCDA), was one of the founding groups of ACA. Leaders of NVGA were the first leaders of ACA and even today continue to play a prominent role in the leadership of ACA. The journal of NVGA became the journal of ACA. The staff of NVGA became the first staff of ACA. The influence of NVGA/NCDA permeated and continues to play an important programmatic and leadership role in the affairs of professional counseling in the United States.

In the late 1940s, following World War II, counseling was experiencing a time of growth, and several professional associations represented the different aspects of this developing profession. In 1949, a study was presented at the Council of Guidance and Personnel Associations conference in Chicago that called for a unified voice in the personnel profession. A Unification Committee was formed and began meeting in 1950. The four main groups behind the unification movement were the NVGA, the National Association of Guidance and Counselor Trainers (now the Association for Counselor Education and Supervision), the Student Personnel Association for Teacher Education (now the Counseling Association for Humanistic Education and Development), and the American College Personnel Association. These four professional associations became the first four divisions of ACA, followed by the American School Counselor Association in 1953.

The Unification Committee made its report at the 1951 NVGA convention, and a new professional association with a new name was born, the Personnel and Guidance Association (PGA). In 1952, that name was changed to the American Personnel and Guidance Association, and the first officers of APGA included President Robert Shaffer, President-Elect Donald Super, and Treasurer Frank Fletcher, who were also leaders in NVGA. Throughout the history of ACA, more than 25 percent of the ACA Presidents were also presidents of NVGA/NCDA.

At the time of the founding of APGA, the challenge for the United States was how to reintegrate the returning veterans from World War II back into the workforce. President Harry Truman's Fair Deal program was a response to the problems encountered by these returning armed services veterans. The lack of jobs and the subsequent displacement of current workers by these returning veterans were important societal problems that the Truman program attempted to address. The first annual conventions reflected these societal vocational needs. The theme for the 1952 Council of Guidance and Personnel Associations and American Personnel and Guidance Association joint conference was "Improving Human Relations," and the 1953 American Personnel and Guidance Association conference theme was "Human Resources and Manpower Utilization."

The NVGA journal, *Occupations: The Vocational Guidance Journal*, became the journal of APGA in 1952 and was renamed the *Personnel and Guidance Journal* (now *Journal of Counseling and Development*) in 1958.

AMERICAN PSYCHOLOGICAL ASSOCIATION

The *American Psychological Association* (APA), the world's largest psychology organization, has worked for more than 100 years to advance psychology as a science, as a profession, and as a way to promote health, education, and human welfare. Psychology is a dynamic and diverse field. Psychologists follow dozens of career paths and pursue their craft in a variety of work settings. Career development resources available through the APA are as varied as the discipline itself: programs and products for every psychologist, from the bench scientist to the clinician and from the psychology graduate student to the mid-career professional.

APA works to foster innovative and high-quality psychology teaching at all levels, from high school to postgraduate, including research and applied training. APA is the accrediting body for doctoral programs, internships, and postdoctoral residency programs in professional psychology. Accreditation is important, especially for students interested in a career in professional practice, because most state licensing boards in psychology require that licensure applicants possess a doctoral degree from an accredited program.

Preparation for a career in psychology should start early, at the undergraduate level if possible. Psychology students at the high school and undergraduate levels can be affiliate members of the APA. Graduate students can join as APA student affiliates and automatically also belong to the American Psychological Association of Graduate Students (APAGS).

After graduation and internship, early and mid-career psychologists can find important career development resources available from APA, from continuing professional education to midcareer seminars specifically designed for research psychologists, on issues such as analyzing large databases and using MRI (magnetic resonance imaging) technology in brain research (visit <http://www.apa.org/ce>). APA also offers programs and workshops at regional and national conferences for psychologists interested in exploring academic careers.

APA publishes a variety of psychology books, journals, and electronic information products, all useful to students of psychology at any level. Two APA electronic databases, PsycINFO (article abstracts) and PsycARTICLES (full text), cover the psychological literature published from 1887 to the present.

A number of APA books are of particular interest to students. These titles include *The Publication Manual of the American Psychological Association*; *Mastering APA Style Student Workbook*; *Is Psychology the Major for You?*; *Getting In: A Step-by-Step Guide to Gaining Admission to Graduate School in Psychology*; and *Graduate Study in Psychology*. For more information or to purchase APA books, visit <http://www.apa.org/books>.

Also published by APA are 46 peer-reviewed psychology journals, including the *Journal of Social and Personality Psychology* and *Health Psychology*, and two newsmagazines, the *Monitor on Psychology* (monthly) and *gradPSYCH*, a quarterly magazine for psychology graduate students. Preview an issue of each of these at <http://www.apa.org/monitor/> or <http://www.gradpsych.apags.org/>. APA members subscribe to the organization's journals and buy books at member discounts.

The APA annual convention includes opportunities for psychologists to hear presentations by distinguished scholars and leaders in the field. The convention includes hundreds of symposia, panel presentations, poster and paper sessions, and workshops on cutting-edge research, education trends, and practice experience. For more information, visit <http://www.apa.org/convention>.

"Psyccareers" is an online resource for psychology employment, used by both job seekers and organizations with jobs to fill. APA members can post their résumés and search both nationally and internationally for available positions in psychology. For more information, visit <http://www.psyccareers.com/index.cfm>.

ANTICIPATORY SOCIALIZATION

Anticipatory socialization is a term used to describe a variety of programs and initiatives offered by organizations that allow prospective employees to gain work experience prior to full-time employment. These programs include internships, apprenticeships, cooperative education assignments, and informational interviews. Each program is designed to help individuals, usually high school or college students, develop

an accurate self-concept, gain a realistic understanding of various career fields and organizational environments, and allow a check for fit between individual characteristics and the demands of different jobs.

Through these programs, prospective employees can become acclimated to an organization's formal mission, goals, structure, policies, and culture prior to fully joining the organization as a regular employee. Anticipatory socialization initiatives also allow prospective employees to become accustomed to the informal side of an organization through exposure to the less structured employee networks and norms that exist within the hiring company. Anticipatory socialization initiatives have become increasingly popular as a way to bridge the transition from the classroom to the work world. Indeed, it is estimated that three-quarters of all college students complete some form of an internship or cooperative education assignment during their academic careers.

Research assessment of anticipatory socialization programs has also expanded recently, reflecting greater interest both in the design of these programs as well as the consequences for individuals and organizations. In general, prior research has viewed anticipatory socialization programs as positive developmental experiences for high school and college students, having found linkages with a number of favorable outcomes. For example, anticipatory socialization assignments have been found to improve individual career decision-making self-efficacy, strengthen the crystallization of vocational self-concept, allow for the acquisition of job-relevant skills, and provide a comparative advantage in gaining full-time employment at graduation. In terms of postassignment effects, prior research has identified subsequent outcomes such as improved perceptions of job fit in the early career, greater objective success in the early career, greater job stability in the early career, and reduced feelings of entry or reality shock upon full-time employment.

In addition, anticipatory socialization assignments provide job experiences that are valued by hiring organizations and give the student greater self-confidence in securing full-time employment. Beyond these instrumental aspects, it is also believed that these assignments provide students with a greater degree of confidence over their job and career selections, since it is believed that the experience gives them the opportunity to develop a more accurate self-concept and test for a fit between their own individual characteristics and the demands of the real-world work environment.

Hiring organizations also benefit from anticipatory socialization programs. First, these programs provide a risk-free method to companies for evaluating prospective hires, and they provide a steady stream of motivated human resources who are comparatively less expensive than regular full-time staff. Furthermore, anticipatory socialization practices can help organizations gain a positive recruiting image and ensure an available pool of talented newcomers. They can also play a secondary recruiting role, since students returning to school can spread the word to other students that a particular organization is a favorable place at which to work.

The wide acceptance of anticipatory socialization programs by students, educational institutions, and employing organizations shows how these programs have become a popular and useful method for ensuring a fit between a prospective employee and the company doing the hiring. For the future, it is expected that anticipatory socialization activities will become more prevalent, given that they lead to improved career decision making and development for individuals and a better prepared and more committed workforce for employing organizations.

ANTISOCIAL WORK BEHAVIORS

Antisocial work behaviors are typically broadly defined as physical and verbal assaults, threats, coercion, intimidation, and various forms of harassment that occur in the workplace. Although the media and popular press often highlight lethal forms of antisocial work behaviors, research evidence clearly demonstrates that non-lethal forms such as those listed above are the most prevalent, problematic, and costly to individuals, organizations, and society. This entry outlines the theory, research, and evidence concerning the causes and consequences of antisocial work behaviors. Because nearly all of these behaviors are nonlethal and the evidence concerning causes and consequences is more firmly grounded in this domain, this review is limited to non-lethal forms of antisocial behavior.

Four perspectives can be used to explain why individuals engage in antisocial work behaviors and to describe the causes of antisocial work behaviors. First, the *organizational frustration approach*, based on the frustration-aggression model from psychology, suggests that certain environmental frustrators prevent or intrude on an individual's ability to achieve personal goals. Research demonstrates that any number of factors, such as job-related information, tools and equipment, materials and supplies, budgetary support, required services and help from others, time availability, role conflict, and work overload, can act as frustrators and trigger antisocial work behavior. A second perspective that can help explain antisocial work behavior is the *social learning model*. In this view, individuals can learn aggressive work behavior through direct experience or through observational learning. A supervisor, for example, may learn that work is completed quickly by subordinates if he or she threatens them. This direct experience may encourage the supervisor to engage in this behavior more frequently. Individuals also may learn from observing others. Using the preceding example, another supervisor may observe the threat or be told by the perpetrator that it is effective. If models of the behavior are rewarded, the observers may add that behavior to their repertoires. A third view is the *cognitive appraisal model*, which suggests that environmental factors (e.g., certain demands on the job) heighten emotions and lead to a search for the causes of the emotions. Because individuals tend not to believe that negative outcomes are self-caused, they

are likely to ascribe blame to other individuals and may lash out in return. A fourth perspective is the *justice view*, which suggests that distributive injustice (unfairness of outcomes), procedural injustice (unfairness of procedures), interactional injustice (unfairness in interpersonal treatment), and supportive cognitions prompt negative emotional reactions (e.g., anger, frustration) and may trigger a desire to “even the score” by engaging in antisocial work behaviors.

Research also suggests that several characteristics of individuals are related to antisocial work behaviors. People who are higher in terms of negative emotionality (a tendency to experience negative emotional states) or emotional susceptibility (a tendency to experience vulnerability, helplessness, and discomfort in response to even mild frustration) tend to engage in antisocial work behaviors more frequently. Higher levels of competitiveness, time urgency, and irritability, a constellation often referred to as the *Type A behavior pattern*, also relate positively to antisocial work behaviors. The personality dimension referred to as *locus of control* may also play a role depending on the situation. *Internals* (individuals who believe they are in control of their own destinies) are hypothesized to be more likely to engage in aggressive behavior in situations in which such behavior is seen as instrumental to obtaining a desired outcome, whereas *externals* (individuals who believe that fate, chance, or luck determines what happens to them) are proposed to engage in aggression in response to instructions from others or because they are provoked to anger and do not think of the effects of their actions.

In terms of the consequences of antisocial work behaviors, research shows that targets, witnesses, and survivors of workplace violence often report feelings of guilt, depression, vulnerability, suicidal thoughts, and increased levels of substance use. The impact of nonviolent or milder forms of antisocial work behaviors is also strong. Research clearly demonstrates that reactions to sexual and other forms of harassment, undermining, abuse, bullying, incivility, and petty tyranny include psychological distress, such as depression, high levels of somatic or minor health complaints, poor or negative job attitudes, low levels of commitment to jobs and organizations, low levels of job performance, and high levels of withdrawal behaviors. In addition, the negative effects of antisocial work behaviors on the attitudes, behaviors, and health of employees are much stronger or more potent than the positive effects on the outcomes of behaviors such as social support. Perhaps because they are much

rarer than positive interactions and events, the effects of antisocial work behaviors are much stronger than the effects of positive behaviors.

In addition to costs associated with being the target of antisocial work behaviors, the costs to organizations and society are also very high. One estimate places the cost of a single act of workplace violence at about \$250,000 per violent incident, in terms of lost work time and legal fees. Estimates regarding the costs of serious but nonphysical forms of antisocial behavior range from \$17,000 to \$24,000. Another estimate places the cost of antisocial work behavior on a broader scale (i.e., to the United States as a whole). This study suggests that the total cost of antisocial work behaviors to the United States is at least 1.75 million lost days of work and \$55 million in lost wages (in 1994 dollars).

Due to the implications of antisocial work behaviors for individuals and organizations, researchers are placing increasing attention on identifying the causes of such behaviors, as well as finding ways for individuals to effectively cope with being the targets, witnesses, or survivors of such behaviors in workplace contexts. This research not only continues to refine the definitions of the types of antisocial work behaviors but also continues to explore the magnitude and intensity of the outcomes of these behaviors.

APPRENTICESHIPS

An *apprenticeship* is defined as the service or condition of an apprentice, the state in which a person is gaining instruction in a trade or art, typically under legal agreement. The core definitional attribute of being an

apprentice is learning as a beginner, normally for a trade or an occupation. Formalized apprenticeships are viewed as a developmental sequence of supervised competency-based, work-based training of increasing independence for young adults seeking entry into the trades. Apprenticeships are widely available in many European and other countries but are used more narrowly in the United States. Within the context of career development, the concept of apprenticeship has become more widely applied to a variety of hands-on, work-based learning experiences for young adults and for high school youth as well. In recent years, the term apprenticeship has been applied to structured forms of mentoring and as a learning modality termed *cognitive apprenticeship*. Formal apprenticeships have been widely studied for their educational and economic benefits.

COGNITIVE APPRENTICESHIP

The concept of cognitive apprenticeship characterizes teaching and learning cognitive skills in various subject areas, by designing learning environments that incorporate content, pedagogy, learning sequence, and the sociology of learning. A cognitive apprenticeship is viewed as a prototype for effective education because it simulates how learning more naturally occurs through coaching and practice, with a focus on valued work and an integration of academic and vocational instruction. Many educational researchers have looked at the learning benefits of the cognitive apprenticeship method, with particular interest in its embedded learning, the scaffolding of instruction, the modeling and use of social and physical contexts, and the promotion of higher-order thinking and problem-solving skills. In recent years, the apprenticeship concept has also been applied to hands-on learning in academic and research programs for youth and adults.

APPRENTICESHIP SYSTEMS IN THE UNITED STATES

Apprenticeship systems have long existed in several occupational sectors in the United States, specifically, metalworking, construction, and the trades. Typically, apprenticeship sponsors, including employers, associations, unions, and governmental agencies, pay most of the training costs, including apprentices' wages. Sponsors provide on-the-job learning and academic instruction using recognized industry standards and licensing requirements. In 2003, there were 480,000 apprentices enrolled in 29,326 apprenticeship programs

across the nation. Further expansion of the adult apprenticeship system in the United States is hindered by difficulty in finding firms to sponsor apprentices and an inadequate infrastructure to support apprenticeships outside unionized trades. Over the past 20 years, several federal initiatives have attempted to expand apprenticeship opportunities nationwide in traditional partner industries such as construction and manufacturing, in new industries in health care and information technology, and in partnerships with U.S. military branches.

Hundreds of academic partnerships for apprenticeships exist with colleges that offer associate degrees, bachelor's degrees, and certifications. By the 1990s, 25 percent to 35 percent of two-year colleges provided the academic or general education portion of traditional apprenticeship programs, with a sponsor providing job-specific training at the work site, usually on a cyclical schedule. Most were in the established trades (e.g., machining, sheet metal working) and automotive, with some incorporating the unions in a three-way partnership. Students completing an apprenticeship program are certified and advance to journeyman status, as determined by the sponsoring agency and state.

YOUTH APPRENTICESHIP IN THE UNITED STATES

During the late 1980s and early 1990s, the creation of apprenticeship programs at the public educational secondary and postsecondary levels was viewed as key to addressing youth employment and educational difficulties in the United States. The goals of these programs were to reduce the increasingly lengthy and uneven transition of youth into gainful employment after high school and to create formal career development pathways. Such school-to-work transitions were becoming more difficult for poor and minority youth, who were experiencing prolonged unemployment and difficulty gaining access to potential jobs in a labor market that was increasingly demanding more skilled workers.

Various national and state proposals were made to revamp the existing secondary and postsecondary educational pathways to incorporate more general availability of apprenticeship options and progressions of occupational competence assessments. Many educators and policymakers studied youth apprenticeship systems of Germany, Japan, and other countries for replication, focusing on the benefits of fostering an equilibrium between labor market demands and

interests across a range of sectors in the economy and structured career preparation and skill development. The federal Commission on the Skills of the American Workforce proposed the creation of a system of standards and certifications for various occupations and a restructured secondary and postsecondary educational system that incorporated career internships and apprenticeships for non-college-bound youth as a means of more rigorously integrating career development into academic programs.

Even in the early stages of its revival, however, the feasibility and utility of youth apprenticeship were debated hotly. There was widespread concern that these programs would lead to unequal educational opportunities, particularly for low-income and educationally disadvantaged youth; that quality could not be monitored effectively; and that employers would be reluctant to participate.

Although a national youth apprenticeship policy failed in the early 1990s, some states revamped their systems to broaden apprenticeship options and workforce assessments in selected trades and industries. By the mid-1990s, several states had extensive youth apprenticeship programs in many occupational and technical areas. By 1994, an estimated 11 percent of all high schools had tech-prep (spanning secondary and postsecondary education) or other youth apprenticeship programs, primarily in technician-level occupations in industries with labor shortages, such as printing, hospitals, and manufacturing.

Aspects of a youth apprenticeship system became incorporated into secondary education by the fostering of more school-to-work career pathways locally and nationally and better articulation with postsecondary education for technical courses of study. Other improvements included more internship opportunities in secondary and postsecondary systems; career-focused programs of study, including career academics; revamped vocational studies; and tech-prep programs. Presently, youth apprenticeship continues to be promoted as one of a number of strategies to improve adolescents' contact with employers and colleges and promote the development of work-based readiness skills and achievement.

APPRENTICESHIP SYSTEMS IN EUROPE

Apprenticeship systems have been used widely in European and Asian countries, although they operate in a somewhat different manner than in the United States.

Germany created a dual system in which employers and the educational system share training and education responsibilities. In France, 50 percent of youth leave school with a certificate of professional aptitude that can lead to employment. Great Britain offers those leaving school one- and two-year paid apprenticeship training opportunities, while in Sweden, most adolescents select a general, vocational, or technical pathway in upper-secondary school. Currently, the apprenticeship system remains strong in Germany, especially in banking, because it reduces recruitment costs, enhances workplace flexibility, and fosters worker loyalty. Similarly, in Great Britain, Australia, and New Zealand, apprenticeships continue to be the primary means of training for skilled manual trades.

CURRENT RESEARCH ON APPRENTICESHIPS

Economists and labor development experts continue to examine the benefits of apprenticeship systems from several vantage points for workers, industries, and governments. Such studies have focused on the social rate of return of apprenticeship training to the employer, the apprentice, and the public sector and have considered the policy implications of shifting more of the costs of general training to the apprentices and the potential for increasing specialized training. Others have looked at employment transitions within various European countries and found apprentices have a better transition to their first jobs than do vocational school graduates.

Some educational researchers have examined apprenticeships for the nature of learning they reflect and for their utility as a means of vocational development. A primary research question is whether apprentice training is simply the acquisition of competency-defined skills or reflects vocational development that requires learning within a culture of practice. Others have found that workplace training such as an apprenticeship is more effective than classroom instruction in training employees. Finally, some researchers have shown that when apprenticeship programs are managed as jointly sponsored union-management programs rather than as unilateral employer-sponsored programs, it improves the retention of women as skilled-craft apprentices.

ARMED SERVICES VOCATIONAL APTITUDE BATTERY (ASVAB)

The *Armed Services Vocational Aptitude Battery* (ASVAB) is the most widely used multiple-aptitude test battery in the United States. CAT-ASVAB, the computer-adapted version of the ASVAB, is administered to all applicants to the U.S. armed services. Over one-quarter of all high school students eventually take the paper-and-pencil ASVAB through participation in the ASVAB Career Exploration Program.

The ASVAB consists of eight subtests (General Science, Arithmetic Reasoning [AR], Word Knowledge [WK], Paragraph Comprehension [PC], Auto & Shop Information, Mathematics Knowledge [MK], Mechanical Comprehension, and Electronics Information), which provide a broad and comprehensive view of the aptitude domain. The Armed Forces Qualification Test, a measure of intelligence (*g*), consists of the combination of AR, MK, WK, and PC. Norms are based on a nationally representative sample of individuals who participated in the 1997 National Longitudinal Survey of Youth (NLSY97), sponsored by the U.S. Departments of Labor and Defense. The paper-and-pencil and CAT versions of the ASVAB are psychometrically equivalent to each other.

The ASVAB is one of the most well-respected and well-researched tests in modern history. Literally hundreds of studies have demonstrated its substantial psychometric and statistical characteristics, its ability to predict success both in military and in civilian

occupations, and its strong relationships with other aptitude and achievement tests and measures. Extensive research demonstrates that the ASVAB is a valid predictor of success in military training, first-term attrition, and job performance in military occupations. Similarly, extensive national studies have also demonstrated the test's ability to predict success in a wide array of civilian occupations. Virtually all published reviews of the ASVAB agree that it represents the state of the art for aptitude and achievement testing. Psychometrically speaking, the ASVAB is probably the most technically advanced and sophisticated test battery in the world.

ASVAB CAREER EXPLORATION PROGRAM

Started in 1968, the ASVAB program provides a comprehensive vocational assessment package at no cost to participating schools or to their students. Funded entirely by the Department of Defense, this comprehensive program contains the Interest-Finder, a measure of career interests, the ASVAB, and a number of exercises that help students identify and investigate occupations for which they show both interest and ability. The ASVAB program fulfills two major purposes. First, it provides age and developmentally appropriate materials to support high school and postsecondary educational and career counseling. Second, the program is useful to the military services by helping to identify interested students who meet the qualifications for entrance into the U.S. armed forces.

The ASVAB program was designed to meet the career development needs of twenty-first-century high school students in two ways. First, relevant occupational information from the U.S. Department of Labor's Occupational Information Network (O*NET) was incorporated into the ASVAB program. Second, three broad skill areas, verbal skills, math skills, and science and technical skills, are used in the occupational search process. Because of its skill-based occupational linkage, the ASVAB program presents a full spectrum of career opportunities to all students, regardless of gender, ethnicity, or ability level.

Relying on the ASVAB's well-established capacity to assess the ability to learn new skills and predict success in a wide variety of jobs, the program views students' ASVAB scores as snapshots of their knowledge, skills, and abilities (KSAs) in the verbal, math, and science and technical skills domains. ASVAB-based KSAs have been linked to equivalent O*NET

importance-based KSAs through expert judgment. Based on this linkage, students can compare their current skills profiles (i.e., verbal skills, math skills, and science and technical skills) with the corresponding skill-importance profiles for more than 400 occupations in the O*NET database. This approach is particularly helpful for students with differing levels of skills in these three areas, and it provides a flexible approach to career exploration.

ASPIRATIONS IN CAREER DECISIONS

The *American Heritage Dictionary* defines *aspiration* as a strong desire for high achievement, or an object of this desire. According to this definition, an aspiration is either the desire to achieve an end state or the end state itself (goal). Theoretical interpretations of aspirations encompass both elements of the above definition. Researchers have defined the concept of aspiration as an expectation or goal comprising intentions and attitudes. An intention is a plan of action undertaken to achieve a particular goal, whereas an attitude represents one's personal orientation toward a goal. Thus, the intention to pursue the goal and the attitude toward the goal comprise an individual's aspirations. Career aspirations are the desire and intention to pursue an occupation or a particular position within an occupation. Aspirations play an important role in career decisions because they reflect the goals and intentions that influence individuals toward a particular course of action.

Aspirations develop over time. Throughout childhood and adulthood, individuals dream of places they

would like to go, things they would like to experience, and ideas they would like to test. Adults often ask children, "What do you want to be when you grow up?" The younger the child, the less realistic the answer usually is (e.g., "I want to be a princess"). As young people grow, their vocational preferences begin to take on more realistic shapes. Individual characteristics such as sex, race, and social class may influence these vocational preferences.

The hopes and dreams of young adulthood often crystallize as career aspirations through experiences in the workplace. At work, individuals gain a sense of their own interests and abilities and begin to gravitate toward tasks, jobs, and occupations that most closely match their preferences and talents. Cognitive factors that are salient at work, such as valuing rewards associated with particular positions and feeling comfortable performing certain types of tasks, influence career aspirations and, ultimately, career decisions.

Career decisions are internal processes that allow individuals to analyze various alternatives and, finally, to accept or reject them. Career decisions may be broad, such as what type of occupation to enter, or narrow, such as whether to accept a promotion that will require relocation. Aspirations are a component of many career decision models because they represent the commitment an individual makes toward a particular course of action, and they also serve as the basis for feelings of success, a facilitator of career decisions. An individual's experiences and the degree of success and failure associated with those experiences depend on whether the achievement is above or below an expectation or level of aspiration. The level of aspiration is fundamental for the experience of success and failure, and, ultimately, changes by success and failure.

An individual is more likely to feel successful when he or she sets a challenging goal (high level of aspiration) and is able to determine his or her own means of attaining the goal, the goal is important to the individual's self-concept, and the goal is actually attained. Thus, experiencing feelings of success is a fundamental component of an individual's career aspirations.

Career decision-making models that describe how individuals actually make decisions encompass aspirations and the related feelings of success. These descriptive models conceptualize the process of decision making as a sequence of cognitive events. The sequence begins with collecting information, assessing the information, and predicting outcomes of various courses of action in terms of probability and

desirability, identifying alternatives, evaluating and selecting, and implementing the decision. The essential cognitive components involved in the career decision-making process include the outcome (goal or aspiration), the value of the outcome (importance of the goal or aspiration to the individual), and the likelihood of achieving the outcome (success or failure).

Descriptive career decision-making models assume that individuals choose careers believed to result in the greatest personal benefit, provided they believe that there is a good probability they can actually obtain positions in those careers. More specifically, an individual is likely to decide on a career if the career choice holds valuable outcomes, the individual feels that entering into that career can attain the outcomes, and the individual believes that there is a high probability he or she will be able to enter into that occupation. Therefore, aspirations form the component of the career decision-making process that inspires individuals to engage in career-related behaviors as long as they are positively reinforcing.

A prevalent theme in career decision-making theories is that optimal career outcomes arise from the fit between individual characteristics and the rewards and demands of the job. For example, major determinants of job success are an individual's abilities and skills, whereas predictors of job satisfaction include an individual's needs, values, and interests. Career aspirations operate internally to encourage individuals to develop skills that they value, seek out environments in which they can successfully apply these skills, and receive rewards in ways that are meaningful to them.

An understanding of the developmental nature of aspirations and its effect on career decisions is important to individuals and organizations. Individuals must first be able to envision the outcomes associated with a career choice before they engage in activities that will lead to a decision. The experiences of success and failure associated with various job tasks will help to steer individuals toward or away from particular goals. Individual support mechanisms, such as a supervisor's support of an individual's career aspirations and encouragement to accept appropriate developmental assignments, can help individuals further crystallize their career aspirations. A clear understanding of one's aspirations will lead to more successful career decisions.

Organizational mechanisms such as performance management, training, and career development systems designed to foster the exploration of aspirations will support staffing, knowledge management, and

succession-planning initiatives. Furthermore, recruiting costs (both implicit and explicit) decrease when promotion takes place from within the ranks of an organization. Fitting the right individuals with the right jobs can increase career satisfaction, job involvement, and organizational commitment.

ASSESSMENT CENTERS

Although a center is typically a place where something occurs, an *assessment center* is not so much a place as it is a method. A key principle of this method is *multiple-attribute assessment*. That is, assessment focuses on multiple attributes or dimensions relevant to an individual's overall performance. Another key principle is that assessment is not based on any single method. Rather, evaluations are derived from assessment across multiple methods. In an assessment center procedure, an individual's performance is observed in multiple situations or exercises. Performance across these exercises serves as the basis for an assessment of several performance-related dimensions. A unique characteristic of this approach is that small groups of people are evaluated simultaneously, as opposed to one person at a time. Another important characteristic of the assessment center approach is that final assessments are usually made by a group of assessors observing performance and working together to reach a consensus.

ASSESSMENT CENTER BACKGROUND

The history of assessment centers as a formal approach to assessment begins with the work of the World War II era Office of Strategic Services (OSS). A wartime intelligence agency, the OSS was concerned with the selection of officers for intelligence positions. Candidates for these positions were evaluated in a week of interviews, tests, and exercises intended to ascertain whether they had the necessary capabilities (e.g., mental ability, motivation, physical stamina, emotional stability, stress resistance). Following the war, AT&T modified and adapted this approach for use in managerial selection. AT&T's managerial assessment centers demonstrated considerable value in predicting advancement through the organizational hierarchy. As a result, the assessment center has traditionally been viewed as a tool for selection into managerial jobs. However, given that multiple individuals are evaluated simultaneously, assessment centers are particularly advantageous for direct evaluation of interpersonal variables. Consequently, assessment centers are a potentially valuable selection tool for any jobs in which social skills are of particular importance and thus are being used more frequently for purposes other than managerial assessment. Today, assessment centers are used in numerous private and public organizations to evaluate thousands of people each year. For example, assessment centers have been used to evaluate salespeople, teachers and principals, engineers, rehabilitation counselors, police officers and firefighters, and various customer service positions, as well as for managerial selection. They have also been used to assist high school and college students with career planning. In addition, while predominately used as a selection tool, the use of assessment centers for training and development purposes has increased dramatically. Specifically, assessment centers are often used as a tool for identifying individuals' relative strengths and weaknesses with respect to key performance domains.

ASSESSMENT CENTER DIMENSIONS

Most assessment centers are designed specifically for the jobs and/or organizations in which they are used. Assessment center "dimensions" are typically developed around organizationally specific values and practices derived from a systematic analysis of the job and/or organization. Thus, specific assessment centers are

relatively idiosyncratic with respect to the performance dimensions being assessed. The dimensions might represent personal traits, job-specific competencies, or general knowledge or skill constructs. A recent review of the assessment center literature, for example, compiled a list of more than 168 different labels for performance dimensions assessed across different assessment centers. However, examination of these labels indicated that the vast majority of these dimensions could be assigned to one of seven general categories. These categories are communication skills, problem-solving skills, consideration and awareness of others, ability to influence others, organizing and planning ability, drive, and tolerance for stress or uncertainty.

Assessment related to *communication skills* focuses on the extent to which an individual conveys oral and written information and responds to questions and challenges. *Problem solving* focuses on the extent to which an individual gathers information; understands relevant technical and professional information; effectively analyzes data and information; generates viable options, ideas, and solutions; selects supportable courses of action for problems and situations; uses available resources in new ways; and generates and recognizes imaginative solutions. *Consideration and awareness of others* focuses on the extent to which an individual's actions reflect a consideration for the feelings and needs of others as well as an awareness of the impact and implications of decisions relevant to other components both inside and outside the organization. *Influencing others* focuses on the extent to which an individual persuades others to do something or adopt a point of view in order to produce desired results, and takes action in which the dominant influence is the individual's own convictions rather than the influence of others' opinions. *Organizing and planning* focuses on (a) the extent to which an individual systematically arranges his or her own work and resources as well as that of others for efficient task accomplishment and (b) the extent to which an individual anticipates and prepares for the future. *Drive* focuses on the extent to which an individual generates and maintains a high activity level, sets high performance standards and persists in their achievement, and expresses the desire to advance to higher job levels. And finally, *tolerance for stress or uncertainty* focuses on the extent to which an individual maintains effectiveness in diverse situations under varying degrees of pressure, opposition, and disappointment.

ASSESSMENT CENTER EXERCISES

Assessment center exercises are performance tests designed as samples or abstractions of the jobs for which individuals are being assessed. While assessment centers typically do not include high-fidelity work samples or simulations, the exercises are designed to reflect major job components. Although there is a great deal of variability across assessment centers with respect to the exact content of exercises, the form of these exercises is relatively consistent. Almost all assessment center exercises may be classified with respect to six different types: leaderless group discussions, in-basket exercises, case analyses, interviews, presentations, and one-on-one role play.

Leaderless group discussions are probably the most commonly used and well-known assessment center exercises. There are many variations of this type of exercise. Typically, a group of four to eight participants is given a problem to solve, a time limit in which to do so, and a requirement to develop a written solution agreed to by all members of the group. Specific roles may be assigned to the various group members. However, no one is assigned the role of leader or chair. Rather, leadership behaviors must emerge during the discussion. A common variant of these exercises is the competitive leadership group discussion, which adds the requirement of persuading others to adopt a particular solution or outcome while still maintaining the requirement of a consensus decision.

In-basket exercises are another commonly used exercise. These exercises are not group exercises. Rather, they are designed to simulate administrative work and are performed individually. They usually include a simulated set of memos, messages, e-mails, letters, and reports, such as might accumulate in a manager's "in-basket," as well as other reference material (e.g., organizational charts, personal calendars). The materials are usually interrelated and vary with respect to complexity and urgency. Participants are typically asked to play the role of a person new to the job, working alone with the goal of trying to clear the in-basket. Scoring protocols differ across in-basket exercises but often include a follow-up interview in which participants are asked to explain their approaches to the exercise and reasons for actions taken.

Although leaderless group discussions and in-baskets are the most commonly used exercises, many assessment centers include other exercises, such as one-on-one role play, case analyses, and presentations.

In addition, assessment centers often include interviews. Unlike more typical employment interviews, however, interviews used in assessment centers are usually highly structured and may incorporate role play or other simulated components.

Typical assessment centers include three to five exercises to assess anywhere from 3 to 25 performance dimensions. Exercises may be of different types or variations of a common type (e.g., a competitive and a non-competitive leaderless group discussion). Similarly, dimensions may represent different major categories (as presented above) or subcomponents of the major categories (e.g., oral communication and written communication). The general strategy is for exercises and dimensions to be crossed such that each exercise allows for an assessment of each performance dimension. Often, however, particular dimensions are not assessed in a particular exercise (e.g., written communication may not be assessed in an interview).

Participants in an assessment center are observed by one or more "assessors" in each of the exercises. Assessors observe and record participant behaviors relevant to each performance dimension to be assessed. An assessor may also directly interact with participants either as a role player or as an interviewer. After all of the exercises have been completed, assessors typically meet as a group to review and discuss each participant's performance across exercises. The goal of this discussion is to generate a consensus rating representing each participant's standing on each performance dimension. In addition, an overall performance rating may be generated.

ASSESSMENT CENTER DESIGN

Although there is a great deal of variability with respect to the design and implementation of assessment centers, several design issues are important for the ultimate success of the assessment process. These issues are the number of performance dimensions assessed, the number of assessors needed, assessor qualifications, and assessor training.

As noted above, the number of performance dimensions evaluated in a given assessment center ranges from 3 to 25, but the average number of dimensions included is approximately 9. However, research suggests that assessors may have difficulty differentiating among a large number of performance dimensions. In one study, assessors were responsible for rating 3, 6, or 9 dimensions. Those assessors who

were asked to evaluate 3 or 6 dimensions provided more accurate assessments than those asked to rate 9 dimensions. This suggests that when asked to evaluate a large number of dimensions, the demands placed on assessors may make it difficult for them to process information at the dimension level, resulting in less accurate assessments. It appears that 5 to 7 may be an optimal number of dimensions to include in a given assessment center.

A similar concern exists with respect to the number of assessors needed to effectively evaluate participants. That is, as the number of assessment center participants any given assessor is required to observe and evaluate in any given exercise increases, the demands placed on assessors make it more difficult to evaluate each participant. Although some assessment centers have required each assessor to simultaneously observe and evaluate as many as four participants, the typical ratio of participants to assessors is 2:1. Exceeding this ratio should be considered very carefully.

Another potentially important design factor focuses on the assessors. What qualifications should assessors have? Assessors may be psychologists, human resource specialists, job incumbents, or managers. Assessor teams may also be some combination of these. In general, assessors should be good observers, objective, and articulate. Some authors posit that as a result of their education and training, psychologists and similarly trained human resource professionals are better equipped to observe, record, and evaluate behavior. Alternately, managers and other job incumbents or experts may have more practical knowledge with respect to the job as well as the organization and its policies. There are both costs and benefits associated with different types of assessors. These costs and benefits must be weighed carefully in the assessment center design process.

Regardless of assessor qualifications, assessment center ratings are obviously inherently judgmental in nature. Consequently, training assessors is a crucial element in the development and design of assessment centers. A recent review of assessment center practices indicates that assessors may receive anywhere from one day to two weeks of training. In addition, the type of training is also an important consideration. For instance, there is a consensus in the literature that frame-of-reference training is a highly effective approach to assessor training. *Frame-of-reference training* typically involves emphasizing the multidimensionality of performance, defining performance dimensions, providing a sample of behavioral incidents representing each dimension (along with the

level of performance represented by each incident), and practice and feedback using these standards to evaluate performance. The goal of frame-of-reference training is to train assessors to share and use common conceptualizations of performance when making evaluations. However, irrespective of the training approach used, more extensive assessor training is generally associated with more effective assessment.

ASSESSMENT CENTER VALIDITY

In general, assessment centers demonstrate positive utility as a tool for selection as well as training and development. A great deal of research has examined the validity of assessment center ratings with respect to job performance. Content-related methods of validation are regularly used in assessment center development in an effort to meet professional and legal requirements. In essence, both dimensions and exercises are derived from a content sampling of the job. An important component of a manager's job, for example, may be participating in meetings with peers. Leaderless group exercises serve as a representation of this aspect of the job. Evidence supporting the criterion-related validity of assessment center ratings is also consistently documented. Research suggests that assessment center ratings of specific performance dimensions as well as overall assessment center ratings can predict job-related criteria such as supervisory performance ratings, sales performance, promotion rate, and salary progression. Evidence for the construct-related validity of assessment center dimensions, however, has been less promising. Specifically, assessment centers are designed to evaluate individuals on specific dimensions of job performance across situations or exercises. Research, however, has indicated that exercise rather than dimension factors emerge in the evaluation of participants. Thus, a lack of evidence of convergent validity, as well as a partial lack of evidence of discriminant validity, has been extensively reported in the literature. These findings have led to a prevailing view that assessment center ratings demonstrate criterion-related validity, while at the same time lacking construct-related validity. Research continues to examine this issue, since it is inherently inconsistent with the current unitarian view of validity.

Over the past several decades, assessment centers have enjoyed increasing popularity. The validity of assessment centers is undoubtedly partially responsible for their popularity. In addition, assessment centers tend to be well accepted by both organizational

decision makers and participants. This approach to assessment can be quite labor-intensive and thus quite costly. In addition to the time required of the participants, assessment centers require a considerable investment of time on the part of assessors. Despite these costs, assessment centers present a unique tool for the assessment of individual differences.

ASSIMILATION AND MUTUAL ACCEPTANCE

Organizational *assimilation* is a necessary process that benefits both organizations and newcomers. Some perceive assimilation to be a negative necessity in

organizational life. This unenthusiastic view stems from a conceptualization of assimilation as newcomers conforming to existing organizational norms and rules, thereby stripping neophytes of their individuality. Essentially, newcomers are coerced into conformance by more powerful organizations. However, as will be discussed, assimilation involves not just newcomers' adjustment but also involvement from others within the organization, especially the immediate work group, a recursivity entailing *mutual acceptance*.

Assimilation is the process by which individuals become integrated into the culture, social network, and role system of an organization. Fredric Jablin has argued that assimilation is largely a mutual communicative exchange whereby individuals accept the rules and norms of organizations and begin to identify themselves as being a part of their organizations. Karen Myers and John Oetzel's model of organizational assimilation depicts six processes associated with transitioning from outsiders to insiders. *Becoming familiar with others* enables the development of productive working relationships. *Acculturating and adapting* refers to learning about the culture and normative behaviors and adapting to them. *Becoming involved* causes newcomers to feel like contributing members. *Feeling recognized by others* confirms the new members' value to the organization. *Learning job skills* enables members to feel productive in their new roles. Finally, *role negotiating* involves attempts by the newcomer to revise the role and its associated performance expectations.

Jablin's definition and the Myers and Oetzel model suggest that while assimilation may require newcomers' adaptation, others in the organization must be involved in socializing newcomers and accepting them into the organizational social system. Although newcomer adaptation is central, others in the social system also are dynamically involved in training and introducing newcomers to the culture and normative behaviors. Most important, incumbents are involved in accepting newcomers into the organizational system. Without such acceptance, established members are unlikely to make extra efforts to enable newcomer integration, such as introducing recruits to crucial social knowledge and involving them in group interactions, helping newcomers to feel that they belong. Stated differently, new members cannot "integrate" without acceptance from others in the group and organization, who also must adapt to newcomers to enable their assimilation.

Others in the organization, and in particular in the immediate work group, have the ability to either

accept or reject the newcomer, thereby enabling or disabling the process. For example, imagine a new employee who has just joined an organization and wants to fit into existing organizational social circles. He may sincerely want to assimilate, attempting to adopt normative work habits and generally behave like the others in his immediate work group, but until he is accepted by fellow workers, he cannot assimilate. The newcomer's opinions might not be solicited, and he might not be included in work group conversations. Until the new recruit receives accepting communication from his peers welcoming him into the social circle, he will not be integrated into the social network. Therefore, newcomers do not assimilate in a vacuum; rather, assimilation requires mutual acceptance on behalf of the newcomer and incumbents in the organization or group.

In this sense, there is a "duality" to organizational assimilation. The significant practices bound up in assimilation (newcomers' uncertainty and cultural alignment with the organization coupled with group/organizational members' acceptance and adaptation) are accomplished through underlying structural principles (conformance; socialization turning points, such as intern reviews; organizational knowledge and routines, etc.), which do not merely enable the assimilation practices we observe but also recursively reproduce the structures involved to produce and transform them.

As new employees assimilate, shaping their behaviors to "the way things are done" within the organizations serves a larger, essential function. Recruits bring with them behaviors and assumptions acquired from previous work and life experiences and thus can bring about positive changes to the organization. They can be sources of novel ideas that bring about change in perspectives, behaviors, and goals within their work groups, even throughout the organization. Of course, novel perspectives and behaviors can also impede effective coordination. To ensure the organization's long-term success, organizations must train and mold recruits into valuable assets that will benefit the organization and also blend into the existing culture. Therefore, organizations introduce newcomers to "the way things are done" with the dual purpose of shaping newcomers into loyal members and easing coordination of activities between new and existing workers.

Integrating into an organization involves learning how to perform necessary job duties, but equally important are recruits' needs to reduce uncertainties they feel during entry and to determine how they can assume desired organizational roles. These uncertainties often surround more subjective aspects of getting along in the workplace, such as behaving in accordance with existing standards of behavior, customs, politics, and generally accepted ways of thinking and feeling. Grasping and accepting what is considered "normal" inside the organizational culture is a significant part of assuming new organizational roles. In fact, in some cases, recruits seek out and desire more structure and guidance to help them resolve ambiguity and learn how to behave and communicate.

In conclusion, organizational assimilation is a necessary process that involves acquiring shared member understandings in order to perform in ways that will contribute to organizational practices. Acquiring this knowledge enables new members to reduce the uneasiness of transitioning into organizations. At the same time, incumbents permit assimilation by accepting newcomers as fellow organizational members. Thus, assimilation is more complex than newcomers' abandoning individuality and succumbing to organizational requirements to be accepted. Instead, organizational assimilation is a recursive process involving newcomers and others in the organization. Mutual acceptance enables newcomers to become integrated into the organizational system and assume full membership.

B

BENNETT MECHANICAL COMPREHENSION TEST

The Bennett Mechanical Comprehension Test (BMCT) measures aptitude to comprehend mechanical applications in realistic situations. The original form was published in 1940 by the Psychological Corporation and was developed to aid in training and employee selection as well as job performance predictions.

Currently, Form S and Form T of the BMCT are available. These forms were developed from previous forms and updated by editing the wording of earlier versions and increasing the range of item difficulty of questions. The two versions of the forms, S and T, are comparable. Both forms contain 68 items, each covering 18 categories of mechanical comprehension.

The BMCT is a paper-and-pencil test that contains items composed of pictures of simple mechanical concepts and questions regarding the pictures. Results can be used to discriminate aptitude in a range of mechanical applications as well as the level of comprehension of each application. The test also has been formatted into a videotape version for those with reading skills below the test's sixth-grade reading level. A paper-and-pencil version in Spanish to be used with non-English-speaking test takers is also available.

Reliability evidence is provided in the 1994 *Manual for the Bennett Mechanical Comprehension Test*, by George K. Bennett. The split-half reliability for both forms on samples of skilled-trade job applicants and technical and academic high school students ranges from .81 to .93. In addition, research found no practice effects after taking either Form S or Form T

in close succession with an older version (BB) of the BMCT that included some items identical with those on the later forms.

Evidence of the validity of the BMCT includes scores on the BMCT Form S and Form T that correlated .63 with a job knowledge test for operators at a chemical plant. In addition, Michael Mount and his colleagues found, for two samples of college students in a laboratory work study, that scores on the BMCT correlated .58 and .51 with a simple mechanical task and .55 and .62 with a complex mechanical task. Research by Paul Muchinsky also found that compared with the Flanagan Aptitude Classification Test-Mechanics and the Thurstone Test of Mental Alertness (Form A), the BMCT was the best predictor of job performance for an electromechanical-manufacturing employee sample.

In addition, evidence of convergent and discriminate validity has been shown for the BMCT. For example, BMCT scores correlate .74 with the U.S. Army's Mechanical Aptitude Test scores and .66 with scores on the College Board Spatial Relations test. On the other hand, scores on the Cooperative Reading Test correlate .14 with scores on the BMCT. The BMCT was developed for use in employee selection for jobs demanding mechanical comprehension. In addition, it has been used to predict performance in jobs requiring mastery of mechanical principles. The 1994 test manual also suggests that the BMCT can be used as a measure of training program effectiveness and for employee career services.

BICULTURALISM

Biculturalism refers to an individual's ability to interact competently in two different or disparate cultural systems. Cultural systems are based on ideas, values, beliefs, and knowledge learned and shared by individuals within the same culture and can include those based on national origin and ethnic background. The meaning derived from cultural systems represents shared perspectives and expectations that serve as interpretative frames to influence individuals' affects, cognitions, and behaviors. Research on biculturalism seeks to understand the processes and outcomes associated with individuals who have membership in two distinct cultures and engage in interactions in both cultures. To a lesser extent, the research also considers monocultural individuals participating in cross-cultural exchanges.

Research has determined that besides having other characteristics, culturally competent individuals (a) possess strong self-identities, (b) are knowledgeable of and have facility with the beliefs and values of their cultures, (c) display sensitivity to the affective processes of their cultures, (d) communicate effectively in the language of the target cultural group, (e) perform culturally and socially sanctioned behavior, (f) maintain active social relationships within the cultural group, and (g) effectively negotiate the institutional structures of the target culture. Cultural competence is not a categorical construct such that one is either completely or not at all competent. Indeed, the literature on biculturalism has found significant variance in the manner in which individuals experience and manage multiple cultural systems. However, it is generally suggested that the more levels in which an individual is competent within two cultures, the fewer problems he or she will encounter in operating effectively within those cultures.

Biculturalism scholars assert that individuals who live within and move between two cultural systems can possess dual cultural identities and engage in real-time cultural frame switching, whereby they move between different cultural perspectives in response to environmental cues. For example, research has shown that when primed with either Western or Asian cultural cues, Hong Kong and Chinese American bicultural people exhibit behavior characteristic of Western or East Asian people, respectively. In other words, bicultural people can access and switch between multiple cultural meaning systems and appropriate sets of behavior depending on the context. Recent research has determined that while some bicultural individuals perceive their cultural identities as compatible and perhaps even complementary, others perceive these identities as being in conflict with one another. The extent to which bicultural identities are integrated within an individual's self-concept is referred to as *bicultural identity integration*, and the degree of this integration has been linked to cognition, attributions, and behavior.

Biculturalism research has emerged from the theorizing of scholars such as W. E. B. DuBois and the consideration of *double consciousness*, based on the experience of secondary cultural immersion experienced by various immigrant groups in the United States (e.g., African slaves, Chinese laborers). As of the writing of this entry, research on the impact of biculturalism on career and organizational outcomes is at an early stage and draws on research examining effects associated with biculturalism in the disciplines of anthropology, education, clinical and social psychology, and sociology. Research across these disciplines has tended to find positive associations between biculturalism and psychological well-being, and educational and professional motivation and achievement. Recent research has established that bicultural experiences can exert significant influence on career identity development among Black and White women in the United States, with implications for these women's expectations and management of majority colleagues and their own career progression. Other career development research among bicultural women has found that Black professional women have complex life structures and that some include a high degree of compartmentalization to manage bicultural demands. In other words, to manage the stress of disparate expectations between their professional or mainstream cultures and their initial cultures, some

women maintain clear barriers between their professional identities and interactions and their personal lives and nonprofessional identities.

Biculturalism may also be understood in contrast to other primary models of second-culture acquisition, including assimilation and acculturation. *Assimilation and acculturation* comprise processes whereby a new cultural identity based on the beliefs, values, and norms of the dominant or high-status culture supplants an individual's initial cultural identity. These models assert that marginalization is a result of bicultural contact and identification until the individual is successful in achieving full assimilation or acculturation within the dominant or mainstream culture. Outcomes associated with these models of cross-cultural contact and cultural competence ideally include integration into the mainstream culture and society; however, social marginalization and generally negative economic and psychological effects on individuals have often been found.

Accordingly, at least two sources of conflict may arise for individuals attempting to assimilate or become acculturated in new or secondary cultures. First, they face the psychological and cognitive stress of monitoring and switching between cultures. Second, they face the likelihood of rejection from the dominant or majority cultures. These individuals may also be rejected by members of their initial cultures for exhibiting dominant-culture values, such as education and career aspirations, or because of other perceived violations of the initial cultures' norms, which may include disparagement or suspicion of dominant cultures. The resulting marginalization, or awareness of partial membership in two cultural systems and a lack of full acceptance in either culture, is theorized to lead to psychological conflict and a divided self. Biculturalism scholars, however, assert that people who live at the juncture of two cultures do not inevitably suffer.

Of note to human resource professionals and others with an interest in organizational and career effectiveness are research findings indicating that in contexts in which different cultures are in intimate contact (i.e., multicultural contexts), biculturalism has been associated with favorable outcomes. Individuals with greater levels of bicultural competence have been found to exhibit less stress than those with less bicultural competence in cross-cultural and culturally ambiguous contexts. For example, biculturally competent and identified Asian American and Latin American students

(including university students) have demonstrated motivation and achievement advantages, in addition to less psychological stress, relative to bicultural Asian and Latin American students who are nonidentified or choose to identify exclusively with either their initial/ethnic or the mainstream (U.S.) culture.

Other research examining outcomes associated with bicultural education and training initiatives has found greater improvement in cross-cultural skill level and efficacy among mainstream society members (e.g., Whites in the United States) than among societal minority members. These results are consistent with research in human resources that recommends bicultural training for expatriates and other individuals who cross cultural boundaries as a part of fulfilling their organizational roles. This includes host country language and cultural training related to social values and norms. Similar training has also been called for to develop skills associated with minority subcultures for mainstream students and rank-and-file organization members (e.g., White students and employees in U.S., Canadian, and Australian schools and organizations) who must work with, manage, and be managed by individuals belonging to societal subcultures. Increasingly diverse consumer and labor pools and the increasingly global nature of work may render bicultural competence a valuable asset for career development and progress.

BIG FIVE FACTORS OF PERSONALITY

People differ in many respects, some important, some trivial. Personality traits are among the individual-difference characteristics that are important and powerful in explaining human behavior in the world of work. Myriad psychological characteristics can be used to describe people and distinguish them from one another. For example, in the English language, in excess of 12,000 words can be used to describe psychological characteristics of individuals and their tendencies to think, feel, and behave in certain ways. Many of these words are adjectives that refer to individuals' personality characteristics. For example, we can describe individuals as introverted versus extraverted, hardworking versus lazy, friendly versus hostile, anxious versus relaxed, or curious versus un-inquisitive.

Research examining how various personality characteristics relate to one another has led to the widely accepted conclusion that they can all be clustered under the umbrella of five broad personality dimensions. These five broad categories of personality attributes have become known as the *Big Five personality dimensions*. Adjectival descriptors of these five dimensions are referred to as the *Big Five factor markers*. Each dimension of the Big Five encompasses a group of traits that are more closely related to one another than to traits from the other dimensions.

The Big Five dimensions of personality are (1) Emotional Stability, (2) Extraversion, (3) Openness, (4) Agreeableness, and (5) Conscientiousness. The names of these dimensions sometimes vary by preferences of the researcher and author. For example, some authors prefer to refer to the third dimension as Intellect or Intellectance, rather than Openness. Others prefer to refer to Emotional Stability by its opposite, Neuroticism. Nonetheless, for the most part, the contents of the five dimensions overlap across the many different conceptualizations of personality.

The Big Five dimensions of personality have been useful in providing a framework for organizing

personality attributes used in industrial, work, and organizational psychology research and practice. They have been investigated in relation to many areas of interest, including occupational attitudes, behaviors, and outcomes. For example, studies have linked characteristics from the Big Five framework to occupational interests, finding employment, career success, job performance, and job satisfaction. The first part of this entry presents a brief history of the Big Five dimensions of personality. Then, each Big Five dimension is described. The entry concludes with a review of the relevance and usefulness of the Big Five in work and career contexts.

A BRIEF HISTORY OF THE BIG FIVE

Personality characteristics existed long before human beings made their entry into this world and have probably existed for as long as most animals. In fact, personality characteristics have been documented in chimpanzees, gorillas, monkeys, hyenas, dogs, cats, donkeys, pigs, rats, guppies, and even octopuses. *Personality* can be viewed as a relatively stable, enduring psychological characteristic of any moderately complex being, be it human or nonhuman.

Personality descriptions have existed in human language since the very beginning of verbal communication. However, the questions of how these characteristics relate to one another and whether there is an organizational scheme that can be used to reduce the vast number of personality attributes to a parsimonious set have been scientifically considered only in the last 100 years or so. In examinations of personality structure, it is necessary to make a distinction between the development of theoretical models representing underlying individual differences in personality and the development of taxonomies of how trait-descriptive terms of personality characteristics are encoded in language. A *theoretical model* describes how personality traits manifest themselves in observable behaviors and outcomes, whereas a *taxonomy* merely provides a framework for clustering similar traits. The origin of the Big Five can be found in the latter: a taxonomy provided by the natural language of personality description.

Sir Francis Galton was the first to propose the idea that the most important characteristics of individuals are captured in the words that people use to describe each other and thus become embedded in languages around the world. This is referred to as the *lexical hypothesis*. Using *Roget's Thesaurus*, Galton identified

and cataloged personality descriptors. The lexical hypothesis was utilized in the 1930s by psychologists Gordon W. Allport and Henry S. Odbert, who used the second edition of *Webster's Unabridged Dictionary* to identify and catalog over 17,000 words that distinguished one person from another. They sorted these words into groups: personal traits, evaluative and metaphorical words, temporary states, and moods. More than 4,500 words were found to be descriptive of personality traits. In the 1940s, Raymond B. Cattell examined these trait-descriptive words and reduced them to 35 traits, each of which was described by clusters of adjectives and phrases. In the 1960s, Warren T. Norman studied the personal-trait words from Allport and Odbert's effort and judged about 3,500 of these words to be related to stable personality characteristics. However, such lengthy lists were simply too long and cumbersome to be useful for applied and scientific purposes. Thus, the task was to discover whether these words could be organized into a scientific taxonomy of smaller, more meaningful groups.

A descriptive model or taxonomy is vital if personality psychology is to advance as a science. Over the years, personality has been conceptualized from various taxonomic viewpoints. In fact, there have been so many conceptualizations of personality and so many tests and scales used to measure them that the less enthusiastic (some say more pessimistic) researchers have compared conducting research in personality psychology to building the Tower of Babel. Approaches to integrating seemingly diverging models that aim to make sense of varying postulated factor structures should be commended, as they will enhance knowledge of the personality domain and increase our ability to hypothesize important relationships. Without a generally accepted taxonomy, personality research cannot properly communicate empirical findings, let alone systematically cumulate them.

In science, taxonomies provide the foundation that helps characterize how different categories of studied phenomena (e.g., species or chemicals) relate to one another. How can thousands of words describing individuals be clustered into meaningful groups? Statistical data reduction techniques broadly referred to as *factor analysis* can be used for this purpose. Factor-analytic procedures are used to reduce and organize many personality descriptors into a few dimensions or factors. Variables that more closely relate to one another are grouped together. When adjectives describing

people are used to characterize individuals, the resulting data can be factor-analyzed to decipher the structure of the underlying traits. In the 1940s and 1950s, a number of psychologists (among them Louis L. Thurstone, Raymond B. Cattell, and Donald W. Fiske) applied factor-analytic techniques to personality trait descriptors. Thurstone and Fiske found that five broad personality factors could explain their respective data. However, they did not follow up on their findings and moved on to other research endeavors. Cattell claimed to have found over 12 factors, but reanalyses of his data replicated only five. In fact, the "fathers" of the Big Five were probably Ernest C. Tupes and Raymond E. Christal, who, in a series of studies between 1954 and 1961, found five replicable personality dimensions in ratings of human personality. Unfortunately, their findings were buried in a U.S. Air Force technical report and were not generally available to the scientific community (their landmark technical report was reprinted in a scientific journal only in 1992). In the 1960s, Norman confirmed the five-factor structure of personality descriptors; however, he continued to believe that there were likely to be many more personality factors than those he had found.

In the past 30 years, psychologists John M. Digman and Lewis R. Goldberg, who started out as critics of the Big Five, along with their colleagues have produced many studies using a variety of approaches showing that five dimensions are reasonably sufficient to explain observed personality differences among people. Incidentally, Goldberg can be credited with coining the term "Big Five" for what had previously been referred to as "Norman's Five."

In addition to studies researching the lexical hypothesis, personality measures were developed asking individuals to rate themselves (or others) on statement-based (rather than adjective-based) stimuli. Some current examples of these include the NEO Personality Inventory (NEO PI-R), Hogan Personality Inventory (HPI), International Personality Item Pool (IPIP), Personal Characteristics Survey, and the higher-order factors from the Sixteen Personality Inventory (16PF). It should be noted that even the factors of the 16PF are easily reduced to the Big Five personality dimensions. The developers of the NEO PI-R, Paul T. Costa and Robert R. McCrae, have been successful in demonstrating that the same Big Five personality dimensions are assessed in a multitude of different personality measures (e.g., the California Psychological Inventory,

the Myers-Briggs Type Indicator, the Minnesota Multiphasic Personality Inventory) that were developed outside the five-factor framework.

To date, hundreds of studies have provided evidence indicating that the Big Five are generalizable. A large body of literature and factor-analytic evidence has accumulated in the last decade providing compelling evidence for the robustness of the Big Five dimensions of personality across different theoretical frameworks (both abstract personality models and concrete natural language trait descriptors), using different tests and measures and in a variety of samples (including those defined by different ages, sexes, cultures, and ethnic origins). The five factors have also been shown to hold across different types of assessments and rating sources (self and peer). Cross-culturally, evidence supporting the Big Five or its variants has been found in many languages, including English, German, Polish, Turkish, Italian, and Tagalog-Filipino. Such cross-cultural and cross-linguistic generalizability is crucial if personality psychology and its applications in organizations are to transcend parochial sociocultural settings. Because of its broad generalizability and replicability, Big Five has become the term that stands for the most widely accepted framework of personality attributes.

DISSENT AND DISAGREEMENT OVER THE BIG FIVE

Despite the volume of research supporting Big Five factor models of personality, there is still some dissent on the structure and organization of personality traits among personality psychologists. However, it is now clear that one cannot take seriously taxonomies of personality that postulate an inordinate number of factors, given that consistent replicable empirical support for these is lacking. The empirical evidence marshaled in support of the Big Five is impossible to overlook. Most important, the Big Five is an organizational scheme that helps one locate a given personality characteristic in relation to other personality traits. Perhaps the five dimensions of personality can be conceptualized as analogous to longitude and latitude in cartography. They help establish coordinates on maps of personality traits. From a utilitarian perspective, the Big Five personality dimensions have been pivotal in organizing and summarizing research findings. However, the Big Five have met with several criticisms. These criticisms center on comprehensiveness, breadth, theoretical basis, and

social importance, as well as the predictive and explanatory value of postulated traits. Some of these criticisms are considered below.

First, it should be noted that although critics have argued that the Big Five is at best a taxonomy of adjectival descriptors and that there is no theory associated with it, recent publications have articulated comprehensive personality theories based on the Big Five model. These theories suggest that the five factors of personality are enduring traits that manifest themselves in behavioral patterns that are deeply rooted in the biology of human behavior. In five-factor theory, little room is given for learning and experience to influence personality.

Second, there are substantive disagreements about the precise subdimensions that make up each Big Five factor and its meaning. There are also questions about whether broader traits may encompass the Big Five. For example, proponents of fewer than five dimensions, such as Hans J. Eysenck, have argued that Conscientiousness and Agreeableness should be combined into a broader dimension referred to as Psychoticism (i.e., a lack of these two traits). There are also more than a dozen studies providing evidence that the Big Five can be further clustered into two even broader factors: one dealing with ascendancy and dynamic qualities, hallmarks of “getting ahead” (a combination of Extraversion and Openness), the other dealing with socialization, or “getting along” (a combination of Conscientiousness, Agreeableness, and Emotional Stability).

Third, the Big Five have been criticized as being too broad to be useful in the explanation and prediction of valued behaviors and outcomes, including those at work. The argument is that differences exist within each of the Big Five and that these differences cause inconsistencies when trying to predict and understand work behavior and effectiveness using information at the factor level. Proponents counter that the breadth of predictor variables should be matched to the criteria and outcomes being predicted. That is, when the goal is to predict complex real-world behaviors, broad factors such as the Big Five may be useful.

DESCRIPTIONS OF THE BIG FIVE PERSONALITY DIMENSIONS

Personality characteristics can be organized hierarchically. The lowest level at which we can examine personality is at the single, individual behavior level (e.g., telling a joke). Similar behaviors form habits

that constitute the next level of the hierarchy (e.g., tendency to make others laugh). Clusters of interrelated habitual behaviors constitute levels further up the hierarchy (e.g., sociability, gregariousness). At an even higher level, one finds broad factors of personality (e.g., Extraversion). It is important to think of each Big Five factor not as a single entity, but as a collection of clusters consisting of interrelated habitual behaviors that have a common core and carry little specific meaning. Many proponents of the Big Five place the five factors of personality at the highest level of the hierarchy. The clusters of interrelated habitual behaviors that are aspects of each of the Big Five are typically referred to as *facets* or *subdimensions*.

Emotional Stability

The first factor, which refers to an individual's tendency to become emotionally upset, is most frequently called Emotional Stability, or by the name of its negative pole, Neuroticism. This dimension characterizes individuals in terms of their proneness to experience emotional distress and maladaptive coping strategies. Common traits associated with the neurotic end of this dimension include anxiety, depression, anger, embarrassment, emotion, worry, fearfulness, instability, and insecurity. Emotionally stable individuals are well-adjusted, relaxed, self-assured, hardy, even-tempered, and calm. Individuals scoring low on Emotional Stability are described as moody, anxious, worrying, insecure, hypochondriacal, and tense. Some hypothesized facets of neuroticism include anxiety, hostility, depression, self-consciousness, vulnerability, low self-esteem, negative affect, and lability.

Extraversion

Extraversion encompasses traits relating to sociability, dominance, energy, and positive affect. It has also been referred to as "surgency." It includes a person's tendency to seek interpersonal stimulation and capacity for joy. Individuals scoring high on this dimension are described as energetic, active, vigorous, talkative, assertive, fun-loving, gregarious, persuasive, and positive. They seek social situations in which they can interact with others and be socially dominant. Individuals scoring low on this dimension are described as introverted, silent, submissive, passive, unenergetic, retiring, reserved, or "loners." Main facets of Extraversion are dominance/assertiveness, sociability/gregariousness, energy level/activity, and positive

emotions. Excitement seeking and warmth have also been suggested as facets.

Openness

This factor has been interpreted frequently as openness to experience, intellect, or culture. Traits commonly associated with this dimension include imagination, curiosity, originality, broadmindedness, and intelligence. Openness results in tolerance for ambiguity, and artistic sensitivity. This dimension describes individual differences in tolerance for and attraction to the unfamiliar. It has been described as a trait influencing an individual's breadth and complexity of mental experiences. High scorers are described as having wide interests, being imaginative, curious, creative, and insightful. They prefer complexity and change over familiar and stable situations. Low scorers are described as shallow, conventional, unanalytical, down-to-earth, and lacking in imagination. Openness is the most controversial of the Big Five, as there are many issues relating to its definition and measurement about which personality experts disagree. For example, measures of Openness are moderately associated with cognitive ability (i.e., intelligence) and particularly with divergent thinking. One conceptualization of this dimension includes facets such as openness to ideas, actions, values, feelings, aesthetics, and fantasy. Other conceptualizations suggest facets of complexity, culture, creativity/innovativeness, curiosity, intellect, and having a preference for change and variety.

Agreeableness

Agreeableness includes characteristics such as likability, kindness, courteousness, and nurturance. Individuals scoring high on Agreeableness are described as amicable, cooperative, popular, easy to live with, affectionate, sensitive, caring, altruistic, kind, tender-minded, and softhearted. They are interested in helping others and behaving in prosocial ways. Individuals scoring low on this dimension can be described as uncooperative, disagreeable, unfriendly, selfish, hostile, and egocentric. Facets of Agreeableness have received little attention in the literature. Depending on the conceptualization, they include nurturance, trust, modesty, tolerance, likability, straightforwardness, and tender-mindedness. Some conceptions of the Big Five include warmth as a part of Agreeableness, and others place warmth with

Extraversion. Similarly, some measures of the Big Five suggest that hostility is a marker for the negative pole of Agreeableness, and others include it as part of Neuroticism.

Conscientiousness

Conscientiousness refers to the cluster of traits relating to prudence, achievement, dependability, persistence, order, and impulse control. Although this dimension has most frequently been called Conscientiousness, it is sometimes referred to as “conformity” or “dependability” (carefulness, thoroughness, responsibility, organization, efficiency, planfulness). Because of its relationship to a variety of educational achievement measures and its association with volition (hard work, achievement orientation, perseverance), it has also been called “will to achieve.” Typical behaviors characterizing individuals high on this personality trait include careful planning, delaying gratification, following rules and norms, organizing, working hard, and persisting in goal-directed behavior. Individuals scoring high on Conscientiousness are also described as organized, thorough, competent, work oriented, perfectionistic, and driven. Individuals scoring low on Conscientiousness are often disorganized, quitting, irresponsible, careless, negligent, weak-willed, undependable, and sometimes hedonistic and impulsive. According to various conceptualizations, facets of Conscientiousness include reliability (dependability), orderliness, impulse control (cautiousness), decisiveness, deliberation, punctuality, formalness, conventionality (having traditional values), achievement orientation, and industriousness (hard work).

It should be noted that the Big Five personality dimensions can be combined to create composite or compound personality characteristics. This can be viewed as analogous to combining primary colors to create a multitude of shades in the color spectrum. For example, integrity is a trait made up of high Conscientiousness, Agreeableness, and Emotional Stability. Studies indicate that there may be greater predictive value for such compound personality traits than for each of the Big Five factors or their facets alone.

THE BIG FIVE AND CAREERS

The last decade and a half has witnessed the utilization of the Big Five framework in multiple occupational domains. Many studies have examined how the Big

Five relate to organizational behavior and outcomes. In addition, researchers have also taken advantage of the organizing scheme offered by the Big Five to quantitatively summarize a number of existing studies.

Career Attraction, Choice, and Job Search

The Big Five have been linked to occupational interests and career decisions. Individuals with investigative interests tend to score high on Openness, whereas individuals who express interest in artistic jobs score high on Openness and somewhat low on Conscientiousness and Emotional Stability. Social interests are related to Extraversion, prosocial ones to Agreeableness. Interest in enterprising jobs is associated with high Extraversion, low Agreeableness, and low Openness. Individuals with interests in conventional jobs score high on Conscientiousness and low on Openness. Students who score high on Conscientiousness, Agreeableness, and Emotional Stability tend to be more decided about their career choices. Interestingly, these three dimensions are often aggregated into a compound trait called “integrity.”

Extraversion and Conscientiousness are useful predictors of college students seeking and obtaining employment upon graduation. This finding can be explained in terms of particularly effective job-seeking behaviors and patterns among the extraverted and conscientious. Individuals high on Extraversion and Conscientiousness network more intensely and use multiple job search methods.

Career Preparation: Educational Success and Job Training

Conscientious individuals tend to do well in settings in which knowledge acquisition is a central activity. Conscientiousness is a consistent, positive predictor of educational success in high school, college, and graduate school. Other dimensions of the Big Five have also demonstrated predictive value for academic success, but their utility has not been as strong, as consistent, or as generalizable across educational settings. Openness, because of its relationship with cognitive ability, does not incrementally enhance the acquisition of declarative knowledge.

Job-training performance is also predicted well by Conscientiousness. That is, individuals who score high on Conscientiousness scales tend to be more

successful in job training. Furthermore, both Extraversion and Openness are also associated with performing well in training and provide about the same level of predictive power as Conscientiousness.

Job Performance and Its Components

Task Performance and Overall Job Performance. Hundreds of studies have examined how the personality attributes clustered under the umbrella of the Big Five relate to job performance. These studies have been summarized using a quantitative-data-pooling technique called *meta-analysis*. The conclusions from meta-analyses indicate that Conscientiousness is the Big Five dimension that is most consistently related to task performance, overall job performance, and effectiveness across diverse jobs, settings, and cultures. For jobs that require interpersonal interactions, such as management and sales, Extraversion is also related to job performance. For both these job categories, the assertiveness/dominance facet of Extraversion is responsible for the lion's share of prediction of job performance. At times, some factors (e.g., Agreeableness) can be used to predict lower performance in some domains (e.g., negotiation) and higher performance in others (e.g., teamwork). It is noteworthy that studies suggest that the validity and usefulness of personality measures are not destroyed or even markedly degraded by motivated response distortion of test takers in high-stakes assessments (e.g., personnel selection).

Organizational Citizenship Behavior. Performance behaviors that are not part of the formally prescribed tasks comprising a given job have been termed *citizenship behaviors* (OCBs) or *contextual performance*. Aspects of citizenship behaviors include helping and cooperating with others as well as promoting the employing organization in general by going beyond the call of duty. Meta-analytic reviews of studies linking the Big Five and OCBs indicate that Conscientiousness, Agreeableness, and Emotional Stability are useful for predicting the interpersonal facilitation dimension of OCBs. Also, Conscientiousness and Emotional Stability have nonnegligible, positive relationships with job dedication. Conscientiousness is also linked to altruism and generalized compliance. It is, overall, the most consistent predictor of OCBs.

Counterproductive Work Behaviors. Workplace deviance (encompassing behaviors such as theft, misuse of

resources, excessive absenteeism, workplace aggression, and violence) is strongly related to three of the Big Five dimensions: Conscientiousness, Agreeableness, and Emotional Stability. Individuals who score low on these three Big Five factors engage in counterproductive behaviors to a greater extent than do others. Integrity tests that are typically used to predict counterproductive work behaviors and workplace deviance usually assess these three dimensions of the Big Five.

Work Attitudes and Organizational Behaviors

Job Satisfaction. Understanding and explaining satisfaction among workers has also benefited from the Big Five personality framework. Emotional Stability and Extraversion have been shown to predict job satisfaction across jobs and settings. Although some substantial relations have been reported for Conscientiousness and Agreeableness, these are not as pervasive and generalizable. Openness appears unrelated to job satisfaction.

Motivation. There are multiple motivational theories and accompanying frameworks. Across three of these, specifically, goal setting, expectancy, and self-efficacy motivation theories, Emotional Stability and Conscientiousness have been found to relate to performance motivation. It seems that not only cognitive appraisal of external incentives and personal goals influence the strength of performance motivation; Conscientiousness and Emotional Stability also seem to relate to motivation through their influence on self-regulatory processes.

Leadership. All dimensions of the Big Five except Agreeableness have been linked to leadership emergence as well as leadership performance in groups. However, across settings, the strongest and most consistent predictor of both emergence and performance is Extraversion. Transformational leaders, who are charismatic, elicit cooperation and loyalty, and inspire and motivate their followers to reach common goals, tend to score high on Extraversion and low on Neuroticism.

Career Success

Career success can be conceptualized in many ways, including being successful in terms of salary

and occupational status or being satisfied with one's choice of occupation and position. Longitudinal studies indicate that Conscientiousness and Emotional Stability predict occupational status and income. That is, individuals who are conscientious and emotionally stable attain higher-status occupations and earn higher salaries. Conscientiousness alone has been found to predict long-term career satisfaction. For people-oriented jobs, Agreeableness also relates to salary level.

CONCLUSION

A leading personality psychologist has noted that a scientific taxonomy assists researchers in organizing and integrating research results by offering a standard scientific nomenclature. This is exactly what the Big Five model has helped to accomplish. The purpose of a model such as the Big Five is not to reduce the complexity of individuals to just five easily manageable traits. Rather, the Big Five personality dimensions have provided a framework in which to organize and describe personality characteristics in order to further our knowledge via scientific research. They are the building blocks in the hierarchical structure of personality. Furthermore, they can be used to conceptualize and describe personality traits in a hypothetical multidimensional space and thus further our understanding of human behavior.

Evidence supporting the validity of the Big Five factors of personality is compelling. The Big Five have facilitated communication of results among work psychologists who use personality variables in their research and organizational practice. The Big Five taxonomy has been instrumental in allowing for the cumulation of empirical findings across individual studies and has thus promoted a science of organizational behavior and industrial psychology that includes crucial individual differences. Personality traits from the Big Five framework have been linked to career choice, preparation, job performance, work attitudes, organizational behaviors, and career success. The impact of the Big Five in the world of work is pervasive. The applied uses span career guidance, personnel selection and placement, staffing, and many other human resource interventions. Any personnel decision would benefit from taking information on individual differences in personality into account.

BLUE-COLLAR WORKERS

Blue-collar workers, or the working class, comprise a segmented and stratified population in which economic location influences potential career mobility. Defined as manual or services laborers, this working class can be divided into five categories, based on skills and type of industry: self-employed, skilled or craft employees, semiskilled or unskilled employees in core sectors, semiskilled or unskilled employees in periphery sectors, and the marginally employed working less than 27 weeks per year, according to William Form and George Putman. Mobility is often influenced not only by individual skills but also by the structure and economic strength of the organization in which the worker is employed. The direct context of occupational mobility resides in the firm or organization.

Organizations may be divided into the categories of *core* and *periphery*. Core organizations are capital-intensive, profitable, and labor-intensive, employing low-skilled workers with high-paying and relatively secure jobs. Blue-collar workers represent a dependable workforce as well as an investment for core organizations; thus, the chances for movement within the organization are greater than for workers in periphery organizations. Large organizations use a vacancy mechanism and channel mobility through internal routes, with experienced workers having more favorable opportunities. Periphery organizations tend to be small, less profitable, and labor-intensive, consisting of a less stable workforce. Thomas DiPrete has characterized the periphery workforce as temporary workers, part-time workers, and workers on contract. Additional structural factors affecting worker mobility may be defined by industry growth patterns and hierarchy mechanisms.

Josef Bruderl has defined *vacancy mechanism* as positions created either by individuals exiting the organization or organizational growth offering individuals a chance for upward mobility. Opportunity is dependent on hierarchy structures and the individual's location within the hierarchy, and as the individual proceeds upward, chances for advancement decrease. Organizational expansion or contraction is an important factor in worker opportunity. Expanding organizations represent a positive opportunity, while contracting organizations have a negative impact, especially on blue-collar workers. Contracting organizations will dismiss blue-collar workers in order to protect white-collar

workers. These actions have a cultural basis as well as an economic consideration.

Given these organizational factors, several mobility characteristics can be observed. Among the skilled-worker category, sons are more likely to assume their fathers' occupations, but skilled workers tend to experience more upward mobility and less downward mobility than those in other categories. Although children of skilled workers are more likely to assume their fathers' occupations, two to three times the percentage of children of skilled workers are likely to pursue higher education. Changing characteristics of blue-collar work and lack of opportunity must be considered when discussing blue-collar mobility.

Recent restructuring by employers has created a number of low-wage occupations in which workers are unable to provide basic family needs. The percentage of working families who earn less than the basic family budget for their communities increased to 29 percent in the late 1990s. Factors such as globalization, deregulation, changing financial markets, and changing institutions have forced a change in how employers do business and in attitudes concerning the workforce. Cost-cutting efforts have most often focused on the wages of employees. Approaches such as wage freezes, increased production requirements, benefit loss, temporary employment, outsourcing, and relocation to low-wage environments have created low-wage occupations that offer little or no chance for mobility. Survival has become the norm, with little chance for advancement. Outsourcing and offshoring, secular declines in wages and job stability for blue-collar workers, and increased competition with immigrant workers have produced increased prospects for displacement, downward income and status mobility, and geographic mobility.

Self-investment is an important factor in this environment, and chances for mobility decrease with age and tenure on the job. Education often leads to occupational upgrading and is viewed as an important channel for mobility. The lack of opportunity for education and training constitutes a main cause for individuals remaining in low-wage jobs or failing to obtain employment. Schooling, ability, and job experience function as a means and resource for mobility, and although the children of professionals and managers have increased access to educational resources, educational opportunities have remained stable in the twentieth century and uniform across industrial nations. Labor and management have recognized the important role of

education and adopted a number of programs to increase worker opportunity.

As corporate restructuring has weakened job ladders, education and training have been viewed as a conventional response for worker mobility. Six out of 10 workers in today's economy can be considered skilled, with basic computer literacy required by 75 percent of all workers. Education and training must be considered a lifelong requirement. Bill Fletcher and Richard Hurd have indicated that labor has responded to the need for education with extended apprenticeship programs and programs designed to educate workers in the areas of union leadership, public speaking, literacy, algebra, and computers. The National Joint Apprenticeship Training Program of the International Brotherhood of Electrical Workers & National Electrical Contractors Association has a \$150 million annual training budget. Programs using formalized mentoring, such as the Wisconsin Regional Training Partnership (WRTP), have helped workers adapt to technological and work process changes while increasing wages and producing a 70 percent employment retention rate. Despite these efforts, many workers point to barriers such as lack of time, lack of financial resources, and distance to learning facilities as barriers to mobility chances. Combined with blue-collar values, these barriers impede career mobility among the working class.

Blue-collar workers face a number of obstacles in career mobility. Cultural values impede the desire for advancement and substitute the value of "good money" and "doing a good job" for mobility. The belief of not fitting into the white-collar culture increases resistance to seeking upward mobility. Cultural attitudes combined with organizational factors and changes in the corporate environment leave little chance for moving beyond the working class. Individuals who achieve upward mobility often experience a sense of being an outsider or misplaced.

Difficulties abound for the blue-collar worker seeking upward mobility. Blue-collar culture and class consciousness supply two of the primary obstacles to career advancement. Alfred Lubrano has described a "duality of consciousness" that exists among blue-collar workers who have become upwardly mobile, and he coins the descriptive term "straddlers" to reinforce their existence in both a blue-collar world and a white-collar one. Individuals from blue-collar backgrounds are governed by the cultural capital created by family and social setting. Conformity, obedience, and intolerance of other social classes are the characteristics

possessed by a "good blue-collar worker" and are present in the home. Patricia Gurin and others suggest that this class consciousness is the basis of a blue-collar identity and helps establish the perception of a "place in society" and a sense of collectivism. Blue-collar workers who obtain upward mobility often find themselves in awkward social and work situations as the result of "cultural ignorance." The identification with blue-collar values combined with economic difficulties and reduced opportunity impairs the mobility of most blue-collar workers. Mobility experts suggest that downward mobility has increased 7 percent in the last three decades and that upward mobility has had no significant increase. Blue-collar workers have less than a 30 percent chance of moving into white-collar jobs.

BOUNDARYLESS CAREER

The *boundaryless-career* concept widens our perspective toward a range of possible career forms both within and across organizations, but it is not primarily determined and driven by the career system of a single organization. The formulation of the boundaryless-career concept responds to the observation that stable

employment and careers within organizations account for the career experiences of some people, but not necessarily all. Boundaryless careers can unfold in a variety of ways. The use of the boundaryless-career concept commonly describes careers that involve moves across the physical boundaries of separate employers, such as stereotypical Silicon Valley careers. Boundaryless careers also occur when individuals are either involuntarily forced or voluntarily choose to leave their employers and thereby put an end to career advancement within the organization.

The boundaryless-career concept is not only relevant to any physical change of employers. It also applies to careers that draw validation and marketability from outside the present employer, as in the case of certain highly skilled professionals or academics; careers that are sustained by external networks; or careers that rely on information from outside, as in the case of a real estate agent or financial broker. Likewise, careers can be described as boundaryless when individuals base career choices on internal standards, such as personal or family reasons, rather than external career opportunities. Moreover, the boundaryless-career perspective acknowledges people's subjective construction of their career situations despite or regardless of structural constraints.

UNDERSTANDING THE BOUNDARYLESS-CAREER CONTEXT: A FOCUS ON EMPLOYABILITY

The boundaryless-career perspective challenges the overriding influence of large, bureaucratic organizations on people's careers. Observing the consequences of large-scale corporate restructuring, scholars have argued that the promise of long-term employment has been replaced by employment relationships that are increasingly transactional and insecure. Even if full-time employment with a single organization may continue to be a prevailing experience for many individuals, the psychological contract has changed significantly. Under this new contract, employment is less a result of loyalty to one's employer than of "employability" in terms of the marketability of one's skills and knowledge in the external labor market.

The boundaryless-career perspective is particularly relevant to industries with unpredictable and opportunistic markets. Here, employees are exposed to a high degree of employment uncertainty because firms seek to pass on the uncertainty from external markets

by using temporal, project-based forms of organizing. For example, in cultural industries such as publishing, film, and the arts, where funding is typically limited, organizations seek to maintain flexibility by providing freelancers only short-term employment on discrete projects. In the information technology (IT) sector, firms need to manage the risk that results from rapid technological changes. By employing contingent IT staff, firms avoid being stuck with obsolete technical competencies and shift responsibility for skill development to IT professionals themselves. In other industries, the use of temporary contractual workers or interim managers may not be the dominant organizing principle but simply provides firms with flexibility at the fringes of leaner hierarchically organized core businesses.

Not So Flexible After All

Despite the apparent reorientation of labor markets toward flexibility and marketability of skills, the reality of boundaryless careers is neither unconstrained by social structure nor exclusively regulated by market principles. Studies from a diverse range of industries suggest that boundaryless careers are embedded within social networks, institutional environments, and communities. The ways in which social networks facilitate and constrain mobility differ across industries. In cultural industries, access to social networks is important because they provide continuity and access to skills in environments in which production is characterized by short-term funding of project-based organizations. Since the quality of specific social relations, as opposed to individuals' competencies alone, shapes how people produce creative products and services, individuals need to rely strongly on informal networks of friends, family, agencies, and unions to develop a reputation and mitigate the insecurity of freelance employment. Individuals who lack this type of social capital may find it difficult to acquire, because collaborative relationships tend to be deeply rooted in their particular locality, for example, London's advertising community in Soho or the Los Angeles film industry.

In other occupations, collaborative relationships may be less specific. For example, careers for IT professionals or MBA graduates are more strongly influenced by the codification of a clearly defined set of skills and knowledge. In these settings, people benefit from access to diverse networks that help to update

their skills and knowledge. As studies of IT professionals and entrepreneurs suggest, informal social networks can become platforms for the exchange of socially embedded knowledge and competencies.

Previous research suggests a range of other contextual factors that constrain career mobility. Among these are a country's institutional frameworks and macroeconomic environment. Moreover, individuals' enactments of careers are often guided by the socially shared meaning, values, and preferences of ethnic groups, nations, and career communities. Cultural values can have a pervasive influence on careers because obligations to family and local community determine aspirations and values and thereby constrain how people think about their careers.

CAREER DEVELOPMENT IN A BOUNDARYLESS-CAREER CONTEXT

From a boundaryless-career perspective, career development needs to strengthen individuals' self-direction and adaptability within a more transactional employment context. Rational approaches of career development see self-direction and adaptability as primarily determined by a person's ability to engage in beneficial exchanges. Drawing on institutional economics, rational approaches seek to improve career mobility and employability through the development of relevant competencies and social networks.

A Competency-based View of Career Development

A competency-based view of careers suggests that career actors' accumulation and understanding of their own unique bundle of competencies in "knowing why," "knowing how," and "knowing whom" can provide individual-centered guideposts in a turbulent and ambiguous career landscape. "Knowing why" competencies provide individuals with answers about their career motives, personal meaning, and identification, based on which they can commit to firms, projects, or personal enterprises in a less certain world of work. "Knowing how" competencies represent individuals' understanding of job-related skills and career-related knowledge and provide the confidence to master current and prospective jobs. "Knowing whom" competencies reflect individuals' understanding of career-relevant networks, based on which they can generate knowledge, learn, and develop a reputation. Based on

their understanding of career competencies, people can evaluate which of their skills, knowledge, networks, or identities may facilitate mobility in the future and which competencies may become obsolete over time.

This competency-based view has become a widely accepted framework for positioning scholarly work in the area of career development. For example, studies of entrepreneurs and investors suggest that the combination of different competencies acquired during earlier corporate career stages contributes later on to career success in entrepreneurial settings. Career competencies such as a proactive personality, openness to experience, career insight, an ability to access mentors and internal and external networks, relevant skills, and a sense of career identity have been associated with indicators of career success, including perceived career satisfaction, perceived internal marketability, and perceived external marketability.

A Socially Embedded View of Career Development

Based on the argument that boundaryless careers are both facilitated and constrained by social networks, career scholars have argued that a critical determinant of career success in a boundaryless-career environment is access to social support. As individuals' commitments to their employers are increasingly turning transactional, relationships to a wider career community of mentors, current and previous work associates, and alumni are often becoming sources of longer-term commitments. The general conclusion in this area is that relationships with people from different social systems allow individuals to gain access to a wider range of sources of support. Yet diversity alone is not sufficient, since psychologically close relationships with one or a few mentors may provide greater learning and job satisfaction than diverse networks alone.

SHAPING PERSONALLY MEANINGFUL CAREER JOURNEYS

Confidence in one's ability to cope with changes in the external employment market results not only from one's ability to maintain physical career mobility. The shift of responsibility for career development from the organization to the individual has stimulated increasing attention among career scholars to the duality between

individuals' objective and subjective experiences of careers. Traditional criteria of career success such as salary, benefits, or advancement seem no longer appropriate, as individuals view their careers as "personal projects" and seek to define themselves through work. Career scholars who have drawn on the humanistic notion of work as a terrain where individuals can develop and express their potential have examined how individuals can proactively transform their careers to develop personally meaningful identities.

From a boundaryless-career perspective, developing a clear sense of identity is important for several reasons. First, in an increasingly individualized and transient society, an adaptive identity gains in importance because individuals need to cope with the social and emotional costs that may arise from career changes and the loss of attachment to families, local communities, and traditional organizations. Second, since traditional criteria of career success may be difficult to attain and may not necessarily be desirable to career actors, viewing oneself as able to adapt to changes is crucial to developing and maintaining a sense of psychological success. Third, exploring one's deeper motives with regard to work is also instrumental in steering one's career trajectory through a context in which organizational career systems can no longer serve as a point of reference.

Attention to the subjective experience of boundaryless careers provides a more comprehensive understanding of boundaryless-career experiences that do not deliver advancement in terms of traditional criteria of career success. For example, research on career mobility, international careers, and women's careers suggests that these experiences may be more adequately understood when accounting for individuals' personal reasons.

Women's Career Experiences

For women, who are more likely than men to pursue boundaryless careers, career moves often represent adaptive, and in some instances identity-transforming, responses to other events in their lives, rather than advancement of their careers. Boundaryless careers may be the last available resort when alternative forms of long-term employment or advancement within a firm seem blocked. Women are also more likely to switch to another employer if they wish to "follow" the career move of a partner who is also the primary financial provider, perceive limited opportunities for

intraorganizational advancement as a result of having children, or experience marital breakdown. Although such change, triggered by external events, does not always bring about improvements in terms of traditional criteria of career success, it may nevertheless improve perceptions of intrinsic job characteristics such as challenge, variety, freedom, quality of work life, and learning potential.

International Career Experiences

Intrinsic rather than extrinsic motives also seem to characterize individuals' decisions to initiate international assignments. Studies of expatriate careers suggest that individuals engage in foreign assignments not so much because of career progress or economic benefits. Instead, the motives for international moves are often the perceived opportunities for personal development, enriching one's life, and learning new skills. Thus, having used organizational opportunities to achieve personal career objectives, the expatriate experience may become an entry point to a boundaryless career upon repatriation, since opportunities for career advancement within the same firm can often seem limited.

Identity-based Approaches to Career Development

There are many ways in which individuals can gain clarity about their career identities. Often, this process may commence introspectively, supported by self-assessment tests, self-help books, participation in professional networks, and coaching. However, to be actionable and successful, such self-reflective exploration needs to be embedded in a person's real experiences. In other instances, changing one's career may follow a "first-act-and-then-think" sequence.

Among the many assessment tests, the exploration of *career anchors* and the Intelligent Career Card Sort (ICCS) represent career development activities that help ground introspective self-exploration in a person's career reality. Focusing on a boundaryless-career context, the ICCS draws on the "knowing why," "knowing how," and "knowing whom" framework described earlier. In this activity, individuals are called to select seven items from each of three larger card sets that represent the three ways of knowing. Individuals are then asked to explain the personal meaning that each selected item has in their own

careers. In contrast to traditional career development approaches that focus on identifying relevant competences and career strategies, the ICCS seeks to elicit subjective knowledge based on which individuals can create personal career narratives that are relevant to their particular career contexts.

Implications for Organizations

The changing employment context characterized by the boundaryless-career perspective also has implications for how organizations think about the development of their employees. As a consequence of individuals assuming more personal responsibility for the development of their careers in response to increasingly transactional employment relationships, organizations must manage employees who have become less loyal.

For the human resource function, the boundaryless-career perspective implies a shift of priorities away from managing “human capital” and toward managing relationships in ways that enable organizations to respond flexibly to market changes. This changing agenda must coexist with the provision of sufficient stability in the processes of recruiting, developing, and retaining people’s talent and knowledge. For example, in a more transactional career context, organizations need to resource knowledge and talent increasingly from a pool of people with diverse, possibly idiosyncratic, career paths. As a result, it becomes difficult for organizations to base their resource allocation decisions on organization-specific career structures and competence systems. Organizations may respond to this changing context in two ways. Either they can develop processes that allow them to evaluate and assimilate the diverse experiences and competencies that people gained prior to joining the organization, or they can reduce the risk of incompatibility by using contingent work contracts.

The implications of the changing terms of the psychological contract characterized by the boundaryless-career perspective go beyond recruitment and resourcing. For organizations, new challenges arise from the need to manage for flexibility while continuing to motivate employees, despite weaker bureaucratic and cultural mechanisms of control and coordination. Practicing community values is one approach through which organizations may be able to balance the harshness resulting from a stricter

market orientation. By encouraging employee participation in project and occupational communities beyond the boundaries of the firm, organizations enable learning and knowledge sharing; foster individuals’ capacity to respond with resilience to job, career, and life changes; and maintain the safety nets and supports that make people less vulnerable to dynamic market changes.

From a boundaryless-career perspective, it becomes increasingly difficult for leaders to instill motivation through commitment to an elusive organizational vision. Moreover, in settings in which teams are composed of members from different organizations, individuals’ motivation may be difficult to manage, because people with similar experiences and competencies may work under different contractual arrangements. An organizational context that is characterized by ambiguous boundaries and a membership that finds itself in constant “flux” requires the ability of leaders to mobilize members through the creation of metaphors, symbols, and cultural interpretations that build coherence, meaning, and anchors for group identification.

THE ROAD AHEAD

There are several priorities for advancing our understanding of career development in an increasingly boundaryless-career context. First, to develop the theoretical and practical relevance of this perspective, further research needs to examine the determinants and outcomes of particular boundaryless-career trajectories, thereby strengthening the generalizability of findings. This may be achieved with research that identifies determinants of career outcomes, such as mobility, career success, and satisfaction, through systematic comparison of boundaryless-career trajectories within and across different settings.

Second, further research needs to explore how people’s understanding of their competencies, networks, and the meaning of their careers influence each other and shape their career behaviors. For example, studies may explore how particular learning needs determine particular network structures. Likewise, systematic preferences for particular types of competencies and network configurations may influence individuals’ evaluation of experiences and formation of career identities.

Third, the further development of the boundaryless-career perspective requires attention to the dynamics

between individuals' search for self-determination and structural constraints to career mobility. Attention to both the objective and subjective experience of careers promises to enrich our understanding of how career actors' behaviors and attitudes may help them respond to structural constraints and a perceived lack of mobility.

Finally, the application of the boundaryless-career perspective to more traditional areas of research in organizational behavior and human resource management would be particularly beneficial. The boundaryless-career perspective reminds us that individuals will respond to their contexts not only from the viewpoint of their current jobs but also from the longer-term perspective of their careers. Once we accept that both individuals and organizations are participants in the same, increasingly boundaryless career context, there are new possibilities. From this perspective, individuals would be concerned about accumulating career capital in terms of knowledge, skills, social networks, and identity investments. Accordingly, organizations would be concerned about building intellectual capital in terms of their capacities for adaptation, innovation, and knowledge retention. Traditional ideas about permanent jobs or lifetime employment fail to recognize these changing concerns of both parties.

In conclusion, a decade of research exploring boundaryless-career phenomena provides individuals, organizational practitioners, and career scholars with a more balanced view of the internal and external dynamics that influence individuals' abilities to enact boundaryless careers. Internally, boundaryless careers promise adaptability, the development of career identities that are aligned with personal values, and the attainment of subjective criteria of career success. Externally, boundaryless careers require attention to the marketability of competencies, social networks, and institutional environments that constrain and facilitate mobility and to the economic, social, and emotional costs of boundaryless-career moves. The relevance of the boundaryless-career perspective for career development and human resource practices will depend on our ability to give consideration to these dynamics.

BRIDGE EMPLOYMENT

As the workforce ages, career counselors will increasingly be working with older workers, especially adults who work during retirement. Career counseling can now extend to a client's retirement. Some individuals do take the traditional retirement route (i.e., move from full-time work to full-time leisure), but a substantial number of older Americans remain in the labor force after they leave their career jobs. Labor and employment economists have found that by age 60, more than half of all persons have left their career jobs, but only one in nine is fully retired. These individuals who have retired but have not left the workforce take jobs, known as *bridge employment*, that act as a transition between long-term career positions and total retirement. Bridge employment often involves a

combination of fewer hours, less stress or responsibility, greater flexibility, self-employment, and fewer physical demands.

According to the U.S. Administration on Aging recent statistics, Americans are living longer and healthier lives. People who live to age 65 can expect to survive beyond this average (19.4 years of age for a female and 16.4 years for a male). Will these adults have sufficient resources to live comfortably these many more years? Bridge employment contributes to older adults' economic security by providing additional income. In addition, bridge employment contributes to an adult's emotional well-being. Adults who work in bridge jobs report they feel better about themselves both physically and emotionally, have more balanced lives, and enjoy the work they are doing. They view their bridge jobs as the opportunity to do something meaningful in their lives and to assert control of their work (i.e., task assignment, time, and flexibility), which they may not have experienced in their long-term careers. Older workers are more likely to retire into bridge jobs that are similar to their long-term careers (i.e., within same environment or using similar skills), because they like being connected with the work they had done previously. Some adults like the fact that their bridge jobs allow them to focus on what they love doing and not worry about the promotion career ladder.

When older adults switch to their bridge jobs, even to jobs within their career fields, they may experience different levels of difficulty. Possible barriers include watching their jobs disappear due to technology advances, experiencing age discrimination, questioning their ability to learn, or not knowing how to do a job search. Many adults who have mapped out long-term career paths and planned their financial futures fail to plan their next career step in retirement. They do not anticipate certain consequences of the transition, such as changing their work roles (e.g., from supervisor to worker), adjusting to new environments, going back to school, or dealing with the expectations of family and friends.

Regardless of the many challenges, most older workers are able to successfully move into bridge jobs without any career assistance. They rely on their past life experiences and skills to handle the transition. However, a significant number of retirees struggle to find a niche in retirement. They are overwhelmed with the job search process, which is new to them; discouraged with their unmet expectations; and frustrated

with the limited opportunities that offer both flexibility and challenging work. Those who persevere through two or three different bridge jobs often eventually find satisfaction in their new career efforts.

Career counselors can play an instrumental role in helping individuals make this transition more easily. Unfortunately, older adults are less likely to take advantage of career counseling services, such as seeking out help from a career counselor, attending a career development workshop, joining a support group, or reviewing career/job resources (i.e., publications and Internet). Many older adults see themselves as their own transition resources. Therefore, the career counseling community must reach out to this demographic group and promote the benefits of career counseling for adults who plan to work in retirement. Possible promotion strategies include connecting with financial planners, human resource managers who are responsible for employee retirement benefits, and the aging network (e.g., Area Offices on Aging, Title V Programs).

In making the decision to work in retirement, most older adults want to work, but only on their terms, which encompass two factors: (a) asserting control (e.g., how they work, whom they work with, what they work on, where they work) and (b) doing something meaningful (e.g., impact on their own development, family, community, or society). As these two factors have different meanings for individuals, counselors need to help their clients identify and clarify these conditions. Counselors must consider their older clients as individuals and avoid grouping them indiscriminately into one category, and they must also be aware of the unique issues faced by older workers, especially age discrimination. In this regard, counselors should become familiar with the different forms of age discrimination; understand the Age Discrimination Employment Act (ADEA), including the law's scope and older workers' legal rights; and refer clients who feel they have experienced age discrimination to the appropriate resource. Older adults have lengthy work histories, which have given them opportunities to acquire an extensive array of skills and experiences, and career counselors must help clients sort out and assess their preferred activities, especially their functional skills and interests. As there is a good likelihood that older workers have not done recent job searches, counselors must coach their clients on the entire process, including networking, using the Internet, developing résumés, and preparing for interviews.

Work has redefined retirement. More and more older adults are recognizing that bridge employment is a viable choice for their retirement. Eighty percent of baby boomers plan to work in retirement, which means the trend of older workers retiring to bridge jobs will not be going away. Career counselors can be an integral part of this trend by recognizing that their role does not end at a client's retirement but extends for many more years.

BURNOUT

Many individuals feel "burned out" from their jobs. Indeed, *job burnout* can be a substantial obstacle to employee and organizational well-being. Christina Maslach, a pioneer in the study of the burnout process, has defined job burnout as a prolonged response to chronic (that is, long-lasting) stressors in the workplace. Maslach has also developed several versions of the Maslach Burnout Inventory (MBI), the most popular instrument used to measure employee burnout.

It is generally believed that there are three aspects or dimensions of job burnout: emotional exhaustion, depersonalization and cynicism, and a lack of personal accomplishment. That is, employees who are burned out from their jobs are emotionally exhausted, feel cynical about their work and detached from others in the workplace, and feel ineffective at work. Although burnout was initially studied among employees in the human services and health care fields, who have emotionally intense contact with clients or patients, it is now recognized that burnout can be experienced by employees in a wide range of occupations and industries.

FACTORS THAT PRODUCE BURNOUT

Although several different theories have been proposed to explain why employees experience burnout, one common theme is the belief that burnout is caused by a lack of fit between the job situation and the person. For example, a variety of work stressors, such as an ambiguous work environment, a heavy workload, extensive work pressure, and stressful events at work, are associated with emotional exhaustion and, to a lesser extent, depersonalization. Presumably, these stressors produce burnout because they represent obstacles to achieving a fit between the employee and the job. Factors such as a lack of resources at work, the absence of social support, and a diminished feeling of group cohesion and community can also produce emotional exhaustion and depersonalization, although they don't seem to have quite as strong an effect on burnout as do the work stressors related to lack of fit.

Maslach and her colleagues have recently identified six areas of work life that can produce job burnout: excessive workload, lack of control, insufficient rewards, lack of community, feelings of unfairness, and conflict in values between the individual and the organization. Problems in each of these six areas make it difficult for an employee to achieve congruence or fit between his or her goals or values and the work environment.

Although the job situation has a powerful effect on employee burnout, the individual's personality may also play a role in job burnout. It is possible that some personality characteristics (such as neuroticism and an external locus of control) make employees more susceptible to stress and burnout, whereas others (such as high self-esteem, hardiness, openness to new experiences, and agreeableness) protect employees from

burnout. Nevertheless, Maslach and other scholars believe that the job situation has a stronger and more consistent effect on job burnout than do personality characteristics.

CONSEQUENCES OF BURNOUT

Job burnout has been linked to such work-related outcomes as diminished performance on the job, a lack of commitment to the organization, a low level of job satisfaction, and a desire to quit the job. Beyond these consequences, burned-out employees can experience negative emotions, apathy, and physical health problems. Job burnout can also affect an employee's family life. For example, research has shown that burned-out police officers tend to be moody and withdrawn at home and dissatisfied with their marriages. Moreover, an employee's job burnout can "cross over" to his or her spouse, producing a high level of burnout in the spouse. Clearly, burnout has a wide range of negative consequences to the employee and, ultimately, the organization.

ACTIONS TO REDUCE THE INCIDENCE OF BURNOUT

Because both job characteristics and personal characteristics can produce burnout, interventions can focus on either changing the organization or changing the employee, although these two approaches are not mutually exclusive. Interventions that target the organization for change attempt to reduce the organizational stressors that produce burnout. Interventions that target the employee try to enhance the individual's ability to recognize and cope effectively with the stressors that are producing the burnout.

A number of scholars have observed that the research conducted to evaluate burnout reduction interventions is quite limited. Nevertheless, some studies have demonstrated the effectiveness of such interventions, and Maslach and her colleagues have recently developed a comprehensive, research-based program to prevent burnout in organizations. Research should continue to find ways to help organizations become less stressful and more supportive of their employees so that both parties—organizations and employees—can thrive and function effectively.

BUSINESS SIMULATIONS

The term *business simulations* refers to exercises that represent processes involved in the production and delivery of goods and services. These exercises may be used to study the processes themselves, to enhance their teaching, or to assess proficiency in their management. When the exercises are scored, they often are called "business games."

Business simulations may represent processes phenotypically or genotypically. In a *phenotypical representation*, the process is modeled mathematically; in a *genotypical representation*, it is played out in a form constrained by the setting of the exercise. The marketing process, for example, is represented phenotypically when participants of the simulation sell goods to fictitious customers. The same process is represented genotypically when participants sell goods to each other. Both types of representation may be included in a single exercise.

Many business simulations are computerized, but the computer's role in the exercise can vary substantially. The simulation can be computer directed, computer based, computer controlled, or computer assisted, depending on the relationship among participants and between the computer and the participants. The nature of these relationships determines the resources required to develop the simulation and the settings to which it may be applied.

A simulation is *computer directed* if the participants interact primarily with the computer, which controls the flow of events. In these simulations, a participant's actions are limited to deciding the pace, starting point, and ending point of the simulation. Often, the simulation animates a sequence of events. It may show, for example, how goods are delivered and payment received in international transactions.

A simulation is *computer based* if the participants, interacting primarily with the computer, control the flow of events. These simulations are often called *discrete-event simulations*. They may be implemented using either a general-purpose spreadsheet program or a specialized software package that supports animation. Typically, the participant launches the software repeatedly, to see how changes in values and algorithms affect the outcome.

A simulation is *computer controlled* if the participants, interacting primarily with each other rather than with the computer, must conform to a mandated flow of events that strictly constrains the number of decisions they can make and the time they have for making their decisions. These simulations are often designed to enable teams, each representing the management of a firm, to compete against each other. Accordingly, the results of the decisions made by each firm depend on the decisions made by the other competing firms. This type of simulation was introduced in the late 1950s, when mainframe computers became widely available. They are used extensively in schools of business administration, especially in the disciplines of management and marketing.

A simulation is *computer assisted* if the participants, interacting primarily with each other, control the flow of events. In these simulations, the computer program presents a scenario, tracks accounts, processes transactions, and facilitates interactions, generally performing the kinds of supportive tasks that computers perform in the everyday world, without strictly constraining the number or timing of participants' decisions. Thus, decisions may be entered whenever participants choose to enter them, and each decision is executed whenever the necessary conditions for its execution have been met. When this kind of simulation is played competitively, the advantage generally goes to the player who acts first, so participants tend to be more keenly aware of the pressure of time than they would be with the formal deadlines of computer-controlled simulations.

With respect to scope, business simulations may be functional, total enterprise, or total economy in scope, depending on the scenario they present and the roles they make available. *Functional simulations* limit themselves to the concepts of a particular business discipline, such as marketing or operations management. They put participants into discipline-specific managerial roles. *Total-enterprise simulations* encompass all the functional areas of business. These put

participants into top-management roles. *Total-economy simulations* give participants multiple roles, such as consumer, investor, and company manager, which jointly support a sustainable economy.

With respect to technological sophistication, business simulations range from simple board games to software packages that track every participant and coordinate activities remotely through the Internet. The *simple board games* are useful for occasional events in variable settings. They are usually amenable to shorter or longer play, depending on the circumstances. *Internet-remoting software* packages are ideal for distance education, as they allow participants to interact with each other even when they are not physically present at the same place and time. Between the two extremes are *batch-processed setups*, whereby participants enter decisions on paper or electronic forms that are sent to an administrator for processing, after which the administrator returns the results. Batch-processed setups generally are run for 4 to 12 rounds. Transmission between participants and administrator may be physical or by fax, telephone, electronic file transfer, or electronic mail.

Free riding, endgaming, and chance factors are issues that must be managed when business games are used in a context in which scores have serious consequences for participants. *Free riding* occurs when some participants receive credit for work that is not theirs, a situation that arises when teamwork is required. It is attenuated when the simulation supplies individual scores in addition to team scores, when teams are limited to three members, and when teams have the authority to remove recalcitrant members. *Endgaming* occurs when participants take account of the impending termination of the exercise in the decisions they make. It can be reduced by not announcing the termination period of the exercise in advance, by requiring a narrative justification of each participant's or each team's final state, and by running the exercise for a longer interval. Chance factors arise from stochastic elements in the simulation's algorithms and from the circumstances of the exercise. These factors are mitigated by running the exercise for a longer interval and by a tournament approach, whereby each participant associates with a different collection of other participants in each phase of a multiphase exercise.

The learning benefits of business simulations have been studied extensively. Simulations supply experiences, the value of which depends on the participants, setting, design, and execution of the exercise. How the

benefits are affected by differences in these factors is a subject of continuing research.

BUTCHER TREATMENT PLANNING INVENTORY (BTPI)

The *Butcher Treatment Planning Inventory* (BTPI) is a behaviorally oriented, 210-item, true-or-false measure of factors relevant to psychological treatment planning. It is intended to be atheoretical, though it was informed by behavioral and cognitive-behavioral treatment orientations. It requires roughly a sixth-grade reading level and, under standard conditions, can be completed in 30 minutes. It can be scored by hand, using templates, or using computer programs. Computer-based interpretations of the results are available. In addition to norms based on a general sample, norms also exist specifically for college students (which can be used in both research and clinical practice) as well as for psychotherapy patients (which are intended for research purposes).

SCALE DESCRIPTIONS

The BTPI items provide individual scores on 14 scales that fall into three clusters. The Validity Indicators assess contradictory response patterns (Inconsistent Responding, INC); unrealistically positive

self-presentation (Overly Virtuous Self-Views, VIR); symptom exaggeration (Exaggerated Problem Presentation, EXA); and resistance to new behaviors and ideas (Closed-Mindedness, CLM). The Treatment Issues scales assess difficulties in allying with others (Problems in Relationship Formation, REL); tendency to somaticize distress (Somatization of Conflict, SOM); negative attitudes about psychotherapy (Low Expectation of Therapeutic Benefit, EXP); self-centeredness (Self-Oriented/Narcissism, NAR); and experience of a negative psychosocial environment (Perceived Lack of Environmental Support, ENV). The Current Symptoms scales assess low mood (Depression, DEP); tension and nervousness (Anxiety, ANX); hostile attitudes (Anger-Out, A-O); self-blame (Anger-In, A-I); and potentially delusional beliefs (Unusual Thinking, PSY). A General Pathology Composite combines scores on DEP, ANX, A-O, and A-I. A Treatment Difficulty Composite combines scores on PSY, REL, SOM, EXP, NAR, and ENV.

USES OF THE BTPI

The BTPI scales provide extensive information regarding numerous patient characteristics that could affect the psychotherapy process, particularly those that could prevent or delay therapy-related change. The BTPI can be administered at several different points over a course of psychotherapy. In the early stages of psychotherapy, it can highlight initial treatment foci, whether psychological symptoms, process factors, or interpersonal variables. For example, an elevated score on Problems in Relationship Formation might suggest a need to make special efforts to engage a patient in a therapeutic alliance, over and above whatever steps typically might be taken early on in psychotherapy. Initial scores can also serve as baseline data for subsequent evaluation of psychotherapy-related change, providing an empirical basis for decisions about issues such as extending or terminating psychotherapy. Either the full measure or one of three briefer forms (the 80-item Symptom Monitoring Form, the 171-item Treatment Process/Symptom Form, or the 174-item Treatment Issues Form) can be readministered to gauge psychotherapy progress and outcome.

Early research on the BTPI highlights its potential usefulness in guiding the treatment-planning process. Given that it bridges the traditions of objective personality assessment and psychotherapeutic intervention, it enables clinicians to make thoughtful,

data-based decisions about how to proceed with the care of their patients, increasing the likelihood that psychotherapy resources will be allocated sensibly and in a manner that promotes psychological growth.

C

CALIFORNIA PSYCHOLOGICAL INVENTORY

The *California Psychological Inventory* (CPI) was first published in 1956. It has a historical relationship to the Minnesota Multiphasic Personality Inventory (MMPI) and shares many items with the older, well-known MMPI. The CPI has been studied extensively and has been widely used in both research and applied contexts. As a general-purpose personality assessment tool, it is widely respected and arguably the most effective instrument available for use with normal populations.

An important source of the utility of the CPI is found in its structural complexity. Use of the CPI involves application and interpretation of the instrument at three different levels. The CPI consists of 20 dimensions of personality with a strong interpersonal orientation. The most recent version of the CPI employs 434 items. Three of the 20 scales are validity scales that assess attitudes related to test taking. Harrison Gough has referred to the dimensions measured by the basic scales as “folk concepts,” that is, concepts that are used in routine daily life by people to describe patterns of behavior in themselves and others. Empirical methods of construction involving contrasted groups were used in developing 13 scales. Four scales were developed using internal consistency as the primary construction strategy, and 3 were constructed using a combination of empirical methods with the internal consistency criterion. In almost 50 years since its first publication, considerable validity evidence has collectively accumulated for these scales.

The structural characteristics of the 20 scales have been studied extensively. In general, five factors appear to underlie the 20 basic scales of the CPI. Although factor analysis was not a method employed in developing the CPI scales, a relatively stable factor structure has been reported that generally resembles the one reported in the CPI manual.

One of the guiding principles in the development of the CPI was that it was to be an *open system*, a system of constructs to which others might be added if they proved to be useful or necessary for some particular purpose. Indeed, a number of special-purpose scales have been developed, such as Managerial Potential, Work Orientation, and Leadership. The scoring keys for 13 scales designed for special purposes are provided in the CPI manual.

A major feature emerging from the 1987 revision of the CPI was the addition of three vector scales. The specific procedures by which these vector scales were actually developed have been a source of some criticism of the CPI. Nonetheless, these vectors are recommended as a source of information in profile interpretation. Vectors 1 (External vs. Internal) and 2 (Norm Favoring vs. Norm Questioning) are placed in perpendicular relationship to one another to create four types: Alphas, Betas, Gammas, and Deltas. The four types represent types of lifestyles into which individuals may be classified as the first level of profile interpretation. The third vector, Level of Realization, forms the third dimension of a cuboid model of personality structure and is represented on a seven-point scale. Individuals' ratings on this scale reflect the degree of ego integration and realization of the positive potential of their type. The 20 basic scales

may be used for more specific exploration after the vector scores have been interpreted.

The CPI has several strong features to recommend its usage. An extensive manual with over 400 pages, including appendices and references, is a significant resource. The standardized reports for results on individuals are well designed and organized. These reports include reliability data, graphical and narrative description of lifestyle type and level for the individual (based on the three vector scores), a graphical profile for the individual on the 20 folk scales with same-sex norms and mixed-sex norms, and helpful interpretive information for use by professionals. The standardized report also includes results for seven of the special-purpose scales that would often be relevant in the context of career assessment or exploration. The use of nonpathological constructs in common usage is a noteworthy advantage of the CPI in use with normal populations. The folk constructs were selected to maximize cross-cultural applications. Its emphasis on constructs with significant social relevance is also a useful characteristic in practice. The related-applications guide serves as a resource for those working in career development areas.

Strengths and weaknesses of the CPI have been thoroughly addressed in the literature over the last four decades. Certain theoretical criticisms of the CPI have persisted over the years but do not distract from the applied uses of the instrument. Since the 1987 revision, one controversy over the CPI has involved the development of the vector scores and their use in forming the types and levels of the cuboid model of personality. Anne Anastasi and Susana Urbina discussed the implications of converting continuous-scale scores to dichotomous groupings and further pointed out issues related to measuring personality types or categories instead of continuously distributed constructs. In recent years, psychometricians have argued for and against such practices, depending on their theoretical views of the nature of personality and demands of its assessment. There seem to be reasonable arguments on both sides of this issue. Since the 1987 revision, the CPI has included serious efforts to define and validate the four types based on lifestyle or personality characteristics. Alternatively, the availability, validity, and usefulness of the folk scales of the CPI remain intact, so that one need not rely on the typologies provided. In fact, continued research on the relationship of the typologies to the folk scales seems important.

The relevance of the CPI to career development in general is highly notable. Gough provided a thorough review of several applications of the CPI to the world of career and work. Jody Newman, Elizabeth Gray, and Dale Fuqua reported substantial relationships between factors and scales of the CPI and career indecision status, while other researchers found relationships between career maturity and both personality type and social adjustment as measured by the CPI. Growing interest in the relationships among personality constructs and vocational interests may also support career-related uses of the CPI. There is little doubt that the CPI will continue to be a major resource for career development professionals and the clients they serve.

CAMPBELL INTEREST AND SKILL SURVEY

The *Campbell Interest and Skill Survey* (CISS), developed by David P. Campbell, measures self-reported interests and skills. Used primarily in career exploration, it was designed for individuals who plan to pursue careers requiring a college education. It is helpful for adults considering career changes, trying to understand job dissatisfaction, or thinking about retirement. Written for individuals with a sixth-grade reading level or above, the CISS can be given to adults and adolescents age 15 years and older. It is appropriate

for use in high schools, colleges/universities, human resource departments, and outplacement firms.

The CISS reports interest and skill standard scores on 7 Orientation scales (Influencing, Organizing, Helping, Creating, Analyzing, Producing, Adventuring); 29 Basic Interest and Skill scales (e.g., Leadership, Supervision, Counseling, Art/Design, Science, Animal Care, Athletics/Physical Fitness); 60 Occupational scales (e.g., Attorney, Accountant, Teacher K-12, Fashion Designer, Physician, Architect, Police Officer); and 3 Special scales (Academic Focus, Extraversion, Variety). Three procedural checks (Response Percent Check, Inconsistency Check, Omitted Items Check) detect problems with answer sheet completion or scoring.

The seven orientations are similar to John Holland's six RIASEC types (Realistic, Investigative, Artistic, Social, Enterprising, and Conventional), although there are some differences: Influencing measures leadership, while Enterprising focuses on sales; Organizing relates to management and financial services, while Conventional deals with clerical and office work; and the two CISS scales of Producing (mechanical, construction, and farming activities) and Adventuring (military, police, and athletic activities) are represented by Holland's Realistic scale. The CISS orientations provide the organization for the Basic Interest and Skill scales and the Occupational scales.

Published in 1992, the CISS has one form, available in two languages, English and Spanish, and two formats, pencil-and-paper and online administration. Most people complete the CISS in 30 to 45 minutes. It is scored by machine with several options: MICROTTEST Q Assessment System software for local scoring, optical scan scoring, mail-in scoring service, and the Internet.

The CISS items and response choices are integrated into one booklet. The 320 items are current, and each occupational title includes a brief description. Respondents indicate their attraction toward or liking of 200 academic and occupational items, alphabetically arranged in three sections: 85 occupations (e.g., architect, designing new homes and buildings; nurse, caring for patients in a hospital); 43 school subjects (e.g., music, algebra, psychology); 72 activities (e.g., manage the work of others, operate scientific equipment, plan an advertising campaign); and the respondent's self-evaluated skills in 120 occupational activities (e.g., developing computer programs, writing a newspaper story, selling a product or concept).

Each item has a six-choice response format, ranging from *very positive* to *very negative*, with no neutral or

middle alternative. Responses for interest items are *strongly like* to *strongly dislike*. Choices for skill items are *expert* to *none* and measure self-efficacy or confidence to perform the activities, not actual ability.

In a comprehensive, 11-page individual profile, CISS standard scores are presented numerically and graphically on unisex or combined-gender scales. For each Interest scale, there is a corresponding Skill scale. An individual's responses are compared with the responses of employed people who enjoy their work. Narrative descriptions provide interpretations. Four defined patterns of interest and skill scores are reported: *Pursue*: seriously consider, high interest, high confidence; *Develop*: seek training, high interest; low confidence; *Explore*: apply abilities in another field, low interest, high confidence; *Avoid*: not consider, no interest, no confidence. Patterns in which interests and skills fall in a midrange are not labeled.

The Interest/Skill Planning Worksheet and the CISS Career Planner assist respondents to organize results, consider themes, and examine career directions. The CISS manual includes development procedures; technical information (norms, reliability, validity); interpretation guides with case studies; and transparency masters for group interpretations.

The Orientation scales and the Basic scales were normed on a general reference sample of 5,225 employed people (3,435 men and 1,790 women), including 248 ethnic minorities, in 65 occupations. The 60 Occupational scales were normed on men and women employed in each occupation. Sample sizes ranged from 35 to 199, with a median of 76. The Orientation scales and the Basic Interest and Skill scales are homogeneous. Each scale consists of similar items that are highly related.

The Occupational scales have heterogeneous item content, as they were developed by contrasting the responses of occupational samples with those of the general reference group. The Occupational scales allow respondents to compare their interests and skills with those of people employed in different fields.

Using modern technology, development of the CISS was based on knowledge and experience gained from statistically designed career assessments, originating with E. K. Strong Jr. in 1927. The CISS is psychometrically sound; it was well constructed and technically tested. Using a standard score of 50 to represent the mean of the general reference sample on all sets of scales makes results easy to interpret. The scales function as they were intended. People in

different occupations report different patterns of interests and skills.

CAREER

Derived from Latin and French, the term *career* originally denoted a pathway or racecourse; the course or rapid motion of people, horses, hawks, heavenly bodies; or a course of action. By the early nineteenth century, it had taken on some of today's meanings and since then has come to refer to some key features of Western society. It is now called into use in a variety of ways in several domains, for different purposes, from different perspectives, and with different underlying assumptions. These diverse uses create many contextualized meanings so that career is not a universally definable concept, but a range of constructs, often with some elements in common. These many meanings endow career with a multilayered richness, although this can make the term ambiguous and even ambivalent and necessitates care in interpreting any specific use of the word. Today's greater international

interchange on career matters also hinders translation of the term into other languages.

CONSTRUCTS OF CAREER

A few examples can be used to show how meanings of career vary both between and within different domains. However, the word *career* is often not clearly defined, even in academic usage, and is frequently interchanged with the term *vocational*; and when it is used to modify other terms, such as *development* or *guidance*, the meaning of the term is generally taken for granted.

Career is a familiar term in lay language, in which it is used to denote, among other things, individual work histories, sequences of and patterns in occupations and work positions, and upward progress in an occupation or in life generally. Characteristically, it is differentiated from "just a job" and applied particularly to the work history and progress of professionals, managers, and other elites. However, it may also be used more generally to refer to a biography or life history or as an overarching construct to make sense of life.

Constructs of career are used in several academic disciplines, such as sociology, labor economics, vocational and career psychology, and work psychology. For example, career is used in a range of sociological explanations. From the perspective of those interested in the role of occupations in social stratification and mobility, career choice is construed in terms of influences and constraints on the individual, such as family of origin, education, race, ethnicity, and gender. Other sociologists who use the construct of career in studying organizations see it in terms of, for example, career patterns, trajectories, contingencies, turning points, the accumulation of cultural capital, and issues of power and control in and over employees. A different perspective on career was taken by the early-twentieth-century Chicago sociologists, whose work has become classic in career literature. They saw it as the transitions made by individuals in a wide range of contexts, not just in occupations or organizations, and their ethnographic research suggested that individuals develop both their identities and their roles as they move through a series of status passages. Hence, their construct of career fuses objective and subjective and plays a recursive role in linking individuals to institutions and structure.

Very different constructs are to be found in vocational and career psychology. Here, the emphasis is on

the individual, and there is limited concern for wider contextual factors and their constraints and opportunities for the individual. However, the effects of race, ethnicity, class, and gender are now receiving greater acknowledgment. Career has particular significance in this domain, and only a few of the most commonly found constructs can be noted here. One focuses on the congruence of person and occupation, using the differentialist, trait-and-factor approach that matches individual traits, abilities, and dispositions to the demands of occupations. Another frames career in terms of the implementation of the individual's self-concept and development through life, recognizing the stages, tasks, context of development, and career maturity. Other constructs view career in terms of individual agency, social learning, information processing, planning, and decision making. Others focus on how people make sense of their experiences and construct meaning through actions, narrative, and metaphor. Further constructs of career are used in work (industrial, occupational, organizational) psychology, where career is construed in terms of the relationship between (a) the individual and the organization and (b) the influence of the structure and dynamics of the organization, the design of jobs, the reward system, performance management, managerial style, and control.

Career is also a key construct in several areas of practice. In career guidance and counseling, career choice and development are construed in terms of how people can both fit into society and fulfill themselves by entering appropriate jobs and developing themselves further through their work. Constructs focus on the need, formerly of young people and now increasingly of adults as well, to gain appropriate information about occupational opportunities and constraints, be aware of their own strengths and weaknesses, make realistic decisions in the light of these, and become empowered in their work lives. More recent national priorities have introduced another construct of career that is concerned less with clients' fulfillment than with their employability, achieved by developing themselves and managing their careers.

In education, constructs of career have traditionally been used in addressing the transition from school to work, but now increasing concern about the relevance of all levels of education for the world of work highlights the significance of educational and career choices. Constructs focusing on informed, realistic decision making are used directly by career guidance

specialists and indirectly in the school and higher-education curriculum material designed to increase awareness of work-life issues.

In human resource management, which aims to achieve the effective performance of an organization through its employees, the construct of career represents the engagement of the individual with the organization. From this perspective, career plays a part in organizational reward and control systems, and career management is more than people managing their own careers. It refers to how managers attempt to influence their employees' careers in the interest of both individuals and organizations by planning, facilitating, and monitoring employees' progress through the organization and by specific interventions. Here, constructs of career development concern what organizational experiences and sequence of jobs will best develop, motivate, and retain employees and what personal investment in skills they will need to make.

In the domain of public policy, career is used primarily to modify terms such as *education* and *guidance*. Faced with the need for new skills, adaptability, and redeployment in their workforces and with the problems caused by unemployment and social exclusion, governments in the industrialized world today are concerned with developing human capital. Government perspective on career guidance is that it has a key role in helping labor markets work effectively in the interests of national competitiveness and in helping education systems meet their goals, promoting equity, combating the negative effects of social exclusion, and supporting lifelong learning. It is needed not only by young people entering the labor market but also by adults throughout their working lives, so that people need to develop the skills not just of initial decision making but also of managing their careers.

The many meanings of career are evident in the different ways in which the same terminology, such as *career development* and *management*, is used in various domains. Nevertheless, there have been some attempts to develop a more comprehensive understanding of career by, for example, integrating sociological and psychological interpretations.

INFLUENCES SHAPING THE CONSTRUCTS OF CAREER

Career has taken on new significance and meanings as its social and economic context has changed over time. In the midtwentieth century, as large-scale

bureaucracies were burgeoning in increasingly complex Western industrial societies, career started to receive attention in theory and practice. Representing individual mobility and meritocracy, it captured something of the relationship between the individual and society or organization at a time when the ethos of individualism was growing even as, it was being argued, a mass society was emerging. In this particular context, emphasis on the effective matching of person and occupation, advancement, continuity and future planning, and the separation of home and work became characteristic of twentieth-century constructs of career.

Toward the end of the twentieth century, this context changed considerably, and new forms of career emerged, such as the boundaryless, portfolio, and protean forms, with the emphasis on networks rather than hierarchy. Concern with discontinuities, endings and beginnings, flexibility, instrumentality, self-management and self-direction, employability, lifelong learning, and work-life balance have now become characteristic of constructs of career. As the context continues to change, new constructs of career are likely to develop.

The assumptions underpinning constructs of career have also changed over time. Midtwentieth-century conditions and social norms ensured that opportunities for upward social mobility and occupational advancement were greatest for White, male, middle-class workers, so that career was then a construct used largely of the experiences of White, male professionals and managers or those who aspired to such elite status. Indeed, when some terms are translated into French and Spanish, career is rendered as “profession.” The frequent use of college students for the large-scale samples in much career research built those norms into the career theories of the time as largely unquestioned assumptions. However, those norms are now being challenged as multicultural diversity is recognized and accepted; the construct of career is no longer regarded as being of relevance only to elites.

Constructs of career are also underpinned by even more basic assumptions. Science, which has shaped thinking in modern times, informed the interpretation of the individual, the environment, and the relationship between them and generated the methodological approaches to studying them that have been adopted in much highly respected career research. Toward the end of the twentieth century, however, new views that critique those assumptions have gained some currency.

Constructivism, social constructionism, contextualism, and postmodernism offer different ways of understanding and argue that knowledge is constructed in historical and cultural context through social processes and actions. Such approaches propose that what have traditionally been regarded as facts, such as the structure of an organization or individual traits, are interpretations constructed in a particular context for a particular purpose. These views also highlight the way career is constructed through social interaction, throw into question some key notions such as rational decision making, and underpin the interpretations of career in terms of personal constructs, narrative, metaphor, and contextual action theory that are now becoming more common.

These new views also suggest that different communities have their own discourses that construct and configure meanings that are central to their identities, interests, and power relations and use rhetoric to promulgate and sustain them. Hence, the various approaches to career seen in the several domains above can be taken as discourses of career. In other words, there are several types of stakeholders in career, and they all view the construct from their own perspectives and use it for their own purposes. In addition to individuals, stakeholders include government, employers, academics, counselors, and society itself. They use the construct rhetorically to convey their own viewpoints and values and to shape others’ interpretations. Vocational psychologists use career to empower clients; employers use career to motivate and retain staff; and policymakers use career to develop human capital and strengthen social inclusion. By regarding career as tying people to labor markets and employment in ways that are both personally meaningful and beneficial to work organizations and society, the rhetorical use of the construct supports the ideologies of society and thereby contributes to its stability.

COMMON ELEMENTS IN CONSTRUCTS OF CAREER

Across the range of constructs used to understand career, some common elements can be inferred. Career refers to movement (of an object or person) through time and (social) space. Most commonly, this is through occupational or organizational space, but it could be through a series of identity-bestowing roles or situations, as in the career of the TB patient or marijuana user. This movement is contextualized,

anchored in a specific space (setting in motion the process of constructing a range of meanings).

Movement through space is gauged in relation to some known point, which for career is located within social space, whether construed as social structure or a network of relationships. This means that the understanding of an individual's career is achieved by reference to others, whether individual or collective, and hence according to the norms, such as status, worth, or rates of progress, which give differential values to roles and relationships and the moves between them. Hence, evaluative judgments and normative expectations inform some constructs of career, whether explicitly or implicitly.

The movement of career was traditionally seen as continuous, with discontinuity or a break in career calling for explanation. The single actions or steps that constitute this continuous movement are not considered piecemeal or haphazard; between them is implied a connective tissue that transforms the whole into a course or trajectory. Different constructs of career make their own interpretation of this tissue; for example, the objective pathways individuals follow, the agency of individuals whose decisions and actions shape their career movement, or the story line individuals weave of their hopes, decisions, and actions. Despite discontinuity in the objective pathways of many of today's careers, this connective tissue can still be inferred in subjective experiences.

Career is also movement through time and relates a person's past, present and, importantly, future. Some constructs of career approach time in linear fashion, with the present flowing from a known past toward an expected future. Others, Janus-like, look backward from the present to interrogate the past and forward to construct the future, or address how the future motivates action and the construction of meaning in the present. Thus, career has been used to construct actions and events, and in some instances, the self, across time. This has informed the interpretation that career attributes coherence, continuity, and social meaning to individual lives.

Many constructs of career reflect some of its original meanings, frequently, the dual meaning of pathway and movement along it. This view points to the most distinctive characteristic of career. Career represents the coexistence of the objective and the subjective, both the social reality and the individual's experience of it; even when the focus is on the former, the latter, though submerged, is still present. Career also represents other dualities: individual and

collective, and rhetoric and praxis. Its two faces make career inherently ambivalent. It is not "either/or" but "both/and," making career a very powerful and fascinating construct that can continue to offer meaning for the twenty-first century.

—Audrey Collin

CAREER ANCHORS

The concept of *career anchors* evolved from research on adult development. Most of career theory focuses

on selection of an occupation or on a classification of types of careers embedded in the occupational structure. Career anchor theory deals with the choices adults make when they are well into their careers and classifies adult careers in terms of the major motivational forces that drive them. Career anchor theory focuses on the “internal” career, the career as experienced by the career occupant.

Within any given occupational group, there will be people with different career anchors; hence, this is not a theory of occupational type. In fact, what is striking is that in any given occupation, one will find many different career anchor types pursuing that career. Career anchor theory focuses on how motivation, competence, and values gradually combine into a career self-concept that constrains and determines career choices throughout adult life. People with different career anchors desire different kinds of work settings, are motivated by different kinds of incentives and rewards, and are vulnerable to different kinds of career mismanagement.

ORIGIN OF THE CONCEPT

The basic research leading to the concept of career anchors was begun for an entirely different purpose. In the mid-1950s, there was considerable concern over corporate indoctrination of new employees, best articulated by William H. Whyte’s 1956 book *The Organization Man*. In the aftermath of the Korean conflict, the concept of “brainwashing” entered the English vocabulary, and a concern developed that corporate socialization practices were uncomfortably close to the “coercive persuasion” that had been observed in Korean POW camps and in Chinese Communist prisons on the mainland.

General Electric’s (GE) management development center at Crotonville, New York, was boldly identified as the GE “Indoctrination Center.” IBM was not only engaging in coercive “culture-building” activities, such as requiring all sales trainees to sing songs together glorifying IBM, but explicitly indoctrinated management trainees by first asking trainees to analyze cases and then give the “correct” IBM solution, grading each trainee on how closely he or she came to that solution, then sending the grades back to the boss who had sponsored the trainee.

Career research at that time was primarily concerned with selection and the prediction of occupational success from aptitude and personnel tests of

various sorts. Major research projects undertaken within Exxon, the Bell Telephone System, and GE attempted to locate the personal factors that would predict career success, usually measured by rank and salary achieved within a corporate structure. Because the research was primarily done by a few large corporations, much was learned about careers in those corporations, but little was learned about the variety of careers that people were pursuing outside of large organizations. To that end, one had to start with alumni samples and follow people longitudinally.

The research that led to career anchors was originally designed to study the process of corporate socialization and indoctrination. To this end, three panels of Sloan School master’s degree students (15 in 1961, 15 in 1962, and 14 in 1963) were formed. Students were randomly selected, to ensure that a broad range of careers would be tapped, and invited into the study conducted by Edgar H. Schein. Students were interviewed about their past educational and vocational histories and were given a battery of self-concept, attitude, and values questionnaires. Prior research had shown that faculty attitudes and values differed from managerial attitudes on a number of important dimensions. Students started out closer to the faculty attitudes. It seemed reasonable to assume, therefore, that student attitudes would shift away from business attitudes while they were in school but would show evidence of indoctrination during the early years of corporate life.

To test this assumption, each alumnus (all were men in the early 1960s) was reinterviewed and tested 12 months later. Each was asked to identify his boss and peers, permitting the researchers to send him the same attitude survey to determine whether the alumnus had moved toward the attitudes of his boss and peers during that first year. The survey results failed to reveal any consistent pattern. Some people did become more business oriented, but others either showed no change or, in a few cases, showed movement away from business attitudes.

On the other hand, the interview results revealed that the transition from school to industry was difficult, often disappointing, and fraught with “reality shock.” Alumni were not only learning what life in industry was really like but also, more important, were discovering some things about themselves that they did not realize while at school. Whereas every single person had indicated in his first-year interview that he wanted to be a “captain of industry” and “climb the

corporate ladder,” many alumni said they realized within a year or two that such a traditional managerial career was not what they wanted at all.

The important career process that was going on in this early stage of the career was not indoctrination, but learning—the organization was learning about its new employee, and the new employee was not only learning about the organization but also, more important, about himself. This learning was still going on when the alumni were resurveyed 5 years out, but a new pattern of results showed up when the sample was reinterviewed 10 years out. The interviews were structured to get each person to review the major steps of his education and work life. For each event mentioned, the question of “Why did that happen?” was asked. What emerged from these interview accounts was that the “external-career” events might be all over the map but the reasons for them happening were highly patterned. It became clear that while a person was making many different kinds of career moves, there was a growing logic in what the person was looking for and a growing self-concept based on initial motivation and actual early job experiences. In other words, in the “internal career,” one could see patterns that could not be inferred from educational and job decisions. The focus of the research then became the dynamics of the internal career as it evolves in adults during the first decade or so of their external careers.

These dynamics revolve around the kinds of questions that each alumnus faced: (a) What are my talents, skills, and areas of competence? (b) What are my main motives, needs, drives, and goals in life? What do I want or not want, either because I have never wanted it or because I have realized after some work experience that I no longer want it? (c) What are my values—the main criteria by which I judge what I am doing? Am I in an organization or job that is congruent with my values? How good or bad do I feel about what I am doing in my work life? How proud or ashamed am I of my work and career? (d) If I am offered a promotion, a job move to another department or another city, should I take the offer or not? (e) If I am laid off or decide to resign, what should I do next?

THE CONCEPT OF CAREER ANCHORS

The patterns of answers to the above questions had the character of becoming a kind of guidance system

that informed career choices. Career occupants found themselves seeking or avoiding certain kinds of job situations, and if the current job context did not fulfill the desired expectations, the guidance system functioned to “pull the person back to something that felt more congruent.” Job choices that did not work were followed by feelings of “being pulled back into a safe harbor.” These and other images reported by the alumni led to the concept of the career anchor.

Formally defined, a career anchor is the pattern of self-perceived areas of competence, motives, and values that guide and constrain career choices. The emphasis is on self-perception, though such self-perception is built on the 10 years or more of job experiences that the person has up to that point. Younger people who have not had much work experience will, by definition, have no career anchor. They will not have obtained enough feedback to know what their competences, motives, and values really are.

TYPES OF CAREER ANCHORS

The interviews revealed a surprising diversity in what people really wanted out of their careers, but within this diversity, some clear patterns emerged that were sorted into the eight types that will be described below. In extensive further research reported by Schein in 1985 and in 1993, the eight types have been observed in all kinds of occupations, are equally applicable to men and women, and have been found in other cultures.

Anchor 1: Technical/Functional Competence

Some people discover as their careers unfold that they have both a strong talent and high motivation for a particular kind of work. What really “turns them on” is the exercise of their talents and the satisfaction of knowing that they are experts. These are the people we think of as “craftsmen,” “professionals,” and “experts.”

This anchor occurs in all kinds of work. For example, an engineer may discover that he or she is very good at design; a salesperson may find real selling talent and desire; a manufacturing manager may encounter greater and greater pleasure in running complex plants; a financial analyst may uncover talent and enjoyment in solving complex capital investment problems; a teacher may enjoy his or her growing expertise in the field; a police officer may find that he

or she loves the technical side of gathering evidence, and so on.

These people build a sense of identity around the content of their work and the technical or functional areas in which they are succeeding, and they develop increasing skills in those areas. Although others might be more concerned about the context of the work, this type of person is more concerned about the intrinsic content of the work.

Technical/functional people want to be paid for their skill levels, often defined by education and work experience. A person with a doctorate wants a higher salary than someone with a master's degree, regardless of actual accomplishments. These people are oriented toward external equity, meaning that they will compare their salaries with what others of the same skill level earn in other organizations. Even if they are the highest-paid people in their own organizations, they will feel that they are not being treated fairly if they are underpaid compared with those in similar positions in other organizations.

The specialist values the recognition of his or her professional peers more than uninformed rewards from members of management. In other words, a pat on the back from a supervisor who really does not understand what was accomplished is worth less than acknowledgment from a professional peer or even from a subordinate who knows exactly what was accomplished and how difficult it might have been. The most important form of recognition is to be given more challenging assignments in their specialties and to be given educational opportunities to become even more competent.

Anchor 2: General Managerial Competence

Some people discover as their careers progress that they really want to become general managers, that management per se interests them, that they have the range of competencies required to be a general manager, and that they have the ambition to rise to organizational levels in which they will be responsible for major policy decisions and in which their own efforts will make the difference between success and failure of the organization.

When they first enter organizations, most people have aspirations to get ahead in some general sense. Many of them talk explicitly of ambitions to rise to the top, but few have a realistic picture of what is actually

required in the way of talents, motives, and values to do so. With experience, it becomes clearer that they need not only a high level of motivation to reach the top, and succeed as a general manager, but also a mixture of talents and skills in the following three basic areas.

Analytical Competence. An individual must have the ability to identify, analyze, synthesize, and solve problems under conditions of incomplete information and uncertainty. General managers constantly point out the importance of being able to decipher what is going on, to cut through a mass of possibly irrelevant detail to get to the heart of a matter, to judge the reliability and validity of information in the absence of clear verification opportunities, and to pose the problem or question in such a way that it can be worked on.

Interpersonal and Intergroup Competence. An individual must have the ability to influence, supervise, lead, handle, and control people and groups at all levels of the organization toward organizational goal achievement. General managers point out that this skill involves eliciting valid information from others, getting others to collaborate to achieve synergistic outcomes, motivating people to contribute what they know to the problem-solving process, clearly communicating the goals to be achieved, facilitating the decision-making process and decision implementation, monitoring progress, and instituting corrective action if necessary.

Emotional Competence. An individual must have (a) the capacity to be stimulated by emotional and interpersonal issues and crises rather than be exhausted or debilitated by them, (b) the capacity to bear high levels of responsibility without becoming paralyzed, and (c) the ability to exercise power and make difficult decisions without guilt or shame. These competencies must be exercised 24 hours a day, 7 days a week.

The essence of the general manager's job is to absorb the emotional strains of uncertainty, interpersonal conflict, and high levels of responsibility. People with this anchor will measure the attractiveness of a work assignment in terms of its importance to the success of the organization, and they will identify strongly with the organization and its success or failure as a measure of how well they have done. In a sense, then, they are real "organization people," whose identity rests managing an effective organization.

Managerially anchored people measure themselves by their income levels and expect to be very highly paid. They are oriented toward internal equity in that they want to be paid substantially more than people at the level below them and will be satisfied if that condition is met, even if someone at their own level in another company is earning more. They also want short-term rewards, such as bonuses for achieving organizational targets, and because they are identified with the organization, they are very responsive to benefits such as stock options that give them a sense of ownership and shared fate. Managerially anchored people prefer frequent promotions, based on merit, measured performance, and results, to positions of higher responsibility.

Anchor 3: Autonomy/Independence

Some people discover early in their working lives that their need to be on their own is more important than the actual content of what they do. They cannot stand to be bound by other people's rules, procedures, working hours, dress codes, and other norms that almost invariably arise in any kind of organization. Regardless of what they work on, such people have an overriding need to do things in their own way, at their own pace, and according to their own standards. They find organizational life to be restrictive, irrational, and intrusive into their private lives; therefore, they often prefer to pursue more independent careers on their own terms or organizational jobs that provide maximum freedom, such as being a salesperson out in the field. If forced to make a choice between a present job that permits autonomy and a much better job that requires giving it up, the autonomy/independence-anchored person would stay in his or her present job.

Everyone has needs for certain levels of autonomy, and these needs vary during the course of life. For some people, however, such needs come to be overriding; they feel that they must be masters of their own ships at all times. Sometimes extreme autonomy needs result from high levels of education and professionalism, in which the educational process itself teaches the person to be totally self-reliant and responsible, as is the case for many doctors and professors. Sometimes such feelings are developed in childhood by child-rearing methods that put great emphasis on self-reliance and independent judgment.

People who begin to organize their careers around such needs gravitate toward autonomous professions,

but every occupation has autonomous job possibilities within it. A lawyer or doctor can work for a big firm or open his or her own office; a police officer can become a private detective; a manager can open his or her own store or become an independent consultant. If interested in business or management, a person may go into consulting or teaching or end up in areas of work in which autonomy is relatively possible even in large organizations: research and development, field sales offices, data processing, market research, financial analysis, or the management of geographically remote units. If this kind of person does end up employed within an organization, he or she prefers clearly delineated, time-bounded kinds of work within his or her area of expertise. Contract or project work, whether part-time, full-time, or even temporary, is acceptable and often desirable.

Anchor 4: Security/Stability

Some people have an overriding need to organize their careers so that they feel safe and secure, so that future events are predictable, and so that they can relax in the knowledge that they have "made it." Everyone needs some degree of security and stability throughout life. At certain life stages, financial security can become the overriding issue, such as when one is raising and educating a family or approaching retirement. However, for some people, security and stability are predominant throughout their careers, and these concerns guide and constrain all major career decisions. Security and stability come to be more important than the content of what they do.

Such people often seek jobs in organizations that provide job tenure, that have the reputation of avoiding layoffs, that have good retirement plans and benefit programs, that have the image of being strong and reliable, and that have a reward system based on seniority and loyalty. For this reason, government and civil service jobs are often attractive to these people, and they obtain some of their satisfaction from identifying with their organizations even if they do not have high-ranking or important jobs. Every occupation has security/stability-anchored members, who are often the stable element in that occupation.

Anchor 5: Entrepreneurial Creativity

Some people discover early in life that they have an overriding need to create new ventures of their own by

developing new products or services, building new organizations through financial manipulation, or taking over existing businesses and reshaping them to their own specifications. Creativity in some form or other exists in all career anchor groups, but what distinguishes the entrepreneur is that creating a new venture of some sort is viewed as essential to the career and to self-fulfillment. Inventors or artists or researchers also depend heavily on creativity, but they usually do not become committed to building new ventures around their creations. The creative urge in this anchor group is specifically toward creating new organizations, products, or services that can be identified closely with the entrepreneur's own efforts, that will survive on their own, and that will be economically successful. Making money is, then, one key measure of success.

Many people dream about forming their own businesses and express those dreams at various stages of their careers. In some cases, these dreams express needs for autonomy—to get out on one's own. The difference is that entrepreneurially anchored people typically begin to pursue such dreams relentlessly and early in life, often starting small moneymaking enterprises even during their school years. They find they have both the talent and an extraordinarily high level of motivation to prove to the world that they can succeed. Entrepreneurially anchored people often fail in their early efforts but keep searching for opportunities to try again and again. They are restless and continually require new creative challenges.

For this group of people, ownership is ultimately the most important issue. Often they do not pay themselves very well, but they retain control of their organizations' stock. If they develop new products, they want to own the patents. Entrepreneurs want to accumulate wealth, not so much for its own sake, but as a way of showing the world what they have accomplished. Entrepreneurs are rather self-centered, seeking high personal visibility and public recognition. Often they display this quality by putting their own names on products or companies.

Anchor 6: Sense of Service, Dedication to a Cause

Some people enter occupations because of central values that they want to embody in their work and careers. They are oriented more toward these values than toward the actual talents or areas of competence involved. Their career decisions are based on the desire to improve the world in some fashion. People

with this anchor are attracted to the helping professions, such as medicine, nursing, social work, teaching, and the ministry. However, dedication to a cause clearly also characterizes some people in business management and in organizational careers. Some examples include the human resource specialist who works on affirmative action programs, the labor lawyer intent on improving labor-management relations, the research scientist working on a new drug, the scientist working for environmental protection, and the manager who chooses to go into public service to improve some aspect of society in general. Values such as working with people, serving humanity, saving the environment, and helping one's nation can be powerful anchors in one's career.

Service-anchored people clearly want work that permits them to influence their employing organizations in the direction of their values. They want fair pay for their contributions and portable benefits, because they have no a priori organizational loyalty. More important than monetary rewards is a promotional system that recognizes the contribution of the service-anchored person and moves him or her into positions with more influence and the freedom to operate autonomously. Service-anchored people want recognition and support both from their professional peers and from their superiors; they want to feel as though their values are shared by higher levels of management. Like the technically/functionally anchored, they would appreciate opportunities for more education, support for attendance at professional meetings, awards and prizes, and public acclaim for their accomplishments.

Anchor 7: Pure Challenge

Some people anchor their careers in the perception that they can conquer anything or anybody. They define success as overcoming impossible obstacles, solving unsolvable problems, and winning out over formidable opponents. As they progress, they seek ever-tougher challenges. For some, this takes the form of seeking jobs in which they face more and more difficult problems or competitive challenges. Above all else, they want to "win."

Many salespeople, professional athletes, and even some general managers and entrepreneurs define their careers essentially as daily combat or competition in which winning is everything. The type of pay, promotion system, and forms of recognition are all subordinate to whether or not the job provides constant opportunities for self-tests.

Anchor 8: Lifestyle

At first glance, this concept seems like a contradiction in terms. People who organize their existences around lifestyle are, in one sense, saying that their careers are less important to them and therefore that they do not have a career anchor. These people belong in a discussion of career anchors, however, because a growing number of people who are highly motivated toward meaningful careers are, at the same time, finding themselves in situations in which their careers must be integrated with their total lifestyles.

This kind of situation has arisen for more and more people because of changing social values around independence; the growing number of women in full careers, which has led to many more dual-career families; the changing attitudes of employers toward giving less job security and more portability in benefits; and the growing number of families who cannot survive economically unless both spouses work. If people must manage their own careers and they have spouses with careers, it is inevitable that more and more people will think about designing their total life situations, not just their work.

An integration of career and lifestyle issues is itself evolving, and people with this kind of orientation want flexibility more than anything else. Unlike the autonomy-anchored person, who also wants flexibility, those with lifestyle anchors are quite willing to work for organizations, do a variety of kinds of work, and accept organizational rules and restrictions provided that the right options are available at the right time. Such options might include traveling or moving only at times when family situations permit, part-time work if life concerns require it, sabbaticals, paternity and maternity leaves, day care options (which are becoming especially relevant for the growing population of dual-career couples and single parents), flexible working hours, work at home during normal working hours, and so on. Lifestyle-anchored people look more for an organizational attitude than a specific program, an attitude that reflects respect for personal and family concerns and makes genuine renegotiation of the psychological contract possible.

PRACTICAL IMPLICATIONS

All career occupants should recognize their career anchors in order to make better choices about career moves. If individuals do not know their anchors, they are very vulnerable to being given assignments or promotions that do not fit their self-images at all, leading

to unproductive and stressful work situations. By analyzing their own career histories and the reasons for the choices they have made in the past, they can identify what is important to them and use that knowledge in making better career choices.

Most people will find that if they reflect carefully on the decisions they have made that they fit into one of the anchor categories. If more than one anchor seems to fit, the person should examine possible situations that might require a choice and think about what he or she would do if forced to make a choice.

In summary, career anchors are a way of understanding the dynamics of the internal career in adulthood. Career anchors form from experience, and once an individual has developed a self-image around his or her competencies, motives, and values, the anchor then guides and constrains the rest of that person's adult career and life. Career anchors can change if a person encounters dramatically new experiences, but for most people, once they have formed a clear self-image, the tendency is to hold on that image.

CAREER APPRAISAL

The increasing specialization of today's more diverse and technologically advanced labor market challenges employees and job seekers alike to continually evaluate their career choices and engage in *career appraisal*.

The development of a comprehensive career plan is essential in understanding one's interests, attributes, abilities, and values necessary to fit into this ever-changing vocational environment. Moreover, adults find themselves reconsidering previous career choices as they develop new interests or as the job market shifts. Of all these domains, vocational interests serve as the cornerstone of any career plan. John Holland's theory provides an avenue for classifying vocational interests into six categories (RIASEC): Realistic (working outdoors, building, repairing); Investigative (researching, analyzing, inquiring); Artistic (creating or enjoying art, drama, music, writing); Social (helping, instructing), Enterprising (persuading, selling, managing); and Conventional (accounting, organizing, processing data). Interest inventories such as the Strong Interest Inventory (SII) and the Campbell Interests and Skills Survey (CISS) can help users learn which combination of the RIASEC categories describes their vocational interests. Choosing work environments that align with areas of interest is more likely to increase job satisfaction.

In the last decade, researchers have established that career appraisal for the individual is more useful when it goes beyond the six general categories of interests to specific interests. For example, although it is useful to know someone has Realistic interests, knowing concretely whether he or she enjoys military activities or mechanical activities allows for better discrimination. In addition, increased specificity translates to increased ability to determine career fields and educational majors that more closely align with one's interests as well as those that prove to be less desirable. The SII and CISS mentioned above provide measures of specific vocational interests as well as general interests. Although occupational scales on the SII or the CIS implicitly provide greater specificity, scales such as the Basic Interest Scales on the SII make the process explicit and directly interpretable based on the transparency of those scales.

Traditionally, vocational interest assessment has been the primary tool used to assist clients in making important career choices. However, two additional constructs that have emerged in the past decade are also important contributors. The construct of personality has been shown to be an important variable in helping us understand the unique individual from a more holistic outlook. To date, three empirical reviews have examined the overlap of personality and interests. This evidence shows that both have at least

three clear general links: (1) People who are more open to new experiences tend to have more artistic and investigative interests, (2) extraverts tend to have more social and enterprising interests, and (3) people who are more agreeable tend to have more social interests. Vocational counselors who incorporate this knowledge will be in a better position to view their clients more broadly than simply through their vocational interests. For example, clients who are more open to novel and new experiences may be more satisfied with intellectual or creative work environments. Interestingly, personality and interests may be genetically linked; studies show that about 50 percent of their stable variance is genetic.

Just as more rather than less information is better with vocational interests, it seems that more specific information about personality beyond general traits is useful in helping better differentiate vocational interests within a particular general interest. For example, people who are entranced with evocative sights and sounds are more likely to be engaged in artistic interests. In short, researchers are beginning to quilt a fabric of particular areas that more aptly define a unique individual with particular tendencies. The more a vocational professional can assist the client to integrate both aspects of his or her personality and interests, the more equipped that individual will be to make an informed vocational choice.

Unfortunately, it is not enough to consider only the unique aspects of clients' personalities and interests. Rather, understanding these overlapping areas serves as the springboard for placement in engaging careers, but alone, this may not ensure retention. The development of new skills and the refinement of current skills are critical to career persistence. With the advance of social cognitive career theory, vocational self-efficacy has emerged as the third construct in the three-legged stool of career appraisal. Knowledge about personality and interests is helpful in choosing a career or pursuing an area of specialization that is a good fit. However, it may be a person's self-efficacy that will help ensure that a person will follow through on his or her choices and ultimately succeed at the endeavor.

Understanding the triangular structure of the "P," or person, in person-environment (P-E) fit can help vocational counselors directly address which of the three legs of career appraisal is causing the stool to waiver. If a client demonstrates high interest in a career that seems to match his or her personality type but lacks the confidence to enter that career, a counselor can work

directly to increase the individual's self-efficacy within that specific domain. Specifically, counselors can work with clients to increase self-efficacy by ensuring mastery experiences, providing successful models, reducing anxiety, and providing support and encouragement. Likewise, if a client's personality seems particularly well suited to certain interests and those interests are not apparent, the counselor may want to ascertain whether there have been environmental limitations, such as racism, sexism, or poverty, that have limited exposure to potential interests. Moreover, high-ability clients who have the confidence to pursue a range of career options may need reassurance to follow their interests/personality fit with careers rather than choosing careers that are prestigious or would please their parents. Finally, the understanding of these three constructs will be useful for adult clients who may be underemployed or unemployed or seeking to change jobs within their organizations.

The dynamic use of P-E fit is essential in successfully transitioning from one career to the next. In America's mobile society, it is not uncommon for an adult to shift careers based on the needs of the individual as well as demands of the environment. A person may develop additional interests or choose to emphasize different interests based on consideration of salary, family-friendliness of an occupation, or needs of the family. Older adults may seek out fresh new challenges, greater flexibility, or more independence. Adults may leave careers after a few years despite feeling confident, because they may find the tasks associated with the career a poor fit for their personality and interests. Vocational counselors need to provide P-E fit information to adults at these critical junctures when career appraisal is necessary.

Research is accumulating on the intersection of critical person factors in P-E fit. Though interests provide the foundation, building a successful career demands more than the identification of preferred activities. Future vocational researchers and counselors alike may want to adopt an integrationist perspective. This will allow for the expansion of the field's knowledge of how interests, personality, and self-efficacy interrelate in both experimental and applied settings. It is imperative that vocational professionals in both arenas work to inform each other of their accumulated knowledge. This will allow research to inform practice and practice to inform research.

CAREER AS A CALLING

The new era of organizational life has ushered in critical changes in how people conceive of their careers and how organizations think about the work trajectories of their employees. Trends toward shorter relationships between individuals and the organizations in which they work have forced revised ways of thinking about the structure of careers. While the bells that toll to mark the end of the traditional career may be premature, it is impossible to ignore the need to envision different ways to define what constitutes meaningful narratives of work lives as individuals navigate a changed terrain of careers. Because individuals, rather than the organizations they work for, are responsible for their own career directions, the role of personal

values has received more attention as a way to understand what guides individually directed careers.

The concept of a *career as a calling* speaks to the potential for congruence between individual values and the meaning derived from the various components of work that constitute a career path. Individuals who view their work as a calling see the work they do as an end in and of itself and thus are more committed to their work and less reliant on traditional career markers such as advancement and financial rewards as measures of success. Seeing one's career as a calling offers a different model for how individuals interact with structures of work to create meaning and craft work trajectories that are based on the actual work they do, rather than on the markers of success that are traditionally associated with careers and career progress. This suggests that calling-oriented employees are more motivated and better equipped to craft their own career paths despite the complexities evident in the changing employment climate.

THE CHANGING SHAPE OF CAREERS

Changes in organizations have made linear, intra-organizational careers less common, leading organizational researchers to study the ways individuals in a range of occupations might adapt to the accompanying changes in career structures. Sociologists, psychologists, and organizational theorists have proposed that organizational changes foretell the end of the traditional career. In its place, scholars have offered models of the protean career, the boundaryless career, careers of achievement and the "new" career. Most revised models of careers suggest that employees must now improvise, enact, and construct their careers across and outside organizational boundaries. In the popular press on careers, the free agent reigns; job hopping is more common; and taking time out for reeducation and training is essential. There has been appreciably less written about how employees' own values and goals for working operate within this context of careers and how much, if at all, employees have adapted to the changing times.

Traditionally, organizational careers have been represented by models that assume movement up a hierarchy within a single organization, with increasing responsibility and financial gain. While these linear careers may never have been as common as was believed, their decline over the past few decades has left employees in a position to create their own work

trajectories to fulfill superordinate career and developmental goals. Many career scholars have argued that employees have become more entrepreneurial as a result, piecing together work experiences that focus on increased skill and a sense of control over their work experiences, while focusing less on promotions, advancement, and increasing status. Employees in this environment may seek career guidance from a wide network of relationships that are not dictated by organizational boundaries.

These changes in careers are believed to be caused by changes in organizational structures and in the psychological contracts between organizations and employees that result. Just as corporations are continually reorganizing in response to economic demands and global competition, the nature of work in organizations has become flexible to the point of becoming fragmented. Although research has suggested that individual action can affect the arrangements between employees and institutions, less is known about what guides individuals' actions as they carry out their careers. There are primarily two schools of thought: first, that the individual can adapt to changing career structures because they match the individual's preexisting career goals or, second, that the individual must work to adapt to career models offered by the organization. A third option, in which individuals shape their own work lives through the ways in which they make meaning of work, is relatively unexplored but is gaining attention. In effect, this view suggests that in the wake of the weak situations created by organizations, with few guides for individual action, individuals are freer to enact their careers as their own creations because there are no longer strong models with clear structures to direct their career trajectories. Under such conditions, individuals are more likely to use their values, experience, knowledge, and networks to guide their work lives over time. Specifically, the values that individuals bring to their work and the subsequent meaning they make of their work is an important source of influence on how individuals think about their careers.

Individuals have been found to vary greatly in the kinds of meaning they derive from their work. Even within the same occupation, the personal meaning that different individuals attach to their work has been found to vary in ways that are systematically related to changes (even minor changes) in how they define the jobs they do. Importance is thus placed on the individual's narrative of the work, imbued with meaning

and representing a personal orientation toward work that helps to make sense of a complex career environment. One such narrative grows from the meaning individuals glean from their work when they view what they do as a calling.

CAREER AS A CALLING

The idea of viewing one's work as a calling came into common usage with Max Weber's concept of the Protestant work ethic. While a calling originally had religious connotations and meant doing work that God had "called" one to do, a calling in the modern sense has lost this religious connotation and is defined here as consisting of enjoyable work that is seen as making the world a better place in some way. Thus, the concept of a calling has taken on a new form in the modern era and is one of several kinds of meanings that people attach to their work. These meanings, which may be considered more broadly as *work orientations*, guide the process by which individuals select work, as well as how they perform the tasks included in their jobs.

The concept of work orientation is derived from a set of arguments in sociology that claim that work is subjectively experienced by individuals in one of three distinct ways: as a job, a career, or a calling. These three categories represent three different work orientations, defined as the ways in which work relates to one's sense of oneself. Work orientation guides the types of goals individuals strive to meet through working, encompasses beliefs about the role of work in life and, as such, is reflected in work-related feelings and behaviors. The goals associated with work orientation have implications for how individuals conduct themselves in relation to their work. Therefore, work orientation is a useful lens through which to understand what individuals are searching for in their careers. Prior research has shown that each type of work orientation can be found both across and within various occupations and that individuals are unambiguous in reporting that they experience their work as a job, career, or calling. To address the implications of seeing one's career as a calling, it is first necessary to define and explore job and career orientations to work.

Each work orientation is associated with the kinds of goals individuals pursue in their work lives. Thus, those with a *job orientation* toward work are primarily interested in the material benefits from work and do not seek many other types of rewards from it. The

work is not an end in itself, but instead is a means for acquiring the resources needed to enjoy time away from the job. In essence, the main goal of those with job orientations is to make an income, and leisure is kept separate from work.

In contrast to those with a job orientation, employees with a *career orientation* are more personally invested in their work and tend to mark their achievements not only through monetary gain but also through advancement within the occupational structure. This advancement often brings higher social standing and self-esteem, as well as increased power within the scope of one's occupation. Thus, the goal of the career oriented is to increase income, social status, power, and prestige in their occupations, whether within or between organizations. For example, a career-oriented middle manager may strive to become a vice president, or a young attorney may strive to make partner in a law firm.

By contrast, a calling-oriented middle manager or attorney works not for advancement but for the fulfillment that the work brings. Specifically, people with a *calling orientation* tend to view their work as inseparable from the rest of their lives. Individuals with callings are not working for material rewards or career advancement but instead view the work as an end in itself. The goal of those with callings is to gain deep fulfillment from doing work that they view as having a positive impact on the wider world. Most popular examples of calling orientations come from the arts or helping professions (e.g., medicine, social work), as many individuals in these occupations are compelled to do expressive work or to be of service to others. Traditionally, job and calling orientations have been thought of as representing opposite extremes of the same dimension. If one has a strong calling orientation, it is unlikely that a strong job orientation would also be present, given the focus on intrinsic versus extrinsic motivation to perform one's work.

The notion of a career as a calling is supported by research that shows that any kind of work can be viewed as a calling. Work orientation is essentially the frame of meaning applied to the work one does; thus, it is possible to do the same work and view it quite differently based on which orientation is applied to the work. For example, a computer programmer can view the work as a way to make a paycheck (job orientation), as a way to move into project management and infrastructure design on the way to securing a director-level position (career orientation), or as a way

to carry out the enjoyable, fulfilling work of programming that is seen as contributing to knowledge management and creation in the wider world (calling orientation). The calling-oriented programmer is much more likely to thrive in a work world in which career structures are increasingly complex, sequential, and unpredictable, because a calling orientation provides a life narrative to the work that is both deeply meaningful and less reliant on the external career structures of the organization. Thus, calling-oriented individuals are more protected from the episodic and uncertain nature of career progression in organizations, whereas those with career orientations are perhaps most exposed to the changes in organizations that make advancement less certain. Like the calling oriented, the job oriented are also protected from both traditional and modern career structures in organizations, for they are working for pay and little more and thus do not need to impose broader goals for advancement on the work they do. However, in contrast to the job oriented, calling-oriented individuals gain a deeper source of meaning and fulfillment from work, which creates a deeper bond to the work itself. Although those with calling orientations value doing work for the meaning that the work represents, clearly, the financial rewards of work hold some importance for them. However, these rewards are subordinate to the meaning that doing the work itself brings to the person. Work orientations are not mutually exclusive, but instead represent the relative importance to individual employees of their reasons for working.

IMPLICATIONS OF A CALLING ORIENTATION FOR MODERN CAREERS

Viewing one's work as a calling has been shown to be related to a number of positive outcomes for both employees and their employers. Calling-oriented individuals report higher job and life satisfaction, even after controlling for income, level of education, and occupation, than people who view their work as jobs or careers. These employees also report higher work motivation and are less likely to regret their choice of occupations. Individuals who feel called to perform their work also report greater occupational commitment and enthusiasm and are more likely to create new tasks, responsibilities, and approaches to their work. Such new approaches to the work infuse the work with deeper meaning and may help organizations to more effectively meet their goals.

Individuals with callings appear to be at an advantage given today's changing career environment. Modern careers require individuals to interact with changing career structures to fulfill their goals for working. Thus, work orientation, specifically a calling orientation, offers continuity to work trajectories at a time when work histories are more fragmented. Calling orientations endow both the individuals who adhere to them and the organizations that employ such individuals with positive outcomes that flow from a deeper connection to the work and a stronger passion for the activity of performing job tasks. Thus, a calling orientation provides a possible answer to the question of how narratives of identity and life history will be derived in a changing society in which careers are increasingly made up of episodes and fragments. For individuals with calling orientations, a relatively stable set of goals can be pursued in their work that could be expected to persist within, between, and beyond specific jobs.

In this sense, a calling orientation shares some elements with the factors that constitute a protean career orientation, such as the extent to which decisions regarding one's careers are based on personal values versus financial or other extrinsic factors. It follows that individuals who are more attached to the intrinsic nature of the work itself, those with a calling versus job or career orientation, are more likely to take whatever steps are necessary to continue along their preferred paths, what scholars have referred to as the "path with a heart." Indeed, ongoing research in the area of careers has begun to focus on the role of meaning and values in the context of changing career structures. The promise of career as a calling is but one direction that this work has taken, offering an alternative path for understanding the responses individuals could have to a work world in which careers are the responsibility of the employee.

CAREER CENTERS

The comprehensive college and university *career center* is a uniquely American phenomenon that has evolved over the past 100 or more years in response to changing educational, economic, political, and social conditions. This entry identifies several historic events in the evolution of the career center, outlines the core functional elements, enumerates the behavioral objectives, and provides a brief summary and look to the future.

Prior to the passage of the Morrill Act, also known as the Land Grant College Act, in 1862, higher education in the United States was a privilege to which a relatively small percentage of the population had access. Students entering higher education did so largely with a view to entering the professions, and there was little need for career assistance that could not be provided by faculty who took a natural interest in the career development and aspirations of their students. The Land Grant College Act changed all that. With the passage of the Morrill Act in 1862, the

nation entered an era of unprecedented public support for higher education. Prior to that, the majority of those who entered college were generally more concerned with accumulating credits and acquiring licenses than with learning any particular skill while enrolled. The passage of the Morrill Act signaled a sea change in the national philosophy toward and resource commitment to public higher education and redefined higher education as a means by which the masses could acquire not only knowledge but also marketable skills and professional preparation to enter the workforce.

The Truman Commission Report of 1948 acknowledged the economic significance of higher education for the first time, determined that half or more of the American public was capable of completing a baccalaureate degree and, more important, that the public had a "right" to expect that public support of higher education would put a bachelor's degree within reach of any American who had the ability to secure one. Essentially, higher education became a "right" rather than a privilege, and a massive resource influx from the GI Bill and other sources propelled public higher education to unprecedented growth. With this rapid growth and the necessity to meet the needs of huge, diverse student bodies, higher education was forced to specialize. Faculties were no longer able or willing to provide for myriad out-of-class needs of students, giving birth to a new classification of professionals called "student affairs." The offices that evolved to provide for the career development needs of students were called "placement offices," the early forerunners of career services.

By the end of World War II, public higher education had become a major societal force whose *raison d'être* had become so integrated with that of business and government that some critics began to refer to the educational/military/industrial complex in a derogatory way. The single-purpose placement office that had done little more than assist students in finding their first jobs was no longer adequate to meeting the increasingly complex career development needs of students and the greater society.

At the same time that public higher education was experiencing massive growth, the world of work had shifted from being primarily agrarian to manufacturing and was now moving into the postindustrial era: The "knowledge revolution" had begun. With these changes came the recognition that the work of the career center was more than simply finding jobs for students, a

“point-in-time event”; rather, career development was increasingly seen as a complex, lifelong process.

These were the conditions that led to the establishment of the core elements of the comprehensive, modern-day career center as enumerated by Jack Rayman. An annotated list of these core elements is as follows:

- Career counseling and planning: Drop-in, individual, computerized, and group counseling, including formal assessment and evaluation
- Recruitment and employer relations (placement): The establishment and maintenance of formal relationships with a broad range of potential employers, including on-campus recruiting services, vacancy listing services, and elaborate informational resources in support of the placement function
- Career programming, outreach, and marketing: A sophisticated and expansive array of seminars, workshops, courses for credit, and career fairs and the technology to deliver these programs in person, via phone, fax, and the Internet to clients throughout the world
- Information technology support: The technical personnel, hardware, software, and communications network to deliver the broad array of career services described above 24/7, anywhere in the world, and the technical capacity to free up professional career services staff time for tasks that require human sensitivity
- Career information management and communications: A well-developed career library and employer information center including Web and Internet access and the communications network to deliver all informational resources on demand to students, faculty, staff, employers, and alumni clients anywhere in the world
- Training: The staff, facilities, and commitment to provide continuous and ongoing professional development and training to work-study students, volunteers, interns, graduate assistants, counselors in training, graduate students, clerical and professional staff, and postdoctoral interns seeking to enhance their skills as career services counselors and professionals
- Research, assessment and evaluation: The staff, resources, and commitment to conduct ongoing career development and choice research, assessment, and evaluation, including evaluation of all facets of the center’s staff, functions, and services, both summative and formative

Perhaps the most important factor in defining the modern career center is a set of nine behavioral objectives or learning outcomes for clients who use those services. The following is a set of widely accepted

behavioral objectives for clients of the modern career center:

1. Increased exploration and understanding of career information and options
2. Increased self-understanding in terms of values, interests, skills, and abilities and how those personal characteristics relate to a variety of careers
3. Increased awareness of the need to plan and to take responsibility for one’s own career destiny
4. The development of greater understanding of one’s self, occupations, and the relationship between self and occupations
5. The development of a realistic, appropriate, and congruent occupational choice
6. Increased knowledge of available career options and an understanding of the means of attaining those options
7. Increased knowledge of appropriate job-search strategies and job-seeking skills and experience using those strategies and skills
8. Placement into a job, acceptance into further education or training, or some client-accepted alternative life/career objective
9. The development of an awareness that career development is a lifelong process and the development of a set of skills to ensure the successful navigation of that process

In the last century, the college and university placement office has evolved from a single-purpose administrative unit offering a narrow range of placement services to a comprehensive services center providing a complex array of career services to multiple constituent groups throughout the life span. While career centers vary in size, mission, and organizational structure, the trend is inescapably toward greater size, increasing centralization, and a broader, more comprehensive mission.

CAREER CHANGE

Career change has been alternatively defined as any major change in work role requirements or work context or as a process that may result in a change of job, profession, or one's orientation to work while continuing in the same job. Here, career change refers to a subset of work role transitions that include a change of employers, along with some degree of change in the actual job or work role and the subjective perception that such changes constitute a "career change." Examples of career changes include interfirm, interindustry, and intersector transitions or occupational changes, as, for example, when a litigator leaves law to run a nonprofit organization, a corporate employee starts his or her own business, a government official enters private industry, or a consultant becomes a movie producer.

A compelling scholarly argument has been made that career change is on the rise in our society: Careers are "boundaryless" and unfold outside traditional organizational parameters; business firms continue to downsize, restructure, and lay off; and values have changed such that people increasingly change work settings in search of greater autonomy, life balance, and meaning in work. Despite this well-documented litany of trends, the last two decades have witnessed a scarcity of empirical research on career change, and key theoretical issues pertaining to the antecedents, process, and outcomes of career change remain undeveloped.

Many alternative conceptualizations and approaches to the study of career change exist. The socialization literature has been a rich source of guidance for researchers concerned with work transitions of all sorts. Most of the empirical work on which existing conceptual models are based, however, concerns early career socialization and highly institutionalized status passages, such as entry, promotion, and transfer. Career change, in contrast, tends to occur later in a

person's career and is rarely guided by institutionalized separation, transition, or incorporation processes and rituals. Instead, the person creates the rupture with the old career while generating and learning about new alternatives.

This entry is divided into three sections. The first section reviews the literature on antecedents of career change. Self-conceptions, social networks, and exogenous events emerge as key influences in an unfolding process. The second section deals with the transition processes and dynamics of change, noting the need for new theory to guide empirical research on noninstitutionalized processes. The third section explores outcomes of career transition, highlighting a range of factors that have been identified as potential moderators of the likelihood of change or the ease and duration of the transition process. Throughout, the entry highlights key unanswered questions for future investigation.

WHY DO PEOPLE CHANGE CAREERS?

Both exogenous conditions and individual factors explain change or deviation from an established career path; these might pull individual toward a new career or push them away from the old (see Figure 1). Situational factors include external market forces that determine what alternatives are available. These may prompt individuals to exit an organization or career voluntarily in search of better opportunity (pull) or, alternatively, may result in restructuring, downsizing, and other forms of job loss (push). While labor economists have focused primarily on the supply and demand of labor, in recent years, organizational scholars have also documented the role of market intermediaries, such as headhunters, in facilitating career changes as well as changing occupational configurations that have created new choices, such as contract work. Individual factors include the skills, talents, preferences, past experiences, developmental stage, and self-conceptions that individuals bring to their work roles and careers. Three themes or categories of antecedents emerge as highly influential: self-conceptions, networks, and triggers.

Self-conceptions

Professional identity represents the relatively stable and enduring constellation of attributes, beliefs, values, motives, and experiences through which

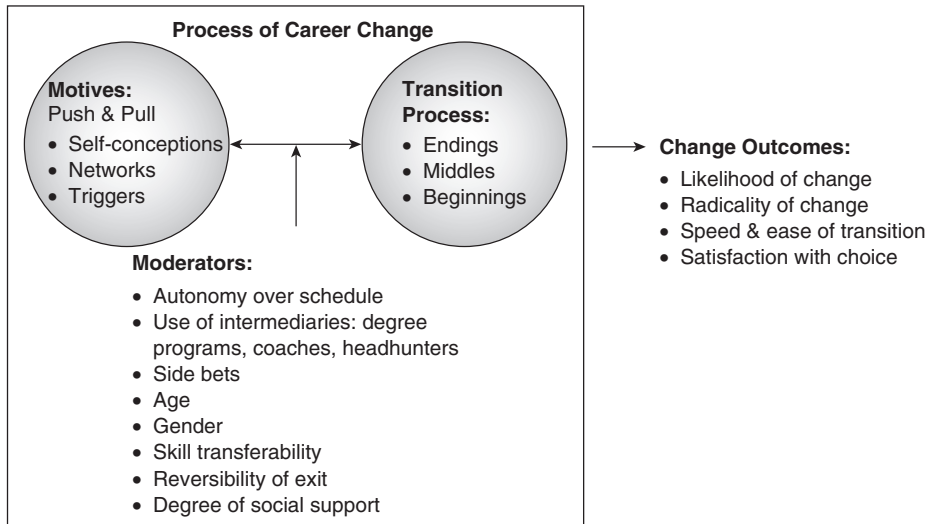

Figure 1. Process of Career Change

people define themselves in professional roles. A basic assumption is that professional identity forms over time with varied experiences and meaningful feedback that allow people to gain insight about their central and enduring preferences, talents, and values. Identities affect career change by their impact on people's perception of fit between their sense of who they are and their current careers. But identities also exist in the future and in people's heads as possible selves, images about who one might become, would like to become, or fears becoming. Possible selves affect career change by affecting perceptions of fit between individuals' ideas about who they would like to become and their beliefs about future opportunities afforded by their current careers.

Self-conceptions motivate change or deviation from an established career path in one of two principal ways. First, a person's chosen path may cease to reward the preferences and skills the person brought to it or reduce opportunities to work toward his or her career goals. In a study of physicians, Seymour Sarason, for example, found that encroaching bureaucracy and a rising need for malpractice protection disillusioned many doctors, who felt these preoccupations detracted from their role as healer. Faced with declining opportunity as the career pyramid narrows or the organization enters a period of downsizing or decline, or offered more consonant opportunities outside, a person may exit a career. Second, people may change with experience and adult development and come to find that their interests and preferences have changed such that they now

conflict with the chosen career. A person who valued getting ahead earlier in his or her career may come to desire a greater balance between work and personal life, for example, or a person who valued corporate status may come to desire the autonomy of an entrepreneurial career.

Social Networks

Career decisions are socially embedded and are thus influenced by the social networks that affect referrals and opportunities as well as the development and change

in people's identities over time. Thus, it stands to reason that the desire to exit or remain in a career is in part a function of a person's relational context.

If career change involves moving from one firm or sector to another, networks high in external relationships will be more valuable. Contact with people in alternative occupations provides information about new options as well as validation for changes one may be contemplating. In one recent study by Gideon Kunda, Steven Barley, and James Evans, for example, the decision to enter contracting required exposure to people or opportunities that made contracting seem more viable or attractive than taking another full-time job. Most people who switched to contract work had worked beside contractors in previous jobs, where they had the opportunity to observe the realities of freelance work. Similarly, Toby Stuart and Waverly Ding found that having network ties to scientists who have left academia for commercial science increases the likelihood of making the shift oneself. These extra-university ties, they have argued, facilitate the formation of a reference group that condones what the scientific community sanctions.

Networks also affect career change by providing role models that embody future possibilities. Daniel Levinson noted the key role of "guiding figures" in helping the person in transition to endure the ambiguity of the transition period by conferring blessings, giving advice, and, most important, believing in his or her "dream." The guiding figure embodies the fledgling possibility and shapes it through his or her efforts

as teacher, critic, sponsor, or mentor. People may consciously seek to establish ties compatible with desired future selves, using these new relationships to pull themselves into new social and professional circles. Alternatively, fortuitous encounters with people who have already made a transition to a different kind of work may lead a person to make a similar shift.

Finally, social networks can hold a person back from making a career change. About one-fifth of Helen Rose Ebaugh's sample reported that someone significant to them responded negatively; this negative response interrupted the exiting process or retarded the process for a significant time period. Similarly, Herminia Ibarra found that people considering career change face doubt, skepticism, conservatism, and pigeonholing on the part of friends, family, and close work associates. She argued that career transitions are facilitated by dual relational tasks: forging new, high-quality working relationships while, at the same time, ending or diluting the strong ties within which outdated role identities had been previously negotiated.

Trigger Events

A diverse set of studies and theoretical perspectives have converged on the key role of trigger events in stimulating change. Triggers may be positive or negative, momentous or small. They range from major job, organizational, and personal life changes or shocks to jolts produced by more mundane interactions. Scholars concur that critical events do not directly produce change; rather, they trigger personal explorations and trial experimentation with new forms of social interaction, which may later lead to career changes. Kunda and colleagues, for example, found that triggers such as getting laid off were insufficient to tip the balance in favor of becoming a contractor; but such triggering events were crucial for deciding to move from permanent to contingent employment because they led informants to consider their options. Positive triggers, such as a chance encounter with someone who becomes a role model for a possible professional future, may play a similar role in clarifying possible selves and increasing the motivation to explore alternatives.

HOW DOES THE TRANSITION PROCESS UNFOLD?

How does the process of career change unfold? *Transition* refers to the process of simultaneously leaving

one thing—a role or identity, for example—without having fully left it, while, at the same time, entering another without being fully a part. Meryl Louis has defined *career transition* as the period during which an individual is changing roles or changing orientation to a role already held; thus, the term transition suggests both a process of change and the period during which the change is taking place. Most existing models of the transition process identify phases or stages of change, with most models based on three phases of a rite of passage: separation, transition, and incorporation. A similar model consists of endings, a “neutral zone” or “in-between” phase, and beginnings.

Socialization researchers have devoted most of their attention to the incorporation or beginnings phase and its associated rites and rituals. In Nigel Nicholson's preparation, encounter, adjustment, and stabilization model, for example, the encounter period extends from the time of entry into the new situation until the individual has adjusted to that new situation. With the exception of involuntary job loss, these theories treat incorporation as negotiated adaptation to an existing and easily identifiable next position.

A defining feature of career change, however, is that it is not guided by institutionalized transition processes. Whereas separation in early career is accomplished through institutionalized events, such as promotions, transfers, layoffs, retirement ceremonies, and so on, there are no institutional forces to impose a separation from the old role at midcareer, unless a person is fired. Much of the work of incorporation is also self-initiated, often according to the person's own timetable. Although in many cases movement may be clearly away from the old, the destination, or the new career, in many cases, remains undefined and uncertain for a good portion of the process. In career change, therefore, separation and incorporation are often overlapping stages; the fact that both are occurring simultaneously defines a transition stage that is indeterminate in length and not necessarily finite (as when the individual fails to find a suitable career alternative). As a result, several theoretical issues pertaining specifically to career transition as a process remain undeveloped—in particular, how people identify alternatives and what replaces institutionalized separation and incorporation mechanisms.

BEGINNINGS AND ENDINGS

Scant career change research has examined the separation/endings stage, with Ebaugh's “becoming

an ex” study a notable exception. Although her primary samples were ex-nuns and transsexuals, Ebaugh found that similar processes characterized physicians leaving the practice of medicine and other occupational exits. The process begins with simmering doubts that give way to a search for alternatives, followed by a turning point that symbolizes the impossibility of return.

In many cases, endings are long and gradual; often people are not aware that they are laying the groundwork for a career exit: They simply take up a side activity that over time encroaches more and more on their time and interest. Ebaugh describes the case of an ex-astronaut who, over a 10-year period, found himself spending more and more of his time on real estate investment. In Ebaugh’s study, about a fourth of those who changed careers had begun retraining while still in their current jobs, in several cases going to back school part time or working in the new area on the side as a personal interest or hobby. Such side activities are an important way people learn about new career options and test unfamiliar waters from the safety of their current jobs: Provisional activities such as moonlighting, freelance or consulting work, side projects, volunteer work, and enrolling in courses often precede a more permanent shift to a different career. Entrepreneurs, for example, often spend years building a business on the side, maintaining a “day job” until the new enterprise becomes clearly viable. Side activities directly augment a person’s capacity to become a realistic candidate by allowing him or her to accumulate relevant experience and a network of social contacts in that sphere.

Career change, therefore, requires identifying a future path, a difficult task given that most recruitment and socialization experiences are aimed at workforce entrants and attaining some degree of anticipatory incorporation into the new occupation in order to become a credible entrant to the new field. Future research on career change must take into account ignorance of, or uncertainty about, alternative possible careers as well as the necessity of taking time to consider options and gain enough firsthand experience with them to be a plausible candidate.

When there are no institutional forces to impose a separation from the old role, the decision to separate and the act of separating are left to individual initiative: There is no prescribed start or end point. In Ebaugh’s study, the majority of exit decisions occurred in connection to some abrupt and dramatic turning point in the person’s life. But triggers alone are insufficient for sparking change; people may

ignore the information, dismiss it as irrelevant, blame the undesired outcome on fate, or deny its validity. Alternatively, what might objectively appear to be a trivial episode may be infused with great significance by an individual on the brink of change. Whether the turning point is an objectively significant event or simply bears emotional significance for the person, its function is to justify and rationalize the change. Future research is needed to provide a basis for predicting the impact that trigger events will have on the course of transition.

TRANSITIONS: IN THE MIDDLE

To date, the transition phase has been mostly treated (a) as a matter of anticipatory socialization, whereby the individual begins to take on the identity, attitudes, and relationships of the next role before he or she has actually attained it, or (b) as the state of marginality experienced by a new recruit who has yet to make his or her place in a new role and organization. Qualitative studies of a broad range of career change, from exiting an occupation to moving into a very different line of work, however, suggest that transition periods have unique characteristics, in particular, the experience of liminality: People in transition invariably feel “between identities,” describing the state as like being “in a vacuum,” “in midair,” “neither here nor there,” or “at loose ends.” This liminal period is not a literal space between one job and the next but a psychological zone in which the individual is truly between identities, with one foot still firmly planted in the “old world” and the other making tentative steps toward a new one.

In some cases, the experience of liminality results from the simultaneous pursuit of two different career paths, as when a would-be entrepreneur works on a new business idea on the side while continuing a day job; in others, it is created by diverse forms of “time-out,” as when a person is laid off, follows an outplacement program, takes a sabbatical to reflect on what comes next, or follows some form of adult education intended to help him or her change careers. Although Ebaugh reported a high incidence of returning to graduate schools (e.g., law, engineering) among her role exiters and the popular press has heralded business schools and other forms of adult education as means for changing careers, few studies to date have investigated the comparative effects of returning to school on career change.

Emerging thinking on the nature of liminal experience in organizational life raises interesting questions,

for example, the effects on career change of a transitional time that is open-ended compared with one limited to a more fixed period, or transitional space that varies on dimensions such as the degree of physical and social encapsulation of the individual. Future work on transitional states is needed to explore the extent to which variables, such as dedicated time, space, and the support of guiding figures, affect transition outcomes, such as generating viable alternatives or satisfaction with one's ultimate career choice.

WHAT ARE TRANSITION OUTCOMES AND THEIR MODERATORS?

Research on the outcomes of career transition and career change has focused on the extent to which a person and organization engage in mutual adaptation and, to a lesser extent, on the ease and speed of the transition process. Most adaptation work, as noted above, assumes a clear and identifiable next role into which the person will step. The question of interest is the extent to which the person will shape the role to fit his or her interests and strengths or, instead, will conform to the role's requirements. Most scholars concur with Blake Ashforth and Alan Saks that person and role evolve and synthesize beyond a middle ground between unchanging role and self-demands.

In work on institutionalized work role transitions, the ease and speed of transition have been explained to date in terms of the magnitude or novelty of the change from one role to the other, that is, the number and intensity of changes involved in any given career transition or the degree to which the role permits the exercise of prior knowledge, practiced skills, and established habits. The greater the magnitude or novelty, the more difficult and longer the transition process. In research on noninstitutionalized transitions, an additional set of outcome variables becomes important, notably, whether a person makes a career change versus recommitting to stay in a role after a period of harboring doubt and considering alternatives, as well as the ease and speed with which a person arrives at a viable alternative.

Ebaugh found that the kinds of alternatives explored and entered as well as the duration of the transition process are in part determined by the transferability of skills, interests, and experience that the person perceives between the old and potential new career. In her study, some occupational exiters considered jobs at least tangentially related to what they were doing before (e.g., business teachers found jobs

as accountants in business; police officers went into private security work); others, however, notably physicians, moved into completely different lines of work (e.g., law, real estate). Future work is needed to investigate what kind of transition processes lead to more or less radical changes.

A more important determinant than skill transferability of taking the leap may be the capacity to explore alternatives. Teachers and coaches who worked on nine-month contracts were easily able to try out alternative roles during the summer months. Similarly, professionals, including lawyers and consultants, who had greater flexibility in terms of how they spent their working hours (and who also, by the very nature of their jobs, spent much of their time interacting with clients and other outsiders to their organizations) found it easier than corporate managers to explore alternatives. Other important factors appear to be barriers to entry into a new occupation and the extent to which necessary credentials may be acquired by going back to school. Although Ebaugh argued that fields that have relatively low barriers to entry, such as real estate, tend to be attractive second careers, she also found a high incidence of returning to graduate schools (e.g., law, engineering) among her role exiters.

Few studies have investigated whether and why people actually make career changes once a set of alternatives is available or what explains satisfaction with one's ultimate choice. Ha Hoang and Javier Gimeno found, for example, that although getting financial backing is typically the event that pushes a nascent entrepreneur to take the leap, many who secure financing do not continue. Hoang and Gimeno suggested that building an entrepreneurial identity is a process that occurs in parallel with the evolution of the business case. If either is lacking, the person will not become an entrepreneur. Ebaugh suggested an alternative explanation, using Becker's notion of "side bets." Side bets are things of value to individuals that accrue in the course of jobs and careers, which they would have to give up should they give up their careers; these include "golden handcuffs" (e.g., stock options and retirement benefits) as well as intangibles, including security, status, and prestige.

Age or developmental stage may also be an important category of moderators. A long tradition of adult development research suggests that midcareer change is often motivated by age-related concerns. Although the midlife crisis has been debunked as a psychological phenomenon, it does appear that approaching midlife has at least two effects that may motivate

career change: (1) the feeling that time is running out and (2) greater self-knowledge combined with a reduced tendency to make choices based on social or family approval. While reaching a certain age, such as 40 or 50, may not have any distinct objective effect, for many people, it serves as a symbolic marker that the time is ripe to make a change.

Also ripe for future investigation is the subject of gender differences in the incidence and process of career change. It has been argued that men experience radical transitions early in their careers, whereas women maintain a higher rate of divergent mobility throughout their careers. Future work might investigate a range of topics, including how being part of a dual-career couple, taking time out to raise children, or perceptions of limited opportunity affect the likelihood and process of career change.

Other moderating factors include the reversibility of the exit and the degree of social support for making a career change. Ebaugh found that professionals (ex-physicians, ex-dentists, and ex-lawyers), who had all gone through lengthy training programs, tended to experience a prolonged transition process. They tended to see their exits as permanent and irreversible, since professional norms inculcate a sense of lifetime commitment. By contrast, corporate managers who start their own firms or who move into the government or nonprofit sector may be more likely to perceive that return to the corporate world is possible should the new venture fail to meet expectations. Few researchers have investigated involuntary turnover as a trigger for career change or investigated conditions under which job loss may generate a creative response, such as career change. Finally, positive social support also speeds up the process by encouraging people to seriously look at alternatives.

While the list of variables that might moderate likelihood of career change or characteristics of the process may always be lengthened and fine-tuned, an important and unaddressed theoretical question concerns the dynamics and nature of career change: Should scholars view career change as an outcome that can be predicted as a function of facilitating and constraining factors or, instead, as a process in which a tipping point is reached, beyond which career change is inevitable? Nicholson and Michael West argued for a model of careers as made up of changing responses to unfolding opportunities. The scant empirical work since supports their conclusion, pointing to the promise of further conceptualizing career change as a social process.

CONCLUSION

Until recently, research on careers assumed that people developed and advanced largely within the confines of a single organization and occupation and that the transitions that paced their careers were institutionalized in form and timing. New developments have dramatically altered this model. As the myth of lifelong job security unravels, career development increasingly involves moving from one firm, sector, and occupation to another in search of opportunity and fulfillment. Individuals increasingly develop careers as self-employed professionals independent of formal organizations. These self-designing professional trajectories place a premium (a) on individuals' abilities to create, alter, and dissolve career roles and identities as their personal and professional situations change and (b) on our ability as researchers to study and conceptualize these noninstitutionalized transitions.

It is ironic that a field that for the past 15 years has so emphatically heralded the arrival of new career forms and trajectories has so few empirical studies of career change to show for it. In moving forward, we need new theories that explain how people identify new career options, what replaces traditional means of socialization and its concomitant identity transformation, and what provides propulsion in this process, absent an externally imposed role change. A particularly promising theme, prevalent in most recent treatments of career processes, concerns the identity transitions that necessarily accompany career changes. Future studies that focus empirical attention on the timing of changes, how they are embedded in social networks that also cross firms and sectors, and how role changes necessarily imply identity transitions will allow scholars to more fully understand the boundaryless career.

CAREER COACHING

Career coaching has become a popular form of career development services since the mid-1980s. The International Coach Federation has estimated that there are currently more than 10,000 career coaches in the United States. The general goal of career coaching is to assist clients' personal and professional development so that they can (a) better identify or develop their skills, (b) make better career choices, and (c) be a more productive and valuable member at work.

Career coaching is a contractual relationship between the coach and the client for a wide range of career services, depending on the needs of the client and the expertise of the coach. Career coaches can be hired as personal consultants for any work-related issues, such as balancing home and career, job interview skills, managerial efficacy, long-range personal and career planning, business success, financial independence, academic excellence, personal success, physical health, interpersonal relationships, and training managers to become career coaches to their employees. Many coaches identify themselves as coaches, personal coaches, or life coaches rather than career or job coaches, mainly because their consultation is not limited to work issues.

Career coaches come from a variety of vocational backgrounds, such as accountants, athletic trainers, academics, lawyers, clergy, psychologists, business executive officers, theater directors, and homemakers. A survey of International Coach Federation members found that more than 70 percent of the members were former consultants or managers. Career coaches usually advertise their services through Web sites and professional and personal networking. Their contact with clients often takes place via the Internet and telephone, at the clients' homes or workplaces, or in public places, such as coffee shops. Career coaching can also be conducted using a seminar-based program in addition to the one-on-one fashion. The reduction of overhead cost (e.g., office space and administrative support), along with a potentially lucrative income ranging from \$75 to \$300 an hour, make career coaching an attractive career option. One special form of career coaching is called *executive coaching*. Such career services are typically provided by licensed psychologists and delivered to high-ranking managers, such as chief executive officers. This kind of consultation often involves a long-term contractual relationship to assist the manager in strategic planning, organizational and employee development, and productivity improvement.

Y. Barry Chung and M. Coleman Allen Gfroerer have discussed some distinctions among career counselors, career development facilitators, and career coaches, the three major providers of career development services. *Career counselors* are counselors or counseling psychologists by training. They have at least a master's degree in their respective disciplines and may practice only with a state license or under the supervision of a licensed counselor or psychologist.

Career development facilitators often work under the supervision of career counselors to provide career services that do not require professional training (e.g., résumé writing and job interviews). Some major professional organizations offer training programs for career development facilitators (e.g., National Career Development Association, National Employment Counseling Association). The Center for Credentialing in Education, a subsidiary of the National Board for Certified Counselors, awards certificates for Global Career Development Facilitators.

Currently, there is no nationally recognized body to regulate the training, credentialing, and professional conduct of career coaches, nor are there state licensures for the practice of career coaching. However, major coaching institutes do offer training programs, certificates, and ethical codes (e.g., Coach U, International Coach Federation). Formal training can be a two-year program with at least 250 hours of direct service. Seasoned career coaches also provide seminars and workshops in major cities across the country to train other career coaches. The National Career Development Association charged its professional standards committee to explore training and consumer guidelines for career coaching. CoachVille offers international coaching licenses in a number of countries outside the United States.

Whereas career development facilitators perform a subset of career services conducted by career counselors, the work of career coaches overlaps substantially with that of career counselors (e.g., career decision making, job search, work adjustment). Generally, the work unique to career counselors requires professional training in assessment, psychological intervention, or sometimes diagnosis, whereas career coaches may have more expertise in organizational dynamics, corporate and managerial development, and work productivity. Furthermore, career coaching is unique in that career coaches may work with clients in settings nontraditional to career counselors, such as the client's homes, workplaces, and public places.

The boundary between a career coach and client often is not as rigid as in a counseling relationship. Clients may introduce their career coaches to coworkers and allow their coaches to observe work behavior and organizational dynamics in order to advise the clients on how to improve productivity and workplace climate. However, the aforementioned distinctions between career coaching and counseling are not without exceptions, because many career coaches are

counselors or psychologists by training. These counseling professionals choose to provide career services using the title of a career coach. Some advantages for this decision include more flexibility in the consulting relationship and less negative stigma attached to coaching than to counseling. In fact, some people believe that hiring a career coach is as fashionable as having a personal fitness trainer.

CAREER CONSTRUCTION THEORY

Career construction theory provides a way of thinking about how individuals choose and use work. The theory presents a model for comprehending vocational behavior across the life cycle as well as methods and materials that career counselors use to help clients make vocational choices and maintain successful and satisfying work lives. It seeks to be comprehensive in its purview by taking three perspectives on vocational behavior: differential, developmental, and dynamic. From the perspective of individual-differences psychology, the theory examines the content of vocational personality types and *what* different people prefer to do. From the perspective of developmental psychology, it examines the process of psychosocial adaptation and *how* individuals cope with vocational development tasks, occupational transitions, and work traumas. From the perspective of narrative psychology, the theory examines the dynamics by which life themes impose meaning on vocational behavior and *why* individuals fit work into their lives in distinct ways. In coordination, the three perspectives enable counselors and researchers to survey how individuals

construct their careers by using life themes to integrate the self-organization of personality and the self-extension of career adaptability into a self-defining whole that animates work, directs occupational choice, and shapes vocational adjustment.

RATIONALE FOR CAREER CONSTRUCTION THEORY

Career construction theory is one of many career theories that seek to explain occupational choice and work adjustment, each interrogating a different aspect of vocational behavior. Career theories that have risen to prominence have done so because they effectively address important questions. For example, the model of person-environment fit emerged early in the twentieth century to address the question of how to match workers to work. The model of vocational development emerged in the middle of the twentieth century to address the question of how to advance a career in one organization or profession. These theories of vocational personality types and vocational development tasks remain useful today when considering how to match workers to work and develop a career in an organization. However, the global economy of the twenty-first century poses new questions about career, especially the question of how individuals can negotiate a lifetime of job changes without losing their sense of self and social identity.

Career construction theory responds to the needs of today's mobile workers, who may feel fragmented and confused as they encounter a restructuring of occupations, transformation of the labor force, and multicultural imperatives. This fundamental reshaping of the work world is making it increasingly difficult to comprehend careers just with person-environment and vocational development models that emphasize commitment and stability rather than flexibility and mobility. The new job market in our unsettled economy calls for viewing career not as a lifetime commitment to one employer, but as selling services and skills to a series of employers who need projects completed. In negotiating each new project, the prospective employee usually concentrates on salary yet also seeks to make the work meaningful, control the work environment, balance work and family responsibilities, and train for the next job.

While the form of career changes from stability to mobility to reflect the labor needs of postindustrial societies, career construction theory seeks to retain

and renovate the best concepts and research from the twentieth-century career models for use in the twenty-first century. For example, instead of measuring personality traits as realist concepts and trying to prove construct validity, the theory concentrates on how individuals use what they have. In replacing scores with stories, career construction theory focuses on how individuals use their vocational personalities to adapt to a sequence of job changes while remaining faithful to themselves and recognizable by others. The theory does this by focusing on the meaning that structures an individual's career as it plays out across the 10 or more different jobs that a worker today can expect to occupy during her or his work life.

LIFE THEMES

Career construction theory, simply stated, holds that individuals build their careers by imposing meaning on vocational behavior. Personality types and developmental transitions deal with what a person has done and how they have done it. However, they do not address the question of why they do what they do, nor do they focus on the spirit that animates or the values that guide the manifold choices and adjustments that build a career. Thus, career construction theory emphasizes the interpretive and interpersonal processes through which individuals impose meaning and direction on their vocational behavior. It uses social constructionism as a metatheory with which to reconceptualize vocational personality types and vocational development tasks as processes that have possibilities, not realities that predict the future. From a constructionist viewpoint, *career*, or, more precisely, *subjective career*, denotes a moving perspective that imposes personal meaning on past memories, present experiences, and future aspirations by weaving them into a pattern that portrays a life theme. Thus, the subjective career that guides, regulates, and sustains vocational behavior emerges from an active process of making meaning, not discovering preexisting facts.

The *life theme* component of career construction theory addresses the subject matter of work life and focuses on the *why* of vocational behavior. Career stories reveal the themes that individuals use to make meaningful choices and adjust to work roles. By dealing with the *why* of life themes along with the *what* of personality types and the *how* of career adaptability, career construction seeks to be comprehensive in its purview. Although the content of personality and

process of adaptation are both important, studying vocational personality and career adaptability as separate variables misses the dynamics that integrate personality and adaptability into a self-defined whole. The essential meaning of a career and the dynamics of its construction are revealed in self-defining stories about the vocational development tasks, occupational transitions, and work traumas that an individual has faced. In chronicling the recursive interplay between self and society, career stories explain why individuals make the choices that they do and the private meaning that guides these choices. From these prototypical stories about work life, counselors attempt to comprehend the life themes that construct careers and understand the motives and meaning that pattern work life.

The life theme component of career construction theory emerged from Donald E. Super's postulate that in expressing vocational preferences, individuals put into occupational terminology their ideas of the kind of people they are; that in entering an occupation, they seek to implement a concept of themselves; and that after stabilizing in an occupation, they seek to realize their potential and preserve self-esteem. This core postulate leads to the conceptualization of occupational choice as implementing a self-concept, work as a manifestation of selfhood, and vocational development as a continuing process of improving the match between self and situation. From this perspective on the self, work provides a context for human development and an important location in each individual's life, a place that matters.

The life theme perspective highlights the view that careers are about *mattering*. Counseling for career construction aims to help clients understand how their life projects matter to them and to other people. In career construction theory, the theme is what matters in the life story. It consists of what is at stake in that person's life. On the one hand, the theme matters to individuals in that it gives meaning and purpose to their work. It makes them care about what they do. On the other hand, what they do and contribute to society matters to other people. The belief that what they do matters to others sharpens identity and promotes a sense of social meaning and relatedness. What individuals choose to do is the subject matter of vocational personality.

VOCATIONAL PERSONALITY

Vocational personality refers to an individual's career-related abilities, needs, values, and interests. Individuals form personalities in their families of

origin and develop these personalities in their neighborhoods and schools as they prepare to eventually enter the work world. Before these characteristics are expressed in occupations, they are rehearsed in activities such as household chores, games, hobbies, reading, and studying.

Career construction theory prefers to view interests and other career-related "traits" as strategies for adapting rather than as realist categories. Concepts such as interests should not be reified as factors or traits. They do not reside within an individual, and they cannot be excavated from within by interest inventories. They should not be treated as objects by counselors; they are verbs, not nouns. Career-related abilities, interests, and values are relational phenomena that reflect socially constituted meanings. They are dynamic processes that present possibilities, not stable traits that predict the future. From this perspective, individuals can adopt or drop selected strategies as situations call for them. Of course, long-practiced strategies do coalesce into a tested style. This style can be compared with that of other people to form types or groups, but these socially constructed categories should not be privileged as anything more than similarities.

Career construction theory asserts that vocational personality types and occupational interests are simply *resemblances* to socially constructed clusters of attitudes and skills. They have no reality or truth value outside themselves, because they depend on the social constructions of time, place, and culture that support them. Regulated similarities in work environments produce vocational personality types and occupational groups from among individuals with heterogeneous potentials. Thus, career construction theory regards vocational personality types and occupational interests as relational phenomena that reflect emergent and socially constituted meanings. For this reason, career construction theory views vocational personality as an individual's *reputation* among a group of people. Accordingly, the theory concentrates on what individuals can become in doing work, not what they are before they go to work. Work, as a context for human development, provides the outer form of something intensely private; it is the bridge between public and private. Crossing the bridge between self and society is called *adaptation*.

CAREER ADAPTABILITY

In concert with life themes and vocational personality, the third central component in career construction

theory is *career adaptability*. Life themes guide the expression of personality in work, while the expression itself is managed by the process of career adaptation. Viewing career construction as a series of attempts to implement a self-concept in social roles focuses attention on adaptation to a series of transitions from school to work, from job to job, and from occupation to occupation. Career construction theory views adaptation to these transitions as fostered by five principal types of behaviors: orientation, exploration, establishment, management, and disengagement. These constructive activities form a cycle of adaptation that is periodically repeated as new transitions appear on the horizon. As each transition approaches, individuals can adapt more effectively if they meet the change with growing awareness, information seeking followed by informed decision making, trial behaviors leading to a stable commitment projected forward for a certain time period, active role management, and, eventually, forward-looking deceleration and disengagement. For example, an employee begins a new job with a period of growth in her new role, including exploration of the requirements, routines, and rewards of that role. Then she becomes established in the role, manages the role for a certain time period, and eventually disengages from it either voluntarily when further growth readies her to change jobs or involuntarily when organizational changes make her position redundant. In postindustrial economies, people do not work at one job for 30 years. New technology, globalization, and job redesign require workers to more actively construct their careers. They change jobs often and make frequent transitions, each time repeating the cycle of orientation, exploration, stabilization, management, and disengagement. The ability to adapt to new circumstances is enhanced by certain coping resources for solving the unfamiliar, complex, and ill-defined problems presented by developmental tasks, occupational transitions, and work traumas.

In considering adaptability, career construction theory highlights a set of specific attitudes, beliefs, and competencies—the “ABCs” of career construction—that shape the actual problem-solving strategies and coping behaviors that individuals use to synthesize their vocational self-concepts with work roles. The ABCs are grouped into four dimensions of adaptability: concern, control, curiosity, and confidence. Thus, the adaptive individual is conceptualized as (a) becoming *concerned* about the vocational future, (b) increasing personal *control* over one’s vocational

future, (c) displaying *curiosity* by exploring possible selves and future scenarios, and (d) strengthening the *confidence* to pursue one’s aspirations. Increasing a client’s career adaptability is a central goal in the goal of career construction counseling.

COUNSELING FOR CAREER CONSTRUCTION

Counseling for career construction begins with an interview that poses a uniform set of questions to a client. The *career style interview* elicits self-defining stories that enable a counselor to identify and appreciate the thematic unity in a client’s life. In addition to revealing the life theme, data from a career style interview also manifest the client’s vocational personality and career adaptability.

It is critical that neither the counselor nor the client view the career stories as determining the future; instead, they should view storying as an active attempt at making meaning and shaping the future. The stories guide adaptation by evaluating opportunities and constraints as well as by using vocational personality traits to address tasks, transitions, and traumas. In telling their stories, clients are remembering the past in a way that constructs a possible future. Clients seem to tell counselors the stories that they themselves need to hear; from all their available stories, they narrate the stories that support current goals and inspire action. Rather than reporting historical facts, individuals reconstruct the past so that prior events support current choices and lay the groundwork for future moves. This narrative truth often differs from historical truth, because it fictionalizes the past in order to preserve dispositional continuity and coherence in the face of psychosocial change.

In attempting to discern life themes while listening to individuals’ career stories, counselors and researchers can become disoriented by the numerous particulars of people’s lives. To prevent becoming confused by a client’s complexities and contradictions, a counselor or researcher must listen not for the facts, but for the glue that holds the facts together as they try to hear the theme or secret that makes a whole of the life. Arranging the seemingly random actions and incidents reported in career stories into a plot can be done in many ways. Career construction theory proposes for this purpose that the listener try to hear the quintessence of the stories a client tells. Counselors and researchers approach this task by assuming that the archetypal theme of career construction involves turning a personal preoccupation

into a public occupation. As they listen to a client narrate his or her stories, a counselor or researcher concentrates on identifying and understanding the client's personal paradigm for turning essence into interest, tension into intention, and obsession into profession. The progress narrative in the twentieth-century career model that told about climbing the occupational ladder is thus transformed into a progress narrative that tells how individuals can use work to actively master what they have passively suffered and thus move from a felt minus to a perceived plus. Thus, in its counseling application, career construction theory assists clients in fully inhabiting their lives and becoming more complete as they sustain themselves and contribute to their communities.

CAREER COUNSELING

Career counseling is a multifaceted set of activities designed to help people (a) make or remake occupational choices, (b) find jobs, or (c) achieve satisfaction and success in the workplace. Career counseling had its beginnings in the vocational guidance movement, a progressive political reform movement that emerged at the beginning of the twentieth century to improve living conditions and reduce poverty in major urban areas of the newly industrialized United States by helping young people find satisfying and sustaining work. Pioneered by Frank Parsons in the establishment of the Vocational Bureau in Boston's Civic Service House, vocational guidance activities initially were focused on helping the poor and marginalized in American society make more informed choices about work that would provide them with a living wage and a sense of satisfaction.

While career counseling activities today are still largely focused on helping people make more informed occupational choices, career counseling has expanded to include providing assistance with other important work-related tasks, including finding work and achieving more satisfactory adjustment (i.e., satisfaction and success) in the workplace. Thus, career counselors work not only with people who are having difficulties deciding (or redeciding) on the type of work that they want to pursue but also with people who are having problems finding work and those whose job performance or feelings of work satisfaction are less than satisfactory.

COUNSELING FOR CHOICE MAKING

One of the main focuses of career counseling remains on helping people decide on the type of work they want to pursue. People seeking help for choice-making difficulties include adolescents and young adults making first-time career choices and older adults contemplating career changes or returning to the paid workforce after a number of years of absence.

Most counseling interventions for choice-making difficulties that have been empirically tested are based on a model of vocational guidance originally proposed by Frank Parsons in his 1909 book *Choosing a Vocation* and by more recent theories of the choice-making and work adjustment process, most notably John L. Holland's theory of career choice and Lloyd Lofquist and Rene V. Dawis's theory of work adjustment. Parsons proposed that for vocational guidance (i.e., career counseling) to be effective, it needed to help people (a) gain greater self-understanding of their work personalities, (b) gather information on occupations, and (c) combine self- and occupational knowledge to arrive at a choice of occupation via "true reasoning."

The subsequent theories of Holland and Lofquist and Dawis have helped flesh out Parsons' model by suggesting the types of self- and occupational information that are necessary to make an informed choice, a choice that will lead, in the long run, to occupational success and satisfaction. According to Holland, people and occupational environments can both be described in terms of their resemblance to six different personality types: Realistic (R), Investigative (I), Artistic (A), Social (S), Enterprising (E), and Conventional (C). Holland further proposed that the degree of congruence (i.e., match) between an individual's personality type (e.g., RIA) and the personality type of a work environment (e.g., RIA) is associated with increasing levels of occupational satisfaction and performance. Thus, most extant career interventions help people identify their personality types and gather information on occupations that are most congruent with their personalities.

Lofquist and Dawis proposed a somewhat more fine-tuned explanation of how work satisfaction and satisfactoriness (performance) are attained, namely by the degree to which the work environment reinforces an individual's most important vocational needs and the degree to which the individual's abilities are commensurate with the ability requirements of the job. *Need-reinforcer match* (or correspondence) predicts how well a person will like his or her job (satisfaction), and *ability-ability requirement correspondence* predicts how well a person will perform (satisfactoriness). Thus, career choice interventions also often help people identify their vocational needs and abilities and gather information on occupations that are correspondent with both their needs and abilities. Each of these theories has individually garnered a good deal of empirical support, and an important 1990 study by James B. Rounds at the

University of Illinois at Urbana-Champaign found that a focus on both congruence and correspondence did a better job of predicting clients' work satisfaction than did focus on either alone.

Counseling interventions, although usually based on a common model and often built around a common set of theories, vary widely in format, from those that can be largely self-directed via print, computer, and Web-based resources to those that involve a great deal more professional contact. The latter (i.e., those involving professional contact) can take the form of semester-long high school or college courses, shorter structured groups and workshops, or individual counseling of one to several sessions in length.

Much research has accumulated on the effectiveness of career-choice interventions and has resulted in a series of meta-analyses that have shed some empirical light on the effectiveness of career choice interventions and how they might be improved. *Meta-analysis* is a statistical approach to synthesizing the results of numerous studies to arrive at empirical conclusions from a body of research and to suggest some precise directions for future research. The major quantitative yield from most meta-analyses of counseling outcome research is an effect size (usually symbolized as *d*) that estimates the magnitude of effect of an intervention. This effect size is interpreted as the difference, in standard deviations, between the intervention and control or comparison group outcomes. A *d* of 1.00, for example, means that the average person in one group (e.g., the counseled group) improved a standard deviation more than the average person in the other group (e.g., the control group).

Meta-analyses of the career counseling outcome literature have yielded several important findings. First, it is clear that interventions on the whole are effective; people who are seen for career choice-making difficulties improve on relevant outcomes about a third of a standard deviation ($d = .34$) more than those who do not receive career choice-making help. Second, outcome does not seem to vary by intervention format, except that totally self-directed interventions seem to be less effective than interventions that involve some level of professional contact, regardless of whether contact is through classes, structured groups, or individual modes of counseling. Third, self-directed interventions (via print-, computer-, or Web-based formats) can be improved to levels obtained through other formats with counselor involvement at some stage of the process.

The meta-analyses have also yielded insights about how counseling, regardless of format, can be improved. Five intervention components seem to be critical to outcome: (1) having clients, near the end of the intervention, write goals for how they plan to use in the future what they gained through counseling; (2) discussing goals individually with clients and helping them fine-tune their goals; (3) facilitating clients' use of occupational information; (4) helping clients consider how much support they have for different career options and how to build further support for preferred options; and (5) exposing clients to models of effective decision making. Evidence further suggests that the number of critical components included in counseling may be related to increasing effectiveness; one meta-analysis, for example, found that interventions that employed at least three of these components yielded an average effect size of .99, versus an average effect size of only .22 when none of them were employed.

Taken together, the meta-analytic results suggest that career counseling, based largely on Parsons' model of vocational guidance and two prominent theories of career choice making and work adjustment, is effective. Indeed, on the average, people gain about one-third of a standard deviation in choice-making outcomes when they receive counseling compared with those who do not, regardless of whether they are seen individually, in structured groups, or in career classes. The results further suggest that outcomes can be improved further if clients are helped individually to develop written goals, make greater use of occupational information, consider how much support they have from others for their choices, and are exposed to models who have overcome difficulties in the career choice-making process. Clients who have been exposed to at least three of these additional components have improved, on the average, a full standard deviation more than persons who did not receive career intervention and about three-fourths of a standard deviation more than clients who received career intervention without being exposed to any of these apparently critical components.

Despite these quite positive results, there is still a great deal more that needs to be learned about the career counseling process for persons with choice-making difficulties. Foremost among these are (a) whether outcome can be improved further by incorporating more fully other empirically supported career theories into counseling (e.g., social cognitive career theory, Super's theory of career development);

(b) whether intervention effectiveness varies on the basis of, for example, client gender, race/ethnicity, sexual orientation, or help-seeking goals; and (c) how, if necessary, counseling can be modified or extended to meet the choice-making needs of diverse clientele.

COUNSELING FOR FINDING A JOB

Career counseling can also involve helping clients find jobs. People seeking job-finding assistance can include new entrants and reentrants into the labor force as well as those who have lost jobs and those who are seeking to change jobs. There is a wealth of data on factors related to job-finding success that can be used to direct counseling efforts. There are equally impressive data on the effectiveness of specific kinds of job-finding assistance.

Research on factors related to job search success—defined by outcomes such as percentage of clients who find employment, speed of employment, and income—has consistently revealed that job search effort and intensity (i.e., number of different resources used) are the strongest predictors of job search success. There is emerging empirical consensus that job search effort and intensity are related in predictable ways to various personality (e.g., extraversion and conscientiousness), situational (e.g., economic hardship), cognitive (e.g., employment commitment, job search self-efficacy), and social/contextual (e.g., job search support) variables and also that the personality characteristics of extraversion and conscientiousness may influence job search success independently of effort and intensity through their effects on hiring decisions. It is equally clear, however, that job search effort and intensity do not relate consistently to indices of employment quality (e.g., job satisfaction, intent to leave) unless people also engage, or are helped to engage, in some form of career planning that allows them to identify jobs that come closest to matching their work-related needs and goals.

These data therefore suggest that the most effective ways to help people having trouble finding work would involve encouraging, assisting, and reinforcing greater effort in the process and more comprehensive use of job finding resources, including but not limited to making greater use of their social networks to find job leads. The findings on factors related to job search effort and intensity also suggest that effective counseling interventions should help people develop greater confidence (i.e., self-efficacy) in their job

search skills, provide support to sustain efforts, and assist them in more effectively using their social networks to find job leads and in developing more effective job-interviewing skills. Counseling efforts to promote greater social network use and more effective interviewing skills may be especially necessary for those whose personalities may predispose them to be less than comfortable seeking assistance from friends, families, and acquaintances and interacting in one-on-one job interviews.

Finally, data suggest that counseling efforts to increase effort and intensity may need to be complemented by career-planning activities if employment quality as well as job-finding success is a goal of counseling. Although the research is far from clear on what would constitute effective career planning, it is likely to involve helping people identify jobs and employing organizations that fit their values and work-related goals.

Research testing the effectiveness of job-finding interventions has largely supported these findings: Interventions that are built to increase job search effort and intensity, provide support, facilitate job-finding self-efficacy beliefs, and improve interviewing skills are substantially effective in helping people attain leads and procure jobs, but they may not be as effective in ensuring that the jobs people attain will be the most satisfying to them. Two specific job-finding interventions that have received extensive research and empirical support in the literature are Job Clubs and the JOBS program. Although developed from different theoretical models, both interventions are rather intensive, structured group programs that help participants use a variety of resources to locate job leads, provide reinforced practice in job interviewing and other skills necessary to obtain jobs (e.g., cold calling, letter writing, résumé preparation), encourage and reinforce participants to support each other in the job-search process and share job leads, and require participants to establish weekly goals.

The Job Club in particular has received widespread application and has been tested in samples of psychiatric patients, physically handicapped adolescents and adults, welfare recipients, college students and college graduates, and unemployed older adults. Job placement rates have varied from 13 percent for one psychiatric patient sample to 93 percent for an unemployed adult sample, with an average job placement rate of about 70 percent. The JOBS program has demonstrated similar job placement rates with unemployed adult samples, as

well as improved mental health outcomes, but neither the Job Club nor the JOBS intervention has shown as consistent effects on job satisfaction and other measures of employment quality. The latter may be attributable to the fact that neither intervention engages systematically in career-planning activities.

COUNSELING FOR WORK ADJUSTMENT

Employed adults also frequently seek out career counseling because they are feeling dissatisfied with their current employment or are performing less than adequately in it. Some are seeking a new career direction, while others are seeking ways to feel more satisfied or to perform more satisfactorily in their current work. The former (career or job changers) seem to benefit from career choice or job-finding counseling, while the latter need help that is specifically targeted to improving their satisfaction or performance in their current jobs.

Large bodies of research on factors related to job satisfaction and success can provide important insights for counseling about potential sources of dissatisfaction or work performance problems. Both bodies of research have found that the degree of fit between the person and his or her work environment is an important determinant of satisfaction and success. Need-reinforcer correspondence, as suggested by the theory of work adjustment, seems to be substantially related to work satisfaction, while ability-ability requirement correspondence is strongly implicated in work performance outcomes. Facets of the work environment itself also seem relate to satisfaction and success over and above the influence of person-environment fit. Work overload, lack of supervisor support, and role conflict and ambiguity have all, for example, been found to relate to job dissatisfaction, while lack of challenging assignments and mentors has been found to relate negatively to work success. There are, finally, also characteristics of the person that may relate to satisfaction and success, most notably neuroticism in the case of job dissatisfaction and conscientiousness in the case of work performance.

Unfortunately, there is virtually no research that has tested, in the counseling arena, interventions built around these findings for their effectiveness in promoting work satisfaction among dissatisfied workers or work performance among unsatisfactory employees. Thus, although much is known about the reasons

people feel dissatisfied with their work or are performing less than adequately in it, little is known about how these findings might be translated into counseling interventions for the dissatisfied or unsatisfactory workers who make up a large portion of the caseloads of counselors working with adult career concerns.

CAREER COUNSELING COMPETENCIES

Career counseling competencies consist of the knowledge, skills, and personal attributes that career counselors need to deliver quality services to clients. Even in so-called developed countries, large portions of the population are not well served by existing approaches to delivering career development services. Articulating career development competencies that are cross-indexed to client services is a substantial step toward providing comprehensive and quality career development services.

Career development is a lifelong process of managing learning, work, and transitions in order to move toward a personally determined and evolving preferred future. Career paths develop over time, regardless of whether people are planful about the process or leave it to chance. Those who are planful about their education and training and the opportunities they pursue are more likely to achieve a meaningful and satisfying life. When people have a vision of what they want to do with their lives, they tend to be more focused, better able to spot opportunities, and more persistent in pursuit of those opportunities.

Some people naturally develop the ability to create focus in their lives, but others need assistance, especially as the rate of economic, occupational, and social change escalates. Comprehensive career guidance and counseling services are designed to provide that assistance. Providing effective and comprehensive services requires a broad base of knowledge, skills, and personal attributes (i.e., competencies). In addition, those providing the services also need to devote attention to developing an infrastructure that makes such services available and to creating a culture that encourages people to seek assistance when they need it.

BACKGROUND

Over the past 10 years, there have been several initiatives directed at articulating the competencies needed to provide quality career development services to clients. In most cases, the starting point was to identify the types of services clients need, then map out the roles involved in providing those services, and, finally, elaborate on the competencies needed to perform those roles. In most initiatives, career counseling is seen as one of many services that clients need.

Clients also need career information, assessment, advocacy, job-search knowledge and skills, and job-maintenance knowledge and skills. These services are provided by a range of practitioners, with varying degrees of training and a wide variation in competencies. Most initiatives have recognized this and have developed a competency framework that is inclusive of all service providers.

In developing a competency framework, most initiatives have focused on the functions performed in providing comprehensive services to clients. It is a competency-based (rather than a training-based) approach, emphasizing what service providers do to offer quality services to clients rather than how they learned to do it. This approach has many advantages: It recognizes that people become skilled in different ways, not only through formal training; it readily connects to prior learning assessment and recognition; and focusing on the activities professionals perform is easily understood by both practitioners and clients.

COMPETENCY FRAMEWORKS

Most career development competency frameworks have two types of competencies: *core competencies* that all practitioners should have and *specialized competencies* that depend on the nature of a person's work. In most cases, the areas of specialization extend into the core competencies but are elaborated in more detail and at a more advanced level in the specialization. For example, all career development practitioners need to have a certain amount of competence in assessment (core); however, assessment specialists have these core competencies plus many additional and advanced assessment competencies.

Core competencies are usually grouped into categories such as ethical behavior, professional conduct, advocacy, awareness and appreciation of client cultural differences, awareness of their own (i.e., the professional's) capacity and limitations, knowledge of labor market information, and the ability to communicate effectively with colleagues and clients. Specialized competencies are usually grouped into categories such as assessment; ability to design, implement, and evaluate guidance and counseling programs; career counseling; consultation and coordination; group facilitation and educational guidance; program and service management; information and resource management; work development and job placement; research; and community capacity building. All service providers are

expected to have the core competencies, and, in addition, they may have competencies in one or several areas of specialization, depending on the nature of their duties and the services they provide. There is no hierarchy intended between core and specialization or among the specializations. All competency areas are equally valued, and no area of service is more or less important. All competency areas are important in providing comprehensive career development services to clients.

To date, career development competency initiatives have stopped at identifying the competencies needed to deliver quality services to clients. The next step will be to articulate in greater detail the specific knowledge, skills, and personal attributes that make up the competencies, for example, the specific knowledge, skills, and personal attributes needed to work effectively with a diverse range of clients with a social inclusion perspective and in the context of a global labor force. It will also be necessary to specify the knowledge, skills, and personal attributes needed to advocate effectively for all areas of the competency framework. Once these competencies (the knowledge, skills, and personal attributes) have been identified and validated, it will be important for practitioner training programs to modify their curricula to give greater emphasis to these competencies.

PREPARING CAREER DEVELOPMENT PRACTITIONERS

The career development competency initiatives undertaken to date have adopted a broad vision based on providing comprehensive and quality career development services to clients. Most counselor education programs focus primarily on the core competencies outlined above. However, to offer effective service, career counselors will need to extend their expertise beyond the core competencies to include a range of specializations. Thus, the scope of most training programs will have to expand substantially in order to provide the competencies needed to deliver comprehensive services. There is a need for making program evaluation a more integral part of training programs, teaching the knowledge and skills required for more effective interactions with policymakers and fund providers, expanding the role boundaries of career counselors to include social action and advocacy, and including a greater emphasis on assessing and intervening with contextual variables that affect career-life planning of clients.

CAREER DECISION-MAKING STYLES

Career decision making is generally regarded as a process that entails identifying alternatives, gathering information, weighing the options, selecting one choice, and implementing the chosen alternative. While this basic process seems fairly straightforward, it has been noted that individuals differ considerably in how they negotiate the decisional process. *Career decision-making styles* thus have been advanced to describe the variety of ways in which individuals approach, respond to, and behave in career decision situations. These observable variations in career decision making have led to a number of taxonomies of

career decision-making styles and considerable theorizing and research on the effectiveness of different styles.

Early research into career decision-making styles largely focused on developing taxonomies to describe different types of deciders. Lilian Dinklage is widely cited as the initial scholar to identify a set of career decision-making styles. Based on interviews with high school students, she posed a traitlike taxonomy: *Planners* are characterized by methodical pursuit to decision resolution; *agonizers* devote considerable effort to information gathering but often get overwhelmed by the resulting data; *delayers* recognize the need to decide but defer action at present; deciders with *paralysis* are highly cognizant of the need to decide, but are unable to engage in the process; *impulsives* take the first available alternative; *intuitives* choose what "feels right"; *fatalists* leave choice to fate or chance; and *compliant* deciders defer to the recommendation of others.

Similar taxonomies have been proposed by Tanya Arroba, John Krumboltz and his colleagues, and Vincent Harren. Arroba suggested that individuals may use different decision-making styles depending on the particular decisional situation. In her classification, six state-specific styles are identified: *logical* (objective appraisal and selection); *hesitant* (procrastination or postponement of decision making); *intuitive* (choices based on an inner feeling of rightness or inevitability); *emotional* (choices based on subjective preferences or feelings); *no-thought* (little objective consideration, as might occur in a routine decision or in an impulsively chosen alternative); and *compliant* (passive; choice based on expectations of others or self-imposed expectations). In addition, Arroba attempted to identify underlying factors, revealing a clustering of logical and hesitant (implying an element of extended personal time and effort in the decision-making process) and a separate cluster of emotional and intuitive (implying a subjective emphasis in choosing). The no-thought style also appeared to have some association with this latter group. The compliant style consistently appeared as a separate factor.

Krumboltz's taxonomy proposes five statelike styles: *rational* (making decisions in a logical and systematic manner); *fatalistic* (believing that one has little personal control); *intuitive* (relying on nonspecific impressions); *impulsive* (spontaneous, spur-of-the-moment choice making); and *dependent* (relying on the expectations or advice of others).

Harren's taxonomy suggests that styles vary on two dimensions. First, he proposed that deciders vary in the extent to which they view themselves as personally responsible (in contrast to assigning responsibility to others or to fate). Second, he suggested that deciders differ in the extent to which they rely on logic (in contrast to emotion) in their decision making. His widely used taxonomy poses styles as relatively enduring traits, and includes *rational* (individually responsible, systematic, logical); *intuitive* (individually responsible, primary consideration of emotional factors, often impulsive); and *dependent* (responsibility deferred to others, passive, sees limited options).

Additional taxonomies have been offered, drawing on underlying dimensions. Richard Johnson, for example, based his taxonomy on what he termed a "mental factor analysis" of his clinical observations. He proposed that individuals differ in the manner in which they gather information (systematically or spontaneously) and process information (internally or externally). These variations produce four styles: *internal-systematic*, *internal-spontaneous*, *external-systematic*, and *external-spontaneous*. Donna Walsh undertook a comprehensive review of the literature on individual variations in career decision making and offered a taxonomy combining Jungian theory and a review of known variations in the decision-making process. Two bipolar dimensions were proposed: *intraversion-extraversion* (reflecting an orientation toward or away from others in the various aspects of the decision-making process), and *thinking-feeling* (reflecting how judgments are made). Finally, Susanne Scott and Reginald Bruce articulated a taxonomy similar to those described above but not specifically devoted to the career domain, which includes five essential decision-making styles: *rational*, *avoidant*, *intuitive*, *dependent*, and *spontaneous*.

Although the available taxonomies have been presented above in a descriptive frame, there has also been considerable prescriptive endorsement of the benefits of some decision-making styles. Following with the Parsonian "true-reasoning" paradigm of the early 1900s, theorists and researchers (including those noted above) have provided a widespread conclusion that a rational, systematic, and independent approach to decision making is "best." The adaptive decider is seen as objective, systematic, and logical and free of emotional distractions and cognitive distortions and approaches the generally solitary decision-making task with considerable autonomy and independence.

In support of this view is literature in which it is generally concluded that the more systematic, rational decision-making style has proved adaptive: A rational style has been related to an approach to problem solving, rather than avoidance of it, and has been related to greater self-knowledge and to greater progress in making career decisions as well as in implementing those decisions. "Systematic-internals" have been shown to be least likely to experience indecision about a career choice. Furthermore, individuals who have achieved a firm sense of individual identity use a more systematic, rational decision-making style. Mixed results are evident for a link between decision-making styles and vocational maturity, however, with some evidence that the more vocationally mature student uses a less dependent style and other evidence linking vocational maturity to a rational style.

Just as the rational decision-making style has received generally favorable evidence, the dependent or compliant style has been largely linked with less favorable functioning. For example, those whose identity was foreclosed (committed without exploration) tended to rely on a dependent style. Furthermore, a dependent style has been related to negative outcomes such as less progress in decisions, use of an avoidance strategy in problem solving, and lack of problem-solving confidence.

Despite the conclusion suggested by this brief review that rational, nondependent decision making is preferable, there is also evidence that it is definitely not the only adaptive way of making decisions. Other research has focused on developing counseling interventions to aid individuals in making career decisions. This research has shown that different career decision-making styles have successfully predicted the effects of career interventions, whereas a rational style per se does not appear to be predictive of treatment outcome. Rather, evidence suggests that treatments designed to match participants' decision-making styles (e.g., systematic intervention for clients with a rational career decision-making style; feeling-focused interventions for intuitive deciders) are more beneficial to the participants. Furthermore, people with different styles may approach counselors differently, with the more dependent deciders expecting more directiveness, acceptance, and nurturance. (It should be noted, however, that these findings have not been replicated in other learning situations outside the counseling realm.)

More recent perspectives on career decision-making styles have focused on the adaptability of other styles

beyond a rational style. Drawing on literature in decision making and judgment, Susan Phillips noted that the prescribed rational, autonomous decision making may be neither possible nor desirable. Consideration of the limitations on human information-processing capacity suggests that decisions simply are not made with the dispassionate precision of a systematic, comprehensive, rational process. Furthermore, emotion or intuition (implied as risky in some decision style models) can be seen as highly useful sources of information about alternatives. And in the study of expert judges, drawing on the wisdom and expertise of others is seen as highly beneficial. In light of these observations, Phillips suggested that career decision-making styles other than rational (e.g., the intuitive or dependent styles) may not necessarily reflect an irrational (negative) style, but rather may represent a different kind of adaptation that incorporates affective components in decision making and/or collaborates and consults with others.

Finally, there is also an emerging body of literature to suggest that the context of career decision making—particularly the cultural and the interpersonal—may well play a larger role than previously suspected in determining what style an individual uses and how effective that style is. Thus, noting that collectivist cultures place a different value on the role of others in decision making, Wei-Cheng Mau showed that students from a more individualistic culture were more confident if they did not use a dependent decision-making style, whereas students from a collective culture were more confident only if they used a rational style.

Other recent research has focused on exploring how an individual's decision-making style might incorporate "others." Whereas the existing taxonomies of decision-making style acknowledge a role for other people only in the dependent or compliant decision-making styles, Phillips and her colleagues suggested that a relational perspective would provide a more complete and less pathological view of how deciders make decisions in a relational context. They proposed a taxonomy of how deciders use others in decisional situations in more or less self-directed ways (self-directedness) and how others involve themselves in the decision-making process (actions of others). While this perspective is still nascent, there is growing evidence that the use of "others" is valuable and is likely to reduce decision errors, foster vocational maturity, and promote adaptive transitions from school to work.

CAREER DECISION SCALE (CDS)

Samuel H. Osipow, with a colleague and several graduate students, developed the *Career Decision Scale* (CDS) at The Ohio State University (OSU) in the mid-1970s. First published by Marathon Press of Columbus, Ohio, the scale and its manual have been available from Psychological Assessment Resources of Odessa, Florida, since 1986. Although the instrument derives from an effort to establish types of career indecision, the CDS typically is used as a scale to assess degree of career indecision rather than as a set of category descriptors to assign to individuals. The CDS has 19 items, of which the first 2 items constitute

a Certainty scale and act as a validity check on the rest of the scale; 16 items constitute an Indecision scale; and the last item provides an opportunity for the client to present a self-descriptive phrase or sentence if no other item appears to him or her to be sufficiently descriptive. The third revision is the only version of the CDS that has been readily available to researchers or practitioners outside the original group of authors during the development phase. The CDS has been translated from English into French, Hebrew, Korean, Portuguese, Spanish, and Swedish, but these translations have not been marketed.

Professor Osipow and his colleagues initially sought to describe types of career indecision in order to develop interventions keyed to specific problems of varying severity. The original research plan envisioned the outcome to be a set of audiocassette tapes that invited the client to engage in self-assessment and self-counseling for his or her career indecision, either independently or as a precursor of counseling by a professional. Each tape would describe a type of career indecision and present exercises to help the listener resolve the problems associated with that type. The proposed categories and interventions were developed from discussions among the investigators and others of their experiences as career counselors and from knowledge and review of the career decision-making literature. The actual outcome of the initial research program was the CDS, in which each scale item had evolved from the drafts of the scripts originally developed for the audiocassette tapes.

Research using the CDS has been conducted by the original investigators and others in the United States and numerous other countries, primarily but not exclusively in the English-speaking world. In addition to being the subject of thesis and dissertation research (e.g., OSU, Texas Tech University [TTU]), the CDS has appeared in research published in refereed journals and presented at professional conferences. By 1986, the CDS had become one of the most highly cited new works in *Journal of Vocational Behavior* and *Vocational Guidance Quarterly*.

Measurement research on the CDS has focused primarily on the Indecision scale or the Indecision scale and the Certainty scale, addressing questions of reliability and validity across samples, factor structure, and the relative merits of using the CDS as a scale or as a set of categories. Other questions addressed in CDS research have included the relationship of career indecision to vocational interests, gender, irrational

beliefs, alcohol use, success in the first year of college, anxiety, and neuroticism. The CDS has been used to assess the effectiveness of counseling interventions, such as classroom- and computer-based career-planning courses, and to understand possible interactions between degree or type of career indecision and responsiveness to various career counseling modalities. Populations of research interest have included college undergraduates of various nationalities, ethnicities, socioeconomic status, and geographic locations in the United States; students in various undergraduate and graduate majors; traditional and nontraditional students; pre- and postcollege individuals; college students who are physically challenged; individuals employed in various occupations, such as managers or professionals; and parents who wish to help their children make career decisions.

The CDS has contributed strongly to a better understanding of career indecision. The literature of the CDS led to the development of other measures of career decision problems, some more grounded in theory, some emphasizing particular factors suggested by work on the CDS. In particular, the CDS helped focus attention on possible differences between a state of career undecidedness and a more traitlike career indecision. Career undecidedness could be changed by, for example, the provision of specific occupational information, but career indecision suggested the presence of barriers to decision perceived by the client as irresolvable.

The greater attention paid to undecidedness versus indecision has led to the discovery of the apparent usefulness of the CDS in suggesting psychodynamic explanations and interventions for career issues. Three decades ago, what was intended to be a typology became a scale, and what was intended to be a counseling device became a research instrument. The CDS, a scale based in practical counseling experience in what some consider the most mundane and simple counseling issue, has helped to restore interest in the most venerable of psychological theories, for which no counseling issue is mundane or simple. This, perhaps, is the research and practice direction most unexpected for the CDS by its authors. As these authors have reached or approached retirement age, it is a matter of professional satisfaction that the CDS continues to raise new questions for others to pursue.

CAREER DEVELOPMENT INVENTORY

Interest inventories are commonly used to assist high school and college students with vocational choices. However, the results of such instruments offer little value if the individual lacks the requisite attitudes and competencies required to make sound vocational decisions. The *Career Development Inventory* (CDI), created by Albert Thompson, Richard Lindeman, Donald Super, Jean Pierre Jordaan, and Roger Myers, can be used before administering an interest inventory to measure an individual's readiness to make vocational choices or with an interest inventory to determine how best to interpret the interest inventory results.

The CDI operationally defines Super's structural model of career choice readiness among adolescents and emerging adults. Inspired by the construct of reading readiness, Super, at midtwentieth century, reasoned that the readiness to and resources for making fitting educational and vocational choices emerged during childhood and developed during adolescence. He spent nearly 40 years identifying the critical attitudes and competencies that lead to sound educational and occupational decisions, constructed inventories to measure these attitudes and competencies, and studied their development in students from middle school through college.

CAREER CHOICE READINESS

Super believed vocational choice to be an individual's attempt to implement his or her self-concept in a work role. Through fitting work, individuals can manifest their self-concepts in daily activities. Accordingly, the choice of an occupation is a major decision that

adolescents must make as they enter the adult world. Workers' levels of satisfaction and success depend on the realism and wisdom of their occupational choices. To make a fitting choice and avoid occupational failure and frustration, individuals must possess the requisite readiness and resources.

Career choice attitudes denote an individual's disposition with regard to the amount of thought, effort, and planning he or she gives to future occupational or educational choices. *Career choice competencies* denote an individual's ability to apply his or her knowledge and understanding of careers and the world of work in making rational career decisions.

The two most important attitudes are planfulness and curiosity. *Attitudes toward planning* reflect a future orientation, an awareness of choices to be made, and a disposition to be involved in preparing to make imminent and distant choices. Well-developed attitudes toward planning prompt behaviors such as discussing career plans with adults, getting part-time jobs, taking part in college or community activities, and finding out what people do in one's field of interest. All of these can help one gain a clearer understanding of one's vocational interests. *Attitude toward exploration* means curiosity about the world of work and one's place in it. Well-developed attitudes toward exploration prompt behaviors such as information seeking, role-playing, and talking with career counselors, professors, and professionals in one's field of interest.

The critical competencies identified by Super are *knowledge about occupations* and *skill at decision making*. Occupational information, in breadth, means knowing the requirements, routines, and rewards of a variety of occupations in which one may be interested. Information, in depth, means having detailed knowledge about the occupational group that one currently prefers. Decision-making competence means the ability to apply the principles of rational decision making to one's educational and vocational choices.

These four variables, two attitudinal and two cognitive, compose Super's model of readiness for making vocational choices during adolescence. Super and his colleagues operationally defined this structural model of vocational development during adolescence and emerging adulthood by creating the CDI.

INTERPRETATION OF THE CDI SCALES

Two versions of the CDI exist. The CDI School Form is designed for students in Grades 8 through 12,

and the CDI College Form is designed for college students from freshman through senior years. Although both forms measure the same constructs, they differ in content. The different content reflects the educational level of the subjects being tested. Scores are reported for four scales: Career Planning (CP), Career Exploration (CE), Decision Making (DM), and knowledge of the World of Work (WW). CP and CE make up the attitudinal components of Super's model, whereas DM and WW measure the competencies.

Low scores on CP indicate that one may have given little thought to career decisions and therefore may not yet be serious about attending to future occupational or educational choices. One may benefit from increasing one's awareness of current and future occupational decisions that need to be made, as well as engaging in activities that arouse one's curiosity about different occupational paths. High scores on CP indicate that one has actively engaged in career-planning activities and behavior, indicating an appropriate awareness of occupational decisions that need to be attended to, as well as a heightened sense of curiosity with regard to one's place in the world of work. As a result, high CP scores indicate a readiness to narrow one's choices and focus on advanced exploration in a few occupational fields.

Low scores on the second attitudinal scale, CE, indicate one has not yet adequately explored sources of quality information regarding career opportunities available to them. One may benefit from identifying quality resources and investigating a number of different occupational fields. High scores on CE indicate one has actively employed the resources available and gathered information relevant to future occupational choices. One may be ready to engage in broad exploration of the world of work and to investigate occupational fields that are attractive.

Because DM represents one's skill at applying the principles of rational decision making to educational and vocational issues, low scores indicate that the student may benefit from studying and practicing the principles and processes involved in effective decision making, such as identifying the problem and gathering the information required to solve the problem. High scores on DM indicate that the student has developed the essential decision-making skills for making effective vocational decisions. Thus, the individual may now be ready to match his or her abilities and interests to the requirements and rewards of different educational majors and occupations.

The second competence scale is WW, where low scores indicate that the student may need more information about, and inquiry into, occupational fields and career development tasks before making important career decisions and occupational choices. Students may benefit from learning more about their tentative preferences, how people get jobs in those occupations, and how they adjust to those jobs. High scores on WW indicate that students may have a broad fund of information to support their career decision making. However, they still may need to gather more information about the specific occupations they are considering before committing themselves to particular choices.

In addition to the above-mentioned scales, there is a fifth scale, Knowledge of Preferred Occupation (PO). PO measures the amount of in-depth knowledge one has with respect to one's primary field of interest. PO is measured separately from the other four scales and should not be administered to students below the 11th grade. This is due to the fact that it is unlikely such students have acquired the knowledge and maturity to answer the questions in an informed manner. When administered to the appropriate population, low scores on PO indicate students may need to gather more detailed information regarding their occupations of choice. Such information can be ascertained from professors, career counselors, and professionals already working in that field.

The CDI also reports on three composite scales. Career Decision Attitudes (CDA) is the combination of CP and CE. Career Decision Knowledge (CDK) is the combination of DM and WW. Career Orientation Total (COT) is the combination of CDA and CDK. These composite scores exist to help gain a more reliable measure of attitudes toward career, knowledge of careers, and the world of work.

THE CDI ON THE INTERNET

With the permission and encouragement of the CDI authors, the CDI is now available at no charge on the Internet. The CDI is one of a number of career instruments available through Vocopher: The Online Career Collaboratory (<http://www.vocopher.com>). Scoring of the CDI is done on the Internet, and the results are shown immediately to the user. It is important that practitioners take the time to interpret these results with their clients. Practitioners can use the ideas presented herein to help raise their clients' levels

of awareness and curiosity with regard to vocational decisions they will be required to make. Suggestions for improving one's decision-making skills and knowledge about the world of work have also been outlined. Additional ideas are presented in the CDI manual, which is also available on Vocopher.

CAREER EDUCATION

Career education refers to both a historical education reform movement and an evolving concept that reflects a process of bringing occupational relevance to academic curriculum and informing adolescents about themselves and the world of work. As a reform movement in the 1970s, U.S. Commissioner of Education, Sidney P. Marland Jr., initiated and sustained an effort to enact federal legislation supporting career education. Throughout that decade, the concept of career education assumed an increasingly significant role in federal education policy. In 1977, the Career Education Incentive Act (P.L. 95-207) was enacted into law, and throughout the 1970s, more than \$130 million was appropriated by the federal government for career education activities.

Kenneth B. Hoyt, appointed Associate Commissioner for Career Education in 1974, further advanced and shaped Marland's initial efforts. He defined career education broadly, viewing it as a composite of activities and experiences designed to prepare and engage

individuals in paid or unpaid work during their lives. Thus, the notion of career education related not only to preparing students to earn a living (product) but also to developing a way (process) for them to learn. The *process* aspect of learning emphasized the integration of work and careers throughout the academic curriculum, making learning more relevant and meaningful to students.

While formal and informal definitions of career education have been advanced over the years, the most enduring is one proposed by Hoyt. In his 1977 monograph, *A Primer for Career Education*, Hoyt defined career education as an effort to refocus both the U.S. education system and the actions of the broader community to help adolescents acquire and use the knowledge, skills, and attitudes necessary to make work a meaningful, productive, and satisfying part of their lives.

The underlying goal of the career education movement was a total kindergarten to Grade 12 (and post-secondary) school reform process geared to all students regardless of postsecondary plans. The career education concept was also inclusive from the standpoint of incorporating a *careers* focus throughout the entire school curriculum and serving as a means of redirecting the teaching-learning process. Two proposed strategies for achieving reform were the *articulation* of curriculum across grade levels and the *integration*, or *infusion*, of school subjects with work. These strategies were enacted to enhance the occupational relevance of education and reduce social class distinctions between students enrolled in vocational versus academic educational tracks.

Advocates of career education promoted a number of major themes, including the inclusion of career awareness, exploration, and decision-making opportunities; enhancing general employability, adaptability, and "promotability" skills; participation in private-sector education system partnerships; experiences highlighting the interconnectedness of school and work; emphasis on careers; envisioning work as a meaningful part of a total lifestyle; a reduction of bias and stereotyping; and the protection of personal freedom of choice. Philosophically, career educators emphasize the importance of work and work values and view the classroom as a workplace. From this perspective, teachers are charged with encouraging students to recognize the importance of work, rewarding academic work appropriately, introducing a variety of methods and procedures for attaining stated

goals, and emphasizing the practice of good work habits.

The terms *career education* and *career guidance* are often used interchangeably. However, there are important differences between them. Career education refers to the totality of experiences (school-based and otherwise) that help individuals acquire and use the knowledge, skills, and attitudes necessary to make work a meaningful, productive, and satisfying part of life. In contrast, career guidance typically refers to a systematic process of providing self-assessment and information about the world of work to facilitate individual career development and decision making. In this respect, guidance activities can be viewed in a support role or as one component of a comprehensive career education program.

Career education is also distinct from *vocational education* (now known as *career and technical education*), although in recent years this distinction has blurred considerably. Public vocational education was originally established in the early 1900s to prepare young people for the world of work. From its inception, a clear distinction was made between vocational and academic education, with vocational education emphasizing entry-level work skills for youth deemed non-college bound, displaying special learning needs, or otherwise placed at risk of school failure.

Education reform initiatives (e.g., the School-to-Work Opportunities Act of 1994) and rapid changes in the workplace over the past several decades have resulted in significant changes in the orientation of vocational education. In fact, current secondary vocational education reflects many of the principles and practices embodied in the career education movement. For example, current career and technical education programs emphasize academic achievement and preparing young people for postsecondary education and work through school-based and work-based approaches (e.g., apprenticeship, cooperative education, work-based learning, career academies, and programs articulated between secondary and postsecondary institutions). Additional examples are initiatives that integrate academic and vocational curriculum and develop extensive articulation between academic and vocational or secondary and postsecondary programs. Thus, while similar, career education seeks to provide a career-based instructional emphasis for all students, while vocational programs are still, for the most part, separate from general academic curricula and targeted to a smaller segment of the student population.

MAJOR DELIVERY MODELS

During the 1970s, the U.S. Office of Education supported the development of four approaches to implementing effective career education programs, including the school-based (comprehensive) model, employer-based (work/experience-based) model, home/community-based model, and the residential-facilities-based model. The *school-based* or *comprehensive career education model* was the most widely adopted approach to career-education delivery. At the time, it was assumed that many effective career-education programs existed throughout the country and that exemplary program components could be identified and then used as the basis for developing a comprehensive model program. The result was an approach where the classroom was seen as a workplace and both teachers and students were treated as workers. Work values, including the practice of productive work habits, were stressed and rewarded. Infusion of career-education principles in existing K-12 curriculum and instruction was the primary approach used for increasing student understanding of the connections between course content and workplace competencies. This point is important, since many career educators view the emphasis on career as a means to an end—academic achievement, life satisfaction, and success—rather than an end in itself.

The *employer- or work-based model* was first proposed as a way to address the concerns of critics and members of the business community who charged that the U.S. education system was not preparing workers who could meet rapidly changing workplace demands. Given this context, the model assumes that overly rigid, formal educational structures make school irrelevant to substantial numbers of students. These same students, however, might be successful if substantially different methods and environments were used. Thus, this model capitalizes on experiences gained from using the community as a primary resource by making close connections between school curriculum and workplace demands. Developers advocated the operation and support of work-based programs entirely by local employers, parents, and other community organizations. In fact, the notion of joint effort, joint authority, and joint responsibility between the education and business communities was a key element of early efforts. Career educators viewed the community as a *learning laboratory* and made use of a variety of programs, such as work-study,

cooperative education, and job shadowing. Another key element of this model was a flexible approach to designing individualized curriculum plans based on students' learning needs and specific work environments.

The *home* or *community-based model* targeted the needs of adult populations, particularly those who were homebound, women reentering the workforce after raising their children, and older adults. Model designs, inspired by the success of the children's educational program *Sesame Street*, used a multimedia approach that combined educational television and radio shows, correspondence programs, and community-based referral centers to provide career guidance and counseling. A fourth approach, the *residential-based model*, was developed to address the unique needs of disadvantaged rural families. This particular model offered intensive programs at residential centers for all family members, not just heads of household. A broad array of services was provided, including academic education, medical and dental services, independent-living-skills training, career and personal counseling, and welfare services.

While modality and context differ depending on type of approach, each model reflects the same basic sets of components or activities, such as career awareness, exploration, decision making and planning, preparation, entry, maintenance, and progression, in selected career paths. Career education offerings vary, depending on the characteristics and needs of locations and situations and may include one or more of the following: school-business partnerships, infusion of career concepts into school curriculum and instruction, delivery of comprehensive programs, and single events or practices. In addition, each of the four approaches is sequential in nature, progressing from awareness-information to accommodation-skill building to action-application. The basic assumptions and interventions represented by these four models provide a backdrop for current career and technical education and school-to-work initiatives.

CAREER EDUCATION: 1980s-1990s

Despite its appeal to a segment of the education community, federal legislation promoting career education was repealed in 1981 as a result of federal budget cuts and emerging national concerns over the quality of public education. For the next 20 years or so, career education was not a priority in national policy and did not match well with the *academics first* and *back to basics* movements of the 1980s, which

eschewed integrated or infused teaching-learning designs in favor of classroom-based, academic-only approaches. Even so, several enduring features of the federal initiative were evident during this period, including Career Information Delivery Systems, recognition in the 1984 Carl D. Perkins Vocational Education Act of career guidance and counseling programs, and the visibility of National Career Development Guidelines. In addition, many local school districts continued to offer, either in whole or in part, their own career education programs.

In the 1990s, several major educational initiatives, for example, school-to-work, technical preparation (tech-prep), contextualized teaching and learning, and work-based learning programs, embraced the essential character and focus of the career education movement. While not touted as career education per se, passage of the School-to-Work-Opportunities Act in 1994 was viewed by many as a renewal of key elements embodied in the career education movement, including the belief that public schools should offer challenging educational programs for all students by relating subject matter to work, helping students identify career-related interests, and stimulating students to make educational and career plans.

Today, the broader school-to-work movement and the ongoing transformation of career and technical education encompass a number of specific career-related programs, such as apprenticeship, work-based learning, tech-prep, or 2+2 models emphasizing program articulation between secondary and postsecondary curricula, cooperative education, mentoring, job shadowing, and school-based enterprises. Other educational concepts that integrate school and work life include service learning, constructivism, and contextualized teaching-learning. All of these enhance the relevance of education by striving for common goals such as bridging the gap often encountered between school- and work-related demands and experiences, informing adolescents about themselves and preparing them for the world of work, and addressing issues related to the transition from high school to postsecondary education and the world of work.

Although numerous similarities exist in recent work-education initiatives, career education is distinct in three primary ways. First, career education promotes a substantial change in the way education is conceptualized and delivered. Second, career education focuses on work in a broad sense, not on specific job training. Third, general employability skills are stressed, for example, basic academic skills, productive

work habits, and work values, as opposed to an emphasis on specific job skills attainment.

EFFECTIVENESS OF CAREER EDUCATION

A flurry of evaluation studies and reviews of career education programs occurred in the mid- to late 1970s. The vast majority of these reports were never published, and criticisms have been raised about the lack of stringent research designs and generalizable results in many of these investigations. Many of these early studies reported mild but not totally positive increases in student performance. Some studies, particularly those conducted in the late 1980s and early 1990s, have shown no statistically significant advantage in either academic achievement or postsecondary outcomes of students who participate in career education. However, more recent efforts have shown that students in career education programs are more likely to take college entrance and advanced placement exams, graduate from high school, and enroll in two-year or four-year postsecondary education. Future evaluation efforts of career education interventions should address several important questions, including the following: Who should participate in career education activities? What are the characteristics of effective career education programs? Does participation in career education affect academic achievement, high school completion rates, and college enrollment and success?

CONCLUSION

Traditional career education models were designed for a very different workplace, stressing developmental stages, basic and academic learning, employment skills, school-work linkages, and a need for lifelong learning. To a large extent, many of these program goals remain important. However, future career education efforts must also help students adapt to the demands of an increasingly global workforce characterized by a need to take personal responsibility for career, employability skills, interorganizational mobility, flexible work arrangements, teamwork, technology, and international relationships. Thus, *knowing how*, *knowing why*, and *knowing who* must assume greater prominence in career education experiences. Career education must also emphasize career pathways, exploration, and multiple future careers rather than specific jobs and career decision making. Finally, contemporary career education programs must continue to be client focused, mainstream and systemic,

and multifaceted; actively involve students; involve local communities through work experiences; and provide relevant and accessible information about the world of work and adult life.

CAREER EXPLORATION

An individual engages in *career exploration* as a way of gathering information about self and the environment, with a goal of fostering progress and career

development. Although proactive career exploration is common when individuals undergo a career transition and when they are faced with the need to make an imminent career decision, exploration may also be triggered by curiosity and a natural desire to explore.

There are two types of career exploration. *Environmental career exploration* is the investigation of various career options that an individual may consider pursuing at any point in his or her career. In exploring the environment, the individual proactively collects new information on jobs, organizations, occupations, or industries that allow more informed career decision making. *Self-exploration*, on the other hand, is focused on defining and exploring one's own interests, values, previous experiences, and career goals. It is a way of reflecting about and rethinking one's career and gaining a deeper understanding of oneself. As a result of self-exploration, individuals obtain a clearer perspective on their desires and abilities and possibly the type of work environments they want to avoid.

Whereas environmental exploration is primarily behavioral in nature (e.g., informational interviews, library and computer research, site visits, attending networking events), self-exploration is more cognitive (e.g., reflection, completing self-assessment instruments, analysis). This is not a completely clean distinction, however, as self-exploration can also include behaviors such as soliciting and discussing feedback from others, working with mentors and coaches to gain self-insight, and observing one's own behavior. Similarly, environmental exploration can contain cognitive activities such as reflection on personal experiences in potential employment settings, as in interviews, internships, or field projects. But in general, environmental exploration is a more active process, involving getting out there in the employment world, and self-exploration is more internal and cognitive, gathering and processing data about oneself. The two processes may occur at the same time and may influence each other. For example, as a result of an interesting work option encountered during environmental exploration, an individual may decide to conduct more self-exploration and reconsider his or her interests, values, and experiences related to the particular option encountered. Environmental career exploration is measured by the frequency of performing environmental career exploration behaviors, such as exploring other career options; self-exploration, on the other hand, is measured by the frequency of reflecting about oneself and one's past career.

TRIGGERS OF CAREER EXPLORATION

External Triggers

Sometimes career exploration is prompted by external factors, such as the triggers of undergoing a career transition; the contraction, expansion, or other changes within one's organization; or factors related to one's nonwork life (e.g., a work-family issue triggering exploration of other options). Even more distant contextual factors, such as the political and social environment in which an individual lives, can foster or constrain one's exploratory activity. Thus, career exploration may take on different forms and functions in various cultures and time periods; however, there is much to be learned about these cultural influences on career exploration.

Although career exploration is a lifelong process, it has been studied more frequently among students making initial career choices than among employees in later stages of their careers. Nevertheless, it is likely that career exploration behaviors conducted during a school-to-work transition in one's early career are qualitatively different from the behaviors conducted later on. In the early career years, there is a great deal of conscious, purposeful exploration of career alternatives as individuals search for the most suitable career fields, at least for the short term. On the other hand, in mid- and late career, more well-established individuals seeking a career change often search for alternative career options in order to "break their routines" in the particular career fields to which they have become accustomed. In other words, the task in early career is to end exploratory behaviors and "settle down," whereas the task in later career years is to disrupt the habitual routine and engage in exploration that will lead to desired or necessary changes. For example, late-career individuals are often faced with social and contextual factors, such as changes in the labor market or lifestyle preferences, which require them to engage in exploratory activities. In this case, career exploration can be seen as a way of coping and preparing for unexpected shifts in today's work environment. Given the instability of today's employment contracts, the need to be introspective regarding oneself and one's career, in the form of career exploration, is by necessity a lifelong issue.

For example, the importance of lifelong career exploration is highlighted for individuals in the midst of involuntary career transitions, such as loss of employment, which often triggers the exploration of other

career options. Career exploration during this type of career transition can be seen as a coping strategy that allows for more extensive learning about oneself and other career options available in the environment. For individuals experiencing career transitions, it is also common to find that a high level of stress and an immediate need to make a career decision function as powerful triggers for career exploration.

Internal Triggers

In addition to career transitions and other external factors, various internal dynamics and individual characteristics may trigger exploratory activity. One of the important individual characteristics that positively relate to career exploration at the time of transitions is career *role salience*. Individuals who consider their careers to be a particularly salient component of their identity are likely to conduct more career exploration. These individuals feel more concern for their career development and more urgency to act and get involved in their career decision making. Career role salience has been found to influence career decision making in early as well as late career. For example, career role salience is positively related to exploration by students transitioning from school to work as well as by employed adults who aspire to a different position in an organization. Finally, career role salience is also an important predictor of environmental exploration, particularly for individuals facing involuntary career transitions later in their careers.

Other internal triggers of career exploration include intrinsic motivational factors, such as self-determination, natural curiosity, and proactivity. In addition, individuals who are goal directed, have high self-esteem, and are self-confident about their career decision making tend to engage in extensive career exploration. In this respect, career exploration can be considered a subset of a broader human tendency for purposeful action and making sense of one's internal and external experiences. Individuals may be intrinsically motivated to explore and seek out novel experiences, thereby enhancing knowledge about themselves and the world.

There is also some recent evidence that the "Big Five" personality characteristics can serve as triggers of career exploration. The achievement-oriented and self-disciplined nature of conscientious individuals appears to be associated with greater exploration and career information seeking. Similarly, the assertive, gregarious, and energetic nature of the extraverted

person is also associated with career exploration. Moreover, individuals whose personalities are highly neurotic and those who are open to new experiences are likely to engage in self-exploration. Research suggests that neuroticism may lead to behaviors that serve to compensate for feelings of inadequacy and vulnerability. A neurotic person's emotional instability may lead him or her to engage in greater self-exploration for the purpose of reassurance regarding any doubts about the correctness of his or her career choice. On the other hand, emotionally stable individuals facing job loss situations, for example, tend to see reflection and self-exploration as unnecessary tasks; these individuals are very sure of themselves and their career choices, and they perceive self-exploration as a task for individuals who are more disturbed by job loss. Thus, although stressful situations generally trigger career exploration, the effect of stress on exploration may depend to some extent on one's personality characteristics.

Individuals who are open to new experiences are more curious about themselves and prefer a wide range of options with regard to ideas, values, and experiences. Therefore, thinking and reflecting on one's career-related abilities and interests may be particularly stimulating to the open person because they provide opportunities to master new challenges and enhance self-knowledge. Nevertheless, additional research is required to learn more about the relationship between personality and career exploration.

SOCIAL SUPPORT AND CAREER EXPLORATION

Another important predictor of exploration is the involvement of others who are significant to the explorer. Individuals who are able to provide social support and psychological resources can have a positive effect on the explorer's experience. For example, safe and secure relationships within one's family are extremely important determinants of exploratory activity. The support and security obtained in close family relationships promote general exploration in childhood, and this tendency is carried into adulthood. Later in life, career counselors and coaches may also foster exploration by providing constructive support and resources that individuals can use in career decision making. Especially in times of transition, tangible support provided by counselors and coaches can increase one's ability and motivation to explore. In

particular, it is known that counselors can increase clients' control and competence in both self- and environmental-exploration tasks. Thus, any intervention that bolsters one's confidence with respect to decision-making tasks also fosters exploratory activity. In addition, as suggested earlier, individuals may be faced with the need to engage in exploratory activity if they experience stress concerning their careers (e.g., during transitions or when faced with the need to make a career decision). Counselors may help these individuals manage their stress levels while they engage in productive exploration. Finally, it is known that individuals are often prone to biased information gathering and processing, which may lead to insufficient exploration of various options or premature career decision making. Support from career professionals may be especially relevant in helping clients evaluate their career decisions objectively, emphasizing the importance of alternative-hypothesis testing and proper information-gathering processes. Thus, guidance and support can lead to improved self-exploration, as well as to more comprehensive and diverse environmental exploration, allowing individuals to develop exploratory attitudes in relation to their overall life experiences.

OUTCOMES OF EXPLORATION

In addition to understanding the factors that may trigger career exploration, it is important to recognize the specific outcomes of exploration. In considering exploration in a broader context, it is often emphasized that the exploration process fosters a coherent sense of self or identity. Engaging in exploration promotes autonomy and integration of the self. Thus, the core outcome of exploration is self-construction, which refers to the process of developing a coherent and meaningful identity and implementing that identity in a life plan. Exploration can also be seen as a critical means by which individuals can construct and reconstruct themselves throughout the life span and across life roles. Through exploration, individuals seek self-relevant and interest-relevant information in different arenas of their lives.

The exploration process very likely cuts across life roles and domains and yields benefits that may not be limited to one domain. For example, learning about ourselves in the student role through self-exploration may change our self-concepts in general and influence the way we interact with others in our families or at work. Thus, exploration is embedded across life roles and can

be seen as a lifelong process. This seamless quality of exploration allows learning or exploration in one domain to be mutually beneficial across the life space.

As individuals explore, they also gain greater levels of competence, and they may be able to experience an increasing feeling of "ownership" of their adaptive career behaviors and attitudes. Developing a capacity to explore one's environment and one's own internal psychological experiences, especially early in one's career, may offer a unique advantage in an era of rapid social and economic change.

One of the most important outcomes of career exploration is improved occupational decision making. Exploration generates useful information about oneself and alternative occupations, thus helping individuals make the right occupational decisions at any point in their careers. For example, environmental career exploration at the time of an involuntary career loss has been found to lead to the acquisition of a higher-quality job upon reemployment. In this instance, career exploration is used as a coping strategy, and the exploration of various options at the time of transition helps individuals find new jobs that more strongly fit their personal qualities.

Career exploration activities have also been associated with recruiters' ratings of an individual's interview performance during a job search. Thus, career exploration enhances interview readiness, which relates to interview performance and outcomes. In addition, career exploration helps in making more informed job-search decisions, especially during school-to-work transitions. Later in adulthood, exploration is often conducted together with various job search behaviors, and the two processes influence each other. In searching for a new job by looking at job advertisements or talking to colleagues, individuals may encounter options that they may want to explore further, and thus exploration and job search may complement each other.

Thus, it is necessary to maintain this exploratory attitude throughout life and use exploration as a means of coping with and adjusting to a shifting set of challenges presented by a variety of career transitions and challenging job situations. While career exploration following a school-to-work transition can be seen as an adaptive process, conducting repeated exploration allows one to cope with social change and adapt to the realities of the modern world of work.

An exploratory attitude represents an open and nonrigid way of relating to the world, such that individuals are able to approach the vast number of new

situations and changes they face in a manner that encourages growth and further self-development. Cycles of exploration are expected to occur throughout an individual's life, particularly during the period preceding and following career transitions. Career exploration should be viewed as a lifelong process, with implications for individuals' development at all stages of their careers.

CAREER GOAL

Goal setting is often a significant component of performance improvement programs in the corporate

world, because employees who are committed to specific, challenging goals perform more effectively on the job. Researchers have identified a number of factors that explain why goal setting can improve job performance. Working toward a specific, challenging goal motivates an individual to work hard and provides a focus to the individual's effort. In addition, the establishment of a goal helps the individual develop a strategy for accomplishing the task and provides feedback for monitoring progress and performance.

Although substantial research has been conducted on the importance of "task" goals or "work" goals as described above, far less research attention has been directed toward the study of career goals despite the fact that career goal setting is often a central feature of career-planning and career-development programs. This entry discusses the meaning of a *career goal*, the advantages and cautions associated with career goal setting, and the factors that enable individuals to set useful career goals.

THE MEANING OF A CAREER GOAL

Jeffrey Greenhaus, Gerard Callanan, and Veronica Godshalk have defined a career goal as *a desired career outcome that an individual intends to attain*. It is important to note that a career goal is more than a wish or a dream; it also represents an intention or a striving to accomplish the outcome. Many people equate a career goal with a specific target job, such as becoming a vice president of sales or becoming a head coach of a Division 1 collegiate football team. However, Greenhaus and his colleagues point out that a career goal need not target a specific job. Instead, it can represent the *type of work experiences* an individual intends to achieve, or what is called a *conceptual career goal*. For example, an individual might set a conceptual goal to attain a position that involves extensive financial data analysis and preparation of written reports in an office setting with minimal travel. Both types of career goals, conceptual goals and target job goals, are important. Conceptual goals are useful because they focus on the attributes of a position that are compatible with one's talents, needs, and values. Target job goals are important because most work experiences are embedded in specific jobs in an organization. In fact, achieving a target job should enable the individual to meet his or her conceptual career goal. Moreover, it is likely that a number of different target jobs are compatible with a person's conceptual goal.

ADVANTAGES AND CAUTIONS ASSOCIATED WITH CAREER GOAL SETTING

Career goals can be useful for the same reasons that task goals are useful. Holding a specific career goal can motivate an individual to work hard to achieve the desired outcome, suggest useful strategies to attain the desired outcome, and provide feedback on how effectively the individual is directing his or her efforts. For example, a salesperson who sets a goal to become sales manager (the target job goal) may be energized to do what it takes to achieve the position and may explore, through readings and discussions with other people, the most effective strategy for becoming a sales manager. Moreover, because the goal is a consciously held objective, the individual is able to gauge how well his or her actions (e.g., attending a management skills workshop or returning to school to acquire an MBA degree) are facilitating the accomplishment of the goal. Research has shown that employees who set career goals, who are committed to their goals, and who have clear career goals and plans are optimistic and resilient in their careers, highly involved in their jobs, and successful in job-search activities.

Nevertheless, there are some cautions associated with career goal setting. Greenhaus and his colleagues suggest that a career goal is likely to be *dysfunctional* when the goal has the following characteristics:

It is someone else's vision. The goal is seen by another person as what is best for an individual rather than the individual's own vision for meeting his or her personal needs and values.

It ignores family and lifestyle preferences. Some jobs may be so demanding or intrusive that they prevent a person from meeting other important needs for family, leisure, or community service.

It ignores the current job. Some people are so preoccupied with achieving a promotion or another position that they fail to see that many of their needs and values can be accomplished in their current jobs, especially if they work with their managers to improve their jobs to achieve greater fit with their personal preferences.

Is too vague. The conceptual goal discussed previously—a position with extensive financial data analysis, preparation of written reports, office setting, and minimum travel—is specific enough to steer the individual toward a target job and strategies to attain the job. An overly fuzzy conceptual goal (e.g., “a job that is fun”) may not provide enough information to be useful.

It is too easy or too difficult. The accomplishment of a goal that is too easy doesn't provide the same feeling of accomplishment as the accomplishment of a challenging goal. However, a goal that is too difficult is unlikely to be attained and can produce frustration. This is why it is often recommended that individuals set “challenging but attainable” goals.

It is inflexible. People change; technologies advance; career paths disappear; organizations merge; and new industries develop. Individuals who hold on to outmoded career goals in the face of change are not adaptable and run the risk of failing to get their needs met.

FACTORS THAT ENABLE INDIVIDUALS TO SET USEFUL CAREER GOALS

Self-awareness is an essential ingredient for effective career goal setting. An individual who is unaware of his or her needs, values, strengths and weaknesses, and lifestyle preferences can certainly set a career goal. However, it may not be a useful goal. Even if the goal is achieved, it is unlikely to meet the individual's personal needs and values and take advantage of the individual's talents, because it wasn't based on an accurate self-assessment.

An awareness of the environment is also crucial to effective goal setting. Individuals may understand themselves well (high self-awareness), but what if they are unaware of the duties and requirements of different jobs or career paths, the cultures of their organizations or other organizations where they might seek work, the impact of technology on their work lives, or the changing nature of the economy? Their career goal is likely to be flawed because it is not based on a realistic assessment of the environment. Opportunities may be missed (“I never knew that there was such a job as fuel cell technician”); goals may be unattained (“I didn't realize that jobs in farming are declining so much”); or goals may not meet the individual's needs (“It never occurred to me that engineering managers spent more time solving people problems than technical problems”). In short, an effective career goal should be based on extensive knowledge about oneself and the work environment.

Achieving self-awareness and awareness of the environment is ultimately an individual's responsibility. Therefore, people should seize every opportunity to learn about themselves and the work world. People learn a great deal from everyday experiences: introspection, reading, and conversations with colleagues,

mentors, friends, or family members. Awareness can also be derived from more formal activities, such as seeing a career counselor, joining a professional association, attending a conference, or participating in a training-and-development program.

Moreover, organizations can help their employees become more aware of themselves and the environment so they can select a viable career goal. For example, organizations can offer orientation programs for new employees, career assessment and planning assistance, career counseling services, performance appraisal programs, coaching or mentoring programs, job rotation opportunities, job posting, training and development activities, and outplacement services. All of these initiatives have the potential to enhance individuals' knowledge and awareness, which should contribute to their well-being and, ultimately, to the well-being of the organization as well.

CAREER INDECISION

Career indecision, the state of being undecided regarding occupational interest or career path, has been defined in a variety of ways, making it somewhat difficult for investigators in this area to reach consensus on its nature and causes. Researchers have described individuals as undecided if they have not chosen or declared a college major, if they reported that their certainty about vocational choice was low, if they could not name a career choice, if they were unable to articulate career goals, or if they scored below a specified point on a measure such as the Career Decision Scale. The term career indecision has also been used to apply to the range of problems and difficulties individuals encounter during the career

decision process. An individual might, for example, know that she wants to be a therapist but is not sure whether she wants to major in psychology or social work. Another individual might narrow his career options down to two choices but may have difficulties in choosing one over the other. Such individuals might be said to be career undecided to a degree, illustrating that career indecision can be thought of as existing on a continuum rather than as an either/or proposition.

Many people will, at some point in their lives, face a certain amount of indecision related to making career choices. It has been estimated that between 10 percent and 30 percent of college students could be classified as "undecided." In fact, in many cases, career indecision might be thought of as a normative phenomenon, closely related to an individual's age and educational level, with younger and less educated individuals more likely to be career undecided. In this regard, some researchers have suggested that a certain amount of indecision might actually be beneficial. The undecided student or adult may be more likely to systemically explore his or her options in hopes of making a more informed career decision than would the individual who hastily chooses a line of work but is nonetheless classified as "career decided."

Most individuals who are undecided at some point do eventually move forward, make choices, and enter the workforce. However, for some individuals, career indecision is more than just a passing phase or a normative part of the developmental process. For those people, career indecision can be a major impediment to successfully preparing for work, for entering an occupation or profession, or for maintaining a satisfying work life. Since identity and self-concept are closely tied to an individual's occupation and since job satisfaction is positively related to overall life satisfaction, prolonged or chronic career indecision can have a detrimental effect on an individual's mental health and well-being.

The definition of what is prolonged or chronic is not always clear, but career counselors typically become involved after the individual or family members have become frustrated with a lack of progress toward a decision. Since career decision making is an important task in the life-span developmental process, the developmental timetable accepted by a given society often defines the point at which an individual's indecision may be viewed as problematic. In the United States, the educational system expects that college students will declare majors by

approximately age 20. Societal norms suggest that most young adults, unless headed for graduate school, begin to pursue careers after college graduation, when they are approximately 22 years old. Young adults who do not pursue college degrees are expected to choose and enter careers even earlier. However, in light of recent findings that suggest that brain development may not be complete until the mid-20s, as well as the sociological phenomenon of “extended adolescence,” it is not clear that these timetables are always appropriate. One viewpoint is that the diagnosis of career indecision cannot be made reliably until the individual is 25 years old. There is, however, evidence that chronic career indecision can be predicted at a much younger age. Because chronic career indecision is related to underlying psychological issues rather than a normal development process, individuals at risk for chronic career indecision will gain no advantages if they wait until they are 25 years old to begin treatment for their underlying condition(s). Chronic career indecision and its causes are discussed in more detail later in this article.

HISTORY OF THE CONSTRUCT OF CAREER INDECISION

The construct of career indecision has been a focus of investigation since the 1930s. At that time, the population of interest was college students, who were dichotomously characterized as either career decided or career undecided. (Note that even today, most career indecision research focuses on college undergraduates.) In 1937, E. G. Williamson and John Gordon Darley published the results of their investigation into the differences between decided and undecided students in terms of academic commitment and achievement. Even though their results indicated that there were no significant differences between decided and undecided students, Williamson nonetheless extrapolated that there were many causes of career indecision, among them fear, lack of aptitude, and emotional instability. It was not until 1969 that Leonard Baird published the results of two large studies, with a total of more than 70,000 subjects, in which he concluded that there were no significant differences between decided and undecided students, particularly in terms of academic aptitude. His position was in accord with the developmental perspective of career indecision that was pervasive in the 1950s and 1960s, as put forth by theorists such as Donald Super

and Erik Erikson. Baird maintained that his findings had important implications for counseling undecided students. He recommended that such students should not be pathologized. Rather, he maintained that undecided students should be made aware that their undecided status is normative in nature and that they are not academically inferior to students who are career decided.

During the 1960s and 1970s, career-indecision research continued to focus on the question of whether and how individuals who are career decided differ from those who are career undecided. It was hypothesized that understanding the inherent differences between the two groups would yield valuable information as to how counselors could best assist the career undecided. Although many researchers studied various hypothesized differences between the two groups in terms of achievement, aptitude, and personality factors, they could not reach a consensus. Some researchers found no significant differences between career decided and undecided students, while others found undecided students to have, for example, higher attrition rates, lower academic achievement, and lower self-esteem. Those who found no differences between the two groups point to the benefits of not pathologizing career indecision for those students who are undecided. Nonetheless, these contradictory findings did little to settle the question of whether characteristic differences exist between those who are career decided and those who are undecided.

Some of this confusion may be attributed to the failure to distinguish between developmental career indecision and chronic career indecision. Since most undecided individuals do eventually become decided, in many cases, there really are no major differences between the two groups, other than perhaps the age at which individuals pass through different developmental stages. However, researchers also uncovered evidence that career decision making remains chronically problematic for some people. For these individuals, career indecision can be a debilitating condition.

From that point on, researchers began to understand that there are separate, distinct categories of career indecision and that identifying the category into which an individual might fall could aid in the intervention process and help achieve positive outcomes. Much of the investigation that followed centered on the relationship between career indecision and multiple variables, such as personality factors, aptitude, cultural norms, and attachment style.

SUBTYPES OF CAREER INDECISION

Although there seems to be clear consensus that there are multiple subtypes of career indecision, there is less agreement as to the exact nature and definition of those subtypes. Moreover, researchers have been inconsistent as to the variables they have chosen to study in their attempts to explain career indecision. As a result, investigators have devised numerous methods for categorizing and conceptualizing career indecision.

One way to classify career indecision is to ascertain whether the individual is merely career undecided or is generally indecisive. It is important to note that there is an obvious difference between the states of being “undecided” and “indecisive.” Individuals who are career undecided may be that way for a number of relatively benign reasons, including their educational levels, lack of general work experience, or lack of information surrounding vocations. This type of career indecision is often thought of as a normal part of the developmental process. Individuals who are developmentally career undecided may benefit from brief and focused interventions, with the goal of providing information to assist them in making a career choice. Conversely, individuals who are generally indecisive in other areas of their lives are very likely to also encounter difficulties in making career decisions. This type of career indecision is generally more problematic and may require more extensive intervention.

Another way to categorize career indecision is to focus on the relative comfort level of the undecided individual. Some individuals may be career undecided yet experience little or no distress because of their undecided states. Such individuals, further characterized as emotionally stable, may not feel internal or external pressure to make a career decision at a given point in time, and therefore may be said to be comfortable with their undecided states. For other individuals, the inability to make a decision may cause varying amounts of stress and anxiety. These individuals might also report low vocational identity and lower levels of self-esteem.

It has been suggested that individuals with lower levels of academic abilities could constitute another subtype of career indecision. These individuals may see their choices as limited due to their academic disadvantages and may also believe that their career choices are unrealistic. They may become discouraged with their perceived lack of ability as well as their overall ability to choose and enter a career.

Many researchers have investigated the connection between various aspects of personality and career indecision. Some of these aspects include anxiety, self-esteem, locus of control, career self-efficacy (the beliefs that individuals have about their abilities to pursue and succeed in various careers) and vocational maturity (an indication of an individual’s vocational orientation and consistency of vocation preference, along with the level of information about and wisdom of a particular vocational choice).

CHRONIC CAREER INDECISION

A certain degree of career indecision can be seen as a normal part of the developmental process, but when the indecision is related to underlying psychological issues, it is not likely to resolve over time. Bruce Hartman and Dale Fuqua introduced the term *chronic career indecision* in the early 1980s. The factors most often associated with chronic career indecision are anxiety, external locus of control, poor identity formation, and low self-esteem. Much of the current body of research focuses on the relationships between these factors and career decidedness and indecision.

Anxiety is one of the most common conditions researchers associate with career indecision and career indecisiveness. Research has addressed the impact of both state anxiety (associated with the act of choosing a career and/or the condition of being career undecided) and generalized trait anxiety. In essence, anxiety has been characterized as both a by-product of the decision-making process (state anxiety) and as a cause for career indecision (trait anxiety). Individuals who become anxious as a result of having to make career decisions may briefly question their own abilities to make correct decisions, possibly because of perfectionist traits, which can lead to avoidance of the decision-making process. Once these types of individuals ultimately make a decision, however, they are likely to become less anxious. This is in contrast to individuals for whom anxiety is a primary cause of indecision. These individuals may lack confidence in their abilities to make decisions and may also have poor overall problem-solving skills. For such individuals, making a decision leads to increased anxiety and self-doubt regarding the appropriateness of the choice. Trait-anxious individuals may also prematurely drop out of career counseling because of their discomfort with the decision-making process.

A condition related to career choice anxiety is *external locus of control*, in which the individual

perceives little control over his or her own life and life choices. This may lead such a person to avoid engaging in problem-solving processes, which could reduce the level of anxiety and assist in decision making, because of a low level of confidence that such activities will make a difference. This, unfortunately, becomes a self-defeating cycle, as problem-solving skills can only develop through the process of practicing them.

A third area of concern for individuals who are chronically undecided is *poor ego identity formation*. This is based on the stages of psychosocial development described by Erik Erikson, the first five of which must be resolved by early adulthood. Beginning in infancy, these first five stages are trust versus mistrust, autonomy versus shame and doubt, initiative versus guilt, industry versus inferiority, and identity versus identity confusion. If the individual has difficulty in any of these stages, he or she will not successfully form a clear sense of identity, which is thought to be an important precursor of career choice. Possible reasons for this are discussed below, under "Family Influences."

Low self-esteem is another variable that can contribute to chronic career indecision. Research has related low self-esteem to general indecisiveness, as well as to low self-efficacy (belief in one's ability to perform certain tasks) and depression. All of these variables can inhibit the thoughtful problem-solving processes necessary for making effective life decisions.

A final, but somewhat controversial, cause of chronic indecision is referred to as *multipotentiality*. Some individuals who are considered gifted and talented may have difficulty choosing a career path because they have many different interests and skill sets. They may score uniformly high in several areas of aptitude and achievement. Moreover, results of career interest measurements for this group may indicate no clear preferences. Thus, the gifted and talented may be presented with a seemingly endless array of vocational choices, perhaps leading to a condition of career indecision. However, recent research has questioned the methods used to evaluate aptitude and preferences for this population, thereby casting some doubt on whether traditional assessment measures are useful in identifying relevant areas of concern.

FAMILY INFLUENCES

Over the past two decades, career theorists have acknowledged that families and family influences are

important factors in career decision making. The importance of considering family systems becomes even more critical in the current era, in which the definitions of *family* and *work* have become more expansive and complex. Family members may serve as career role models, providing concrete examples of how to succeed in a particular vocational area. Often, family members may be influencers, directing young adults toward high-profile or high-status careers or toward careers that meet the family's needs in other ways, such as joining a family-owned business. Family members can also act as mentors, helping the young adult bypass traditional hurdles and hence overcome obstacles. For example, parents can help their child get a job within their own place of business, bypassing the usual interview process. They may know influential people who are already successful in their child's choice of career and may make introductions, thereby helping the child to network. Family members, conversely, may function as gatekeepers, erecting financial or emotional barriers to careers they deem to be unsuitable for their dependent young adult. They may refuse to pay for college if their child does not pursue the course of study of the parents' choice, or they may subject the child to high levels of guilt.

According to family systems theorists, when a child does not sufficiently gain a level of independence from the family of origin, that child may encounter difficulties in identity formation, a factor that career theorists associate with career indecision. It follows that a young adult's career decision making may suffer when families exert too much influence or when the young adult does not sufficiently separate or differentiate from the family of origin. If the young adult fails to achieve autonomy and is not encouraged to explore career options independently, career indecision may result. Furthermore, researchers have suggested that young adults who are overly dependent or rigidly connected with their families may be conflicted between pursuing careers of their own choosing and careers that their families would prefer. As a result, a condition is created in which career decision making becomes even more problematic. However, this interpretation varies by culture, as discussed below under "Multicultural Considerations."

INTERVENTIONS

Interventions for career indecision must be chosen based on an assessment of type and causes for the

indecision. An individual who is developmentally undecided will tend to benefit from short-term career counseling, the focus of which will be psychoeducational and centered on assessment of interests, needs, and values. Career counselors can provide such individuals with practical information, including descriptions of various careers, workplace environments, and expected salaries. Counselors can encourage these clients to set up informational interviews or opportunities for job shadowing; they may also suggest various computer- or Internet-based tools to help clients with self-assessment and career evaluation. One effective form of intervention is referred to as *cognitive information processing*. This approach teaches a systematic method of identifying and solving problems, and it can be quite effective with those who need assistance in organizing the career choice process. In essence, with developmentally undecided clients, the counselor acts as a facilitator, providing assessment, assistance in gathering information, goal setting, and career plan implementation.

In contrast, the chronically career undecided or indecisive individual may require assistance in determining the underlying reasons for the indecisiveness before coming to terms with choosing an occupation. The counselor must consider that it may be neither the absence of self-awareness nor the lack of vocational information that is rendering the individual incapable of making a career choice. In this instance, a psychoeducational approach alone may be ineffective or even detrimental, as the individual may become even more anxious and frustrated by the continuing inability to make a career decision, even with the help of a counselor.

Among the areas of focus for interventions with chronically undecided individuals are anxiety, career self-efficacy, and family dynamics. Individuals whose career indecision is related to anxiety will benefit from treatment focused on both relieving general anxiety and anxiety specifically related to career decision making. An example of a career-focused intervention for anxiety is *cognitive restructuring*, which helps the individual recognize and change rigid and unreasonable beliefs. These may be beliefs regarding an inability to succeed, their own fit (or misfit) with certain careers, an inflexible demand that the chosen career must provide immediate and high levels of success, and the need to be completely certain before any decision can be made.

To move forward in developing a career plan, it is necessary to believe that one's efforts will be

rewarded and that career success is possible. Interventions focused on self-efficacy attempt to increase the belief that goals can be achieved. Like cognitive restructuring for anxiety, these interventions may focus on helping the individual modify her or his self-defeating beliefs, in this case specifically related to potential for success. The counselor may also structure activities that create successful experiences or help the individual recognize areas in which he or she has been successful that may then translate into career success.

In some cases, chronic career indecision is effectively treated through psychotherapy focused on family dynamics, such as inadequate developmental separation from the family of origin or family dysfunction related to parental alcohol or drug abuse. Those who have grown up in dysfunctional families may tend to think in black-and-white terms, and they are more likely to face psychological problems that interfere with all life choices. In such cases, treatment may be difficult and will initially focus on addressing the family system and psychological issues before addressing career choice.

CAREER INDECISION THROUGHOUT THE LIFE SPAN

Although career indecision, by its very nature, usually is first seen during late adolescence or early adulthood, individuals may be career undecided at any time throughout the life span. Career indecision can occur when an individual is making an initial career choice, considering a career change, returning to work after a break in employment, or even beginning a new career after retirement. The need for ongoing monitoring and reevaluation of career direction may be especially necessary in the current work environment, in which individuals may no longer expect employment for life in any one particular field or industry. This is true for a variety of reasons. One is the rapid pace of technological change, which has made some careers obsolete. Another factor is globalization, which has led to economic pressures on companies to outsource jobs to the lowest bidder, often in other countries. Furthermore, downsizing has forced thousands of workers to suddenly reenter the job market, often with skill sets that may not meet current employers' demands. A career choice that seemed safe and appropriate during the first phase of entering the world of work may look very different several years later, and, in fact, no career may be

considered immune to changes or even obsolescence. Considering the stress and uncertainty associated with the current work environment, even individuals who have not lost their jobs may very well begin to feel anxious and unsettled about their current occupations, thus promoting one of the major conditions associated with career indecision. This may be especially true for individuals who were career undecided in the first place.

MULTICULTURAL CONSIDERATIONS

Much of the early research on career indecision focused on White, middle-class college students and adolescents. In the past decade, research has begun to examine the variables that may uniquely affect career decisions of racial and ethnic minorities; women; lesbian, gay, and bisexual (LGB) individuals; and individuals with disabilities.

The culture of the United States and European countries is focused on individual achievement and autonomy, which encourages decision making independent of the family of origin. This is not the case in more collectivist cultures, however, such as those of Asia and South America. In such cultures, it is normal and expected for the family to have a strong influence on career decision making, and this can result in an inaccurate assessment of career indecision for an individual who appears by U.S. standards to have difficulty making an independent choice. Another important cultural variable is orientation toward time, which in the United States is toward the future. The Latino and Native American cultures, by contrast, are more present focused, and this again may cause an inappropriate assessment of indecision because of apparent inattention to advance planning. When working with individuals from other cultures, it may be important to assess the level of acculturation, or the degree to which the individual has adopted the norms of the host culture. Finally, it is important to consider the degree to which career decisions may be affected by workplace or educational discrimination and by financial barriers faced by individuals of lower socioeconomic status.

Historically, career decision making for women was viewed as secondary to life goals of marriage and child rearing. It is important to note that this view was never universal and that it applied only to women of higher socioeconomic status. Nonetheless, career counseling for women has almost always considered a balance of work and family obligations to be an important factor

in women's career choices. Because of a continuing pull between work and family, it might be assumed that women would face more difficulty with career indecision than would men. However, minimal evidence exists to support this assumption. Similarly, there is little evidence of a relationship between sex role and career indecision. However, for women in nontraditional careers, as well as for LGB individuals, anxiety related to career choice may result from either experienced or anticipated discrimination in the workplace. Measures of career indecision that do not account for barriers related to workplace discrimination may be problematic for such individuals, as well as for racial and ethnic minorities.

A relatively new dimension of diversity in career theory is disability status. Because of new laws providing access to higher education and the workplace, as well as medical advances, students with disabilities are increasingly present on college campuses and seeking advice in career choice. These disabilities may be physical or medical, learning based, or psychiatric. It is not yet clear whether individuals with disabilities experience indecision at a higher rate than do others. Some evidence suggests that individuals with disabilities may experience more self-doubt and that this may lead to higher levels of indecision. Furthermore, individuals with disabilities may tend to aspire to lower-level careers than do their counterparts without disabilities. Additional research is needed to determine the causes of career indecision in this population and whether individuals with disabilities require different interventions than do others.

AREAS REQUIRING FURTHER STUDY

While some research has begun to define cultural variables in career decision making, much more remains to be done. One important task will be to examine the existing career decision models to incorporate the values of interdependent cultures and therefore to refine the criteria for diagnosing indecision. Furthermore, although there is general recognition that career decisions occur throughout the life span, existing models still tend to focus on adolescence and early adulthood. Given the increasing rate of change in the workplace, which has led to a trend toward multiple careers rather than a single lifelong career choice, it will be important for both theory and practice to consider variables that may contribute to career

indecision in older adults. Finally, a relatively unexplored area is the process of decision making and the nature of indecision for individuals whose career exploration process is more spiritually based, that is, those who have followed a “calling” into a career rather than having made a more data-driven decision.

CONCLUSION

It is clear that the concept of career indecision is much more complex than it would appear to be at first glance. There are numerous ways to define the construct and to identify its subtypes, as well as a wide range of antecedent factors and interventions to consider. In particular, it is important to differentiate between indecision as a normal developmental phase and chronic career indecision, which may require psychological intervention. Furthermore, these many factors are affected by multicultural variables that have only recently been addressed in the vocational literature.

CAREER INTERRUPTIONS

Career interruptions are breaks, pauses, or disruptions in one’s current career. A career interruption occurs when an individual’s typical and usual work is interrupted or changed by some internal (e.g., change in one’s desired career path or life’s goals) or external (e.g., job loss or disability) event. Alterations or changes in a person’s career activities can change the course of one’s work either temporarily or permanently. For example, a temporary career interruption may occur when a woman decides to leave the paid workforce to care for her children and reenters that same career at a later time. An example of a permanent interruption of one’s career may occur in the face of an incurred disability or illness that makes it difficult or impossible to return to one’s previous job. The world of work can be conceived of as a series of starts and stops, accelerations and waiting periods. With advances in technology and other global occupational and economic changes workers are increasingly being faced with expanding career options and the challenge of more frequent involuntary career interruptions. Research indicates that a career interruption or transition can be an opportunity for either growth or deterioration. An understanding of career interruptions is needed for counselors to effectively facilitate healthy adult functioning through all types of career transition processes.

There are various ways to categorize career interruptions. Career interruptions can be either anticipated or unanticipated, voluntary or involuntary. Anticipated interruptions are events that are expected to occur.

Examples of anticipated career events are quitting a job, changing careers, or retirement. Unanticipated interruptions are those that one does not expect to happen, such as the loss of a job or an injury or illness that interferes with one's ability to continue in the same type of work or even engage in paid work at all. Career interruptions can also be classified as voluntary or involuntary. In a voluntary interruption, one chooses to interrupt the current course of one's career. An example of a voluntary career interruption is a person who chooses to exit the paid workforce to obtain a college or advanced degree. An example of an involuntary career interruption would be getting fired from one's job. It also is possible to have an anticipated career interruption that is involuntary and an unanticipated career interruption that is voluntary. For example, an individual may anticipate an impending layoff as a result of organizational downsizing. Similarly, an unanticipated voluntary career interruption can occur when a company is sold to another corporation that then offers continued employment, but under less than acceptable terms. In these circumstances, some people voluntarily choose to resign from their jobs, interrupting their careers in order to reassess their career and life goals. As a result, some people might choose to search for more desirable paid work; others may choose to use this opportunity to change careers completely; and others might decide to exit the paid workforce entirely to care for young children or elderly parents.

Although not all career interruptions are experienced as negative, there are a number of common issues faced by those experiencing breaks in their careers. For example, individuals might experience fear and anxiety as they establish a realistic appraisal of their current skills and abilities, confront financial loss or instability, or experience the loss of job security, colleagues, identity, self-confidence, and self-esteem. Counselors attend to three sets of important factors when facilitating transitions through career interruptions: (1) the individual's perception of the interruption (e.g., voluntary versus involuntary, anticipated versus unanticipated); (2) the characteristics of pre- and postcareer interruption environments (e.g., financial, social, and health and ability status); and (3) internal resources (e.g., confidence and abilities) and adaptability. While attending to these factors, counselors can help people achieve adaptive transitions by facilitating the development of agency, optimism, clear and realistic planning, and perceived

opportunity. Specifically, counselors can assist people in developing *agency*, or an internal motivation to take action to make adaptive changes. They can help people reframe the experience from one of loss to one of opportunity. Counselors also can assist clients in developing clear and detailed plans for achieving their goals. Finally, by encouraging the exploration of diverse alternatives, counselors can encourage individuals to expand the range of their perceived opportunities.

Career interruptions can occur for a number of reasons, including leaving paid work to concentrate one's energies on other life roles, such as caring for children or aging parents, job loss, and illness or disability. It is important to have an understanding of the important issues involved in each of these interruptions. One of the most common career interruptions occurs when someone takes a leave from paid employment to care for his or her children. This type of career interruption is more common for women than for men, as women continue to be more involved in caring for the home and children, despite their increased presence and responsibilities in the paid workforce. Much of the literature on women's career interruptions focuses on the difficulty of combining family and labor market work. The length of the break from paid employment can be influenced by a number of factors, including eligibility to take advantage of the Family and Medical Leave Act, availability of acceptable child care, financial resources, work role salience, and compatibility with the role expectations of full-time work in the home caring for one's children. For some women, leaving and reentering the paid workforce might go relatively smoothly given that family leave programs can allow for people to reenter their previous positions without a loss of pay or status.

Other individuals reentering the workforce might find their previous careers to be unsatisfactory given the multiple life roles they must negotiate. For those who choose to stay out of the paid workforce for longer periods of time, a whole new job search process could be necessary. Reentering paid work may be motivated by vocational, family, or financial concerns. For some people, reentry might be precipitated by circumstances related to their spouses or partners, such as disability, divorce, death, or a geographical move due to job relocation. These individuals may never have anticipated working outside the home, may lack the necessary skills and confidence, or may be unsure of how to manage the reentry process into paid employment.

Navigating life transitions through complex life roles such as those of paid worker, parent, and caregiver can result in a number of personal and professional challenges that have the potential to disrupt one's life. The work of raising children and sustaining families can be a barrier to paid employment and lead to professional marginalization and loss of status in the paid workforce. These issues are especially relevant for women, and women of color in particular, who may already be facing the consequences of gender and racial discrimination that have impeded their access to work or advancement within their fields.

Job loss is the second major reason for career interruption. Mergers, downsizing, restructuring, and economic downturns can all contribute to job loss. Losing a job can create stress and negatively affect one's finances, family life, and mental and physical health. Loss of one's previous vocational role, function, and status can be very disruptive in a person's life. Many individuals face shock, confusion, anger, anxiety, depression, feelings of isolation, failure, rejection, and decreased self-confidence and self-esteem.

Reactions to career interruptions due to job loss change over time, creating an identifiable pattern. Five phases (disbelief, sense of betrayal, confusion, anger, and resolution) have been identified in the transition process from unemployment to reemployment. Disbelief is frequently the initial reaction to news that one is being let go from one's current job. It is typical for these situations to be totally unanticipated and for the affected individuals to ask, "Why me?" A sense of betrayal results from a disruption in the belief that if one is a good, responsible worker, one will always be rewarded with continued employment and benefits. It is as if a psychological contract, or agreement, has been breached and one has been dealt with unfairly. Once people recover from the initial shock of job loss, confusion typically ensues over what comes next. When employers provide outplacement or career counseling services, some people vacillate between anger, betrayal and anxiety, and feeling grateful and excited about future possibilities. Over time, most people are able to come to some resolution by moving on to new employment situations. The degree to which an individual is able to successfully move through these transitional stages will depend on a number of factors, including one's psychological resources and abilities, educational and financial resources, coping skills, and personal and demographic characteristics that may make one vulnerable to

career barriers related to age, gender, race, and social class.

Counselors can assist individuals in moving from unemployment to employment in several ways. They can provide counseling to deal with the negative effects of job loss and enhance optimism and self-efficacy. They can also encourage people to seek out social support and encourage them to maintain an active daily schedule. A flexible and adaptive family appears to be important for women, so encouraging communication with family members is recommended. For men, problem-focused interventions, in addition to emotionally focused interventions, are also important. The literature suggests that the psychological effects of job loss need to be addressed before individuals can successfully engage in employment seeking. This includes helping individuals more adaptively cope with emotional and financial concerns, providing support and encouragement, and enhancing job-search skills and job-hunting strategies. In today's economy, counselors must also help individuals to adapt the changing nature of work and recognize the need to be flexible and adaptable and to upgrade their skills.

Disability and illness create a third reason for career interruption. These interruptions occur when individuals are no longer able to function in the capacity required by their current jobs. For example, a surgeon who develops a degenerative eye disease that results in blindness will no longer be able to perform surgical procedures. Although many of the same psychological and physical consequences of job loss for other reasons can accompany job loss from disability and illness, these individuals also are faced with fears and concerns associated with their physical condition.

One of the challenges of conceptualizing the career interruptions of individuals with disabilities and/or illness is the immense heterogeneity of individuals with these difficulties. Thus, individual and environmental factors must be considered in the career interruptions of these individuals. Despite the great strides that have been made in medicine, technology, and accessibility, paid employment presents a challenge to people with disabilities. National polls indicate that two-thirds of working-age people with disabilities are not employed, despite their desire to work. An array of factors has been identified to explain this persistent lack of employment. These include federal policy concerning disability benefits and access to health insurance (e.g., people who qualify for social security disability may

be discouraged from considering employment for fear of loss of benefits, including health insurance), employer attitudes and discrimination, inadequate preparation for work, lack of postsecondary education and training, lack of available community employment services, and perceived difficulties in providing vocational guidance to this group.

A number of factors influence the vocational behavior of those whose careers have been interrupted by disability and illness, including external issues or barriers (such as social policy and laws) and internal factors (such as functional capacities and psychosocial issues). The literature suggests that employers tend to rely on stereotypes of disability and hold inaccurate views of the extent to which a functional impairment may interfere with vocational performance. Despite legislation such as the Americans with Disabilities Act (ADA), these attitudes continue to have an effect on individuals' perceptions of their capacities and their emotional reactions to them. The rehabilitation literature has focused on the effect that negative attitudes have had on lowering work-related self-efficacy, future work expectations, and work motivation. The ADA has positively influenced the formation of occupational goals by reducing environmental barriers that may have previously constrained vocational options. Accommodations mandated in the ADA enable individuals with disabilities to perform a much wider array of jobs than was previously possible.

An important internal factor for career counselors to consider is the meaning of work in the lives of people with disabilities. Work may or may not continue to be incorporated into an individual's life planning. Instead, individuals whose careers have been interrupted by disability or illness may choose or need to focus their energies on managing their physical condition, shifting attention away from previous vocational roles and involvement in paid work.

Career counseling for people experiencing career interruptions due to disability or illness might include a strength-based assessment approach that incorporates informal interview and observational techniques. It might also include helping clients assess and improve self-efficacy and outcome expectations. Counselors may be particularly interested in assessing how these beliefs may have compromised their clients' interests, goals, and future expectations. They may focus on anticipating, analyzing, and preparing clients to deal with contextual barriers, as well as building up support systems to help them persist with their career goals.

Change can be difficult for many people. Given that one's career consumes a large amount of one's time and energy, interrupted careers (whether anticipated, desired, or not) can create anxiety. Unwanted and unanticipated interruptions can be extremely disruptive life events. However, such events also can provide opportunities for positive change given that they require people to regroup and consider new, and possibly more fulfilling, possibilities.

CAREER INTERVENTION OUTCOMES

This entry provides a brief overview of the research related to *career intervention outcomes* or effectiveness.

Traditionally, *career interventions* have been defined as any treatment or effort intended to enhance an individual's career development or to enable the person to make better career-related decisions. This is a broad definition that encompasses a wide range of interventions, including career counseling and other modalities, such as workshops, career classes, computer applications, and self-administered inventories. In the field of vocational psychology, career counseling is often viewed as a subset of career interventions. This entry discusses the outcomes of career interventions in general, identifies which types of career interventions appear to be more efficacious, and addresses research related to which factors or variables (e.g., number of sessions, content of sessions) have been found to be most helpful to individuals needing career assistance.

EFFECTIVENESS OF CAREER INTERVENTIONS

In examining the effectiveness of any intervention, researchers often compare those who have received the intervention to those who have not received it. Concerning the effectiveness of career interventions compared to no treatment, three meta-analyses have been published, and they indicate that career interventions tend to be moderately to very effective. In considering the results of these three meta-analytic reviews, it appears that the overall effect sizes for career interventions tend to fall in the range of .30 to .60. Although complicated weighting procedures are typically used in meta-analysis, an effect size is essentially the average difference between those who received the treatment and those who did not. Thus, an effect size of .30 means those who received a career intervention were about a third of a standard deviation above the control group, while an effect size of .60 reflects that the treatment group was closer to two-thirds of a standard deviation above the control group. Effect sizes in this range are often considered to indicate that the interventions are "moderately" effective. However, even the most conservative effect size of .30 shows that the average career client exceeds 62 percent of the control group. Furthermore, the benefits from career counseling appear to continue for clients. In following up with clients 1 to 12 months after receiving career counseling, Charles Healy found that 85 percent of the clients reported continued progress (e.g., pursuing degrees, gathering information, and changing occupations). Although career

interventions appear to be moderately effective, it should be noted that different career interventions have been found to vary significantly in their effectiveness.

WHICH CAREER INTERVENTIONS ARE MOST HELPFUL?

Susan Whiston combined the average effect sizes from two previous meta-analyses and found that career classes and individual career counseling were the most effective interventions. In fact, both individual career counseling and career classes have very large effect sizes. A second group of interventions had effect sizes in the moderate range, and these interventions were group career counseling, group test interpretation, workshop or structured groups, and computer-assisted interventions. In another study, Whiston and her colleagues directly compared different career interventions and found that participants who used a career computer system supplemented by counseling had better outcomes than those who just used a computer system. In addition, they found that counselor-free interventions (e.g., reading occupational information or completing a self-directed activity) were consistently less effective than other types of treatment modalities, such as individual career counseling, workshops, or career groups. Their results indicate that counselors play a critical role in assisting individuals with their career development and decision making. Therefore, it is important, particularly given the substantial increases in Web-based career assessments and materials, that appropriate counseling interventions provided to individuals be and people are not encouraged to simply go and get some career information off the Web. Research findings clearly indicate that counselor-free interventions are the least effective approach in providing career interventions and that more systematic assistance provides better outcomes for most individuals needing help with their careers.

MEASUREMENT OF CAREER INTERVENTION OUTCOMES

To interpret the research on the outcome of career interventions, one needs to understand the outcome measures, or indicators, of effectiveness. An intervention could produce a large effect size, but the results may be meaningless if a poor outcome measure is

used. Some researchers have recommended using both career (e.g., certainty/decidedness, career maturity) and noncareer (e.g., self-concept, locus of control, anxiety) outcomes, because career counseling probably affects multiple areas of functioning. In career intervention outcome research, the most common measures used are career maturity, career decidedness, and career information seeking. Measures of career maturity typically involve comparing adolescents or young adults with others in the same age group in terms of their career development and determining whether their knowledge and attitudes about career issues are higher or lower than that of their peers. Although career-related measures are often used to evaluate outcome, research has found that career counseling also has a positive effect on noncareer outcome, such as self-concept, anxiety, and depression. Hence, career interventions often have an effect on both career and personal measures of outcome.

COMMON FACTORS IN EFFECTIVE INTERVENTIONS

Across different types of career interventions, Steven Brown and Nancy Ryan Krane found there are five critical ingredients that positively influence outcome regardless of modality or format. These five critical ingredients are written exercises, individualized interpretations, occupational information, modeling, and attention to building support. Moreover, they found not only that these five critical ingredients were important independently but also that combinations of them yielded larger effect sizes than any one ingredient individually. Although no study in their analyses employed all five critical ingredients, adding one, two, or three critical ingredients yielded increasingly larger effect sizes. In a further analysis of this data, Brown and his colleagues found some preliminary findings that the written exercises are more effective if they include (a) opportunities for occupational comparison and future planning and (b) opportunities to articulate future goals and activities related to achieving those goals. They further found evidence that the individualized interpretation and feedback should be targeted toward assisting clients in planning for the future and setting goals. In addition, their research indicates that occupational information should be explored in session and not relegated to homework activities. Related to the fourth critical ingredient, modeling, they found some initial evidence that modeling and self-disclosures by the counselor or facilitator can be potent, thus indicating

that modeling can occur in individual career counseling. The final ingredient has received the least attention, but there are some indications that when career counselors devote attention to helping clients build support for their career choices and plans, the counseling is rated as being more effective by clients. This support may be particularly important when clients are coping with existing or perceived barriers.

The role of career assessments in providing effective career interventions is somewhat difficult to precisely determine. Howard Tinsley and Serena Chu concluded that there was no credible body of evidence to document that test or interest inventory interpretation by a trained clinician is helpful in career counseling. This finding, however, is contradicted by Brown and Krane's conclusion that when the outcome concerns career choice, one of the critical components of career counseling is individualized interpretation and feedback. Although there are no definitive findings related to traditional test interpretation, the world of career assessment is changing, and evolving technologies are having a substantial impact on how career assessments are delivered and interpreted. The influences of developing technologies on career assessment are significant, and we suggest the continued exploration of the effectiveness of both traditional career assessments as well as the use of new technologies related to career assessment.

Other factors that some researchers have found to positively influence the outcome of career intervention are longer and more comprehensive interventions. Brown and Krane found that outcomes improved exponentially as the number of sessions increased from one to four or five sessions. The effectiveness, however, seemed to decrease dramatically after around five sessions, which led them to recommend that career interventions are most effective when they include the five critical ingredients and last around four or five sessions.

WHO BENEFITS FROM CAREER COUNSELING OR INTERVENTIONS?

Sometimes practitioners wonder when or which clients or individuals benefit the most from career interventions. Career interventions have been found to be effective with clients of all ages, with the possible exception of elementary students; however, very little research has been conducted related to career interventions with elementary students. Most of the

research related to career interventions has been with college students, and researchers have found that college students generally tend to see value in career counseling and do not believe there is a significant stigma attached with seeking career assistance. Interestingly, some research indicates that men seem more likely to report a higher stigma attached to career counseling than do women, while other research suggests no gender differences in terms of the usage of career counseling services. Little research, however, has been conducted that has compared different interventions with males and females or explored whether the approach to career counseling should vary based on the gender of the client.

Although much has been written about the unique career development needs of racial and ethnic minorities, there has been very little exploration of the effects of varying career interventions with these different groups. A recent study found that African American and Asian American/Pacific Islander students were more likely than Caucasian students to use career counseling services in their colleges. Hispanic students, however, were the group least likely to seek career counseling compared with other ethnic groups. Some models have been developed to provide career counseling specifically for clients from diverse ethnic and racial backgrounds. One of the more eminent models is that of Nadya Fouad and Rosie Bingham, in which they have proposed a seven-step process. The steps of their culturally sensitive career counseling model include establishing rapport, identifying career issues, assessing cultural variables, establishing culturally sensitive processes and goals, designing culturally appropriate interventions, making appropriate decisions, and implementing the career plan with follow-up. This model appears to hold promise, but it has yet to be investigated empirically, and more research is needed in this area.

CONCLUSION

In general, career interventions tend to have positive outcomes, and most individuals report positive results after receiving some sort of career assistance. Career classes and individual career counseling appear to be the most effective modes of assisting individuals, particularly in terms of facilitating their career development and helping them make career decisions. Other intervention strategies that tend to be more moderately effective include group career

counseling, group test interpretation, workshop or structured groups, and computer-assisted interventions. There is also research indicating that longer career interventions that involve five critical ingredients (i.e., written exercises, individualized interpretations, occupational information, modeling, and attention to building support) tend to be more effective than shorter and less comprehensive approaches. Furthermore, there is substantial empirical support indicating the importance of interventions that involve counseling and the tendency for counselor-free interventions to be ineffective. For example, individuals report better outcomes when counseling is added to the use of computerized career information systems compared with just using the computer systems in isolation. More research is needed to clarify which interventions work best with which clients or individuals. In particular, more research needs to be conducted related to whether different interventions are more or less effective with males and females, as well as with individuals from different racial or ethnic groups. In conclusion, although career interventions tend to produce a positive outcome, additional research is needed to assist practitioners in providing the most effective career interventions to individuals.

CAREER INVESTMENTS

Career progress of various groups is one of the central concerns in organizations, occupations, and work. People choose careers for different reasons. Chief among them are occupational prestige, rewards, and prospects for advancement. People are constantly making conscious decisions on career progress in light of their own interests and circumstances. At the same time, multiple factors shape a person's career aspirations and career trajectory.

The factors and circumstances leading to the career success of men may be different from those for women. Due to differences in historical experience, the educational and career opportunities that are available to men and women are invariably different. For example, in the United States, Title IX of the Education Amendments of 1972 prohibits sex discrimination in federally assisted education programs. This legislation has had the single most dramatic impact on the presence of women in the sciences.

The gender role socialization thesis has been used to account for gender differences in career orientations. Because of their traditional upbringing, men and women are inclined to choose different careers. For instance, school counselors may encourage male students to pursue science careers but advise equally talented female students to choose careers in nursing or teaching. Because of competing commitments to family and work, educated women may avoid positions with rigid career lines and prefer less demanding jobs. Compared with male workers, women are more likely to interrupt their careers owing to marriage and family responsibilities. This is probably why women are disproportionately found in part-time or temporary positions.

Employers' stereotypical views of members of different groups (statistical discrimination, "profiling"), although reducing "information costs" may bias their

hiring and promotion decisions. Employers may hold the (appropriate or inappropriate) belief that personal attributes such as race or gender are related to a person's performance or productivity. These subjective judgments would have an impact on the employers' hiring preferences. For example, because of family obligations, women are more likely than men to interrupt their careers and are therefore perceived as less dependable workers. To reduce training costs and worker turnover, employers would probably favor men over women, all else being equal. All this suggests that women are less likely than men to receive on-the-job training that is firm specific or to be put on the "fast track."

Gender is also embedded in executive succession; not only does top management affect the selection of successors in an organization, but workers can also play an important role in leadership change. Employees of a company could potentially mobilize themselves to support or challenge an incumbent or an outsider for the executive position. Research has also suggested a conflict of gender and professional roles even for female bosses. For instance, the founder's maternity leave could lead to workers' collective effort to increase the firm's independence and weaken the female founder's role.

According to human capital models, productivity-enhancing factors are the key determinants in career attainment. Theoretically, there should be a positive correlation between human capital endowment and a person's productivity. Based on "The more you learn, the more you earn" argument, those with higher investments in human capital, through education and training, are expected to fare economically and occupationally better than individuals with less human capital endowment. Research has shown that the effects of education, work experience, and professional training on career attainment may be weaker for female, minority, and immigrant workers. This is because they tend to have insufficient social capital.

Successful people tend to have the ability to build important, long-lasting relationships. They take bold and strategic actions to become part of the "old-boy" network. It is widely held that "who you know" (social capital) is generally more important than "what you know" (human capital) in career moves. The role of social networking on building one's career cannot be overstated. Due to their marginal status in mainstream society, women, racial minorities, and foreign nationals have a more difficult time than do

men, Whites, and natives in developing and expanding their network ties. Organizational memberships and cross-gender/racial networks can become critical when many job openings are filled by word-of-mouth.

The societal norm of homosociality tells us why women have difficulties in gaining entry into the old-boy network, a form of “social capital” that is essential for career advancement. Aside from similarity in background, men as well as women have more to gain professionally by associating more with men than with women, all things being equal. Due to their master status in the society, men generally have a greater control over a wide range of resources. By comparison, due to women’s subordinate role in the society and limited access to resources, they are in a weaker position to offer professional assistance or support to others. Men who associate with women as equals run the risk of being marginalized. As the gatekeepers of resources for career mobility, men become the preferred choice of social interaction and professional collaboration. In contrast, female networks are less useful. For one, women generally control fewer and less important resources in the society. This can be attributed to their not being part of a much larger pattern of a male, homosocial world. Women’s lack of resources and crucial information makes the “new-girl network” a less valuable asset relative to the old-boy network. In addition, it has been suggested that women tend to have a hard time building up their reputations in the workplace because male-initiated actions tend to be taken more seriously than those initiated by women. The same can be said about the relative status of racial minorities in the workplace. To make up for a deficit of social capital, members of minority groups may need to work harder to demonstrate their worth and to gain acceptance from their peers.

Researchers have also underscored the importance of language use and proficiency for minorities and immigrants in social networking. For both native- and foreign-born minority workers, the language network is one of the most important dimensions of human resources for career mobility. Members in the dominant culture can not only offer one another career information, support, and employment opportunities in mainstream society but can also shape each other’s attitudes, orientations, and approaches to career advancement. Being in an English-speaking network facilitates the assimilation of minorities into the mainstream and improves their career prospects. Conversely, participating in a predominantly non-English-speaking network suggests dissimulation and

fewer opportunities for advancement in mainstream economy. For racial minorities, jobs obtained through segregated networks tend to have less desirable outcomes in terms of rewards, job security, and prospects for advancement. Most of the jobs in immigrant enclaves (i.e., areas with a high concentration of coethnic employers, workers, and customers) tend to be low paying and low skilled.

Being plugged into different channels is a crucial ingredient of career success for educated workers. Networking and sponsorship confer potential career benefits. For example, having a friend in the hiring firm is a decisive influence on salary negotiation outcomes, regardless of the job applicant’s racial background. An employed friend can provide sensitive information and influence in the hiring firm and in the negotiation process. Referral often results in favorable outcomes for the job seekers and employers in terms of job offers, satisfaction, performance, and turnover compared with those obtained through formal methods. Specifically, the exchange of informal information about the job or offers between job applicants and prospective employers via an intermediary reduces uncertainty and risks for both parties. All this suggests that young people should begin to cultivate communal and professional ties early on. They should attempt to build their reputations and gain access to different channels through relationships with peers, teachers, mentors, sponsors, or colleagues.

For women and racial minorities, finding something in common with the gatekeeper or sponsor, such as values or experiences, would be useful in career mobility. The notion of “homosocial reproduction” has been used to characterize the hiring or promotion of someone who has a background or characteristics similar to those of the employer. It is understandable that individuals are more comfortable having people around them who think and act alike. Despite having formal rules of selection and succession in a corporation, “people who are different” are less likely than “people who are similar” to be potential internal or outside candidates for executive positions. If there is an internal labor market for CEOs in a corporation, women and minorities are less likely to be contenders for the top posts. They are less inclined to be groomed as the heir apparent to gain on-the-job training, knowledge, and experience about the firm. The expression “glass ceiling” has been used to describe the artificial barriers against the mobility of women and minorities beyond a certain point in their careers. Thus, women and minorities generally are

at a disadvantage in selection and succession, all things being equal. The accumulation of social capital would be an important means of circumventing these structural barriers.

To create the perception of similarity with the majority, women and minorities can develop social ties with members of the majority group. In addition to developing ties with coworkers, women and minorities ideally should have prior experience in functioning in a statistical minority role in decision making. Members of the majority who have experience occupying a statistical minority role in decision making can also enhance the influence of minority workers in organizational settings.

To build personal relationships or maintain support in workplaces, people can use “soft” (ingratiation and persuasion) or “hard” (coercion) forms of influence. The use of political or interpersonal influence tactics is contingent on one’s relative status and power in the organizational hierarchy. People can rely on their specialized knowledge or technical expertise to maintain control over decision-making outcomes. On the other hand, they may use friendship ties with peers and superiors to obtain political backing or minimize challenge in decision making.

Careers can be conceived of as a sequence of competition: The winner advances to the next level for further competition, while the loser is denied the opportunity to compete for higher levels. According to this “tournament” model, the outcome of each competition has enormous implications for a person’s chances for mobility in subsequent selections. This system may eliminate some very talented workers from advancing to the top, perhaps especially young female workers who are expected to demonstrate their abilities and achieve their best performance at a time when they are most pressed with family and domestic responsibilities.

Combining career, marriage, and family responsibilities poses a challenge for professional women. It is nonetheless possible for women who are highly committed to family to pursue career success. Such individuals tend to have supportive spouses and enjoy reliable child care assistance from relatives or hired employees. For example, it is not necessary to take the linear career path by giving priority to work in order to achieve success. There is more than one way for young people to get ahead. In fact, the traditional, single-minded focus on career is losing its appeal to a new generation of workers. There is a growing desire

for a balance between personal and professional lives among young male and female workers alike.

Being at the right place is also essential for career advancement. First, career prospects can be affected by structural arrangements in the workplace. Women and racial minorities may perform better and have better opportunities for advancement in bureaucratic settings where guidelines for job assignments, evaluations, and promotions are more formalized. Furthermore, compared with the private sector, the government may be more committed to recruiting, retaining, and promoting members of underrepresented groups. Civil services offer well-educated women and minorities job security and attractive employment opportunities. There is also greater sanction for affirmative action at higher levels of government.

Second, organizational cultures have a strong bearing on career processes and outcomes. The impact of workforce diversity on productivity or performance is context dependent. In academic settings, women in “relational departments” tend to fare better occupationally than their counterparts in “instrumental departments.” Relational departments have a positive influence on one’s career because their culture is characterized by cooperation and collegiality. This kind of atmosphere encourages collegial interaction and communication. In contrast, instrumental departments can have a negative impact on women’s careers because their culture is characterized by competition and hierarchy. This kind of departmental culture discourages intellectual exchanges and fosters professional isolation among female faculty. Therefore, instrumental academic departments can be detrimental to women’s career development. Similar situations are observed in other settings. Demographically different people are more affected by organizational culture than are demographically similar people. Collectivistic organizations promote creativity and productivity among diverse workers. Despite their demographic differences, workers in these settings share common organizational interests. In contrast, organizations that emphasize individualism and distinctiveness minimize interaction and collaboration among diverse workers.

Third, restructuring and downsizing have recalibrated the relationship of workers with their employers and the job markets. Recent trends of external outsourcing and proliferation of contingent work have profound implications for the prospects of workers at entry-level positions and upper-level management.

Uncertainties in the markets have compelled employers to reduce fixed costs (e.g., job- or firm-specific training, wages) and to increase flexibility of the workforce (e.g., contingency work, subcontracting). Lifetime job security, attrition based on seniority, and job ladders are a thing of the past. Workers who are able to cross organizational boundaries, to handle complex and interdependent projects, and to operate in team-based environments would be assets to any organization. On the other hand, workers have become less attached to and less identified with their organizations, and employers are less inclined to make investments on upgrading the skills of the workforce. Internal development of employees is less common when more advanced and different skills can be acquired easily from external markets. As a result, it is not uncommon for individuals to self-manage their careers as subcontractors or entrepreneurs.

In sum, to cope with market and technological changes, one is expected to be self-motivated, independent, and innovative. Upwardly mobile people augment their skills and knowledge through self-education and training. For free agents, building up “reputational” capital (i.e., résumé enhancement) is of paramount importance in an increasingly competitive labor market. Even for entry-level clerical jobs, there is a rising demand for basic “hard” and “soft” skills. Many of these jobs are customer oriented and require competent use of computers as well as good communication and social skills. Thus, regardless of the types of jobs, applicants or incumbents need to continuously enhance their credentials, such as education, training, work experience, and references.

CAREER MATURITY

Initially called “vocational maturity,” the construct now known as *career maturity* (CM) was proposed by Donald Super 50 years ago. In the context of developmental theories current at the time, Super saw careers as unfolding in a series of developmental stages, with each stage characterized by certain tasks. The developmental task of relating knowledge of oneself to knowledge of occupations was referred to as “specifying a choice.” Within Super’s framework, individuals are career mature or ready to make appropriate choices when they have engaged in planful exploration and have appropriate occupational knowledge, self-knowledge, and decision-making knowledge.

In specifying the sets of tasks, Super also thought about how progress in these tasks might be measured so that individuals could be compared both ipsatively and with others at the same developmental stage and therefore theoretically undertaking the same tasks. Almost all instrument development and much of the research related to the CM construct has addressed the latter kind of comparison. A number of measures of CM, most often closely aligned with Super’s theories, have been developed for use with adolescents and adults.

One of the largest areas of research into CM has been in relation to the constructs with which it is related. Research into the CM construct and its correlates is now well into its fifth decade. Correlates that have received recurring attention include age, level of education, gender, socioeconomic status, and a wide spectrum of career-related variables, such as vocational identity, career decision, career indecision, and

work role salience. Findings of large bodies of international research in relation to age and gender have produced equivocal findings, although in general, career maturity scores in adolescents increase with age, and overall, the development of CM seems to differ for females and males. While socioeconomic status has been theorized as likely to be an important determinant of career behavior, even if acting largely through moderator variables, most studies have found only a minor or no correlation between CM and socioeconomic status in school-age adolescents and in university students. Several studies have reported that students who were more mature were also more career decided. Similarly, studies have reported that career indecision was the single most important predictor variable of career-immature young people.

A number of studies have investigated whether the amount of part-time work in high school is able to predict CM. Findings have been mixed, with some studies demonstrating no relationship between individuals who did a large amount of part-time work and levels of CM and other studies reporting higher mean scores on CM for students with work experience than for students without. It has been suggested that young people will benefit from part-time employment only when the job area is congruent with their career aspirations.

While research has been conducted on the relevance of CM in ethnic groups within the United States, very little work has been conducted outside the United States to explore its relevance across cultures. Although studies have been conducted in Nigeria, Israel, Lebanon, India, Canada, and Australia, there have been few studies of comparison across cultures. However, a considerable body of work from South Africa has consistently shown that Black high school and university students are less career mature than their White counterparts. Researchers have suggested that measures of CM may be oriented to Western White values and need to focus more broadly on life role salience.

Super envisioned that the relative importance assigned by individuals to roles at different stages of their lives would govern their commitment to and involvement in tasks associated with the roles, as well as the rewards they expected to experience in the roles. Very few studies have examined the relationship between the salience of student or worker roles to aspects of CM. Only a few studies of relationships between these constructs have been reported, with those studies reporting the relationships expected

between student and work role salience and aspects of CM.

RECENT CONCEPTUALIZATIONS OF CAREER MATURITY

With the acknowledgment of the notion that careers evolve in a social context, the 1980s saw a concentrated move to extend theory to situate careers in social contexts and define their relationships with historical eras, geographical locations, race, and culture. A number of authors emphasized the importance of social ecology in careers and stressed the reciprocity of individual and societal development, meaning that the social context is important in the individual's development and the individual is important in the development of social contexts. In addition, the individual and the context may change. The timing of the interaction between the organism and the environment, not sufficiently captured in the portrayal of CM as based on time- and age-based stage models, is an important underpinning of a number of recent theoretical formulations. Research has also demonstrated that CM is influenced by differences in social and political systems.

Constructivists have encouraged career theorists to assist individuals in consciously working to construct their own development. Specifying a career choice involves more than just the cognitive activity of aligning self- and occupational information. This activity takes place within a larger story that engages the sociocultural context of the individual. The individual's career story is the collection of images of the way the individual sees himself or herself in the world. Whereas the informational aspects of the self (e.g., interest, abilities) and of the world of work constitute the content of the story, the individual's constructions of these and the positioning of them within the story—the individual's narrative about self—provide its uniqueness for each individual. And it is the individual's understanding of his or her role in the construction of the story that is a signal point for the traditional construct of CM.

As shown in this review, the construct of CM has received considerable theoretical, conceptual, and research attention, including suggestions for ways in which it can be enhanced to make it more appropriate in times of changing career patterns and more applicable to a wider range of societal groups. The importance of taking contextual factors into account was part of

Super's original formulation of the construct, as was the idea of adjustment as a component of mature behavior. In his later writings, Super himself proposed a change in terminology from "career maturity" to "career adaptability" to better convey the range of career-related attitudes, knowledge, and skills at the various stages and transition points in career development.

The amount of research that continues to be reported on CM, almost 50 years since the construct was first proposed, is indicative of its importance in our understanding of career behavior. The construct has matured to a point where it may change in name or form to better reflect the changing world of work in the twenty-first century. However, it is likely that Super's principles will remain central to any reformulation.

CAREER MOBILITY

Career mobility represents individuals' patterns of transitions between organizations and within organizations in the course of their work lives. It is a very broad term that essentially incorporates all possible movements in one's career. As organizational layoffs

and restructuring are becoming common, it is not surprising that employees, who realize that lifelong job security may no longer be a realistic employment goal, are ready to become more mobile. In fact, moving across jobs and even occupations is now the rule rather than the exception. Unlike in the past, today people increasingly have multiple career transitions and changes, such as internal transfers, job rotations, overseas assignments, switching from full-time to part-time, and changing employers and occupations. These frequent career transitions and changes in recent years are attributed to an increasing emphasis on learning, skill enhancement, meaningful work, personal control, job satisfaction, and career satisfaction.

The interest in obtaining a variety of work experiences across jobs and occupations (careers)—and therefore individuals' constant movement across these boundaries—is causing careers to become increasingly "boundaryless." In the era of boundaryless careers, people's work experiences are not limited to only one or two firms. Instead, their careers span across multiple firms and employment settings. As such, portable skills are important assets. When equipped with portable skills, employees more easily move from one employer to another and from one occupation to another. Multiple career transitions also further facilitate the building of repertoires of skill sets that can benefit individuals' careers in the long run.

Types of career mobility can be differentiated on the basis of at least two dimensions. The first mobility dimension is *vertical-horizontal*. A vertical movement involves changing to a job with a significantly higher or lower level of responsibility. The second mobility dimension is *internal-external*. An internal movement is narrowly defined as changing to a job that is offered by the same employer. An external movement involves changing to a job that is offered by a different employer. Crossing these two dimensions gives rise to four generic types of career mobility, which will be discussed in turn below: internal-vertical, internal-horizontal, external-horizontal, and external-vertical. One's career often contains multiple instances of these transitions.

Internal-vertical career movement involves changing to a job internally with increased or decreased responsibility. Taking a promotion offer from the current employer is a common example. Specifically, being promoted is traditionally the most desired type of career mobility, because it can enhance status, responsibilities, satisfaction, and esteem. Also, promotions often improve one's financial rewards on the

job, which are generally valued. It has been suggested that two theoretical perspectives on upward mobility are particularly relevant to understanding what predicts employees' promotions: a contest-mobility norm and a sponsored-mobility norm.

The *contest-mobility norm* perspective suggests that all individuals have the same likelihood of winning the competition for mobility on the basis of their individual merits. The goal of this system is to give elite status to those who earn it. People compete with each other in an open and fair contest for the advancement, and victory comes along to those who demonstrate accomplishments. For instance, those who have better human capital investments, such as higher levels of education, are more likely to obtain internal promotions. Work experience also increases one's likelihood of obtaining promotions, because work experience is often valued and thus rewarded in the labor market. Skills acquired in training and development programs also equip employees with more competencies and skills for competing for promotions.

In contrast, the *sponsored-mobility norm* perspective suggests that established elites pay special attention to members who are deemed to have high potential and then provide sponsoring activities to them to help them win the competition. Thus, those who have early successes are more likely to receive sponsorship, and those who do not are likely to be excluded from such support activities. For instance, one's broader social network at work should result in greater career sponsorship from senior colleagues, including supervisors and mentors, which can, in turn, increase the chances for promotions. Also, those who are able to manage their impressions better or have stronger social influence skills should also have more promotions because these skills increase interpersonal liking. Thus, this theoretical perspective implies that social factors play an important role in determining who gets ahead. The contest- and sponsored-mobility norm perspectives together suggest that employees' competencies and hard work and employers' support and sponsorship collectively result in upward mobility.

Demotion is another type of internal-vertical career movement. Because layoffs are common in recent years, some employees may accept demotions in return for not being laid off. However, as one would expect, it is a common research finding that demotions lead to unfavorable job attitudes, such as lower fairness perceptions and greater turnover intentions. The exception is when an employee volunteers for the

demotion. One of the motives to do so is to better understand the operations in an organization. Another reason is the desire to equip oneself with different sets of skills. Compared with promotions, the topic of demotions has received less research attention.

Internal-horizontal career movement is changing to a job that entails different tasks or settings without significant change in responsibility, while remaining with the same employer. In response to the intense global competition, organizations in recent decades have frequently downsized or restructured their operations, creating new work tasks or redesigning old ones. This gives rise to abundant opportunities for internal-horizontal transfers, including internal job rotations, relocations to another city or state, and international assignments. This type of career mobility may be increasingly welcomed because, as mentioned, employees may want to work on jobs that allow them to build repertoires of different skills.

More specifically, an internal-horizontal career transition causes disruptions to as well as generates benefits for one's work and career. The possible disruptions associated with such a change may involve losing one's place in line for promotion; losing social ties; disruptions to family, especially if the change involves a geographical move; confusion about one's own goals; and general stress caused by adapting to the new environment. However, such a change can also be beneficial if individuals want to expand their skills sets or networks, obtain new experiences and personal growth, rejuvenate their careers, or forge paths for future promotions or are bored with their current positions. A decision to take the internal-horizontal transition is made when the benefits are believed to outweigh the costs.

One of the most important costs to consider is whether the change involves geographical moves. Horizontal transfers that involve geographical moves are often less welcomed than those that don't. For instance, relocation to another city or state should be less desired than internal job rotation. However, relocation has occurred more frequently in recent years, especially for those who work in large corporations. It has been found in research that those who have less to sacrifice in leaving their current communities (e.g., have fewer social ties) are more willing to accept relocation. However, when the relocation is an overseas transition, more unique factors have to be considered. It is widely acknowledged that expatriates face a variety of obstacles and challenges in their overseas

transitions, such as language barriers, stressful environmental conditions in the assigned county/region (e.g., potentially unstable political situations), learning and sensitivity to cultural differences and local customs, as well as work-related adjustment issues. In terms of research, a number of studies in this area have investigated the adjustment of expatriates. One of the factors that facilitate their adjustment is support from different sources. For instance, it has been found that positive attitudes of and support from spouses facilitate expatriates' transitions. Furthermore, home country organizational support, local country organizational support, and supervisor support are all related to expatriates' work, interactional, and general adjustment. Expatriates' premature departures are said to indicate unsuccessful overseas transitions.

Another increasingly common type of internal-horizontal career movement is changing from full-time to part-time status. The benefits of such a change include freeing up time to take care of families and pursue other interests, decreasing work stress, and making working multiple part-time jobs possible if the individual does not want to work in the same environment all the time. Possible costs include lower income, reduced chances of promotions, loss of some fringe benefits, and feelings of alienation at work.

External-horizontal career movement involves changing to a job with a different employer that entails different work tasks or settings without a significant change in responsibility. That is, it involves individuals leaving their current organizations and looking for similar jobs. It can entail changing employers with or without changing professions. For instance, a nurse may work in different hospitals over the course of his or her career. Another nurse may quit working in a hospital and become an assistant at an elder care center.

Changing employers is said to be highly common in boundaryless careers. A great deal of research has been devoted to identifying predictors of voluntary turnover. One consistent finding is that "morale" factors (e.g., job dissatisfaction) dominate individuals' decisions to change employers. That is, the main reason people change employers is that they are not satisfied with their current jobs or/and organizations. However, in recent research, a number of non-morale-related factors have been identified as being relevant to predicting voluntary turnover. For instance, those who perceive a lack of sufficient opportunity for skill enhancement will express higher intention to change

employers. This is not surprising given that, as mentioned, individuals increasingly emphasize knowledge acquisition and personal learning. Furthermore, employees want creativity at work and in their careers, too. It has been found that employees are more likely to leave when they perceive that their jobs or work environments do not allow or promote creativity. Thus, employees increasingly switch employers for reasons other than general like or dislike of their jobs or organizations.

Changing occupations is a huge decision, though it is becoming common. The individuals have to "start from scratch" and learn a new set of skills for the new occupation. This creates psychological distress and financial burdens for the individuals as well their families. Furthermore, there may be limited choices of occupations. Thus, as in the case of changing employers, research in this area continues to identify predictors of occupational turnover. For instance, it has been found that males, younger individuals, or those who are less satisfied with their jobs have greater intentions to leave their occupations. Furthermore, occupational context variables, such as professional role orientation and occupational commitment, negatively predict occupational turnover intention. Changing occupations can also be precipitated by social factors. When one's network is more diverse (i.e., knowing more people of different backgrounds), one is more likely to change occupations as a result of more career information and opportunities. Also, when one has more instrumental relationships (from which one obtains career-related advice), one is more likely to change occupations.

Finally, *external-vertical* career movement involves changing to a job with a significant change in responsibility and working for a different employer (i.e., a diagonal movement). For instance, an associate professor with an outstanding publication record may be invited by another university to become a full professor. An outstanding football player may self-recommend himself to another team and become the new leader of that team. Some people quit their jobs and become the owners of new firms. Finally, some people may be laid off and settle for jobs that are of lower importance in different organizations (i.e., external demotions). This type of career mobility is perhaps the least desired. Not surprisingly, this group of individuals has more negative job attitudes after transitions, because they constantly compare their current jobs with their previous ones.

A growing number of employees who are laid off choose to start businesses of their own. It has been found

that certain personality traits, such as being emotionally stable, distrusting, expedient (less conscientious), and tough-minded, predict new business start-ups. Entrepreneurial orientation also predicts this type of career transition. Those with a strong entrepreneurial orientation emphasize creating something that is new and valuable. Overall, this type of external-vertical career mobility (business start-ups) is still relatively infrequent, and therefore research on it is still limited.

Bridge employment is another type of external-vertical career movement. It involves a person's employment after retirement from full-time work but before his or her entire withdrawal from the labor force. It usually involves significantly less workload, such as part-time or temporary work. Researchers have found that employees report greater likelihood of engaging in bridge employment if they are healthy, younger, have high organizational tenure, earn lower monthly salary at the time of retirement, have declined previous early-retirement opportunities, and have working spouses or dependent children.

To conclude, career mobility involves intra- and interorganizational transitions. Internal-vertical, internal-horizontal, external-horizontal, and external-vertical career movements have been increasingly common in recent years. Researchers in this area often focus on one specific type of career mobility. However, we also need to make sense of the patterns of career transitions individuals create. For instance, why do some people prefer internal-horizontal transitions over internal-vertical ones? Also, what is the relationship between changing employers and changing occupations? This search for traceable patterns of career mobility is especially important and interesting in the era of boundaryless careers. Though careers are increasingly boundaryless, people still act according to some dispositional sources of influence, such as values, interests, and personality. As such, it is likely that we will be able to predict why certain individuals create certain patterns of changes in their careers.

CAREER MOTIVATION

Career motivation is the desire to exert effort to enhance career goals. It is a multidimensional construct that combines elements of needs, interests, and personality characteristics that reflect the stimulus, direction, and persistence of career-related behaviors. Career motivation is organized into three domains. *Career insight* is the stimulus or energizing component. This is people's ability to be realistic about themselves and their careers. People who are high in career insight have an accurate understanding of their strengths and weaknesses and set clear career goals. *Career identity* is the direction component. This is the extent to which people define themselves by their careers. People who are high in career identity are highly involved in their jobs, their organizations, and/or their professions. They strive for advancement, recognition, and a leadership role. *Career resilience* is the persistence component. This is the ability to adapt to changing conditions and overcome career barriers. People who are high in career resilience believe in themselves, need to achieve, and are willing to take reasonable risks to do so.

Resilience, insight, and identity have their foundation in trait factor career theories. Resilience is conceptually related to the need for reassurance, the ability to

face barriers, hardiness, self-efficacy, agency (being assertive, instrumental, and interpersonally facile), mastery motivation, and achievement motivation. Career insight is conceptually similar to self-concept, feedback orientation, and openness. Career identity is conceptually linked to job commitment, organizational commitment, and organizational citizenship.

The model proposes that resilience results from reinforcement contingencies during childhood, adolescence, and early adulthood. As a result, resilience is less likely to change, but it can be supported by positive reinforcement and chances to learn and achieve. Career insight and identity are the result of information processing and can be more easily affected by feedback and changes in situational conditions. Career insight is affected by support for goal setting, including information about alternative career paths, advice in establishing career goals, organizational flexibility, opportunities for change, and clarity of organizational processes, such as appraisal and promotion decisions. Career identity is influenced by encouragement of professionalism, reinforcement for organizational commitment (e.g., pay bonuses and pensions), leadership opportunities, and programs that recognize and reward excellent performance.

Prospective and retrospective rationality explain how situational conditions influence the career motivation domains and career-related behaviors. *Prospective rationality* suggests that situational conditions affect career resilience, insight, and identity, which, in turn, influence career behaviors. *Retrospective rationality* argues that behaviors influence feelings of career motivation and perceptions of current conditions. So people who are resilient and high in career identity and who take action to support their career goals (for instance, participate in employee development activities) are likely to perceive favorable situational conditions.

The three career motivation domains form different patterns of career development. Career resilience sets the stage for meaningful career insight (e.g., receptiveness to feedback), which, in turn, influences establishing an achievable career identity. People who are resilient at the start of their careers are likely to use information about themselves and the environment to develop accurate career insight and realistic career identity. They will be able to overcome career barriers and, if necessary, redirect their careers. Failure or severe negative feedback may undermine resilience. Career coaches may help people put these negative experiences in perspective, gain insight into themselves

and the situation, and discover alternative directions for career satisfaction and success. People who lack confidence from the start and fail are not likely to break away from an ineffective pattern of career motivation (low resilience, insight, and identity). They are likely to have low or unrealistic career goals and are good candidates for career or psychological counseling.

Career motivation has been measured by developmental assessment centers and questionnaires. A developmental assessment center includes a personal history form, a detailed background interview, personality instruments, interest inventories, exercises on life and career decisions (e.g., reactions to hypothetical job choices), and a career projectives test that asks for reactions to ambiguous pictures of career-related topics. Assessors record and evaluate participants' scores, reactions, and behaviors and rate them on the career motivation domains. The results are fed back to participants as input for career-planning discussions.

Career motivation survey items have also been developed to measure behaviors and attitudes that reflect the three domains. For example, a measure of career insight includes these items: "I have a specific plan for achieving my career goal," and "I have realistic career goals." A measure of career identity includes this item: "I am very involved in my job," and "I spend free time on activities that will help my job." A measure of career resilience includes this item: "I believe other people when they tell me that I have done a good job," and "I am able to adapt to changing circumstances." Research has found convergent validity for different measures of career motivation.

Research has been conducted on the antecedents and consequences of career motivation. Career mentoring has a positive influence on performance by first affecting career motivation; that is, career motivation mediates the relationship between mentoring and performance. Individuals who are higher in career motivation benefit more from training than those who are low in career motivation. Older workers show as much career motivation as younger workers. People who believe that mentoring and new skill development are appropriate for older people have higher career motivation. Part-time workers are higher in career resilience than are full-time workers, perhaps because part-time workers have to adapt to changing work schedules and responsibilities. Career resilience is related to career persistence, and career insight is negatively related to turnover intentions. Overall, situational conditions can strengthen or lessen career motivation components, as the model predicts.

The model has been used to generate guidelines to support career development. Career resilience is reinforced through opportunities for achievement, rewards for innovation, interpersonal concern, and positive reinforcement for excellent work. Career insight is supported by providing career information and performance feedback and encouraging goal setting. Career identity is supported by providing job challenge, chances for professional growth, and opportunities for leadership and advancement.

CAREER-PLANNING WORKSHOPS

American citizens enjoy a relatively large number of educational and career options from which to choose. Thus, planning for career entry or change can require individuals to engage in a number of relatively complex and interconnected career-related tasks and activities. Many individuals elect to facilitate their progress in career planning by participating in *career-planning workshops*, group-based, psychoeducational services offered by most agencies that provide career-related assistance.

Career-planning workshops typically involve a limited time commitment on the part of participants. Most workshops range in duration from just a few hours to a day or two of structured meetings and activities. From a practitioner perspective, career-planning workshops can be one of the most efficient and cost-effective ways to help adults address their career concerns. They generally have the overarching goals of (a) assisting individuals in taking more personal responsibility for their career paths and (b) helping individuals become more intentional in their career behavior so that (c) participants are more likely to identify, implement, and, ultimately, achieve career goals.

The first few hours of career-planning workshops typically focus on helping participants identify and explore a range of career and educational opportunities. Because career development theories are predicated of the idea that a good fit between an individual and his or her career will result in positive outcomes, a notion termed *career congruence*, many, if not most, career-planning workshops include at least one assessment-related activity. These activities help individuals discover congruent career or educational possibilities or confirm the congruence of options already under consideration. Such assessment-related activities probably will include the administration and interpretation of a paper-and-pencil or computer-based career interest inventory; however, some workshops may include less formal career assessment activities, such as career card sorts, career time lines, or narrative methods. Many practitioners believe it is important to augment career interest information with measures of participants' values, personality styles, and abilities. The workshops that these practitioners deliver may be more psychologically oriented and spend relatively more time helping individuals come to know themselves. The availability of self-scoring versions of paper-and-pencil questionnaires such as the Strong Interest Inventory, the Self-directed Search, and the NEO-Five Factor Inventory make it possible for workshop participants to complete, score, and have the results of their inventories interpreted during the course of the workshop. However, because completing these assessments is time-intensive, practitioners may consider providing assessment materials to participants in advance of the workshop, so that face-to-face time can be focused on interpreting participants' results.

Only after participants have achieved a clear understanding of themselves and their situations and have identified a few congruent career or educational

choices do workshop activities typically move to a focus on helping individuals implement their choices. At about this point in a workshop, some participants may come to understand that either personal or environmental factors complicate their identification of viable career alternatives. For example, personal factors, such as being indecisive with regard to important life decisions or having trouble making a commitment to a plan of action, can complicate career planning. Similarly, environmental barriers, such as child care or elder care issues or economic difficulties, can also present challenges. In such cases, referrals for individual career counseling or other supports can often be helpful.

Career implementation pertains to the steps that are necessary to realizing a career-related choice. Depending on participant characteristics such as age, employability, and previous work history, career implementation activities may involve teaching individuals to thoroughly investigate the local job market or to explore educational opportunities such as apprenticeship programs, trade or technical schools, community colleges, or colleges and universities that offer formal educational degrees. Career workshops often teach participants skills such as how to search for jobs and how to write job applications, cover letters, and résumés. Many participants can also benefit with behavioral rehearsals (i.e., role plays) focused on how to communicate with potential employers, including how to conduct a successful job interview. Workshops offered for educationally bound participants may focus, in parallel fashion, on how to select an appropriate college or other educational program and, again, help participants enhance their interaction during the admission process. Such skills are especially important for individuals who have not historically had access to educational experiences.

Because personal characteristics can affect career choice and adjustment, it may be important for practitioners to consider the target audience for any given workshop. Although some degree of heterogeneity among workshop participants can be useful, from a clinical perspective it may be difficult to meet the needs of a group whose lives are vastly different. For this reason, practitioners sometimes find it useful to offer workshops for individuals who have similar needs. Examples include workshops for undecided college students, students of nontraditional age who are returning to school or work, individuals returning to work after beginning a family, individuals returning

to work after an accident or illness, midlife career changers, and individuals transitioning to the workforce after incarceration. Career-planning workshops are often a mainstay of agencies offering career-related service because the group-based, structured nature of these interventions makes them extremely adaptable. However, practitioners will need to anticipate, as much as possible, the needs of their clientele and target workshop tasks and activities accordingly.

Finally, in terms of the efficacy of career-planning workshops, meta-analytic investigations suggest that this treatment modality is, indeed, an effective way of helping individuals. Perhaps more important, meta-analytic findings suggest that five components of career intervention appear to contribute significantly to their effectiveness. These include written or reflective career-related exercises, offering clients individualized interpretations and feedback of career-related assessment, providing access to up-to-date work-related information, offering clients opportunities to model from successful individuals, and helping clients build or access social support for their career choices. Practitioners may wish to ensure that these components are in place as they design their career-planning workshops.

CAREER PLATEAU

Since Thomas Ference, James Stoner, and Kirby Warren's seminal work first defined the *career plateau*, researchers have continued to investigate this

antithetical phenomenon. This is due to the fact that many employees consider promotions and upward hierarchical movement as synonymous indicators of success at work. The career plateau phenomenon involves situations within which an employee perceives a low likelihood of increased responsibility.

There are two types of career plateaus: structural and content. In *structural plateauing*, the individual becomes unable to rise further in the flattened organization's pyramid structure and reaches a point where the likelihood of additional hierarchical promotion is very low. Structurally plateaued employees who equate career success with hierarchical movement may become distressed upon acknowledging their plateaus with their current employers. These employees may take action to remove themselves from the situation, withdraw from organizational involvement, and lower their productivity. All of these scenarios provide a rationale for explaining why career plateauing often has a negative connotation.

Judith Bardwick suggested that employees also plateau when their likelihood of increased growth or challenges associated with the current job is low. When increasing job-specific task responsibility that offers developmental opportunities becomes unattainable, an employee is said to experience a *content plateau*. Content-plateaued employees may already be proficient in their jobs, expect no further challenges to be associated with the job, and feel stifled regarding the job's content. Content-plateaued employees are no longer intrigued by their work and often feel they have reached a dead end. Many researchers have empirically confirmed the existence of both of these plateau types.

Over the years, career plateauing has been subject to a variety of conceptual interpretations and empirical measurements. Career plateauing has been objectively measured and defined as either age or long job tenure when comparing the plateaued employee with the average workforce member. Objective measures fail researchers in two respects. First, chronological age and length of tenure will vary from industry to industry, and these measures fail to capture the notion of a stalled career. When is one stalled? How can age or tenure be a proxy when individuals often move from company to company or through myriad industries and restart careers at a senior age? Second, objective measures fail to capture one's personal perception of being plateaued. Plateauing seems to run along a continuum where some individuals perceive being

plateaued quickly, while it takes others longer job tenures to feel plateaued. Therefore, the exact time (or age) when someone plateaus varies greatly.

Plateauing has also been measured subjectively as the perception of the individual (or his/her employer) regarding one's likelihood of increased responsibility. Many have found that the perceptual measure better informs us regarding work attitudes and behaviors than does the objectively measured construct. Some have suggested that there may be different degrees of "plateauedness" and therefore that the career plateau construct should be measured on a continuous scale. While self-reported measures may cause some measurement bias, in the case of career plateauing it appears that perceptual measures truly capture one's career situation.

REASONS FOR THE CAREER PLATEAU

Researchers have suggested different reasons to explain why employees may become plateaued. Once an individual acknowledges that a plateau has occurred, an attribution to explain why it happened is a common psychological process. Firms may plateau employees for either organizational or personal reasons. Within these broad terms, there are specific types of attributions plateaued employees may recognize. First, plateaued employees may perceive that they are plateaued because of the organization's negative assessment of their capabilities. Individuals may be plateaued because they are seen by the organization either as lacking in ability for higher-level jobs or as not desiring higher-level jobs. Managers within organizations may consciously (or subconsciously) pigeonhole employees as those who are competent and willing to move up the corporate ladder and those who are not. An organization's assessment of an individual, whether it is accurate or not, may be an antecedent condition that the employee believes created his or her plateaued state.

Another situation in which individuals may suggest organizations have caused their plateaus is due to the narrowing employment pyramid. The organizational structure allows fewer and fewer employees to move up to higher management ranks. Also, downsizing eliminates many middle-management layers of the pyramid. As firms cut employees throughout the organization, the structure becomes flattened, creating even more competition than had previously existed. Since flattened organizational structures are a fact of

organizational life for the foreseeable future, fewer higher-level jobs will exist at many firms. These organizational constraints may effectively plateau employees.

An employee's personal preference may be offered as a reason for being plateaued. This reason may become more prevalent given today's high percentage of dual-career couples in the workforce. Some individuals explicitly make their desires known not to be promoted further, while others send ambiguous signals to the organization or place constraints on proposed promotions. The typical employee during the 1970s was the strongly committed, ideal "organization man," whose every desire focused on staying with the company for life and progressing at a sure and steady pace up the hierarchy. Hardly any of these individuals chose being plateaued. However, few of today's workers embody the "organization man." Individuals may choose for personal reasons, such as family or health, not to seek additional responsibilities. This is true for both men and women, since both may be juggling work and family responsibilities. Also, an individual may not feel that the added stress (or income) associated with the promotion is worth what the person may have to give up to do the job. In summary, individuals may be plateaued for organizational assessment, organizational constraint, or personal-choice reasons.

EXAMPLES OF PLATEAU REASONS

Given that two types of plateaus, structural and content, have been identified, along with the reasons one might plateau, a discussion is warranted on the typical plateau attributions an employee might give for his or her plateau status. For example, an employee may be structurally plateaued for *organizational assessment reasons*. An employee may not receive future promotions because management believes the individual lacks the managerial ability or skills needed for higher-level jobs. Or the organization may believe that the employee is not truly committed to the organization or lacks the desire to rise through the ranks. Hence, the organization has made an assessment of the individual that precludes that employee from career advancement within the firm.

Employees may be structurally plateaued due to *organizational constraints*. The lack of positions may be caused by a poor economy, downsizing, inappropriate recruiting and staffing efforts targeted at the same population, or an enlarged management rank. In any of these examples, the actions of the organization have resulted in employees who are structurally

plateaued, with no opportunity for hierarchical advancement. The employee has been plateaued in this case due to issues outside the employee's (and maybe the firm's) control.

An employee may also be structurally plateaued for *personal-choice reasons*. It may be that the employee does not desire a higher-level job, stemming from non-work-related issues. In these cases, the reason the employee is structurally plateaued may have everything to do with the personal choices the individual makes (e.g., not wanting/needing the stress associated with higher-level jobs, not taking a promotion because of possible need for family transfer or health reasons). This situation occurs when one makes a conscious decision and takes control of one's career and therefore may be referred to as being structurally plateaued for personal-choice reasons.

Individuals may be content plateaued for either organizational or personal reasons. When the organization has negatively assessed the employee's capabilities, the employee may not receive any further increases in responsibility associated with the current job. The organization may believe that the employee doesn't have managerial or technical skills, ability, desire, or work ethic to manage more advanced tasks. This is oftentimes deemed being "put out to pasture."

Also, the organization may place constraints on the individual's job such that no further learning may take place. These constraints may include inflexible job descriptions or unavailable training. The employee may want additional increases in responsibility but does not receive them because of personnel decisions imposed by the organization. This may cause the employee to perceive that there is little growth opportunity in the job and hence creates a perception of content plateauing for organizational constraint reasons.

An individual may decide for personal reasons that declining additional increases in responsibility in the current job is agreeable with other life domains. The additional workload associated with more responsibility doesn't seem worth the extra effort. There may be no additional financial remuneration for the excessive work hours; family responsibilities may suffer; or physical or emotional health may be jeopardized. This would be an example of content plateauing for personal-choice reasons.

This summary of the career plateau phenomenon is meant to bring closure to the lack of consensus among researchers about construct definitions. Individuals who experience career plateaus may experience one

or both of its two types, structural and content. Within these types of plateaus, there are also reasons to which individuals may attribute their plateaued states. Organizational assessment, organizational constraint, and personal choice are either external or internal decisions that affect the employee's work situation.

NEGATIVE OUTCOMES ASSOCIATED WITH PLATEAUS

Career plateauing is an important issue for researchers to examine because of the potentially negative outcomes that may affect both the employee and the organization. Career plateauing has been found to produce negative work attitudes and reflects disappointments stemming from one's work domain. Plateaued employees are described as displaying low levels of job involvement and work motivation. Plateaued employees become less job involved because they believe that the organization has devalued their contributions. Employees who perceive that the organization does not care about them report lower levels of involvement in job responsibilities. The organization has plateaued the individual, and this action causes a blow to the individual's self-image. The employee responds with a low level of job involvement as a behavior that is consistent with his or her perception of the situation. The resulting behavior often involves lower job productivity, and plateauing has been found to be negatively related to performance.

Few researchers have investigated the relationship of one's plateaued type to job involvement. Structural plateauing and content plateauing have both been found to be negatively related to job involvement. Researchers have found that structurally plateaued technical specialists report lower job involvement than their nonplateaued counterparts, and state government employees who report being content plateaued also report low job involvement. This negative relationship between both structural/content plateauing and job involvement would be expected given the definition of job involvement.

Plateaued employees report low levels of job satisfaction and career satisfaction. Researchers have found that both structural and content plateauing are negatively related to personal development satisfaction, while content plateauing is related to task dissatisfaction. Others have found that both structural and content plateauing are negatively related to both job and career satisfaction.

Plateaued employees also exhibit a greater propensity for leaving the organization. Results have shown that content plateauing has a negative effect on affective commitment to the organization. This type of employee reaction to career plateauing results in a loss of employee morale and productivity and leads to turnover, which may prove very costly to organizations.

While the organization may experience negative repercussions when the employee experiences a plateau, the employee may also realize some personal consequences. Harmful psychological effects include lower self-worth due to promotions being taken away, lower skill assessment, and less acceptance by peers and superiors due to devalued work contributions. Plateaued employees may experience negative stereotyping as "deadwood," neglect by supervisors, and avoidance by coworkers.

Work-related stress and strain have been examined as outcomes of an employee's plateau state. Structurally plateaued employees have reported greater work-related stress than have nonplateaued employees. Researchers have found that both structural- and content-plateaued employees experience high levels of job strain and that structurally plateaued employees report experiencing high levels of job-induced tension. Although these studies used various stress scales, there seems to be consistency in the direction of these relationships.

It is conceivable that the reasons for structural and content plateauing could be considered work stressors. This may be particularly true when the reason for becoming plateaued is outside the employee's control. For example, structurally plateaued employees may become distressed upon acknowledging there are no more available positions; that is, there are organizational constraints disallowing further promotions. Some suggest that the mismatch between professional employees' advancement desires and available positions, due to shorter corporate ladders, is a significant source of stress. Employees may become distressed should they perceive that the organization has negatively assessed their abilities and therefore has structurally plateaued them for organizational assessment reasons. Content-plateaued employees may respond similarly when they acknowledge that their jobs will no longer be challenging or that they offer little growth, little flexibility, or few increases in job responsibility. Bardwick once noted that the end of job challenge can generate as much stress as the end of the hierarchical or structural climb.

Researchers have found that stress regarding career progression may be equal among people of various career anchors and more prevalent among early career stage professionals. Both male and female employees expect the same chances for career progression and have similar aspirations and social expectations for advancement. Since the firm is taking those opportunities away, employees may become distressed upon realization of their plateau status.

POSITIVE OUTCOMES ASSOCIATED WITH PLATEAUS

Although many negative sentiments have been associated with career plateaus, plateaued employees appreciate a few positive experiences. Most important, some research suggests that given the flattened organizational structures common to many companies, experiencing a career plateau may not be as embarrassing or stressful as it once was. In fact, the plateau event may not be a unique situation but rather the norm for many employees' career progressions. From this perspective, plateaus may be more common and acceptable periods in one's career than was previously thought.

Plateaus are a time when new ideas are digested. They afford highly desirable stable, secure, and restful periods. Plateaus allow for reflection and offer individuals time to regroup and plan the next phase of personal and professional growth. Plateaus permit the employee the time to assimilate new knowledge and integrate that knowledge into his or her functional repertoire. From a more pragmatic perspective, plateaus allow time to "de-stress" and also to take stock of and reinforce accomplishments. Some employees may even hope for a plateau due to their inability to cope with the stress that career mobility and progression impose. In fact, plateaued university employees have reported a greater likelihood of staying with and being committed to their organizations.

Plateaued employees are expected to invest less of themselves in the job and more in nonwork activities. According to compensatory theory, disappointments in one sphere of life tend in some way to be made up for in another sphere. Therefore, plateaued employees psychologically distance themselves from work by becoming more involved in nonwork issues. Individuals become involved in these nonwork activities in order to perform well in another domain and maintain their self-esteem. Similarly, plateaued employees may devote more time to their families,

leisure interests, and community activities. Researchers have suggested that plateaued employees realize their needs are not being fulfilled within the workplace and look to other life domains for fulfillment. These studies suggest that employees experience positive non-work-related outcomes because of their plateau status.

OPPORTUNITIES FOR FUTURE RESEARCH

There are many opportunities for future career-plateauing research. First, researchers need to be aware of the conceptual differences between the structural and content plateau construct types noted herein and pursue studies that validate these constructs. Also, more research needs to investigate the reasons for career plateaus and their effects on work and nonwork outcomes.

Second, it is acknowledged that the current definition of career plateau holds a relatively narrow perspective of career mobility within an organization. It is also acknowledged that the boundaryless career, in which the employee is self-reliant in forging his or her career across organizational boundaries, is becoming the norm. This type of career requires lifelong learning to allow individuals to become functionally capable and marketable. Employees are shifting their notions of careers from an organizational advancement focus to a professional achievement orientation. Therefore, the notion of the professional plateau may be a more timely construct for researchers. However, like career plateau, the definition of professional plateau needs greater clarity.

Third, researchers may want to analyze and recognize the differences between plateaus and permanently stalled careers, and when situations require career shifts. It will not be uncommon in the future for individuals to have as many as 10 different careers. Although lateral moves are excluded from the definition of career plateau, the effects of lateral moves on individuals' perceptions of either career or professional plateauing and work outcomes need to be investigated, given the economy today.

Finally, individual or situational factors may explain why some plateaued employees succeed while others suffer negative psychological, social, or organizational effects. What discriminates plateaued employees who are successful from those who are not needs to be explored. Given that many employees will have stalled careers, organizations want to maintain as many solid contributors as possible. Chaos theory has been used in

the counseling literature to help explain how plateaued employees deal with the events that lead to their perceptions of being plateaued. Future research should consider chaos theory, or other theories outside the management literature, as part of the remedial process of coping with the plateau trigger event.

The notion of a career plateau will continue to intrigue researchers for some time, due to the complexities associated with career management. Whether individuals are in organizationally bounded or boundaryless careers, some pause in career progression should be expected. How and why careers become plateaued and the outcomes associated with these situations, which affect individuals and organizations, will provide many future research opportunities.

CAREER SALIENCE

The word *salience* comes from the Latin word *salire*, "to go out," as out of a door or gate. Salient may also mean "standing out from the rest" or "prominent." Donald Super linked the idea of salience, meaning prominent or standing out from the rest, to career development theory in the 1970s. During the next 30 years, research and development efforts expanded understanding of the relationship of career salience within career development theory and also its uses in career counseling.

Career salience should always be thought of in relation to other life roles and not as something existing by itself, independent of these roles. Career salience relates to the prominence for a person of his or her career role in relation to other life roles, such as the family or leisure role. The responsibilities of raising a family (family role) may lower the importance of a person's career role salience, especially during the time when that person's children are young. Therefore, career salience is not an absolute value but is relative to the salience of other life roles and commitments at any particular time.

Career salience changes for persons as they move through differing career development stages, for example, when moving from the growth-development stage to the career-establishment stage. Thus, career salience for adolescents is often not significantly related to their career salience when they are young adults. Career salience increases or decreases at various times with the increases or decreases in commitment and involvement in other life roles. Although scholars in addition to Super have studied career salience, they have usually done so independent of other life roles and have failed to take into account the developmental nature of career salience.

The concept of career salience is relevant to career counseling because it deals with the special problems and challenges faced by persons engaged in career

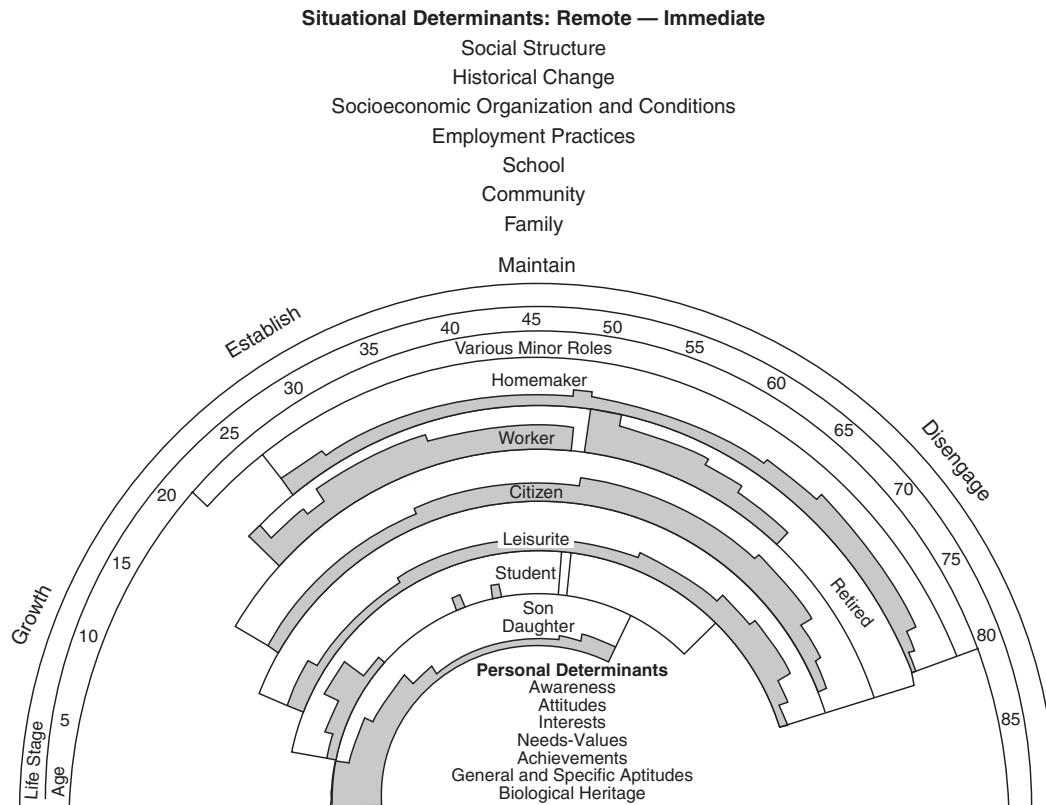

Figure 1. Life-Career Rainbow

SOURCE: Super (1990).

decision making and planning. A majority of workers engage in multiple roles, roles other than career, and these multiple roles put stress on their lives. This is especially true of working women who are also young mothers. Persons from ethnic minority groups experience challenges too, as they often hold values related to work and home roles that differ from those of the mainstream population. Career counseling that helps ethnic minority persons clarify their role priorities in light of their own value systems can help to reduce their alienation and stress related to being different.

LIFE SPAN, LIFE SPACE, AND CAREER SALIENCE

Super developed the Life-Career Rainbow (see Figure 1) to illustrate his “life-span, life-space approach” to career development. The Rainbow presents the role salience of various typical life roles, such as child, student, “leisurite,” citizen, worker, spouse, homemaker, and parent, over the life of an

individual as these roles change in their salience depending on which career development stage the individual is in. The Life-Career Rainbow is a tool that can be used by counselors in introducing a client to the idea of the interdependence of various life roles and their changing importance throughout life. The career development stages represented in the life-span dimension of the Life-Career Rainbow include growth, exploration, establishment, maintenance, and disengagement. Each role in the Life-Career Rainbow is depicted as beginning at a different age and changing in importance or intensity during the rest of a person’s life. For example, the role of son or daughter begins at birth and continues during the life of a son’s or daughter’s parents. When both parents are deceased, the role of son or daughter ceases. The role of worker within a career may begin for a person around age 22 and end around age 65.

The salience to individuals of their career roles is dependent on the salience to them of other life roles at any given point in time. Most working women and

working men fill several roles at the same time. The result for the career role is sometimes positive and sometimes stressful and may even result in role conflict. Super reported evidence that persons engaging in multiple roles can increase life satisfaction and a sense of well-being, especially if their personal self-esteem is high. There is also research indicating that women who engage in both the parenting and career roles at the same time feel more satisfied with their lives. However, role stress is particularly evident for working parents of young children. Role conflict may result when the parents' other role values are in conflict with their work role values. For example, a mother who believes that her first priority is to her child is likely to skip work or come late to work if the child is ill in order to first take care of the child.

CAREER SALIENCE: THREE ASPECTS

Super defined career salience as consisting of three aspects: commitment, participation, and knowledge. *Commitment* means the value or emotional attachment to the role a person feels and his or her degree of identification with the role and its activities. *Participation* means behavioral participation or time spent in the role. *Knowledge* means the degree of information about a career learned either through participation or through vicarious watching of others in that career role. These three components of career salience have been found by various researchers to be only slightly or not at all related to each other for students whose role decisions are still tentative and whose role participation is still limited. That is, a person with high career commitment is not necessarily highly involved in a career or knowledgeable about careers. Super defined *career development tasks and involvement* as beginning in childhood with fantasy play, in which the child takes on adult roles, such as those of sailor, doctor, teacher, or astronaut. Thus, the commitment component and the cognitive component may develop early, whereas the participation or behavioral component will vary in different career-development periods, depending on the demands of other roles, such as student, parent, or citizen.

LIFE ROLE VALUES AND CAREER SALIENCE

The role values a person holds are part of the commitment or affective dimension of career salience. The values satisfied by each role a person engages in are

central to understanding the career salience of that person. Role values are a mix of intrinsic and extrinsic values. *Intrinsic values* are satisfied by participation in a role, whereas *extrinsic values* are satisfied by the outcomes of participation. Intrinsic values include ability utilization and altruism; extrinsic values include economic rewards and prestige. Helen Farmer found that for adolescents and young adults, altruistic values are more predictive than achievement values of high career salience. Altruistic values involve valuing providing a service to others and helping others. Career-related values develop prior to career-related interests; in fact, career interests develop as a means of satisfying the values a person holds. For example, if a person values earning a lot of money, he or she will express this value by engaging in activities that are likely to promote a high salary.

NEED TO ACHIEVE AND CAREER SALIENCE

Joel Raynor pointed out that the need to achieve typically relates to mastering short-term challenging tasks, whereas career salience relates to long-term commitment and participation in a career that the person is highly knowledgeable about. When short-term achievement tasks are viewed by individuals as affecting their long-term achievement goals, for example, acceptance into a particular job or institution of higher education, short-term and long-term goals are contingent and therefore related. Career salience, that is, the commitment to, participation in, and knowledge about a career, is sometimes related to a person's need to achieve in life. However, a salient career is not necessarily a challenging one, whereas high need for achievement is related to seeking out challenging tasks to master. A person with high career salience may choose a career that gives meaning to his or her life and that is highly satisfying, but not necessarily challenging and risky.

GENDER DIFFERENCES AND CAREER SALIENCE

Farmer has shown that adolescent women and men in the career exploration stage score similarly on measures of family and career role salience. However, for adolescent women as well as young adult women, the more they value their family roles, the less they value their career roles. For adolescent and young adult men in these two career-development stages, the valuing of

these two life roles is relatively independent. That is, for boys and young men, both career and family salience may be high. Another relationship found for adolescent and young adult women, but not for boys and young men, is that career salience is significantly related to a positive view of the support available in the workplace for working women. This finding illustrates the importance of a supportive environment or context in determining women's career salience.

SOCIOECONOMIC STATUS AND CAREER SALIENCE

Rabindra Nath Kanungo, in his study of work alienation, demonstrated that some workers prefer other life roles over their work roles. In fact, a majority of the workers in the United States work because they have to. This is true of both men and women. Often workers at the lower end of the economic scale resent work, but they work because of their survival needs and to satisfy their need for pleasure, acceptance by others, and recognition in other life roles, such as the role of citizen. Also, many persons from the lower socioeconomic strata of society do not have the freedom to choose the kinds of careers they will enter. Rather, they choose whatever employment opportunities are open to them. For many workers, the emotional dimension of career salience is low, but the participation dimension is high. If circumstances dictate that a person's career does not bring him or her satisfaction, a career counselor can help that person plan to engage in other life roles, such as leisure roles, that are more satisfying.

CAREER MATURITY AND CAREER SALIENCE

Super and Dorothy Nevill reported that for adolescents, career maturity is a better predictor of career salience than is social class or gender. Super's measure of career maturity includes assessment of career planning, career exploration, career decision making, world-of-work information, and knowledge of the preferred occupational group. If work is not important to an adolescent and his or her career maturity is low, that individual is not ready to engage in career planning and decision making. Also, that person's scores on career interest inventories and other career-planning measures will have low validity. This has important implications for career counseling with

adolescents and adults who are low on career maturity. Low levels of career maturity may suggest that an individual is *career alienated*, that is, sees no value for himself or herself in a career. Other reasons for low career maturity and career salience include the responsibilities and demands of other life roles on the person at the time of the assessment and a possible lack of experience in and knowledge about careers and work. Although Super and Nevill found that among adolescents, both gender differences and social class differences are less related to career salience than to career maturity, gender and social class differences are still relevant, though less so, to understanding adolescent career salience.

CAREER COUNSELING AND CAREER SALIENCE

Nevill and Super proposed a form of career counseling called the *developmental assessment model*. Using this model, the career counselor conducts an initial interview with the client, explaining the life-role planning process and the interrelationships of multiple life roles a person plays at different points in time. The Life-Career Rainbow described earlier is a useful tool in this initial stage. The developmental assessment model of career counseling includes collecting a large array of information about the client prior to engaging in career decision making. To understand whether or not a client or individual is ready to make a career decision using the development assessment model, it is necessary to assess three things. Assessment devices were developed by Super and his colleagues for role salience, the values expectations related to each role, and career maturity. This is to ensure that the client can make an informed choice about a career within the larger framework of multiple roles and life planning. The three measures are briefly described next.

The Salience Inventory

The Salience Inventory published by Nevill and Super in 1986 has been shown to benefit clients in individual counseling, group counseling, and career development workshops and counseling. The Salience Inventory was developed out of earlier work in the 1970s by Super and members of the Work Importance Study (WIS), an international consortium in a dozen European, Asian, Australian, and North American

countries. Super was the coordinator of the WIS. The Salience Inventory assesses the client's current commitment and participation in five life roles: student, worker, citizen, home and family, and leisure. The knowledge component of role salience is not assessed, because it would vary depending on the particular career the client was interested in and/or had participated in. Once the counselor knows the relative importance of the client's career role in relation to other life roles, the counselor may proceed to administer the Values Scale to the client.

The Values Scale

Super and Nevill developed the Values Scale in 1986. The role values included in the American version are those found most frequently among American adults. International versions of the Values Scale may vary, based on the values identified most frequently in the country of intended use. The Values Scale used in the developmental assessment mode separately assesses the importance of 14 values for each of the five roles. Sometimes a person holds two or more values that cannot all be met or satisfied in a particular career. A person who values both altruism and earning a high salary might satisfy earning money through his or her career and satisfy altruistic values in other roles, such as that of citizen or engaging in church activities.

The Career Development Inventory

The third element of the career development assessment model is administration of a career development measure such as the one developed by Super and his colleagues. This measure provides a career maturity score on career planning, career exploration, decision making, world-of-work information, and knowledge of the preferred occupational group. When this step is completed, the counselor reviews the information to determine whether the client is ready to engage in career decision making and is likely to provide valid career interest and ability scores or whether the counselor should encourage the client to do more career exploration.

CAREER SATISFACTION

Career satisfaction is an important variable in research on career development and other areas of inquiry dealing with occupations, work dynamics, and individual adjustment. Although career satisfaction is seldom the primary topic of research investigations, it is often studied as an important criterion variable in relation to many different personal and organizational factors. It should be emphasized that the term *career* refers to all of the work-related activities a person engages in and all of the work-related experiences a person has over the course of a lifetime. Defined this way, *career* applies to everyone who works, not just individuals in a profession or higher-level occupations. On the other hand, most empirical studies in this area have focused on professional occupations in which a career represents a sequence of related jobs over time, with an emphasis on advancement, progression, and cumulative experience.

When researchers ask people to look back over their lives and indicate how satisfied they are with their careers, several assumptions are usually made. First, a career is a concept that has meaning for people as a discrete phenomenon in its own right, as a specific domain of experience. Most people do not have to stop and think about each job they have had and how satisfied they were with each one to tell you how satisfied they are with their careers. They think about their careers as a whole. A second assumption is that careers change over time, and satisfaction depends on advancement. A person who starts out in a higher-level job and ends up in a midlevel job will almost always be less career satisfied than someone who starts out in a low-level job and ends up in a midlevel job. Thus, most scales that are used to measure career satisfaction have one or more items dealing with the progress a person has made over time in key areas such as income and job responsibility and in the development of knowledge, skills, and abilities. Third, as in most areas of satisfaction, the assessment of career satisfaction usually involves consideration of current versus desired or expected level of experience. For example, a career satisfaction item might ask: How satisfied are you with the progress you have made (in your career) toward achieving your goals for earnings? The lower the discrepancy between the current level versus the desired or expected level, the greater the satisfaction. If this model were valid, one possible strategy for achieving career satisfaction would be to keep expectations low. But such a strategy is unlikely given the optimistic expectations most people, particularly those with college degrees, have when they begin their careers. Moreover, it may be difficult to modify unrealistic career expectations, as suggested by studies of individuals in midcareer who still have high levels of ambition and desire for upward mobility while reporting lower levels of career satisfaction.

It is also important to recognize that career satisfaction is not job satisfaction. It is easy to see how satisfaction with career as a whole, covering all jobs, is conceptually differentiated from job satisfaction, which is usually a person's satisfaction with a single job, typically the job he or she currently holds or most recently held. Even if one were tempted to consider career satisfaction as the average level of job satisfaction across jobs, we would not know which direction satisfaction is going or how satisfaction is impacted

by nonjob variables such as work-nonwork dynamics or changes in personality. Another important distinction often made is that career satisfaction represents a *subjective* indicator of career success, as distinguished from *objective* indicators of career success, such as salary or earnings and promotions or professional advancement.

Career satisfaction is often regarded as a key outcome variable representing career success and personal fulfillment. Its value as a criterion of success is such that policy implications are drawn about professional practice and specialty choice based on career satisfaction. In the medical profession, for example, differences in career satisfaction inform theorists and policy analysts about the attractiveness of the medical profession, the impact of managed care, and physicians' quality of life in different areas of specialization (e.g., family practice, internal medicine, surgical specialty, and psychiatry).

One reason so much importance is attached to career satisfaction is that it represents an overall summary of how a person feels about a lifetime of work—which represents about 100,000 hours for the typical American—and all the accompanying personal achievements, feelings of accomplishment, and gratification, as well as the setbacks and disappointments experienced in the course of a career. It is encouraging to see that in most studies, at least two-thirds of the respondents indicate that they fall in the *fairly satisfied* to *very satisfied* range for career satisfaction. Another way to view career satisfaction is as component and predictor of global life satisfaction, which is considered by some to be an overarching existential criterion or ultimate outcome of human experience. For younger individuals who can still modify their work behavior and alter their career trajectories, career satisfaction can serve as a benchmark against which subsequent assessments can be compared, to track career progress and monitor relative success. For older individuals, there are no career “do overs,” and career satisfaction can represent a final summary or subjective report card on the result of all their career endeavors.

Turning to the question of what factors relate to career satisfaction, one starting point is demographic characteristics of the individual. One might expect that career satisfaction increases with variables such as age or education. However, career satisfaction tends to be unrelated, or related at a low level of

magnitude, to most demographic variables, including age, gender, education, marital status, parenting status, child care responsibility, time spent with children, and collegiate grade point average. Moreover, there is evidence to suggest that construct relationships involving career satisfaction, such as the relationship between challenging work and career satisfaction, are fairly similar for most demographic variables, including type of occupation, as well as for individuals working in the same type of job in different countries. Such results offer hope for the development of generalizable models of career satisfaction.

As is the case for many other psychological constructs, career satisfaction can be viewed as the result of *person-environment fit*, or the interaction of person and environment. If a person's career is well suited to his or her personality, career satisfaction should ensue. One way to evaluate this proposition is to examine the relationship between vocational interests and career satisfaction, with an eye toward whether satisfaction increases if career choice or occupational membership is congruent with one's vocational interests. Research findings in this area generally indicate that career satisfaction is, indeed, related to expressed vocational interests and the fit between vocational interests and abilities in relation to occupational membership and career choice. Such results are important for practitioners involved in vocational planning, counseling, and career development, in which the focus is on helping individuals make educational and occupational choices that lead to career satisfaction.

PERSONALITY AND MENTAL ABILITY FACTORS

Another line of research has examined the relationship between personality traits and career satisfaction. One rationale for such research is that people both choose and are satisfied with careers that are consistent with their personality characteristics. A second rationale for linkages between personality traits and career satisfaction is that some traits are generally advantageous for performance, adjustment, and feelings of satisfaction regardless of career path. A recent trend in this area has been to investigate construct relations using both the broadly defined Big Five personality traits as well as more narrowly conceptualized traits. The Big Five model, which includes the traits of Agreeableness, Conscientiousness, Extraversion, Neuroticism, and Openness, has emerged as the most widely accepted and well-validated taxonomy of

normal personality traits in psychological feature. Two of the Big Five traits, Extraversion and Conscientiousness, have been found to be positively related to career satisfaction in occupations in which there is a logical connection (e.g., Extraversion for customer service jobs; Conscientiousness for engineers) and in which the connection is less obvious (e.g., Extraversion and computer programmers). One of the most consistent relationships is for Neuroticism, which is negatively related to career satisfaction in a wide range of occupations. One explanation that has been offered for the Neuroticism-career satisfaction relationship is that there is considerable stress in most jobs these days (especially given the increased demands placed on jobholders and the greater threat of job loss in many fields). Stress accumulates over the course of a career, and less resilient individuals are less able to cope than are more resilient individuals, which can directly impact career satisfaction as well as indirectly impact it through lower performance. In addition, two "narrow" personality traits, Optimism and Work Drive, have been found to be positively related to career satisfaction for a variety of occupations.

Beyond the Big Five personality traits, a variety of other personality-related traits have been found to be associated with career satisfaction for one or more occupations. These personality-related factors include assertiveness, image management, team-mindedness, workaholism, locus of control, tough-mindedness, and proactive personality. One interesting point to consider in regard to significant relationships between personality traits and career satisfaction is that from a life span developmental perspective, personality precedes most of the other variables that have been found to be related to career satisfaction, such as mentoring, training, salary, job satisfaction, and supervisory support, to name but a few. Therefore, not much is known about the independent effect such variables have on career satisfaction, because most of the studies did not first control for the effects of personality traits. It may be that some personality traits account for the effects of, say, promotions or salary increases, on career satisfaction, which may lower the importance accorded to the latter variables as determinants of career satisfaction.

Given that intelligence is related to job performance, income, and organizational level, it is logical to inquire as to whether intelligence is also related to career satisfaction. One initial answer is that it may depend on type of career path and the opportunity to use one's mental ability, as the relationship between career satisfaction and intelligence has been found to

be negative for hourly jobs but positive for managerial jobs.

JOB CHARACTERISTICS

Another area of inquiry has looked at job characteristics and job-related variables in relation to career satisfaction. Because there is continuity of personality over the life span—which means that people are similar over time with respect to attitudes, values, feelings, and dispositions—and because most people work in similar jobs over the course of a career, one might expect job-related variables to be related to career satisfaction. On the other hand, we would not expect these to be highly related to career satisfaction, since the average person works in 10 or more jobs before retiring and has three or four different careers in his or her life. Stronger relationships might be expected in studies of young people who have had only 1 or 2 jobs or if there is a nexus of job features and job experiences over time, which is usually the case for professionals who progress along a single career path. In fact, most of the studies reviewed here are based on a single professional occupation or job group. Whether or not this is a weakness depends on one's point of view. If one is an hourly worker who might expect to change jobs and even careers more than most people, these results might be of questionable value, but if one is a budding professional expecting to build a career in a single field, these results might be quite relevant.

One common finding is that job satisfaction is highly related to career satisfaction for occupations such as teachers, lawyers, managers, and psychologists. Also, a modest, positive relationship between job salary/earnings and career satisfaction has been observed in studies of specific occupational groups as well as studies of diverse occupations and organizations. Several other subjective job-related variables have been found to be moderately related to career satisfaction, including perceiving that one has job security, having challenging job assignments, doing "significant" work, feeling involved in one's work, and having supervisory support. Several of the more objective job measures have been found to have little or no relationship to career satisfaction, including the number of hours worked, job tenure, and type of job; however, working full-time rather than part-time has been linked to higher levels of career satisfaction. Although there have been few studies on the consequences of career dissatisfaction, intentions to search for a new job and a

new employer and to quit a job have been found to be inversely related to career satisfaction, which suggests that a relationship may be found between career satisfaction and the incidence of job turnover as well as the relative frequency of job turnover in a career.

ORGANIZATION CHARACTERISTICS

Another area of research inquiry on career satisfaction has looked at the role of organizational variables. Most of the objective organizational variables studied have been found to have no relationship to career satisfaction, including organization tenure and organization size, though for physicians, there is some evidence that physicians in small-group practices are more satisfied than those in large-group practices. Managers generally report higher levels of career satisfaction than do non-managers, though this may merely reflect the influence of other variables, such as greater income and more challenging work. Organizational norms and values are found to be positively related to career satisfaction, including support and encouragement, training and development emphasis, value for work-personal life balance, and the congruence of personal values and organizational values. Social networks have also been studied in relation to career satisfaction, with results indicating that career satisfaction is positively correlated with having an integrated network of relationships in the organization as well as having more breadth of social networks outside the organization.

CAREER CHARACTERISTICS

One of the most promising and potentially useful approaches to the study of career satisfaction involves examination of career-related constructs and characteristics. Looking first at objective attributes, we find that career satisfaction is moderately related to extrinsic rewards or objective indicators of success, including career income, salary increases, percentage of raises over time, and promotions. On the other hand, type of career path and work experience seem to account for little, if any, variation in career satisfaction.

A number of subjective measures that reflect satisfying experiences, fulfillment of expectations, and positive prospects for the future are related to career satisfaction at levels that range from moderate to high. These include satisfaction with opportunity to achieve career goals, prestige of jobs held, career skills, career identity, perceived promotion opportunities, career prospects, perceived marketability, and career initiative.

From ancient Greek and Roman times onward, more experienced individuals have served as mentors to help less experienced, and usually younger, individuals develop their skills and abilities. Today, mentoring has become an established practice in many work settings to facilitate the professional development and career enhancement of employees. One line of research in this area has focused on the role of mentors and the mentoring process in relation to career satisfaction. Modest relations have been found for having a mentor, length of mentoring relationship, mentor support functions (such as instrumental, career development, and idealized influence), and learning goal orientation. Mentoring functions can also serve as moderator variables; that is, as variables that affect the relationships between other variables. For example, employees who report that their mentors provide more psychosocial support to them appear to have higher levels of career satisfaction when they use self-set goals as a career management strategy. Mentoring functions have also been studied as moderators of career satisfaction relationships. For example, employees who report that their mentors provide more psychosocial support report higher levels of career satisfaction when they use self-set goals rather than other self-management strategies.

With the emergence of interest on the *boundaryless career*, wherein an individual's career spans multiple employers, jobs, and areas of skill development, has come an emphasis on individuals engaging in proactive behavior to ensure career success, rather than waiting for the vicissitudes of economic, technological, and organizational change to impact their career success. Initial results indicate that proactive behaviors (such as taking the initiative to update skills) and having a generally proactive personality contribute to career satisfaction. Similarly, career satisfaction has been found to be positively related to self-management strategies such as self-set career goals and having positive career expectancies.

MULTIPLE SOURCES OF CAREER SATISFACTION

Some studies have looked at how different types of variables uniquely and jointly predict career satisfaction. As might be expected, when multiple sets of predictors are considered, more variance in career satisfaction is explained, with estimates ranging up to nearly half of the variance in career satisfaction being

explained when using demographic, personality, job, organization, and career-related variables. It is somewhat premature to conclude which variables are more important than others, though the picture that is emerging points toward the importance of personality and motivational variables as well as career-related constructs and human capital variables (e.g., training, professional development, education, tenure) as important contributors to career satisfaction.

CAREER STRATEGY

A *career strategy* is any behavior, activity, or experience designed to help a person meet career goals. A career strategy represents a conscious choice by an

individual as to the type of investment he or she is willing to make in attempting to reach career objectives. Ideally, people pursue a particular career strategy based on the expectation that it will result in the greatest chances of achieving personal and professional success.

Research on the effectiveness of various career strategies suggests that developing a variety of skills and having a diverse number of work experiences significantly improves one's chances of attaining career success. Other research has found that the use of strategies such as self-nomination and networking contribute to an individual's career success. The usefulness of a particular career strategy is dependent on a number of factors, including the nature of the job, the type of the industry, and the culture and norms of the particular organization. Indeed, a career strategy that might be successful in one case might not work in another.

TYPES OF CAREER STRATEGIES

Past research identifies at least seven general categories of career strategies that can be used to enhance an individual's chances of career goal fulfillment. The seven strategies include attaining competence in the current job, putting in extended work hours, developing new skills, developing new opportunities at work, attaining a mentor, building one's image and reputation, and engaging in organizational politics.

Attaining competence in the current job is a basic career strategy, given that organizations make promotion decisions, at least in part, on an employee's present performance. In addition, the skills acquired or honed in one job might be essential for performance in another job either with one's current employer or with another organization. The concepts underlying the protean and boundaryless career philosophies make it necessary for individuals to have relevant skills at the times when those skills are required by employers. Focusing on developing abilities in a current job can improve an individual's chances for employability in the future.

Putting in extended hours either at the work site or at home is a popular career strategy, especially in the early career, when an employee is proving himself or herself to the company. Working beyond normal hours can enhance performance in one's current job and can signify to the organization that one is committed to the job and capable of taking on large volumes of

work. However, putting in extended work hours can also result in negative consequences over the longer term, given that extra work hours during evenings and weekends might impinge on the time a person can spend on family or personal activities.

Developing new skills is a career strategy that involves the acquisition or enhancement of work abilities that either improve performance in the present job or will be required in a subsequent position. Michael Arthur, Priscilla Claman, and Robert DeFillippi have called this strategy "knowing how." They have noted that skill development can involve formal occupational training as well as experiential learning. Skill development can include activities such as participation in training seminars, degree or nondegree university programs, or attendance at a leadership development workshop. Employees can also develop skills by acquiring additional responsibilities on their current jobs, working with an experienced colleague, or joining occupational associations that sponsor continuing education.

Developing new opportunities at work includes a number of more specific strategies that are designed to increase one's career options. In their typology, Arthur and his colleagues have referred to this career strategy as "knowing whom." As an example, self-nomination is a frequently observed strategy that involves the willingness to inform superiors of accomplishments, aspirations, and desired assignments. Self-nomination is intended to enhance one's visibility and exposure to those in more senior positions within the organization, which can bring recognition, special assignments, and sponsorship. Another relevant career strategy under this category is networking, which involves the identification of and communication with a group of relevant acquaintances and friends who can provide information, advice, and support regarding career opportunities.

Attaining a mentor as a career strategy has received considerable attention in recent years. Mentoring can be defined as relationships between junior and senior colleagues or between peers that provide various developmental functions. The mentoring role can be filled by a variety of individuals, not by just one person. A mentor can provide coaching, friendship, sponsorship, and role-modeling to the younger, less experienced protégé. In the process, the mentor can satisfy his or her need to have a lasting influence on another person's life.

Building one's image and reputation is a career strategy in which the individual attempts to convey an

appearance of success and suitability. For example, being married, participating in community activities, and dressing properly can provide a positive public image that can bring career rewards. While this type of strategy is not necessarily important in all or most situations, past research has found that significant numbers of employees make the investment in image building because of the perceived high value to career advancement. Building one's work reputation is an important strategy because it is presumed that an individual's past experiences and accomplishments bode well for future performance. Thus, a focus on building a strong work reputation can improve a person's employability regardless of the employer.

Engaging in organizational politics is somewhat similar to the "knowing why" strategy described by Arthur and his colleagues and covers such diverse activities as agreeing with or flattering one's supervisor, advocating company practices, not complaining about rules or regulations, and forming alliances or coalitions with others in the organization. More extreme and often personally unacceptable political practices can include sabotaging another person's work or spreading rumors about a colleague. In many organizations, becoming involved in organizational politics is a career strategy that is necessary for career advancement, although certain behaviors might be viewed as unethical or reprehensible. Nonetheless, regardless of the personal acceptability, engaging in organizational politics is a career strategy that is used regularly.

CAREER SUCCESS

Career success can be defined as the positive material and psychological outcomes resulting from one's work-related activities and experiences. This definition reflects both objective and subjective aspects of career success. Career success is important because it reflects an overall evaluation of the individual's career: the ultimate outcome of career development. Theoretical explanations of career success come from a range of social-science disciplines, including psychology, social psychology, organizational behavior, sociology, and economics. Numerous empirical studies have been conducted, although the primary focus of most studies is on the careers of managerial, professional, and technical workers employed in for-profit organizations. Individual characteristics, work and career-related decisions and behaviors, interpersonal processes, and organizational context and social structural characteristics have all been shown to influence individuals' career success.

Objective career success reflects career accomplishments that are objectively observable by others and can be measured in terms of the individual's level of income as well as the individual's promotion history, hierarchical level in the organization, or job title. Because these outcomes can be seen as rewards that are external to the work itself, they have sometimes been referred to as *extrinsic career success indicators*. However, these factors may also be associated with the psychological experience of intrinsic reward, since they reflect an individual's level of skill and mastery within a chosen field as well as the level of autonomy and responsibility that person exercises in the work role. Thus, objective career success is the preferred term.

Traditionally, the concept of career has been applied to managerial, technical, and professional occupations within large, bureaucratic organizations. This type of employment situation offers relatively clear career paths and a view of career advancement as vertical, linear, and bounded by membership in a single organization. The concept of objective career success seems to rely on the assumptions of this model of career progress. Many scholars have come to question the accuracy of this model for most workers, due to changes in the economy and in the strategies and structures of organizations in the last two decades as well as changes in the goals and expectations of

individuals. *Subjective career success* reflects the individual's personal feelings of satisfaction with his or her career path, career progress, or career outcomes. The concept of subjective career success is necessary because the use of only objective indicators may provide an overly narrow conceptualization of career success. Objective indicators assume that all workers place primary value on vertical career progress and are employed in large hierarchical organizations that have clear vertical career paths. The subjective career success conceptualization recognizes that a number of intrinsic career outcomes, which are not necessarily observable to others, may also be important to the individual. Intrinsic career outcomes may include, for example, interesting and meaningful work, individual autonomy, tolerable stress levels, and work with enjoyable colleagues. Extrinsic outcomes that are less tangible and observable than the objective indicators, such as job security or future employability, may also enter into one's subjective evaluation of career success. In addition, each individual may have a unique set of life goals, interests, and values that leads him or her to value specific extrinsic and intrinsic career outcomes differently when assessing personal satisfaction with a career.

THEORIES OF CAREER SUCCESS

A number of theories have been used to provide an explanation of career success. These theories explain why or how specific variables are associated with career success and provide an account of the processes involved in acquiring higher levels of salary, more promotions, or greater satisfaction from one's career. The source discipline for these theories ranges across areas of psychology and social psychology, organizational behavior, and sociology and economics and focuses on individual traits and abilities, interpersonal processes, and the constraints and opportunities posed by social structures.

Psychological Theories

Individual skills and abilities, including cognitive ability, provide one of the most basic explanations of career success. The assumptions implicit in this approach are based on the rational/bureaucratic view of organizations. According to this view, the possession of particular skills and abilities leads to higher job performance, which is, in turn, rewarded by

supervisors and the organization with higher pay, promotion, greater responsibility, and possibly more pleasant or interesting work. Much of the theoretical development in this area involves specification of the relevant skills or capabilities necessary for productive behavior in specific jobs or in managerial work located in an organizational setting.

Personality, need theories of motivation, and other individual-difference theories have also been applied to the topic of career success. The basic model relating these individual-difference approaches to career success assumes that these traits or predispositions are associated with behaviors that are appropriate or effective across a range of work situations or interact with a more narrow set of work situations or task demands to produce career success. Explanations focus on the relationship between a specific individual-difference variable and job performance, interpersonal behavior, or the nature of the individual's emotional reactions to work and occupational demands. Some personality variables take a more interactionist perspective and explain career success through the tendency either to match oneself to the situation or, conversely, to alter the situation or select oneself into situations that will produce higher satisfaction, performance, and career outcomes.

Theories growing out of the area of vocational psychology and occupational choice are also relevant to the topic of career success. The focus of these theories is on congruence or fit between various work-related characteristics of the individual and the attributes of the work environment, including job, organizational, and occupational demands and rewards. Fit is assumed to produce individual job and career satisfaction and, through job performance and employment stability, career advancement. Theories of career management extend the earlier vocational perspectives to focus on ongoing career-related activities, such as setting career goals, developing career strategies, and adapting career goals and plans to changing circumstances. These activities, centered on the development of greater career self-insight and adaptation, are thought to ultimately result in greater career satisfaction and progress.

Social Psychological Theories

A number of theoretical approaches focus directly on interpersonal behavior, social interaction, or personal relationships as a determinant of career success.

Growing out of the life span development perspective, researchers have devoted considerable attention to the impact, function, processes, and problems of mentors in facilitating career success. Mentors are thought to fulfill important functions that help their protégés to develop a clear sense of identity and commitment to their work roles and practical help planning and managing their careers. *Psychosocial mentoring* involves acting as a role model, communicating acceptance and confirmation of the protégé's identity, counseling, and friendship. *Career mentoring* involves sponsoring the protégé for challenging assignments, providing positive exposure and visibility, and coaching on work tasks and protection from politics. These activities help the protégé succeed at work tasks, overcome barriers and challenges at work, gain promotions in the organization, and adapt to the psychological demands of the job and organization.

Theories based on politics at the interpersonal level focus on the types of influence tactics and impression management strategies used by individual employees. These tactics and strategies range from rational persuasion and bargaining to ingratiation and self-promotion. This approach argues that these interpersonal behaviors influence numerous career-related decisions that indirectly impact career success, including performance evaluations, job assignments, and access to developmental opportunities. Political behavior can also have a direct effect on promotion decisions, apparently through the creation of a sense of similarity and comfort among the key decision makers. Demographic similarity or homophily can also play a role in career success through the perception of similarity between the individual and his or her supervisor or other career decision makers. Gender and race are the two demographic markers typically examined.

Sociological Theories

Social capital theory, growing out of the field of sociology, focuses on the ways that patterns of social relationships facilitate *goal-directed action*, which as applied here refers to the attainment of career success. The pattern of relationships or ties among "actors," known as the *social network*, is viewed as a channel for information and influence flows. One assumption that underlies this approach, well-grounded in empirical findings, is that the social world is "clumpy," with high rates of interaction and information sharing taking place within cliques but relatively little interaction

taking place between them. Individuals are conceptualized as strategic actors who work to develop advantageous social network positions or structures for themselves. For example, centrality in a social network reflects the fact that one has many direct or indirect (for example, "friend of a friend") relationships with other people in the network. Strong ties are intimate, frequent, mutual, and diffuse relationships with others, whereas weak ties reflect casual, infrequent, or narrowly defined relationships. A *structural hole* is defined as the absence of a tie between two contacts who are each linked to the focal individual. Structural position within the full social network, such as centrality, and structural characteristics of the individual's personal social network, such as weak ties and structural holes, are thought to provide advantages because they connect or reach a diverse range of people in different social cliques with a minimum of time and effort invested on the part of the focal actor. Networks that provide access to a diverse range of information, support, or other social and material resources are thought to lead directly (through greater influence over career decision makers) or indirectly (through higher job performance) to higher career success.

Discrimination theory explains differential career outcomes for women and racial minorities. A stereotype is the application of generalizations about broad groups to individual members of that group. Discriminatory behavior is thought to be the result of decision making based on these stereotypes. Stereotypes regarding the ability, motivation, experience, work involvement and commitment, or similarity in values and attitudes work to the disadvantage of women and minorities when career decisions are made. Differences in the gender composition of occupations and organizational hierarchies may also create additional challenges for women and minorities.

Economic Theories

Human capital theory, growing out of the field of economics, assumes that workers invest in their education and training in order to increase their productivity and thus their returns from the labor market. Education serves as a signal of individual productivity. Indicators such as work experience and organizational tenure serve as proxies for investments in training made by the individual, which should also influence productivity. Education may be most important as a determinant of selection and initial pay

decisions upon organizational entry, while training and job experience are rewarded with pay increases and promotions once the individual has been hired by the organization.

Internal labor market and *tournament theories* focus on the opportunity structure of the organization as a determinant of career outcomes. Here, the focus is not on the individual, but on the social structure in which the individual finds himself or herself. Internal labor market theory focuses on factors such as the size, growth rate, and job vacancy rates of the organization, the presence and characteristics of promotion ladders, and characteristics of the incumbent's job, such as skill level, function, or occupational orientation as determinants of individual promotions and pay increases. Tournament theory provides an explanation for certain aspects of internal wage structures and organizational promotion patterns. This theory argues that career advancement can be viewed as a series of single-elimination tournaments in which "players" compete with their coworkers for promotions or wage increases. Since players must win a given round to advance to subsequent tournaments, early career success, such as being promoted sooner than other members of one's cohort, is seen as an important determinant of eventual career attainment. Early career success can also lead the organization to sponsor the individual for specialized training and developmental experiences, which gives the individual cumulative advantage in subsequent rounds. Relative performance ranking rather than absolute performance determines the winner of a tournament, and wage differentials across organizational levels are seen as "prizes" that motivate employee effort, possibly including efforts to sabotage other tournament competitors.

EMPIRICAL RESEARCH ON CAREER SUCCESS

Individual Characteristics

Broadly conceived, this category encompasses all characteristics of individuals that have an impact on career success. Empirical research has examined individual difference variables, including cognitive ability, personality, and motivation; demographic variables, such as age, race, gender, and family structure; and acquired characteristics, such as skills and work experience. Some of these characteristics, such as gender and race, are biologically determined, although their impact on career success may have more to do

with social processes than biology. Individual differences such as cognitive ability and personality are thought to have a biological or genetic substrate. They are viewed as relatively fixed by adulthood. Still other characteristics are learned or acquired, can change over time, and may be the outcome of specific decisions and choices on the part of the individual.

Cognitive ability or *intelligence* is defined as the person's current capacity to perform mental tasks. Intelligence reflects how much information an individual is capable of processing and how quickly a person learns. Cognitive ability is consistently related to job performance across a broad range of jobs. The assumption that high job performance will lead to promotions underlies the theoretical relationship of cognitive ability to career success. Indeed, numerous studies have shown intelligence to be positively related to career achievement, especially extrinsic career success. However, intelligence may interact with other situational or personality variables to produce career success. For example, intelligence may be a more important predictor of job level for those who were less successful early in their careers. Presumably, those with early career success garnered advantages in terms of developmental experiences and social contacts that made their career success less dependent on their cognitive abilities. Likewise, intelligence has been found to predict the career success of individuals possessing MBAs only when combined with high conscientiousness, a personality trait associated with achievement motivation and dependability. Recently, promising developments have been made regarding the role of emotional intelligence at work, but not enough research has been conducted to draw a firm conclusion regarding the relationship between emotional intelligence and career success.

The basic model relating personality and motivation to career success assumes that these predispositions are associated with behaviors that are appropriate or effective across a range of work situations or that interact with a more narrow set of work situations, task demands, or organizational rewards to produce high job performance, career advancement, and satisfaction. Early research focused on *motives*, defined as an unfulfilled need that drives the intensity, direction, and persistence of behavior. A number of motivational variables, including career advancement motivation, motivation to manage, and need for power, were shown to positively relate to advancement in managerial careers. More recently, attention has shifted to

personality traits, which are relatively stable predispositions to think, feel, or behave in particular ways. Several of the “Big Five” personality dimensions have been identified as contributors to career success. Emotional Stability and Extraversion have shown the most consistently positive relationship, while Agreeableness is negatively related to career success. One study showed Openness to Experience to be positively related to subjective career success, although a different study showed Openness to be negatively related to salary. Recent work has shown how personality traits that are more narrowly defined than the Big Five, such as proactive personality and self-monitoring, are associated with specific behaviors that, in turn, lead to career success. *Proactive personality* is defined as a predisposition to taking initiative and effect environmental change. Proactive personality is related to innovative work role behavior, political knowledge, and career planning and skill updating, which are, in turn, related to career success. High self-monitors, people who monitor and control their self-expression to match the requirements of the social situation, achieve higher extrinsic career success than do low self-monitors, apparently due to the fact that they initiate relationships with mentors and, over time, come to occupy strategically important positions in the social networks of their organizations.

Several demographic factors also show a relationship to career success. Age tends to be positively associated with the extrinsic aspects of career success. This appears to be due to the accumulation of training and work experience over time, although some evidence suggests that for women, age is less strongly associated with work experience but has a direct relationship with advancement. The rate of career advancement, however, appears to slow with age, leading to the phenomenon of the *career plateau*. For example, managers who are younger than the average age of other managers at their levels have the highest expectations of advancement and the highest ratings of “promotability,” while managers who are older than others at their levels have the lowest. Nonetheless, salary tends to increase continuously with age.

Race and gender differences in career success are also apparent. Although some evidence suggests that African Americans are more likely to be promoted to entry-level managerial positions, differences in ratings of promotion potential and differences in pay have been consistently found to be to the disadvantage of African Americans. Gender is also associated with

career success, such that men have higher outcomes, especially with regard to salary and hierarchical level. Although gender is associated with a number of career-related choices, gender differences persist even when these differences are taken into account. In fact, it appears that gender interacts with many other factors discussed here such that these factors have different effects on the career success for men than for women. For example, women’s careers are less likely to benefit from moving between firms or from training, development, and work experience. One study found job-specific personality variables to be stronger predictors of career success for men, while career move decisions and occupational opportunity structures were more important determinants for women. Even the outcomes of promotion vary by gender such that women who earn the same number of promotions nonetheless find themselves at a lower hierarchical level. The effects of family structures on career success, such as having a spouse or a dependent, also appear to vary for men and women. Being single has a negative effect on success for both men and women. But for men, being a single parent has a negative effect, and having a spouse who works also has a negative effect. No such negative effects seem to apply for women.

Levels of education, training, and work experience have been consistently and positively related to individuals’ levels of career success, especially extrinsic success. The evidence suggests that educational level is not related to promotions within the firm but is related to managerial level and pay. The type of degree and even the quality of the institution granting the degree also appear to matter. Participation in on-the-job training and development activities, on the other hand, is related to promotions. This is especially true for the participation of technical professionals in managerial development activities and their promotion to initial managerial levels. Employment gaps or the use of leaves of absence are negatively related to promotions.

Work and Career Behaviors

The number of hours worked per week is positively related to extrinsic career success, especially to pay. Job performance has also shown a consistent positive relationship with extrinsic career success, especially for promotions taking place within a single firm. However, job performance appears to interact with age such that high job performance is related to ratings of “promotability” and promotions for younger (approximately

under 50 years of age) but not older (over 50) workers. Race also appears to play a role, with some studies showing that supervisors are less likely to credit internal attributions (performance based on ability and effort rather than luck) to the performance of African Americans and that African Americans receive lower job performance and promotability ratings.

The choice an individual makes regarding occupation, organization, or even a job can have an impact on that individual's career success through the level of congruence such a decision produces. Considerable evidence shows that the degree of congruence or "fit" between the person and the job and between the person and the organizational environment is related positively to job satisfaction and negatively to turnover. More limited evidence demonstrates a positive effect of fit on intrinsic and extrinsic career outcomes, presumably due to higher work performance and similarity to peers and influential decision makers in the organization. For example, one study showed that person-organization value congruence is related to career satisfaction only when the level of perceived organizational support is low or the quality of the individual's relationship with his or her supervisor is poor.

Several career self-management behaviors are also related to career success. Activities such as setting career goals and objectives, formulating career strategies and plans, and updating skills through formal or self-sponsored activities are positively related to intrinsic career success. Job relocation within the same company is frequently listed in the career histories of successful managers and is consistently related to extrinsic success. The effects of job changes across companies, or what economists call an *external labor market strategy*, appear to have a more complex relationship with extrinsic career success. For example, one study showed that White male MBA degree holders who had changed employers after receiving their degrees received higher compensation than those who had stayed with one employer, but the compensation advantage from changing employers was not experienced by female or minority MBAs. Company change may also be more advantageous for younger managerial workers early in their careers than for middle- and upper-level managers.

Interpersonal Processes

Interpersonal processes focus on the way specific social behaviors and relationships affect career

success. For example, leader-member exchange, a construct that reflects the quality of an individual's relationship with his or her supervisor, is related to objective and subjective career success. Impression management strategies are also related to extrinsic career outcomes. One study showed that a supervisor-focused strategy that makes use of ingratiation has a positive effect on advancement, whereas a job-focused strategy based on self-promotion has a negative effect on advancement.

The establishment of a relationship with a *mentor*, usually defined as a more senior manager in one's own organization who is not a direct supervisor, has consistently been found to promote both the extrinsic and intrinsic career success of the mentored individual, or protégé. Mentors engage in a range of activities either with or on behalf of their protégés. Career mentoring includes sponsorship, exposure and visibility, and coaching and protection, and psychosocial mentoring involves acting as a role model, communicating acceptance and confirmation of the protégé, counseling, and friendship. Rather than the type of mentoring activity, the amount of career mentoring provided by the mentor appears to be more strongly related to the extrinsic career success of the protégé, and both career and psychosocial mentoring have positive effects on career satisfaction, although perhaps for different reasons. Psychosocial mentoring, as a form of social support, may have direct effects on career satisfaction, while career mentoring may enhance one's feelings of control over one's career as well as extrinsic success, which, in turn, leads to greater career satisfaction. Employees may have more than one mentor; they can, in fact, maintain a constellation or network of career-supportive relationships throughout the organization. One study showed that employees with multiple supportive relationships at an organizational level higher than their own receive more career mentoring and experience greater extrinsic and intrinsic career success. Mentors at higher levels and in other organizational functions also provide greater access to organizational information and resources, which, in turn, has a positive effect on individuals' careers, independent of the amount of direct career support they receive.

Social networks appear to be important both for securing desirable jobs and for moving up once employed by the organization. Generally, larger personal networks are better. For example, the number of professional memberships and personal contacts

external to one's organization has been found to be related to the organizational level or status of the job position obtained and income. Weak ties, which reflect people to whom we have only a limited or indirect relationship, are often the crucial source of information about new job opportunities. Weak ties reach higher-status people who help one to secure a higher-status job. One's position in the informal social networks within the organization is also important to career success. Being central within the social network of the organization or subunit is related to subsequent promotion. However, maintaining a large number of ties to others requires considerable time and energy and can have a negative impact on one's job performance, which can have a negative impact on career success. Personal networks rich in structural holes are an efficient way to enjoy the information and access benefits associated with a diverse set of contacts while minimizing the time investment. Several studies have shown that such networks are associated with greater career advancement. One study showed that structural holes are associated with a more diverse set of contacts throughout the organization, which, in turn, is associated with greater access to organizational information, resources, and career sponsorship. These social benefits are, in turn, associated with higher levels of extrinsic and intrinsic career success.

Social Structure and Context

It has often been assumed that individual career advancement is determined in part by a range of structural factors, such as industry, occupation, and characteristics of the organization. Our knowledge of the effects of these factors may be limited by the fact that they have rarely been the specific focus in studies of individual career success. But at this time, we must conclude that structural factors are only inconsistently related to career success. For example, the level of an individual's career success, especially judged in terms of compensation, is influenced by the industry in which that individual works. However, the effect is inconsistent across studies, possibly due to differences in the populations sampled or differences in the coding and treatment of industry effects. The same can be said for the impact of organizational function on career success: Differences in salary or salary growth are often noted across categories, but little consistency is obvious in differences between specific functional categories. One exception may be for

general managers, who often earn more than their counterparts in positions as functional managers or professional and technical workers. Even factors such as organizational size and growth rate show no consistent relationship with career success. While larger organizations are more likely to have internal promotion systems and "fast tracks" for managerial promotion, such internal systems are not, on average, related to the rate of career advancement.

CAREER THOUGHTS INVENTORY

The *Career Thoughts Inventory* (CTI) is a theory-based assessment and intervention resource intended to improve thinking in career problem solving and decision making. The CTI measures dysfunctional career thoughts that may inhibit the ability to effectively engage in the career decision-making process. The 48-item inventory is a self-administered and objectively scored measure that can be completed by most clients within 7 to 15 minutes. The assessment is designed to be used by (a) 11th- and 12th-grade high school students choosing an occupation, choosing a postsecondary field of study, or seeking employment; (b) college students choosing an occupation, choosing a major or field of study, or seeking employment; and (c) adults considering an occupational or employment change or reentering the workforce after a period of unpaid work.

The CTI is based on *cognitive information-processing theory*, which states that effective career decision making requires effective processing of information in the four processing domains of self-knowledge; occupational knowledge; decision-making skills (comprising the subcomponents of communication, analysis, synthesis, valuing, and execution); and executive processing (self-talk, self-awareness, and monitoring and control). In addition, the CTI draws on concepts from cognitive therapy specifying that dysfunctional cognitions have a negative impact on behavior and emotions. By learning to identify potential negative thoughts, clients can learn to challenge and, ultimately, alter dysfunctional thinking, resulting in positive changes to their behavior and emotions. The CTI can be used to identify negative career thoughts that may affect the ability of individuals to accurately consider information about themselves or options as well as impede engagement in the career decision-making process. Having identified dysfunctional career thoughts, individuals can begin challenging their thinking patterns and work toward altering negative self-talk regarding career decision making. The *CTI Workbook*, which accompanies the CTI, can be used to further identify, challenge, and alter career thinking that impedes the effective processing of information necessary for career problem solving and decision making.

Instructions for the CTI are to respond to items in terms of the extent of either agreement or disagreement

with the statement. Items on the inventory reflect thoughts that people have when considering career choices. Responses range from *strongly disagree* to *strongly agree*. The total CTI score reflects the extent to which individuals engage in thinking that may inhibit effective career problem solving and decision making. Higher scores are indicative of the presence of dysfunctional thoughts that may impede the processing of information necessary to confidently make an informed career choice. Lower scores reflect few dysfunctional career thoughts that negatively influence the career decision-making process and suggest overall readiness to engage in career decision making. Information on the standardization, potential for bias, readability, reliability, and validity of the CTI is presented in the professional manual.

Three construct scales underlie the CTI: Decision-making Confusion, Commitment Anxiety, and External Conflict. Decision-making confusion is the inability to initiate or sustain the decision-making process due to disabling emotion or lack of understanding about the career decision-making process. Commitment Anxiety refers to the inability to commit to a specific career choice, accompanied by anxiety about the outcome of the choice. External Conflict relates to the inability to balance one's self-perceptions with the input from significant others, which may lead to a reluctance to assume responsibility for the decision-making process. Construct scale scores of the CTI enable practitioners to identify specific blocks that impede the processing of information. Individual items on the CTI may also be used to further assist individuals in identifying statements that limit the ability to move forward in the career decision-making process.

The CTI can be used as a screening tool, for needs assessment, and as a learning resource. As a screening tool, the instrument can be used to identify individuals who may have a low readiness for career decision making. Identifying individuals who are less ready to engage in the career decision-making process may inform the decisions of practitioners and individuals regarding the appropriateness of specific career services and programs offered. Individuals reporting more dysfunctional career thoughts would likely require more counselor assistance, whereas those reporting fewer dysfunctional career thoughts may benefit from the use of available resources and materials, with little counselor intervention or engaging in a self-help mode. For needs assessment, the CTI can

be used to identify the specific nature of dysfunctional thinking identified during the screening process. The individual's construct scores and individual items on the CTI may be of assistance in further clarifying needs assessment. Considering both the context and the complexity of the career problem identified is important as specific career concerns are explored. As a learning resource, the CTI can be used with the *CTI Workbook* to assist clients in identifying, challenging, and altering specific dysfunctional career thoughts identified as problematic in the needs assessment process. Homework assignments contained in the *CTI Workbook* may be used to reframe career thoughts that hinder the career decision-making process and to encourage the use of rehearsal and practice to alter potentially problematic statements so that they become less inhibiting.

The CTI can be quickly administered and scored, easily interpreted, and readily integrated into a variety of counseling modalities. As such, it provides a cost-effective measure for use in career services in a variety of settings. The CTI has multiple uses and can be used during an initial intake procedure or during a counseling session. The use of a limited number of scales on the CTI simplifies interpretation, enhancing its usefulness in practice. When they use it in combination with the *CTI Workbook*, practitioners have access to interpretive information about the scales and materials for test interpretation. Other components of the workbook provide opportunities to develop an action plan for using career resources and learning about the career decision-making process. All of these facets contribute to easier integration into existing programs and services.

CAREER TRANSITION

The term *career transition* has developed out of years of important and groundbreaking research and theoretical work on the process of vocational development. Beginning in the 1950s, Donald Super wrote extensively on the stages of vocational development, with each stage marking a specific "transition" in an individual's career path. These stages span an entire life and include all career-related events, from an individual's first job to the time he or she retires or stops working altogether. Each of these life events is a career transition and serves as an important milestone throughout the life span. However, much of Super's work has focused on career transitions that are expected or planned. There are numerous types of career transitions that involve unanticipated or even undesired shifts in an individual's career path. In addition, the term career transition may refer to the process by which an individual changes from one job to another within the same job family; and it may also refer to a more dramatic career change from one occupational category to an entirely different one. Finally, a career transition takes place when an employee merely shifts to a new position within the same company or organizational structure. Regardless of the type of career shift, many transitions take place in adulthood, and it is important for career counselors to be equipped to handle such midlife career changes with their adult clients.

As a result of this somewhat broad definition of career transition, it is difficult to determine how many people are actually going through such transitions at any time. However, past research has estimated that approximately 5 percent to 10 percent of Americans change occupations each year. Thus, despite the popular notion that adulthood is a time of general stability, these figures indicate that for many Americans, this is not the case. Outside of Super's work, transitions have often been described in the professional literature as "difficult" and even "traumatic" life events. Nancy Schlossberg points out that much of our thinking about transitions has come

out of crisis theory. Daniel Levinson and his colleagues were perhaps the most influential in helping to define career transitions as developmental in nature and as a turning point or boundary between two periods of greater stability. Schlossberg also stated that while the outcomes of life transitions can be negative, they are also frequently positive and may provide opportunities for psychological growth.

Two broad categories of career transitions are *voluntary* and *involuntary*. A voluntary career transition can occur for a host of reasons. For example, individuals might believe that their interests have changed since entering an occupational category, and they want to transition out of that category and into a position closer to their current interests. In addition, many individuals choose career fields based on parental wishes or the desire to earn a lot of money but may find that they are not satisfied once they have entered the occupation. In addition to factors that are negative and thus propel the person to depart from the chosen career, other career transitions result from more attractive career options that cause the individual to utilize approach behaviors in changing careers. In addition to voluntary and involuntary career transitions, Cindy Juntunen and her colleagues have also identified other career transition classifications, including (a) maintenance transitions, or changes in the individual's role without a change in the company or job title; (b) advancement transitions, or the opportunity to shift to a better position; (c) entry or reentry transitions, or the return of an individual to the workforce after a long absence; and (d) leave-or-see transitions, or changes whereby the individual makes the conscious decision to move to a new career.

Given global shifts in the economy, many workers are involved in nonvoluntary career transitions. Companies are increasingly downsizing and shipping jobs overseas, where labor costs are lower, forcing many Americans who would not have opted voluntarily for them into career transitions. This type of involuntary career change is often difficult for workers and families, especially if they reside in communities with few alternative job options. The agricultural crisis of the 1980s in the midwestern United States created many poignant examples of involuntary career change, when farmers and farm families, many of whom had been on family farms for generations, were forced into career transitions. The continued shift from an agrarian and manufacturing society to one based on service and technology means increasing career change for

workers. Workers who previously held stable employment now possess considerably less job security as a result of the skills of newer workers who may have more recent technological training.

In many ways, career transitions have become much more normative as the labor market requires a more fluid and dynamic employment pattern. There is now the expectation that workers will change jobs more frequently, and the image of "career changers" is also evolving. As Edwin Herr and his colleagues have pointed out, career changers previously were seen as having character or personality flaws that caused them difficulty in maintaining a position. They were often seen as malcontents or somehow lacking in the skills necessary to function in a given position. With increasing normalcy of career change, these perceptions are rapidly changing, and the process of career change is seen as an adaptive development stage.

Recent studies on adult career changes indicate that the career change is intricately connected with the individual's psychological adjustment. The process of adaptation is important to the psychological well-being of individuals who are going through (or have recently experienced) some kind of life transition, including those that are career related. Schlossberg has defined *adaptation* as a process during which an individual moves from being totally preoccupied with integrating the transition into his or her life. While some individuals may adapt quite easily to career transitions, others may have difficulty adapting and may be at risk for depressive or anxious symptoms. In fact, in a recent study, the majority of career changers coming to a university-based career center had levels of depression and anxiety in the distressed range.

A number of factors may contribute to an individual's ability (or inability) to adapt successfully to a given career transition. Schlossberg has asserted that the adaptation process may differ according to the type of transition as well as the individual's personal resources. In other words, characteristics of the worker and of the transition interact to predict an outcome. Characteristics of the transition, for example whether the change was expected or abrupt or whether it was voluntary or involuntary, affect how the person perceives the transition and progresses through it. Personal factors that can affect adjustment to transition include the individual's values, self-efficacy, and emotional responses. In addition, many adults engaged in midlife career transitions may have family responsibilities, such as caring for children or partners.

This added factor has the potential to serve as either support or barrier but will, regardless, have an effect on an individual's ability to adapt to a transition. Finally, demographic and environmental factors are important to consider in assessing how well adults may adjust to midlife career transitions. For example, degree of financial freedom and socioeconomic status may play a role in the transition process, again serving as either support or barrier depending on the individual's specific circumstance. Similarly, the individual's racial/ethnic background, gender, and sexual orientation may either help or hinder the adjustment to a new career, whether it is planned or unplanned.

When one considers the numerous and diverse factors that contribute to an individual's psychological well-being during the career-transition process, it is evident that he or she could use additional support and guidance. Specifically, it seems that during times of career transition, many people could benefit from the support provided by counselors. Counselors can help individuals identify the strengths or resources they bring to the career transition and help them overcome the barriers and obstacles they may be experiencing. Among the many tools used for counseling adults in career transitions, one important assessment is the Career Transition Inventory. Through the development of this assessment, the authors sought to create a tool that would help counselors identify resources that could aid clients in career transitions. This 40-item inventory consists of five factors: (1) readiness, (2) confidence, (3) control, (4) perceived support, and (5) decision independence. By identifying his or her strengths, the client could find it easier to progress through the career change.

Many societal factors indicate that the pace of career transitions, both voluntary and involuntary, will accelerate in the future. Understanding the varied types of transitions, the reasons for relative ease or difficulty in moving through them, and the tools available to assist people in their transitions is vital to the field of career development.

CAREERS AND HEALTH

The link between social and occupational standing on the one hand and health on the other has long attracted interest. Michael Marmot has investigated this issue for over 30 years, a program of research for which he received a knighthood in the United Kingdom. In a diverse and broad collection of studies, Marmot and his colleagues have shown that health follows a social gradient, such that the higher one's position in the social-status hierarchy, the better one's health. Simply stated, status has health benefits for a broad range of problems, including heart disease, kidney disease, stroke, lung cancer, infectious diseases, suicide, and violence. This holds true everywhere researchers have looked, including samples of British bureaucrats, Oscar-award-winning actors and actresses, and Swedish PhDs. Marmot has argued that autonomy and the opportunity for full social participation are

central to understanding the social gradient in health and that one's well-being and longevity are intimately intertwined in these factors. Specifically, he shows that people of lower status succumb to illness more often and to death more quickly, not because of poorer habits, diets, medical care, or genes but because they have less control over their lives and their social engagement.

We commonly categorize society and the world into the rich, the poor, and those somewhere in the middle. For the unfortunate individuals who find themselves in the poorest segments of our social world, their social position can have dramatic implications for nutrition, disease, and longevity. In itself, however, this situation is not the social gradient of health, nor is it simply a product of the division between rich and poor. The social gradient of health delineates the hierarchy much more finitely. People with postgraduate education generally have better health and longevity than people with undergraduate education, who generally have better health and longevity than people with high school education. Likewise, doctors are likely to have fewer health problems than skilled workers, who are likely to have fewer health problems than unskilled workers. The same can be said when people are grouped by income, by their parents' social class, or even by height; higher rankings equate to superior health. Thus, regardless of where people fall in the status hierarchy, they will typically have better health than those people lower in the hierarchy and worse health than those people higher in the hierarchy. This trend is what Marmot has called the "status syndrome," and this entry explains that it has important implications and lessons in understanding the relationship between *careers and health*. For this reason, we first need a better understanding of the status syndrome.

Could the status syndrome be the result of individual behavior? Is the status syndrome the result of people's free choice to smoke cigarettes, drink alcohol, eat unhealthful foods, and refuse to exercise? Marmot has shown that the lower people find themselves in the gradient, the more undesirable are their health behaviors. Could this be a function of self-destructive behavior? Marmot has discounted this argument. First, research shows that individual risk factors account for only about a third of the health gradient. For example, at any risk factor level, the risk of heart disease is greater for smokers with lower social rankings and lesser for smokers with higher

social rankings. Second, Marmot has questioned whether unhealthy habits may actually be autonomous choices made by socially deprived individuals who desire some form of control over their lives.

Could the status syndrome be genetically predetermined? Do people end up in life (and by extension, in certain careers) where they do because of who they are, making their social conditions indirectly related to the social gradient of health? While obviously not discounting the role of genetics, Marmot thinks not. Heredity clearly accounts for individual differences in intelligence; however, the degree to which genetics accounts for overall group differences is minimal. Accordingly, genetic differences do not sufficiently explain the gradient; environmental factors must help determine a person's socioeconomic position in the hierarchy of health. Because socioeconomic status is so closely related to occupational class, recognizing this macroconnection is essential to understanding the link between people's careers and health.

Could reverse causality be a plausible explanation, such that good health results in status and success, leading to high social rankings? Do the healthy prevail over the unhealthy? Health-related social mobility actually blurs the social gradient in health, making it appear less steep. Although healthier people are more likely to be upwardly mobile and unhealthy people are likely to be downwardly mobile, a distinct social gradient still exists after accounting for this tendency. Moreover, as healthy people move to a higher social status level, they are still less healthy than the people already occupying that position, and thus, they bring down the average measure of health for that status level. Similarly, as less healthy people move to lower ends of the status hierarchy, they are still healthier than the others already in that group, and therefore, they raise the average level of health for that group. Accordingly, health-related social mobility causes the status syndrome to be understated.

Thus, because bad habits, genetics, and health-related social mobility cannot explain the social gradient of health, Marmot has considered three socioeconomic conditions of societal inequality, namely, money, power, and status, and their relationships with health. Obviously, more money can benefit health for obvious reasons, especially for poorer people, and poverty reflects the inability to lead the lives people wish to lead and to fully participate in society. But there is more to it than money. An equally important distinction is between stress and challenge.

Stress operates through five characteristics, namely, lack of control, weak social support, unpredictable outcomes, absent outlets, and threats to status. This is not to be confused with the challenge of intense decisions, busy schedules, or high demands. Stress concerns the lack of control over the present and the future and the path in between. In the workplace, this describes the situation of lower-level employees, not the stereotypical, highly stressed upper-level managers. High-level executives may well experience great demands, but they have more control in meeting those demands. Thus, having money, status, and power or, alternatively, occupying a position high in the social hierarchy gives people the ability to direct their lives freely and limit uncontrollable stress. This kind of control, or more generally, these social conditions, may buffer individuals against the adverse effects of stress. How do social conditions influence the status syndrome? For Marmot, people lower in the hierarchy are in psychological states of uncontrollable stress more often than those people higher in the hierarchy, and this has negative health effects. Marmot believes that both acute and chronic stress contribute to a multitude of physical diseases.

A second psychological culprit is the feeling of social isolation. Like health, supportive social relations and networks follow a social gradient. Social support is positively related to good health and well-being; however, moving down the status hierarchy, less access to supportive social relations leaves lower-status individuals more vulnerable to a broad range of illness and causes of death. Consequently, both a lack of control and full social engagement underlie the social gradient and thus have important implications for career development and health. The following section discusses the roles that work and careers play in generating social hierarchies and health inequalities.

CAREERS, CONTROL, AND SOCIAL ENGAGEMENT

Occupation is a central determinant of social status or class, and in the workplace, job characteristics are stratified by status, whereby higher-status workers experience more favorable job characteristics, such as job variety, autonomy, and more physically hygienic conditions at work. Similarly, job characteristics are also associated with worker health and well-being. For example, a model developed by Robert Karasek argues that low levels of job control combined with high levels

of job demands lead to a number of stress-related physical illnesses, such as coronary heart disease. Likewise, employee health and well-being can improve with increased control and participation on the job. Conversely, working characteristics, including work overload, job insecurity, and low control, negatively influence workers' physical health. More broadly, research studies have shown a significant association between mental and physical ill health and six workplace pressures, namely, factors in the job (e.g., hours of work, decision-making authority, job variety); organizational role (e.g., lack of power, role ambiguity, role conflict); relationships at work (e.g. support, isolation); career development (e.g., unclear expectations, over- or underpromotion); organizational climate (e.g., organization structure or design, lack of communication); and home/work pressures.

More recent research has shown that both physical and psychosocial job characteristics play a significant role not only in predicting health outcomes but also in explaining the relationship between socioeconomic status and health. After controlling for a number of lifestyle differences (e.g., smoking, body mass, exercise) and the social origins of low- and high-status individuals, job characteristics, such as physical cleanliness on the job, working hours, autonomy, postsecondary training requirements, workload, cognitive demands, and job challenge still help explain the social gradient in health. These findings illustrate the centrality of occupations and workplace experiences in explaining how health inequalities are created. Accordingly, researchers have argued that workplace and job design can be an important vehicle for understanding and reducing societal-wide health disparities.

The social gradient may also be manifest occupationally, helping us understand the link between careers and health. People's choice of occupations and their associated characteristics are not the only "work" factors that determine their social status. Career paths also have a number of implications for a person's position in the social gradient of health. Patterns of work experiences, such as upward and downward mobility, mobility in and out of the labor force, and transitioning into retirement, are also integral to understanding the relationship between socioeconomic status and health. In general, researchers have considered career progression in explaining the relationship between social class and health, noting that occupational demotions have a negative impact

on employee psychological well-being due to the loss of perceived status and opportunity.

Occupational mobility also exerts consequences for status-related health risks. Although occupational classes themselves show a social gradient in mortality, within each class, mortality risks also differ by career paths and development. Specifically, individuals who experience upward occupational mobility to more favorable, higher-status jobs manifest lower mortality risks than individuals remaining immobile in their occupational classes of origin. Generally, greater levels of autonomy, variety, and physical cleanliness will characterize these higher-status occupations. The reverse is true for the downwardly mobile: Workers moving to lower-status positions experience higher mortality risks than their counterparts remaining stationary in their original occupational classes. In this case, downward occupational mobility is associated with an increase in working characteristics that are negatively related to health, such as reduced control and work overload.

Individuals who are promoted to a higher occupational status, however, typically do not achieve the same low-mortality risk levels as individuals already occupying the higher social class, and vice versa. Overall, when people's careers progress or regress to a new occupational status, their mortality risk adjusts to a level that is between the average risk level of the occupants in the class left behind and the average risk level of the occupants in the class joined. A similar trend exists for careers and health as measured by incidents of cancer, where lack of career progression is significantly related to a greater risk of cancer (including cancer in the upper respiratory and digestive track and the lungs) after accounting for various other risk factors. Accordingly, research findings show that although socioeconomic status is clearly important in predicting health, career development and upward career mobility are equally important explanatory factors.

Career movement in and out of the labor force is also predictive of health inequalities, and such moves can be a function of unemployment (and reemployment) or of retirement. Unemployed individuals have lower mental and physical well-being, including life satisfaction, self-esteem, and marital and family satisfaction, compared with employed individuals. The unemployed also have higher depression and mortality. In fact, feeling insecure about one's job or employment has negative health implications even

before employment status changes. Researchers have argued that this health effect occurs because unemployed individuals lose the positive benefits of employment influencing health, such as the opportunity for control and skill use, externally generated goals, variety, environmental clarity, physical security, financial income, socialization, valued social position and status, a feeling of purpose, and time structure.

Marmot has placed specific emphasis on the loss of status, the uncontrollability, and the unpredictability of job loss when considering its health consequences, arguing that stressful situations are defined by these factors. In addition, unemployed individuals' well-being is mediated by social support, such that unemployed people who feel socially supported experience greater well-being than those who do not. Both the quantity and the quality of the support are critical. While unemployed individuals typically have similarly sized social networks compared with employed individuals, their social support comes predominantly from family members who provide emotionally based support, as opposed to friends and colleagues. This type of support can leave the unemployed feeling more vulnerable and socially isolated and therefore lead to further stress. Thus, *unemployment*, by definition the loss and lack of one's occupational role, is ultimately characterized by a loss of control over one's life and the ability to fully participate in society, two factors underlying the social gradient in health. On the other hand, a positive relationship exists between reemployment and well-being, mental health, and physical health. Longitudinal data show that individuals experience declining well-being as they move from employment to unemployment but experience increasing well-being as they move from unemployment to reemployment. Reemployment provides positive benefits of work that are integral to the status syndrome, including increased status, control, social support, and predictability.

The relationship between socioeconomic status and health is not static throughout a person's life. Instead, research has shown that the social gradient in the incidence of cancers is most volatile in the beginning of an individual's career and changes less after midcareer. However, the social gradient in health is present not only during a person's working life. Socioeconomic status at middle age has been found to predict morbidity into old age, and, in general, socioeconomic health differentials persist well into a person's retirement

years. For example, mortality differences between people of high and low employment status have been shown to increase after retirement age. Although evidence conflicts as to whether health improves or deteriorates after retirement, a number of key patterns have appeared. First, people's transitions into retirement are important predictors of their postretirement health. People who have control over the decision to enter retirement, and its timing, experience better health than do people who are forced into retirement. Second, environmental characteristics that motivate the social gradient in health also mediate the relationship between retirement and well-being. For example, retired individuals who perceive that they have the opportunity for personal control, variety in demands and opportunity, environmental clarity, physical security, social or interpersonal contact, and valued social position have better well-being or life satisfaction than do retired individuals who do not experience these benefits. Accordingly, people's careers have implications for their status-related health not only during early or midcareer, when status changes most frequently, but well into their transitional and retirement years as well.

In conclusion, therefore, Marmot has delineated a unique perspective of the social causes of health, explicitly underscoring the role of work in generating health inequalities. This entry highlights various insights and their relevance to career development and health in a number of ways. First, as a macrophenomenon, the social gradient in health is an overarching explanation for societal and occupational health. Second, although job characteristics are thought to contribute to socioeconomic health inequalities, career paths themselves show a gradient in health. In particular, people who have upwardly mobile careers have better health and mortality than do people in the same social class with immobile careers. Finally, autonomy and social participation not only mediate the relationship between socioeconomic status and health but also help explain the relationship between health and other career factors, such as progression, unemployment, and retirement.

CENTER FOR CREATIVE LEADERSHIP

The *Center for Creative Leadership* (CCL) is an internationally recognized resource for understanding and expanding the leadership capabilities of individuals and organizations from across the public, private, nonprofit, government, and education sectors. A nonprofit educational organization founded in 1970, CCL's mission is to advance the understanding, practice, and development

of leadership for the benefit of society worldwide. It pursues this mission through leadership development programs for midlevel to senior managers, leadership research and publication, and networks and events aimed at building learning communities.

CCL'S ACTIVITIES

One of the core activities of CCL is feedback-intensive leader development programs. CCL defines *leader development* as the expansion of a person's capacity to be effective in leadership roles and processes. Feedback-intensive programs provide individuals with a comprehensive assessment of their personal preferences, their capabilities, and how they are perceived by others. The goal is to gain a more in-depth understanding of one's strengths and weaknesses as a leader and to use that understanding to set and work toward goals for enhancing one's effectiveness and satisfaction. The programs make use of assessment tools (e.g., personality measures, 360-degree feedback instruments, value inventories), models and frameworks for understanding leadership work, experiential exercises and simulations, and peer and staff coaching.

CCL offers two types of leadership development programs: *open enrollment* (scheduled programs open to any leader and thus made up of participants from multiple organizations) and *contract* (programs for a single organization that are often customized for that organization's specific needs and context). The various open-enrollment programs are for the most part targeted to address the needs of different populations. For example, there are programs for early career leaders, for top-level executives, for women, for team leaders, and for individuals leading organizational transformations. Increasingly, contract programs are part of longer-term leadership development processes that include activities such as ongoing coaching, action learning projects, and online learning.

Research is another core activity. Historically, research at CCL has focused on individual leader development and on leadership and diversity. One influential study examined key events in managerial careers and produced the book *Lessons of Experience*. This study found that the majority of management development occurs on the job through assignments, relationships, and hardships. Formal development programs were found to play an important and distinct role in leader development, but they are not a substitute for on-the-job experiences.

Another important research thrust looks at issues in developing women and people of color—often referred to as “glass ceiling” research. Recent research in the diversity arena has examined the choices and trade-offs made by high-achieving women and the development of global leaders.

CCL also facilitates a number of networks, councils, and learning communities that bring together alumni, donors, faculty, practicing leaders, and leaders of thought from around the world. These groups provide a setting for members to learn from one another, develop relationships, and gain energy and support from others working in the leadership field.

CCL'S LEADER DEVELOPMENT MODEL

Integrating knowledge developed through its programs, research, and learning communities, CCL has articulated a model that guides its approach to leader development. A key component of the model is developmental experiences. Experiences are developmental to the extent that they provide individuals with assessment, challenge, and support. *Assessment* consists of the formal and informal processes for generating and delivering data about an individual: What am I doing well? Where do I need to improve? How do others see me? How am I doing relative to my goals? What's important to me? *Challenge* is the aspect of experience that pushes people out of their comfort zones, creates disequilibrium, and calls for enhanced knowledge and skills, new approaches, and more developed ways of understanding oneself and the world. *Support* helps individuals deal with the difficulties and struggles of a learning experience and helps them maintain a positive view of themselves as capable, valuable people who can learn and grow. Support often comes from other people but can also come from organizational cultures and systems.

The CCL model of leader development proposes that development is maximized over an individual's career to the extent that he or she (a) has the opportunity to engage in a variety of developmental experiences and (b) has a high ability to learn from experience. The ability to learn is a broad concept incorporating motivational factors, personality factors, and learning tactics. The model also recognizes that any leader development process is embedded in a particular organizational context: the organization's business strategy, its culture, and the various systems and processes within the organization. This context

shapes the leader development process: how it is focused, how well integrated and systemic it is, and who is responsible for it.

Leader development is aimed at enhancing the capabilities individuals need to be effective in leadership roles and processes. These include self-management capabilities (how individuals manage their own thoughts, feelings, and actions), social capabilities (how individuals work with others in a social system), and work facilitation capabilities (how individuals facilitate the accomplishment of work in organizational systems).

Finally, the model suggests three broad strategies for enhancing leader development: (1) create a variety of rich developmental experiences that provide assessment, challenge, and support; (2) develop people's ability to learn from experience; and (3) build an organizational system that supports and values development.

ORGANIZATIONAL INFORMATION

CCL is headquartered in Greensboro, North Carolina, and has campuses in Brussels, Colorado Springs, San Diego, and Singapore. Its work is carried out by 500 employees and a network of adjunct staff. Approximately 20,000 leaders participate in CCL programs and events each year. More information about the organization can be found at <http://www.ccl.org>.

CHILD CARE PRACTICES

The child care market was largely irrelevant to professional careers during the historical period when most professionals were White men with wives in the home performing unpaid work. Beginning in the 1960s, the large-scale entry of women into higher education and professional labor markets changed this situation. That change occurred in large measure because women continue to perform most unpaid child care in the home, while professional careers often demand long hours of paid work during the prime child-rearing years. Work and family therefore often appear as competing responsibilities.

Formal child care can serve as a bridge between these competing demands, permitting women to make commitments to both professional careers and children. However, it has been estimated by the National Council of Jewish Women that 80 percent of child care centers in the United States are of mediocre to poor quality, undercutting the value of this bridge.

Partly as a result of the shortfall of quality child care, many young women continue to view professional careers and family commitments as mutually exclusive. Professional women are less likely than professional men to have dependent children in the home, thereby sacrificing family for career. By the same token, many women who wish to rear children hold high levels of formal education yet do not enter professional careers, sacrificing career for family. These outcomes are unfair in the sense that men are rarely forced to choose between family formation and career; these outcomes are also inefficient, since much valuable talent and human capital are lost when parents abandon careers for family.

Beginning in the 1970s but with faster growth during the 1980s and 1990s, some corporations responded to these issues by developing on-site child care centers. Such centers are typically expensive on a per-child basis, in part because utilization rates are difficult to predict except in very large establishments. The single most important predictor for the implementation of on-site child care is the proportion of professional, technical, and managerial employees in the workplace. The long hours required by professional careers help explain the connection between these occupations and on-site child care. In addition, however, it seems likely that the high wages provided to many professionals and managers help make

on-site child care economically viable. The flip side of this economic argument is the frequent complaint with regard to on-site child care that it is too expensive for nonprofessional employees to afford. In part due to the latter dynamic, on-site child care remains relatively rare.

More common among corporations are limited child care subsidies and programs providing referrals and other information relevant to the search for formal child care arrangements. These programs facilitate the employee's ability to meet work responsibilities and may be associated with higher-quality child care.

An alternative route to the provision of child care is for parents to reduce their hours of employment while children are young, returning to full-time employment as children grow. Relevant reduced hours options attracted the term *mommy track* during the 1980s, a term denoting the fact that men rarely reduced working time in response to family responsibilities and denigrating the women who chose not to work long hours for their employers.

Regardless of these problems, the time arithmetic of professional careers and child care tends to drive researchers and policymakers back to reduced-hours options. If professionals are typically present in the workplace for 50 to 60 hours per week and spend another 10 hours per week commuting, the complete replacement of parenting time by paid providers involves 60 to 70 hours per week of formal child care. Most parents do not view such long hours of child care in a positive light, so they strive to reduce working time in one fashion or another.

Somewhat belatedly, men have also responded to these issues. Fathers in dual-earner couples increased their time devoted to child care by 6 hours per week between 1981 and 1997, such that men were performing 46 percent of all parental care by the end of the period.

It seems likely that some mixture of private market, mother, and father care will continue to provide the best options for professionals striving to simultaneously make and meet family commitments, perhaps with the help of limited tax subsidies from the government (i.e., Dependent Care Assistance Programs) and subsidies from employers. For young professionals seeking quality child care, the increasing acceptance and expectation of accreditation for child care centers by the National Association for the Education of Young Children must be viewed as a positive development. For women, a less positive note is sounded by

the emergence of discriminatory behavior among employers against mothers, particularly against mothers attempting to sustain professional careers.

CHURNING OF JOBS

Churning the workforce is an approach to talent management that relies on use of the outside labor market to meet changing skill needs. Specifically, employers needing new skills, knowledge, and abilities, perhaps most often to meet changing demands from product markets, acquire them by hiring employees from the outside market. The employees they currently have, whose skills are no longer needed, are then laid off.

Churning as a human capital strategy represents a sharp contrast to what had been the dominant model for accommodating change in the workforce: retraining and relocating existing employees to meet the demands for new and different skills and internal development of skills more generally. Lifetime employment models that were popularized in Japan and also operated in the United States were essentially based on this retraining and relocating approach.

Evidence of the prominence of the churning approach comes from several indirect sources: high

levels of layoff rates, higher among white-collar and managerial employees than among other occupation groups even when overall economic indicators are strong; growing use of search firms and job boards that facilitate outside hiring; and growing turnover across organizations. There are also some direct sources of information: Only 3 percent of large corporations in the United States reported to the Conference Board in the mid-1990s that they still offered job security to their employees, although they had previously; only 35 percent of U.S. establishments in the 1997 Census National Employer Survey reported that they retrained workers who were at risk of layoff because of obsolete skills.

Several factors appear to have increased the use of the churning strategy: the notion that the pace of change that businesses must accommodate has increased over time and that it is no longer possible to meet those demands by internal restructuring; the labor market infrastructure that makes it possible to hire from the outside (e.g., job boards, search firms) has grown vastly; and at least some employees in large corporations are more resistant to geographic relocations that might allow them to stay in the same corporations, albeit in different positions.

At the extreme, the churning approach raises interesting questions about what constitutes a firm and its competencies. Especially for companies whose competencies seem strongly related to knowledge or human capital, the boundary of a firm and its competencies seems less clear if all the talent is hired from the outside market and is changed on a continual basis. Silicon Valley companies would seem to fit this model, and some say that their true competency is the ability to assemble the right talent in ways that essentially reinvent the firm.

There has been a long academic discussion about the merits of the churning approach, especially the negative consequences for employment security. A number of alternative models have been offered to allow employers to achieve high levels of flexibility in response to changing demands while preserving something like stability in employment relationships.

Perhaps the best known of these alternative arrangements is the *core-periphery model*, based on the notion that firms have certain core resources and capabilities that are important to protect. In this case, those resources refer to people. The *core* refers to employees whose skills are crucial to the organization and difficult to replace. Ups and downs in business

demand are then accommodated by shifting all the fluctuations in employment to groups other than this core, what one might think of as “peripheral workers,” whose skills are less crucial and easier to replace. A good example is a professional services firm, such as a law firm, in which partners represent the core knowledge and skills of the firm, and the associates, counsel lawyers, or other nonpartner lawyers are hired to meet peak demand and then let go if business falls off.

Although the logic of core-periphery models is appealing, there is little evidence that organizations make much use of it. Part of the reason is that the variations in demand to which organizations must respond are changes not simply in the volume of products and services they produce but also in the types of products and services. With the latter, it is more difficult to think of a permanent “core.”

An alternative model, which has been especially prominent in Europe, sees *functional flexibility*, the ability to reassemble existing competencies in new ways, as a substitute for *numerical flexibility*, the ability to respond through hiring and layoffs. Exactly what practices and policies constitute functional flexibility may not be completely clear, but teamwork, employee involvement, and other systems of work organization that provide opportunities to respond to change quickly appear to be important components. Here, the evidence is more supportive, especially case studies that show that the capacity for internal adjustments and flexibility may reduce the need for hiring and layoffs. There is also evidence, however, that firms may make use of both functional flexibility and numerical flexibility to accommodate the changes in their markets.

The churning approach to human capital is clearly tied to broader changes in the economy that demand more rapid updating of overall business strategies and underlying competencies. It has both helped drive and responded to related changes in employment relationships, such as declining loyalty between employers and employees and the rise of infrastructure to facilitate outside hiring. Many believe that the consequences for firms have been positive, allowing them to restructure more quickly and in more dramatic ways. The consequences for employees, however, have been mixed. On the upside, workers now benefit from greater opportunities associated with more hiring across companies; on the downside, more face layoffs because of mismatches with changing firm needs.

There have been two policy responses to help employees address the downside of the churning strategies. The first, which is associated with European perspectives, is simply to limit an employer's ability to lay off workers, especially when the motivations concern demands for new competencies and not poor performance or declining demand. Restricting the ability to lay off, in turn, reduces the ability to hire from the outside. The goal of these restrictions is to force firms to meet their needs for flexibility through internal restructuring. The second response, which is associated with the U.S. system, takes the exact opposite approach in trying to make it easier for employees to move across employers. Here, policy interventions include making pensions and other benefits more portable, so that it is easier to change jobs, and giving workers more information about employment prospects and related skill requirements to help them make better decisions. These two different perspectives are at the core of economic policy differences between the United States and Europe.

CIRCUMSCRIPTION AND COMPROMISE

Vocational choice is a search for a life career that fits one's concept of self, both socially and psychologically. According to *circumscription and compromise* theory, four developmental processes guide this person-job matching process during the first two decades of life: *cognitive growth*, age-related growth in cognitive ability; *self-creation*, increasingly

self-directed development; *circumscription*, progressive elimination of one's least favored vocational alternatives; and *compromise*, accommodation to constraints on implementing one's most favored alternatives.

COGNITIVE DEVELOPMENT

Children progress from thinking intuitively in the preschool years to concretely in the elementary years to abstractly in adolescence. With age, they become able to take in, understand, and analyze larger bodies of information, make subtler distinctions among people and occupations, compare them along more dimensions, infer internal states, and discern patterns in their own behavior.

By adolescence, most young people perceive the same complex social structure of work that adults do, specifically, a cognitive map of occupations that arrays jobs according to sex type and prestige level and, within that array, according to field of work. Young people develop increasingly individualized self-concepts, however, as they become better able to discern who they are as unique psychological beings. This learning process is inherently complex. The challenge for counselors is to enhance learning by reducing the complexity of the information they provide and to accommodate counselees' differences in ability to learn and comprehend.

Self-creation

Children are born into a preexisting occupational world that can be observed and explored, but none is born with an already-formed self. Our personalities, interests, and other enduring traits are not stamped in by either our genes or our environments. Rather, those traits develop and are revealed only via experience as we daily engage the world around us. Each self is unique because both the genotypes and personal environments that jointly shape the flow of personal experience are unique. An inner "genetic compass" is the core of our individuality, however, because it quietly but incessantly inclines us to take some paths rather than others, be attracted to or repelled by certain activities, seize different opportunities, respond differently to the same environments, and create different social niches for ourselves when given a choice. Children gain greater control over their lives as they mature, thus becoming—or having the potential to become—more active agents in their own self-creation.

Vocational interests represent constellations of genetically influenced personality traits and abilities. The activities that would activate, exercise, and consolidate these constellations as distinct vocational interests are not available to people of all ages or in all places, so many adolescents lack sufficient experience to know what their vocational interests and talents might be. They are thereby less able to recognize ill-fitting expectations and circumstances, break away from them, or fashion lives more compatible with their own interests, abilities, and goals. The counseling challenge is thus to optimize experience, by both providing broad menus of vocationally relevant activities for young people to sample and promoting self-agency in seeking out formative experiences.

CIRCUMSCRIPTION

Early vocational choice proceeds as a process of elimination. As children become aware of occupational differences in sex type, then prestige, and finally field of work, they successively rule out more sectors of work as unacceptable for someone like themselves.

Stage 1: Orientation to Size and Power (Age 3-5)

Children in the preschool and kindergarten years begin to classify people in the simplest of ways: as big and powerful versus little and weak. They also begin to recognize occupations as adult roles and cease reporting that they would like to be animals or fantasy characters when they grow up.

Stage 2: Orientation to Sex Roles (Age 6-8)

Children at this age have progressed to making simple distinctions among people and jobs, primarily because of their most concrete, visible attributes. The most obvious and salient distinction for them is sex role, which they see simplistically in terms of sex-appropriate clothing and behavior. They start to eliminate occupations that seem incompatible with their gender self-concepts.

Stage 3: Orientation to Social Valuation (Age 9-13)

Children have now become acutely aware of differences in social status: in particular, which occupations

are higher up the social ladder, which personal attributes (especially academic ability) help individuals get higher-level jobs, and what the minimum threshold is for being thought successful in their social circles. They eliminate from further consideration all occupations that are too low in prestige for someone like themselves, as well as all that seem out of reach in terms of ability or effort required. These choices may not be wise, but they tend to be permanent unless challenged in some way.

Stage 4: Orientation to Unique, Internal Self (Age 14 and Older)

Children take their preferred social selves—their self-defined *social space*—for granted by adolescence. This social space is much circumscribed, but it becomes more densely populated with occupational alternatives as adolescents begin to recognize how diverse work is across different fields of work. They are now also better able to make out their own interests, values, and goals, and they struggle to determine which field of work best fits their emerging pattern of interests and talents. Circumscription at this stage thus involves rejecting incompatible fields of work (for example, Realistic or Investigative fields, from John Holland's theory).

The challenge for counselors is to prevent or reverse inappropriate circumscription by promoting *self-insight*: specifically, by helping young people to inventory and integrate relevant information about themselves and promoting a sound conception of which career lives would best fit and satisfy the developing self.

COMPROMISE

Not all suitable choices are accessible, so individuals must often compromise. Theory predicts that individuals will opt for work in a different field within their social space rather than compromise either prestige or sex type of work. If no such work is accessible, they will opt for lower-level work before seeking jobs that conflict with their gender self-concept, because the latter is more central to one's self-concept.

Accessibility is limited by labor market conditions, the availability of appropriate training, and many other factors over which the person has no control. It is also limited, however, by the cost and effort of locating current opportunities for education, training,

and employment. Individuals increase the accessibility of their preferred options when they seek information more widely and in a timely manner, are more persistent and optimistic, and take steps to increase their competitiveness for available opportunities. The counseling challenge is to minimize unnecessary compromise by optimizing *self-investment*, specifically, by helping young people assess the accessibility of their preferred education, training, and employment and by promoting self-agency in improving their own opportunities, qualifications, and support network.

CIVIL RIGHTS ACT OF 1964

The *Civil Rights Act of 1964* was passed by President Lyndon B. Johnson in the wake of the assassination of President Kennedy and as the civil rights movement continued its struggle for social equality. Although a bill prohibiting discrimination in the workplace had been introduced in Congress every year since 1943, the filibuster and other political tools had kept the proposed bills from being passed, and the same result seemed certain after President Kennedy introduced

his highly controversial antidiscrimination Civil Rights Act in 1963. However, President Johnson was able to gain the support of influential senators in support of a version of the bill that was even stronger than what Kennedy had proposed. On June 10, 1964, after 57 days of debate due to a well-planned filibuster by the bill's opponents, the bill's supporters were able to amass the requisite two-thirds of the Senate to vote to end the filibuster, and the Civil Rights Act of 1964 became law. The act's constitutionality was immediately challenged and upheld.

The Civil Rights Act of 1964 is a comprehensive piece of legislation banning discrimination based on race, color, religion, sex, or national origin in numerous aspects of society, such as public schools and public accommodations, and a full discussion of the significance of the act could take volumes. However, as only Title VII is relevant to career development and issues in the workplace, it will be the sole focus of this writing.

Title VII of the Civil Rights Act of 1964 applies to a wide range of employers due to its broad definition of *person*, which in part is a key component to the definition of *employer*. The definition of person includes, for example, governments, government agencies, labor unions, partnerships, corporations, mutual companies, trusts, and receivers. An employer must have at least 15 employees to be covered by the act.

Title VII was aimed at both prohibiting intentional discrimination and widening the door to employment opportunities. Title VII makes it "an unlawful employment practice for an employer . . . to fail or refuse to hire or to discharge any individual or otherwise discriminate against any individual with respect to his compensation, terms, conditions, or privileges of employment, because of such individual's race, color, religion, sex, or national origin." It also prohibits employers from engaging in practices "to limit, segregate, or classify his employees or applicants for employment in any way which would deprive or tend to deprive any individual of employment opportunities or otherwise adversely affect his status as an employee, because of such individual's race, color, religion, sex, or national origin."

The language of Title VII has provided employees who believe they were subject to discrimination with an arsenal of legal claims and numerous methods of proving them. Two of the most commonly used claims are (1) an employee's claim that he or she has suffered from disparate treatment and (2) its cousin, adverse or

disparate impact. Under the *disparate-treatment theory*, the employee alleges that he or she has been treated differently from other employees due to his or her protected characteristic of race, color, religion, sex, or national origin. Disparate-treatment claims can be further divided into single-motive claims and mixed-motive claims. In both types of cases, the employer argues that the allegedly discriminatory act was based on a nondiscriminatory reason; in a *single-motive claim*, the employee alleges the act was solely motivated by discrimination, and in a *mixed-motive claim*, the employee alleges the employer was motivated by both legitimate and unlawful factors. A 1991 amendment to the Civil Rights Act addressed the uncertainty that had surrounded the mixed-motive cases until that time by clarifying that even if other legitimate factors also motivated the employer's actions, the employer violated Title VII if the protected characteristic was a "motivating factor" in the employer's act.

If an employee cannot establish intentional discrimination, another option is to bring a claim under the *disparate-impact theory*. The disparate-impact theory addresses the situation in which an employment practice or policy is neutral on its face, but as applied has a disproportional effect on a protected group in a manner not justified by business necessity. Examples include educational requirements, experience requirements, arrest and conviction records, or dress requirements. The disparate-impact theory was created in a 1971 Supreme Court case and remained a judicially created cause of action until the 1991 amendment to the Civil Rights Act, which specifically included practices that cause a disparate impact as unlawful. Statistical evidence is generally used to establish such claims.

Other than disparate-treatment and disparate-impact claims, Title VII provides claims that an employer has subjected the employee to a hostile environment, that the employer discriminated against the employee as retaliation for opposing a discriminatory practice, and that an employer has failed to accommodate the employee's religious expression. In a *hostile-environment claim*, the employee alleges that the employer's unwanted conduct has created an environment so pervasive that a reasonable person would find it hostile or abusive and that the employee bringing the claim did, in fact, find the environment abusive. The most common form of hostile-environment claim is based on one type of what has become known

as *sexual harassment* (the other type of sexual harassment is the more clear-cut quid pro quo claim, which also violates Title VII). In a *retaliation claim*, the employee alleges that he or she was discriminated against for opposing a discriminatory practice or participating in an investigation of a potential Title VII claim. Finally, an employee has a distinct claim under Title VII if the employer failed to accommodate his or her religious expression when doing so would not have caused undue hardship to the employer.

The Civil Rights Act of 1964, which has been called the greatest civil rights statute since Reconstruction, has been amended several times, including a significant amendment in 1991. Over the years, the act has seen waves of strict construction and liberal interpretation by the courts. However, even under its strictest interpretation, there is no denying that the act was a major step toward equality in the workplace.

CIVIL RIGHTS ACT OF 1991

The Civil Rights Act of 1991 is compromise legislation passed after a heated two-year political struggle and ambitiously amended Title VII of the Civil Rights Act of 1964 (referred to as "Title VII"); the Americans with Disabilities Act of 1990; Section 1981 of the Civil Rights Act of 1866 (referred to as "Section 1981"); the Attorney's Fees Award Act of 1976; and the Age Discrimination in Employment Act of 1967 (ADEA). President George H. W. Bush had vetoed an earlier version of the bill in 1990, based on what he perceived to be its encouragement of quota-based hiring.

However, the struggle continued, and after the much-publicized Clarence Thomas confirmation hearings in the summer of 1991, the president signed a newly passed Civil Rights Act of 1991. In large part, the act counters a succession of seven significant Supreme Court decisions that had made it more difficult for employees to prove discrimination and provides for compensatory and punitive damages in cases of intentional discrimination.

Prior to the passage of the Civil Rights Act of 1991, the Supreme Court had reached several decisions involving employment discrimination, five of them in 1989 alone. The act was intended to address these rulings. One such ruling was the 1989 decision of *Wards Cove Packing Co. v. Antonio*, involving a claim of disparate impact, which until this time had existed only by judicial creation. In *Wards Cove*, the Supreme Court held that the plaintiff employee has the burden of proving both that the challenged practice disproportionately affects a protected group and that the employer does not have any legitimate business justification for the practice at issue. If the plaintiff is unable to prove that the challenged practice does not have any legitimate business purpose, he or she can still prevail by proving that there are alternatives to the practice that did not have a disparate impact. This test places the whole burden on the plaintiff and proved very difficult for a plaintiff to meet.

The Civil Rights Act of 1991 reversed a portion of the *Wards Cove* decision by codifying the disparate-impact claim and shifting some of the burden to the employer. Once the plaintiff establishes that the challenged practice has a disparate impact on a protected group, the burden of proof shifts to the employer to prove that the practice is justified by business necessity. The act clarifies that the employer must demonstrate that the challenged practice is “job-related for the position in question and consistent with business necessity.” Neither *job-related* nor *business necessity* is defined by the act.

These definitions, or lack thereof, were at the heart of the controversy that had surrounded earlier versions of the Civil Rights Act. Previous versions had included a definition of “job-related” that required a much closer relationship between the challenged practice and the job in question than the loose “any legitimate business objective” standard that existed under *Wards Cove*. Opponents of the 1991 act believed that the combined effect of shifting the burden to the employer and requiring a high degree of relatedness

between the challenged practice and the job at issue would force employers to adopt quotas in order to avoid litigation under the disparate-impact theory. The enacted version of the act thus does not include any definition of “job-related,” leaving the issue undecided. On the other hand, the act does decide that an employee who cannot pinpoint a particular practice that caused the disparate impact but can demonstrate that the “elements of a respondent’s decision making process are not capable of separation for analysis” can challenge the whole process as one practice, a method not permitted under *Wards Cove*.

The passage of the Civil Rights Act of 1991 also clarified what had been a hotbed of confusion: the mixed-motive claim of intentional discrimination. In the 1989 Supreme Court case *Price Waterhouse v. Hopkins*, the Court held that an employee is prohibited from recovering in cases where he or she alleges that the employer had both legitimate and discriminatory reasons for its challenged practice if the employer demonstrates that it would have made the same decision for nondiscriminatory reasons. Under the Civil Rights Act of 1991, it is unlawful if the protected characteristic was a “motivating factor” in the employer’s decision, even if the employer would have made the same decision based solely on a legitimate business decision. However, if the employer does demonstrate that he or she would have made the same decision, the employee is not entitled to damages and can receive only declaratory relief, attorney’s fees, and costs of the action.

On the subject of damages, the Civil Rights Act of 1991 provided that for the first time, employees who could successfully prove intentional employment discrimination under Title VII could be awarded with monetary damages and could seek a trial by jury. A plaintiff can recover compensatory damages, and if the employer has acted “with malice or reckless disregard” for the plaintiff’s rights, that person can also recover punitive damages. The act caps the amount of total damages at a rate dependent on the number of employees, ranging from \$50,000 for a company of 15 to 100 employees to \$300,000 for a company with more than 500 employees.

The Civil Rights Act of 1991 contains several other significant provisions, including applying Title VII to employees working abroad for American companies; prohibiting the use of “race norming,” or adjusting test scores based on a protected characteristic; and extending the statute of limitations for certain cases under

Title VII and the ADEA. The act also allows unhappy employees to challenge prior-consent decrees entered to remedy discriminatory conduct only if they had not received prior notice that the settlement would hurt their interests; permits successful plaintiffs in Title VII and Section 1981 claims to recover expert fees and attorney's fees; and applies Section 1981 to racial discrimination in all phases of the contractual relationship, not just hiring decisions as previously held. Finally, the act creates the Glass Ceiling Commission, to study the barriers to the advancement of women and minorities, and the EEOC's Technical Assistance Training Institute to assist in the implementation of the act. The Civil Rights Act of 1991 is a sweeping legislation that, even with its ambiguity, reduces the obstacles to establishing discrimination and provides disincentives to employers for violation of the rights of their employees.

COGNITIVE DIFFERENTIATION GRID

The assessment and investigation of vocational processes represents some of the most active and sustained contributions that have derived from George Kelly's 1955 personal construct theory. Kelly's theory is often interpreted as an early forerunner of contemporary cognitive theories, although his emphasis on personal agency, meaning, choice, and growth have variously aligned him with humanistic, existential, and postmodern positions.

The *Cognitive Differentiation Grid* is an early adaptation of Kelly's Role Construct Repertory Test,

a measure designed to elicit a representative sample of an individual's personal construct system and to assess the organizational properties of these construct dimensions. In its original form, the Cognitive Differentiation Grid provided individuals with a fixed set of 12 different careers (e.g., lawyer, teacher, artist, carpenter) together with a fixed set of 12 vocational constructs (e.g., high vs. low salary; blue-collar vs. white-collar; high vs. low education) and asked them to rate each of the 12 occupations along each of the 12 vocational constructs, yielding a matrix of 144 ratings. These ratings were then subject to a wide variety of analyses designed to explore the organizational properties of the vocational construct system.

The vocational construct system is understood as the set of idiosyncratic dimensions, or constructs, that an individual brings to bear in viewing the world of work. As bipolar dimensions of personal meaning (e.g. stimulating vs. boring; secure vs. insecure employment; creative vs. technical skills), systems of constructs collectively form networks of meaning that enable the individual to understand, evaluate, and negotiate career alternatives, choices, and development. Importantly, while broader social and cultural forces ensure some commonality among individuals' vocational construct systems (Kelly's Commonality Corollary), no two systems are presumed to be exactly alike (Kelly's Individuality Corollary).

Individual construct systems can differ not only in the content of their dimensions but also in the organization and complexity of those dimensions (Kelly's Organization Corollary). Two people may share a set of three common constructs, for example, but those constructs may occupy different positions in the overall vocational construct system and may be related differently to one another as well. For example, two individuals may evaluate careers in relation to, for example, salary (high vs. low salary), security (high job security vs. low security), and creativity (creative vs. boring). For one individual, salary may be the most important dimension, whereas for the other individual, creativity may be the most critical feature. Moreover, one of them may view salary and creativity as positively related to one another (i.e., he or she anticipates that more highly paid jobs will enable greater creativity), whereas the other may view them as inversely related (i.e., he or she anticipates that higher paid jobs tend to be more boring and permit less creativity). In each instance, Kelly's personal construct theory places emphasis on individual differences,

underscoring the idiosyncratic ways in which an individual perceives the world and orders, structures, or organizes his or her perceptions. In this regard, the theory is closely allied with postmodern developments in psychology, because a greater emphasis is placed on personal perception than on reality or the correspondence of that perception to a reality independent from the knower. It follows from Kelly's Individuality Corollary that no two people are likely to rate all 12 occupations exactly alike in relation to all 12 constructs, and individual differences in this regard are the subject of particular interest.

COGNITIVE DIFFERENTIATION

The concept of *cognitive differentiation* refers to the number of different dimensions of meaning, or personal constructs, that a person has available within his or her system of meaning. Vocational construct systems that are composed of multiple, relatively independent dimensions of meaning would situate the individual to understand the world of work in relatively complex ways, whereas a system marked by only one or two dimensions of meaning would restrict the perspectives that could be brought to bear in making career decisions or evaluating career options.

The Cognitive Differentiation Grid specifically assesses this property, the number of relatively independent vocational constructs available to the individual, and hence it provides a measure of an individual's vocational complexity. Although the specific forms of calculating this complexity may vary, they share a common conceptual rationale. That rationale relies on the notion that two vocational constructs are different to the extent that they are used differently in perceiving and ordering different occupational alternatives. In other words, if the 12 different occupations are rated identically along two different constructs, those constructs are regarded as functionally identical. Despite the fact that they may have different labels (high vs. low salary, and high vs. low status), if they are used identically (e.g., a perfect correlation between the ratings of salary and status), they are functioning in the same way in perceiving or organizing the world of work, and hence they are counted as the same construct. In the limiting cases, all constructs could be used the same way in rating all 12 of the occupations (i.e., low complexity), or each of the 12 constructs could be used in functionally different ways in ordering or rating the set of 12 occupations

(i.e., high complexity). In practice, individuals ordinarily fall somewhere between these two extremes and therefore reflect relatively high or low levels of vocational differentiation.

THE EFFECTS OF DIFFERENTIATION

From its inception, the assumption has been that more highly differentiated vocational construct systems should be linked to more effective career decision making and more appropriate career choices. This assumption and its implications have been the subject of ongoing research since the introduction of this instrument. Research has provided a range of evidence in this regard and noted the sensitivity of the instrument to the wide variety of adaptations it has received. Contemporary applications of the measure tend to emphasize the idiographic nature of the construct dimensions themselves, rather than their organization or differentiation alone. Returning to Kelly's original Role Construct Repertory Test instructions, individuals are often given sets of three different occupations at a time and asked to indicate "any way in which any two of these are alike in some way" (e.g., high status) "and different from the third" (e.g., low status). This vocational construct (e.g., high versus low status) is then entered on the Cognitive Differentiation Grid and used to rate the full set of 12 occupations. The procedure is repeated 11 more times, until all 12 occupations have been rated along all 12 personally elicited construct dimensions and the idiographic nature of the constructs themselves, as well as their organization and differentiation, is available for analysis and discussion with the individual.

COGNITIVE INFORMATION PROCESSING IN CAREER COUNSELING

There is an old adage, "Give people a fish and they eat for a day, but teach them how to fish and they eat for a lifetime." This wise maxim succinctly captures the ultimate aim in using the *cognitive information processing* (CIP) approach to career counseling: to enable individuals to become skillful career problem solvers and decision makers. Through the CIP approach, individuals learn not only how to solve the problem at hand but also how to generalize this experience to future career problems.

In the early 1970s, a line of inquiry emerged from the field of cognitive science that offered a new way of thinking about human problem solving and decision making. This paradigm, referred to as "cognitive information processing," was initially formulated in the works of Earl Hunt, Allen Newell, and Herbert Simon and of Roy Lackman, Janet Lackman, and Earl Butterfield. When applied to the realm of career choice, this paradigm, herein referred to as the "CIP model," provides a way to describe the fundamental memory structures and thought processes involved in solving career problems and making career decisions. With the CIP model, career counselors are able to assist clients in becoming better career problem solvers and decision makers.

DEFINITIONS AND CONCEPTS

The following are key definitions in the CIP model:

Career problem: A gap between an existing state of career indecision and a more desirable state of decidedness. The gap creates a state of cognitive dissonance that becomes the primary motivational force driving the problem-solving process. The presence of a gap results in tension or discomfort that individuals seek to eliminate through problem solving and decision making.

Problem space: All cognitive and affective components contained in working memory as individuals approach a

career problem-solving task. In the lives of clients, the problem space entails the career problem at hand in addition to all the issues associated with it, such as marital and family relationships, as well as the emotional states embedded in them.

Career problem solving: A complex set of thought processes involved in the acknowledgment of a gap, an analysis of its causes, the formulation and clarification of alternative courses of actions, and the selection of one of these alternatives to reduce the gap. A career problem is solved when a career choice is made from among the alternatives.

Career decision making: A process that not only encompasses career choice but also entails a commitment to and the carrying out of the actions necessary to implement the choice.

Career development: The implementation of a series of career decisions that constitute an integrated career path throughout the life span.

THE PYRAMID OF INFORMATION PROCESSING AND THE CASVE CYCLE

Two fundamental structures constitute the CIP model: (a) the Pyramid of Information Processing and (b) the CASVE Cycle.

The Pyramid of Information Processing

For individuals to become independent and responsible career problem solvers and decision makers, certain information-processing capabilities must undergo continual development throughout the life span. These capabilities may be envisioned as forming a pyramid of certain "information-processing domains," with three hierarchically arranged domains (see Figure 1). The Knowledge Domain lies at the base, the Decision-making Skills Domain constitutes the midlevel, and the Executive Processing Domain is at the apex.

The Knowledge Bases. Two Knowledge domains, Self-knowledge and Occupational Knowledge, lie at the base of the pyramid. *Self-knowledge* includes knowledge about one's interests, abilities, skills, and values based on an ongoing construction of one's life's experiences. *Occupational knowledge* consists of one's own unique structural representation of the world of work and an understanding of individual occupations in terms of their duties and responsibilities, as well as education and training requirements for attaining them.

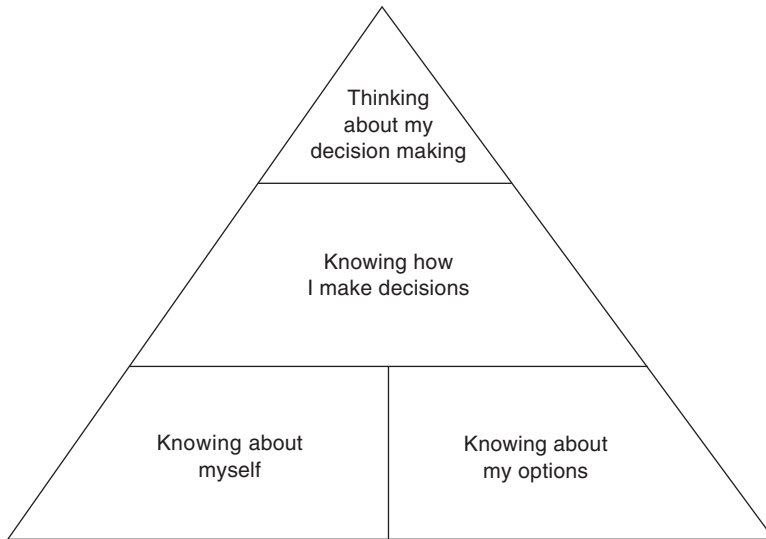

Figure 1. What's Involved in Career Choice

SOURCE: Reprinted from *The Career Development Quarterly*, 41, 1992, p. 70, copyright NCDA. Reprinted with permission of the National Career Development Association. Used with permission.

The CASVE Cycle. The middle level of the Pyramid of Information Processing, referred to as the “Decision-making Skills Domain,” involves generic information-processing skills that combine occupational knowledge and self-knowledge to solve a career problem and to make a decision. A five-step recursive information transformation process, the CASVE Cycle (pronounced “ca-sah-veh”), is used as a heuristic for the career counseling process (see Figure 2).

Communication (C). Information is received and encoded that signals that a problem exists. One then queries oneself and the environment to formulate the gap (or discontinuity) that is the problem. It also entails getting “in touch” with all components of the problem space, including thoughts, feelings, and related life circumstances.

Analysis (A). The causes of the problem are identified, and the relationships among problem components are placed in a conceptual framework or mental model.

Synthesis (S). Possible courses of action are formulated through the creation of possibilities (synthesis elaboration) and then narrowed (synthesis crystallization) to a manageable set of viable alternatives.

Valuing (V). Each course of action or alternative is evaluated and prioritized according to its likelihood of

success in removing the gap and its probable impact on self, significant others, cultural group, and society. Through this process, a first choice emerges, and the career problem is solved.

Execution (E). An action plan is formulated to implement the choice, which becomes a goal for the client. A series of milestones are laid out in the form of a means-ends relationship that will lead step-by-step to the attainment of the goal. Thus, a career decision is made when individuals move deliberately toward a goal, such as enrolling in a training program or taking a job in a chosen occupational field.

Upon executing the plan, there is a return to the Communication phase of the cycle to evaluate whether the decision successfully removed the gap. If so, the individual moves on to solve succeeding problems that arise from the implementation of the solution. If not, one recycles through the CASVE cycle with new information about the problem, oneself, and occupations acquired from the initial pass through the CASVE cycle.

The Apex. The apex of the pyramid, the Executive Processing Domain, contains metacognitive components that guide and regulate the lower-order cognitive functions. We describe this domain as “thinking about thinking,” which entails the ability to view oneself as a career problem solver from a detached perspective. The domain involves metacognitive components that (a) control the selection and sequencing of cognitive strategies to achieve a goal and (b) monitor the execution of a given problem-solving strategy to determine whether a goal has been reached.

READINESS FOR CAREER PROBLEM SOLVING AND DECISION MAKING

An initial consideration in the application of the CIP model in career counseling is acquiring an understanding of two critical factors, *complexity* and *capability*, associated with readiness for undertaking the task of solving a career problem. These factors are taken into account in administering assessments and prescribing learning experiences to enhance the acquisition of career problem-solving and decision-making skills.

Complexity. The career problems of clients often emanate from highly complex lives. The career

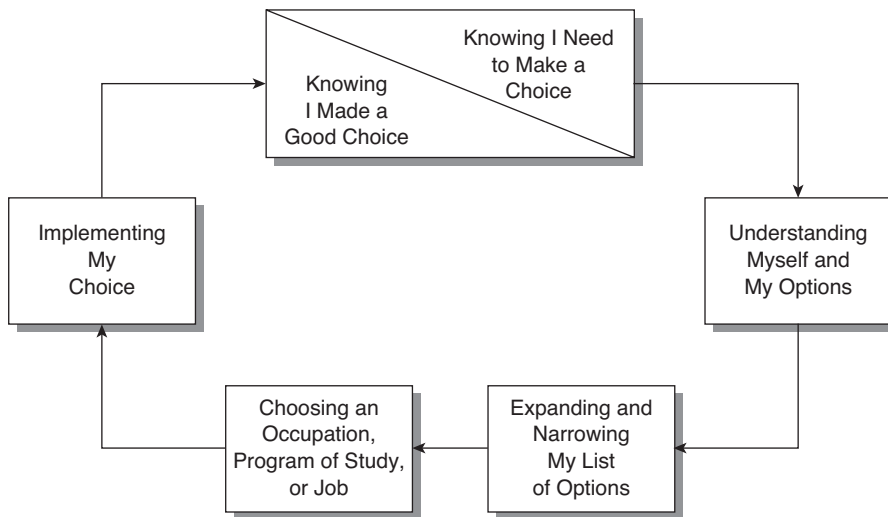

Figure 2. Guide to Good Decision Making

problem space may include, in addition to career concerns, many personal issues, such as the desire to have committed relationships, children and family responsibilities, property ownership, community and spiritual involvement, and leisure pursuits. These aspects are interrelated with the presenting career issue and directly influence how a client engages the respective stages of the CASVE Cycle.

Capability. Clients bring a wide range of individual differences in prior learning experiences and general problem-solving abilities to the career decision-making process. Moreover, clients vary in terms of aptitudes for further education and training, attitudes toward risk taking, self-esteem or self-efficacy, family support and values, and thoughts, beliefs, and assumptions about the world of work.

OPERATIONS AND INTERVENTIONS

The Assessment of Client Learning Needs

Assessment from the perspective of the CIP model concerns what clients need to learn to enhance their career problem-solving and decision-making skills so as to effectively address the career problem at hand. The Pyramid and the CASVE Cycle serve as heuristics for the identification of client learning needs.

Assessing Readiness for Career Problem Solving and Decision Making

Not all clients are prepared to immediately engage the career problem-solving process. They may require intensive personal assistance from a career counselor to manage factors in the problem space that impede learning before they are able to begin.

The assessment of readiness may be accomplished through the integration of information gathered through the administration of the Career Thoughts Inventory (CTI), followed by a client interview. The CTI is a 48-item self-report measure

that assesses the level of a client's dysfunctional thinking through three principal construct scales, Decision-making Confusion (DMC), External Conflict (EC), and Commitment Anxiety (CA). Scale scores along with responses to individual items enable a career counselor together with the client to identify discrepancies in the Pyramid or blocks in the CASVE Cycle that impede career problem solving and decision making. On the basis of the readiness assessment, clients may be assigned to one of three levels of career service: (1) self-help, (2) brief staff assistance, and (3) individual case-managed career counseling.

Assessing Career Problem-solving Skills

The assessment of problem-solving and decision-making skills entails identifying specific domains in the Pyramid that require further development in order to be able to solve the career problem at hand.

Self-knowledge. The assessment of self-knowledge is often a confirmatory process in which interest inventories, such as the Self-Directed Search, allow clients to clarify and reaffirm their interests. Computer-assisted career guidance (CACG) systems, card sorts (values, interests, skills), and autobiographical sketches may also be useful.

Occupational Knowledge. Occupational knowledge may be assessed through traditional vocational card sorts or through using a card sort as a cognitive-mapping task. Through the use of a think-aloud procedure, clients reveal their knowledge about occupations as they sort the cards into *Like*, *Dislike*, or *Maybe* piles. In a cognitive-mapping task, the clients reveal a schema of the world of work by sorting cards into piles of related occupations and then identifying the pile *Most like me*.

Decision-making Skills. The CTI may be used to identify specific phases in the CASVE Cycle in which a client is experiencing blocks in the career problem-solving process brought about by dysfunctional career thoughts. The Decision-Making Confusion (DMC) scale reveals dysfunction in the Communication, Analysis, and Synthesis phases, which entail the derivation of career alternatives. The External Conflict (EC) scale addresses the Valuing phase, in which clients weigh the importance of their views in relation to the views of significant others. The Commitment Anxiety (CA) scale alludes to the transition from arriving at a solution to the career problem in the Valuing phase to making a commitment to action in the Execution phase.

Executive Processing. Dysfunctional thoughts in this domain may also be assessed through responses to individual items on the Executive Processing content scale of the CTI. In addition, during interviews with a client, a career counselor may listen carefully for instances of negative self-talk, ineffective cognitive strategies, and lack of control in staying focused on the task at hand.

The outcome of the assessment process is the development of an individualized learning plan (ILP) that comprises the goals of counseling in order to address the identified deficiencies and blocks that impede problem solving and decision making.

HELPING CLIENTS ACQUIRE CAREER PROBLEM-SOLVING AND DECISION-MAKING SKILLS

The Pyramid and CASVE Cycle are instrumental in developing interventions that facilitate the acquisition of self-knowledge, occupational knowledge, and career problem-solving and decision-making skills.

Acquiring Self-knowledge. The acquisition or clarification of self-knowledge may be accomplished through the use of interest inventories, values inventories, and ability and skills assessments that typically affirm and clarify the elements of the Self-knowledge Domain. Autobiographies may also be helpful in describing and organizing life experiences that bear on the career problem at hand.

Acquiring Occupational Knowledge. In career counseling, clients engage in the processes of *schema specialization*, in which they are able to make finer discriminations among occupations, and *schema generalization*, in which they form more extensive networks of connections among extant occupational knowledge structures. When career counseling takes place within comprehensive career centers, the acquisition of occupational knowledge may be facilitated through the use of a variety of media, such as print materials in the form of occupational briefs, vocational biographies, and reference books; special-topics books are an efficient means of acquiring factual knowledge about occupations, interactive media, and Internet Web sites. Reality testing through job shadowing or interviews with incumbents allows clients to experience occupations even more directly.

Acquiring Career Problem-solving and Decision-making Skills. The concept of the Pyramid of Information Processing is presented directly to clients in the form of a handout, "What's Involved in Career Choice." The concepts of Communication, Analysis, Synthesis, Valuing, and Execution, as well as the cyclical relationship among these concepts, are learned through presenting a visual representation in the form of a handout, with a figure depicting the CASVE Cycle and easy-to-grasp statements describing each stage. Then, through subsequent considerations of activities included in the ILP and feedback from a counselor, clients begin to *accommodate* and *assimilate* the CIP model into their own decision-making styles. At the termination of counseling, the counselor reviews the decision-making process undertaken and demonstrates how the CIP model can be used in future career problem situations.

Acquiring Metacognitive Skills in the Executive Processing Domain. When dysfunctional or negative thoughts have been identified in the assessment

process, clients learn how to change their dysfunctional or negative career thoughts using the ICAA algorithm (Identify, Challenge, Alter, and Act). *The CTI Workbook* takes clients step-by-step through a cognitive-restructuring process. Clients also learn how to self-monitor their progress through the CASVE Cycle.

IMPLEMENTING THE CIP MODEL IN CAREER COUNSELING

A seven-step career service delivery sequence is used as a heuristic for implementing the CIP model in career counseling:

1. *Initial interview.* The career counselor gathers qualitative information about the nature of the presenting career problem.
2. *Preliminary-readiness assessment.* An individual's readiness for career counseling is assessed through administering the CTI and the Problem Space Worksheet. The findings are reviewed with the client.
3. *Define the problem and analyze the causes.* The counselor and the client come to a mutual understanding of the career problem and related issues. The specific causes of the problem lie in the deficiencies within the respective domains of the Pyramid or blocks that impede or inhibit progressing through the CASVE Cycle. We refer to this as the "career diagnosis," according to the CIP model.
4. *Formulate goals.* The counselor and client together formulate a set of attainable goals, stated in behavioral terms, to remove the respective deficiencies or blocks.
5. *Develop an individualized learning plan (ILP).* For each goal, the counselor and client develop learning activities to attain the goal and identify resources used in the activities, estimate the time needed to carry out the activities, and establish priority in the sequence of goal attainments as well as an indicator or measure of their attainment.
6. *Execute ILP.* Clients carry out the ILP while the counselor monitors the attainment of the respective goals and assists the client when required.
7. *Summative review and generalization.* At the conclusion of the ILP, the client and counselor review the process used to solve the problem, make the decision at hand, and evaluate its effectiveness. They also explore how the CIP model might be applied to future career problems or even life problems in general.

IMPLICATIONS FOR BEST PRACTICES IN CAREER COUNSELING

The CIP model advances the state of the science in career counseling by providing a theory base for introducing a value-added dimension, that is, using the problem at hand as a means of furthering the acquisition of career problem-solving and decision-making skills. Furthermore, focusing specifically on what clients are required to learn to improve their career problem-solving skills, counselors are freed up to look beyond the traditional one-on-one counseling relationship and creatively develop facilitative learning environments. Finally, the assessment of readiness for career problem solving enables counselors to match career service delivery resources to the depth and scope of the presenting problem, thereby fostering greater efficiency in the administration of career services.

The intent of the CIP model is to serve as a heuristic to enable individuals to systematically think through a career problem that will improve opportunities for career and lifestyle enhancement. Through the application of the model to solve a presenting problem, clients become better career problem solvers and decision makers, which, in turn, ultimately leads to satisfying, meaningful, and productive careers.

COLLECTIVE BARGAINING

Collective bargaining is an activity that takes place between workers and employers. It can be defined as the ongoing process by which workers and their employers negotiate to resolve disputes over workplace issues. These issues typically include compensation (wages and other pay, such as overtime, holiday pay, vacation pay, and benefits, which include health care and retirement); hours of work; and conditions of work (work rules, safety and health procedures, work duties, seniority provisions, etc.). The formal resolution of the disputes is written into a collective bargaining agreement or contract. In the United States, bargaining is done through a labor union (or employee organization) that the workers have chosen to represent them in dealing with their employer for collective bargaining purposes. It takes place under governmental labor relations regulations and is strongly influenced by prevailing economic and political conditions.

In the United States, labor relations are regulated by the National Labor Relations Act (NLRA), which covers private employers and the unions that deal with them, and by various federal, state, and local laws and ordinances, which cover the relationship between the public or government sector and the unions representing government employees. Under such regulations, labor-management relations in the United States focus on collective bargaining, which has evolved into two mutually supporting levels: (1) negotiating the bargaining agreement, or contract, and (2) enforcing that contract through the use of grievance and arbitration procedures and other means to ensure that the terms of

the contract are followed. The average duration of a labor agreement is three years, but both shorter and longer contracts are frequent, depending on what the two parties agree on. As a result, bargaining for a new contract occurs every three years or when the contract expires. Contract enforcement bargaining takes place whenever problems arise in implementing an existing agreement.

Regardless of the type of employer and the legal restrictions that apply, collective bargaining follows the same general process, a sequence of activities that includes preparing, negotiating, and finalizing the agreement. Bargaining takes place under union staff or officers, who represent the workers, and management persons, representing the employer. These representatives, with their respective committees, meet together and conduct the actual negotiating. In the United States, the law regulates the conduct of the parties and how they behave relative to each other, but it does not regulate the outcome or final results of the bargaining. The results depend on the relative economic power of the two parties.

It should be recognized that collective bargaining takes place under a complex set of relationships between employers and managers, on one hand, and the workforce and the union, on the other. While basic relations between employers and employees exist in any enterprise, these relationships take on a special form when the workers have organized into a union. They have a degree of power in dealing with their employers that unorganized workers do not have. One school of thought considers the dynamics between the parties in bargaining as essentially a power struggle. Others, typically in human resource positions, consider the main purpose of bargaining as the maintenance of labor peace and minimization of conflict at the workplace.

The relationships existing between the parties are influenced by the prevailing political and economic conditions outside the business, the state of the overall economy, the employer's competitiveness, and conditions in the local community. The motivations and expectations of each party in the bargaining process are usually quite different. Their positions, in turn, are heavily influenced by each party's interests, that is, what each side thinks is important to its well-being and thus needs to protect and improve. Reaching a compromise that is acceptable to each side can be a difficult task. When this fails to happen, a strike or lockout usually occurs. In recent years, however, over

98 percent of contract negotiations were concluded without strikes or lockouts. Considerable skills are needed for an individual from either party to be an effective bargaining representative.

Workers, and therefore their union representatives, normally focus on bettering wages, maintaining benefits, and improving work conditions. In some situations, the financial condition of the employer exerts unusual pressures for concessions and other undesirable changes in the terms of the contract. Employers historically have been mainly concerned about maximizing profits (in the private sector) and maintaining workforce control (in all sectors). Employers naturally worry about how collective bargaining and the union's power will impact these two objectives. This fuels their natural opposition to unions. Coupled with the enormous economic and political clout of corporations in today's society, this opposition creates a formidable obstacle for unions to successful bargaining.

As this brief discussion of collective bargaining indicates, the representatives from management and the union are by necessity trained professionals who are familiar with labor law, understand the dynamics of interpersonal relations, are experienced in the bargaining process from both their own perspective and that of the other party, and are skilled at the art of negotiating. Either party may choose a labor relations lawyer to represent it in bargaining, but unions often fall back on trained staff, while management frequently uses human resource personnel.

Training for management positions in collective bargaining is commonly part of university-level programs in management, especially in personnel relations and human resource management. However, some companies still rely on on-the-job training for selected managers as preparation for collective bargaining. Preparation for a position as a union representative is considerably more varied. Some unions look to hiring and training college graduates with labor studies or industrial relations degrees. Others hire pro-labor lawyers and integrate them into the union's bargaining philosophy. Still other unions prefer to promote promising members who have been active in their local unions to staff positions and to train them for collective bargaining roles. Finally, law schools offer a wide variety of labor law courses that prepare students for work in labor relations.

As in other careers today, the world of collective bargaining is in transition. Since the 1970s, economic changes such as the shift from manufacturing jobs to

service-providing jobs, deregulation, free trade, and globalization, along with changes in political attitudes and the manner in which the federal government implements the NLRA, have resulted in layoffs, plant closings, and downsizing. This has reduced union membership, especially in the goods-producing industries. Unions that represent workers in retail trade and service industries and public sector unions are holding their own or growing. The net result is fewer and smaller-sized unions in the goods-producing sector. This has even led to the demise of certain unions, usually through mergers into larger unions. As a consequence, fewer companies are unionized, so less bargaining takes place. Thus, the number of job opportunities in collective bargaining has correspondingly declined. Such positions still exist, but they are harder to find. Properly prepared individuals can still find careers in collective bargaining and related fields, but it now takes an intelligent, well-planned effort to do so.

COLLEGE STUDENT CAREER DEVELOPMENT

College student career development refers to the processes involved in making career decisions and the outcomes of those decisions for individuals in college. According to developmental theories of career decision making, traditional-age college students are often attempting to refine their understanding of themselves, learn about the world of work, and discover

how they might make work a part of their lives. Nontraditional-age college students report similar challenges, although they generally have less need to select career goals than do younger students. Not all individuals who pursue a college education do so solely for the purpose of preparing for a career, although for many, career preparation is a significant factor contributing to their decisions to enroll in a college or university. Thus, the primary vocational challenge faced by college students is choosing a major and deciding on career goals. Other important challenges include performing effectively in academic pursuits and learning skills that will enable students to succeed in a desired career.

COLLEGE MAJOR AND CAREER CHOICE

Some students enter college with clearly defined academic and career goals that do not change over their college years. However, many students find that college promotes self-exploration, and many individuals begin to gain specific information about the world of work during the college years. Just as the average adult changes jobs and even career fields multiple times, the average college student changes majors at least one time. Changing majors and/or career goals is a positive event for many students who discover new areas they believe will be highly satisfying. On the other hand, because changing majors may result in delayed graduation, deciding on a satisfying major early can be beneficial. Deciding on a major with which the student will be satisfied represents an early challenge.

The process of deciding on a major differs from student to student. Some students first decide on a career and then seek an academic major that will help prepare them for that career. For example, a college student who wants to become a physician may choose to major in biology. Other students first decide on a major on the basis of their interests or skills and then seek a career for which they are prepared. As an example, a student may major in history because he or she has enjoyed an introductory history course and then search for specific careers or jobs for which a history degree is beneficial.

Students' decisions about majors and careers are often made on the basis of their interests and their perceptions that the major and/or career will allow them to satisfy their interests. The trait-and-factor approach to career decision making suggests that individuals

seek activities that allow them to express their interests and personalities. With respect to choosing a major, for example, a student who enjoys artistic expression would be most likely to choose a major such as dance, creative writing, or theater.

Students also choose a major and career goals on the basis of their expectations about being able to succeed in the field and their expectations of having positive consequences associated with choosing that field. *Self-efficacy* refers to a student's appraisal of his or her likelihood of success. A young woman who doubts her ability to succeed in college math classes, even if she has very good math skills, is considered to have low mathematics self-efficacy, and accordingly, she may be less likely to major in mathematics. Students also make choices on the basis of their beliefs that choosing a given major or career goal will result in positive outcomes, a concept referred to as *outcome expectations*. If becoming an engineer would present benefits in terms of approval from others, for example, then a student would be more likely to choose engineering as a major.

Other influences on a college student's career development include family members, who can have both positive and negative influences. Some students perceive their family members as exerting pressure to pursue particular college majors or careers. As a result, they feel free to choose only from a restricted range of possible majors or careers. Other students perceive their family members as providing support and validation for their decisions and therefore experience greater perceived freedom to pursue goals they believe will lead to satisfaction.

A variety of role models, including influential teachers, academic advisors, and even famous people the student does not know personally, can also influence a student's career decision making by increasing his or her awareness of possible careers and what is involved in attaining them. For example, suppose a memorable grade school teacher has inspired a college student to become an education major. If the student talks to the teacher about how she advanced in her career, the student may learn important information about what it takes to be a successful teacher.

The process of choosing a major and career is also influenced by culture. The socialization of gender roles in Western cultures is such that boys are often encouraged to pursue activities that involve action, whereas girls are encouraged to pursue activities that involve affiliation. For example, in high school, girls

may not be reinforced for achievements in science and math classes, and boys may not be reinforced when they show interest in cooking or caring for youngsters. These influences continue into college, and this may explain why men are less likely to choose a careers in nursing and women are less likely to pursue careers in science, engineering, and technology. Students of color; gay, lesbian, and bisexual students; students with physical disabilities; and nontraditional-age college students may experience additional challenges that affect career decisions made during college. For example, students of color in a predominantly White university may find it difficult to find similar role models from whom they can gather career information that resonates with them. Nontraditional-age college students, as well as some younger students, experience challenges managing multiple roles, such as those of student and worker or student and parent. Multiple-role conflict may also affect students who are not yet parents or spouses but anticipate having families in the future and are trying to select career goals they believe will be compatible with other roles they want to pursue in life.

Some college students simply do not know of majors or careers they would like to pursue. This state of being uncertain about career goals is referred to as *career indecision*. On the other hand, some students are certain that they have chosen an academic or career path that will lead to satisfying learning experiences and employment. The extent to which students have decided on a career is known as *career decidedness*. Many students experience career indecision at one time or another, so in many respects, this is a normal part of the career development process. However, a prolonged period of career indecision is problematic because for many students, being undecided about a career or college major not only delays entry into a field of study but is also associated with psychological distress.

There are many potential reasons why a student may experience career indecision. Some students have difficulty making decisions in many areas of life, perhaps because they believe that it is important to make perfect choices and that choices are irreversible. For other students, the source of career indecision may be low *career decision self-efficacy* (i.e., confidence in one's ability to make a career decision). Students with high levels of career decision self-efficacy have confidence in their abilities to engage in the tasks necessary to make a career decision, and for these students, the

process of making career choices is manageable. Students with low levels of career decision self-efficacy perceive career decision-making tasks to be beyond their abilities, and they may benefit from career counseling or other interventions.

ACADEMIC ACHIEVEMENT

Academic achievement represents an important aspect of a college student's career development. A student must demonstrate adequate academic performance to remain in college, and most college students aspire to a career that requires a college degree. Each year, up to 25 percent of first-year college students leave their colleges or universities before the sophomore year, and the graduation rate for an entering class of freshmen may be only 50 percent. Leaving college before graduating is a positive decision for some students. For example, a student may decide to pursue a career that does not require a college degree. For other students, the decision to leave college is not voluntary, such as when poor grades lead to a student being academically dismissed; in this case, academic difficulties may slow progress toward attaining a satisfying career.

A second reason academic achievement is important is that it increases the likelihood of the student securing a satisfying job after college. In a tight job market, students with the best academic records will have a competitive edge. This achievement extends beyond the classroom to the securing of desirable internships, volunteer experiences, and part-time employment in the student's field of study.

Academic achievement also helps build a student's self-efficacy with respect to his or her area of study. Successfully performing a behavior is one of the key ways in which a student develops the expectation that the behavior can be successfully performed in the future. For example, earning high grades in several sociology classes would increase a student's self-efficacy for completing the tasks necessary to succeed as a sociologist.

Academic achievement in college appears to be facilitated by strong academic skills, good preparation in high school, a motivation to do well, beliefs that one can succeed in college, valuing the process of learning, and integration with the institution. Some barriers to academic achievement in college center on problems with a student's ability to perform well in the classroom. Such problems might include inadequate

preparation in high school, specific learning disabilities that have not been identified, or unrealistic expectations about the amount of work required to do well in college classes. Other barriers to academic achievement in college include low motivation, such as when a student feels pressure to attend college from family members but does not really want to be in college. Finally, social problems may interfere with academic achievement. For example, college students who experience significant homesickness after making the transition from living at home to living at college may simply not do well in their classes until they have become integrated into the campus community.

THE INITIAL JOB SEARCH

Finding a job after college is often a primary goal of a college student. Students in this stage of career development must learn skills such as résumé writing and interviewing. Students often have had experience applying for jobs, but finding the first career job after college is an imposing challenge for many students. Many students are able to find employment in their desired occupation shortly after graduation, but many students do not. Some of these students merely delay entry into a career consistent with their major, but other students find work in completely different areas.

Market forces, such as the unemployment rate, can dramatically affect a student's success in finding a job after graduation. Job market constraints can pose potential barriers, such as when jobs in a student's desired career field are very competitive or scarce. However, characteristics of the job market may also facilitate a student's entry into work from college, such as when that person's academic training allows him or her to fulfill needs in careers for which there is great demand.

Graduation from college does not always correspond to an immediate job search, because many students continue their education beyond the four-year degree. For some career goals selected by college students, a graduate degree or additional professional training is necessary. As graduate students choose areas of specialization for postcollege training, they may experience challenges similar to those encountered by undergraduate students when selecting a major. The career development process for graduate students is not unlike that for undergraduate students, with one exception being a more limited range of career options for graduate students given their more specialized training.

ASSESSMENT AND INTERVENTION

Most colleges and universities offer career assessment and counseling services to assist students as they encounter developmental challenges associated with career development or when they experience particular career development difficulties. Regarding assessment, it is often desirable to assess a student's interests, skills, values, and self-efficacy with respect to different majors and careers. Assessment in general helps with the process of exploring information about oneself, and an accurate understanding of oneself is a critical component of making career decisions. The assessment of interests provides information about the types of activities the student enjoys and can help a student identify specific careers or areas of study in which he or she might be interested. The identification of skills and self-efficacy helps a student narrow down the types of careers that he or she might be prepared to pursue. Many assessment instruments are administered and interpreted by a counselor, but self-guided computerized assessment procedures also exist. Regardless of the format, the assessment process is often a helpful way to enable a student to identify a specific career path that might lead to success and satisfaction.

Because of the large number of college students who would benefit from career development intervention, many colleges and universities offer courses or brief workshops designed to teach self-exploration and job search skills. In such courses and workshops, students may learn about the career development process, engage in self-assessment, learn about the world of work, and learn skills that will help them as they begin to seek employment.

When individualized treatment is desirable, career counseling may be used to reduce barriers associated with making career decisions. If a student is identified as having low career decision self-efficacy, for example, interventions may be implemented that provide opportunities for success. Sometimes a student is undecided about a major or a career because he or she has been depressed or has experienced a personal emotional upheaval. In these cases, career counseling may focus on the personal issues as a way to reduce their impact on career development.

Most colleges and universities also have career centers or other offices that can aid students with practical job skills. Workshops may help students develop résumés, hone interviewing skills, and find internships, for example. Many colleges and universities

keep databases about current internships and part-time job opportunities that may be available for students. Colleges are also well equipped to help students experiencing academic difficulties.

Whether career intervention takes place in the classroom, at a counseling or career center, or in a job placement office, the goal is typically to help students learn how to make important life and career decisions both during and after college. As such, it is usual for interventions to enhance the student's understanding of how to make effective career decisions, rather than just considering the decision made in college as the final outcome of career intervention.

COMPARABLE WORTH

Comparable worth is a policy implemented by a small number of state, local, and national governments to remedy wage disparities between men and women due to occupational segregation, a situation in which women are more likely to be employed in low-paying occupations and men are more likely to be employed in high-paying occupations. Comparable worth requires "equal pay" for "equal worth," where worth or value is not determined by the market but via a job-rating scheme that assigns point values to different job attributes, such as skill level, responsibility, and working conditions, and aggregates them to a measure of job worth or value. Jobs with equal value would be paid the same wage; jobs with higher value would be paid a higher wage; and jobs with lower value would be paid a lower wage. In addition to raising wages in female-dominated occupations, comparable worth might also lower wages in male-dominated occupations.

Proponents of comparable-worth legislation view the negative relationship between wages and the proportion of females in a given occupation as an undervaluation by society of "women's work" relative to "men's work." For these proponents, such undervaluation of work performed primarily by females is thought to arise from two sources. The first source, *crowding*, refers to the large number of women forced into certain occupations as a result of discrimination. The large supply of women to these occupations depresses wages. The second is society's *devaluation of work* performed by women simply because it is performed by women. Evidence presented for this thesis is that earnings are statistically negatively related to the proportion of women in an occupation, even after controlling for observable and measurable job characteristics. Comparable worth is proposed as a way to raise the wages of women in female-dominated occupations to their "true" higher value.

Some opponents of comparable-worth legislation note that salaries set according to comparable worth do not consider the personal characteristics of workers or the unobservable or unmeasured job attributes that affect pay, such as flexibility and overall family-friendliness, and so this disparity in occupational choice may not be due to discrimination. Women choose to enter these lower-paying occupations because these unmeasured job attributes compensate for the lower pay. In the jargon of economists, women

are willing to pay a compensating-wage differential (that is, accept a preferred working environment for less monetary pay) in order to better combine work and child-rearing responsibilities. These opponents point out that since this is not discrimination, no remedy is needed.

Opponents who accept discrimination as a factor that leads to occupational segregation note that interfering with market wages has negative unintended consequences, even though increasing women's wages to combat discrimination may be a laudable goal. One of these potential unintended consequences is a reduction in the employment of women in female-dominated occupations. Employers faced with paying higher wages in these occupations will substitute other inputs for these workers and decrease production overall in response to the increased cost of labor. Another consequence of interfering with market wages is the creation of unemployment in these female-dominated occupations due to the surplus of women desiring to work at the now-higher wages. Yet another negative consequence is the depression of the wages of men and women in the male-dominated occupations caused by an increase in the supply of workers to these occupations—a result of women who are unable to find employment in the now-higher-paying female-dominated occupations moving into the male-dominated occupations. Finally, if wages are artificially lowered as part of a comparable-worth policy that both increases some wages and decreases others, this will lead to the decreased quality of the workers in the male-dominated occupations.

Finally, even if the negative effects on employment and wages are deemed acceptable, it is difficult to put the concept of comparability into practice, given the subjective nature of the job evaluation process and the need to allow market forces and the efforts of workers to play a role. Evidence has shown that different job evaluation studies assign different points or weights to various skills, leading to different job comparisons and wage adjustments depending on the particular evaluation used. In addition, different localities are subject to different market forces. A private national employer with employees all across the country will need to take these local market forces into account in order to remain profitable. If a firm is not allowed under comparable worth to address such market forces with wage differences, an employer might choose to adjust production in such a way as to employ workers in the female-dominated occupations only in labor

markets where wages are low and employ workers in male-dominated occupations only in labor markets where wages are high. To encourage individual employee productivity, merit bonuses and raises for extra effort may be necessary, while to discourage turnover, seniority may also need to be rewarded. Finally, overtime may be necessary for some workers but not others. These important factors are ignored when computing wages strictly according to the "equal value" principle of comparable-worth policy.

HISTORY OF COMPARABLE WORTH

Early U.S. legislation attempting to address the inequality of pay between men and women included the U.S. Equal Pay Act of 1963 and Title VII of the U.S. Civil Rights Act of 1964. Similar legislation was put in place in the 1970s in other industrialized countries, such as the United Kingdom, Canada, Spain, and France. The focus of this legislation was the provision of "equal pay for equal work" performed by both men and women. However, critics claimed that because of occupational segregation, men and women were rarely performing equal work. As a response to this perceived inequality, comparable-worth policy was first proposed in the United States in the late 1970s to instead promote "equal pay for equal value." In the United States, comparable worth was primarily adopted by state and local governments rather than private employers, as public employers are not subject to profit-maximizing constraints. However, when other industrialized countries followed suit in the early 1980s, some required comparable worth in the private sector as well. Some people believe that unions have the potential to bring comparable worth to the private sector in the United States as a result of the increasing feminization of labor unions.

JOB EVALUATION SCHEMES IN DETERMINING EQUAL WORTH

Job-rating schemes have long been used by employers with internal labor markets, including public employers and large private firms that participate in collective bargaining with unions over wages. These schemes assign points to various characteristics of a job, such as skill level, level of responsibility, working conditions, and physical and mental effort required. The points are then summed (and possibly

weighted) to assign a particular total value to a particular job. The point total is used to compare the particular job to other jobs in determining "equal worth." Equal points mean equal worth and equal pay; higher points mean higher worth and higher pay; and lower points mean lower worth and lower pay.

A problem with this technique of assigning points, however, is that it is quite subjective. Characteristics such as physical strength that are more often associated with male-dominated jobs may be rated more highly than characteristics such as communication skills that are more often associated with female-dominated jobs, leading to lower values for female jobs. However, over the years, several gender-neutral evaluation methods have been developed and used to implement comparable worth.

PAY BASED ON JOB EVALUATION SCHEMES: DETERMINING COMPARABLE-WORTH WAGES

Once each job is assigned a total point value, total points are plotted against wages, and a line is fit to these data using regression analysis, an accepted statistical technique. Once the equation of the line representing the relationship between wages and value is determined in this manner, it is often revealed that most female jobs are below the line, while most male jobs are above the line, where the standard for categorizing an occupation as female dominated is 70 percent or more female workers and the standard for categorizing an occupation as male dominated is 70 percent or more male workers. This suggests that as long as no important job attributes that affect wages have been omitted from the calculation of the total point value, female-dominated jobs are paid less simply because they are performed by females.

The most transparent method of increasing female wages is to directly match female-dominated jobs to male-dominated jobs that are deemed equivalent because they fall within the same range of overall job point values. The wage in the female-dominated occupation is then assigned the wage paid in the matching male occupation. If more than one male-dominated occupation matches a particular female occupation, a rule must be followed in determining which wage will be applied. In practice, however, this can lead to the lowest wage being applied. It can also lead to female-dominated occupations with higher point values being assigned lower wages than female-dominated occupations

with lower point values, given idiosyncrasies in the markets for workers in male-dominated occupations.

There are, however, several other ways to determine female wages under comparable worth that are not subject to these concerns. One method is to estimate a wage equation for male-dominated occupations and use that estimated equation to compute a wage for each female-dominated occupation. Another method is to estimate an earnings equation over all occupations, controlling for total job points and the proportion of females in an occupation, and then add the estimated reduction in wage due to the proportion of females to existing wages in each of the female-dominated occupations. Finally, another way is to estimate an earnings equation using data on wages and job values for all occupations and then use that equation to adjust all workers' wages, both male and female. In this scenario, some individuals, primarily females, would experience an increase in wages, while others, primarily males, would experience a decrease in wages. This is less politically feasible, however, than any of the other methods.

ECONOMIC THEORY AND COMPARABLE-WORTH OCCUPATIONAL SEGREGATION AND CROWDING

Economic theory predicts a negative effect of comparable worth on women's employment. This is because increased wages in female-dominated occupations would lead employers to make fewer of these jobs available. Employers cut back on production when faced with higher input costs, requiring less of all inputs. In addition, employers substitute other inputs for the now-more-expensive female workers. Theory also predicts an increase in unemployment in female-dominated occupations due to an increase in the number of women looking for work at the now-higher wages at the same time the number of available jobs is declining. Economic theory also predicts that the supply of females to male-dominated occupations where wages are not directly adjusted via comparable-worth policy will increase due to the decline in employment in the female-dominated occupations covered by the policy. This will depress wages in the male-dominated occupations and will possibly even lower wages for the women below those they would have received without comparable worth in the female-dominated occupations.

Finally, if comparable worth not only increases wages in female occupations, as is often proposed, but

also artificially decreases them in male occupations, economic theory predicts there will be a shortage of workers in male-dominated occupations, as fewer individuals will be willing to work at these lower wages. As a result of this shortage of workers in male-dominated occupations, the quality of workers in these occupations could decline, as firms might need to accept lower-quality workers in order to meet staffing requirements. Thus, comparable-worth policy affects not only the employment and unemployment of workers in female-dominated occupations but also the quality of workers hired and hence the quality of the final products or services produced by workers in the male-dominated occupations.

EMPIRICAL EVIDENCE ON COMPARABLE WORTH

Effectiveness of Comparable-worth Policies with Respect to Women's Wages and Employment

Empirical evidence suggests that the benefits of comparable worth in the form of a lowered wage gap between male- and female-dominated occupations are smaller than proponents of comparable-worth legislation expected and that the decline in employment is also much smaller than opponents expected. One potential reason for these small estimated effects is that comparable worth is limited primarily to the public sector. This sector makes up only a small portion of employment in many, if not most, female-dominated occupations. Another reason suggested by empirical research is that male-female pay differences within an occupation are predominantly interfirm and interindustry, not intrafirm, and thus not subject to comparable-worth policy that affects pay differences only within a particular firm or establishment.

Effectiveness of Comparable-worth Policies in Satisfying the Prevailing-Wage Principle

Wages paid by public employers are usually set with the prevailing-wage principle in mind. This principle states that public employees are to receive wages equal to those they would be paid if they were working in an equivalent job in the private sector. If the ratio of public to private wages is equal to 1, then the prevailing wage principle is satisfied. While perfect

correspondence between wages in the public and private sector does not occur in the absence of comparable worth, the estimated ratio is close to 1. Empirical results indicate, however, that when comparable-worth policy requires wage increases for female-dominated occupations but disallows decreases for male-dominated occupations (as is often the case in practice), public sector wages are moved away from this prevailing-wage standard. However, if decreases in the wages paid in male-dominated occupations are allowed, although in practice this is usually not politically feasible, then one would be moved toward the prevailing-wage standard. Hence, both the competing principles of prevailing wage and comparable worth must be considered when designing comparable-worth policy.

A DIFFERENT APPLICATION OF COMPARABLE WORTH

A situation in which the issue of equal pay for equal worth arises outside the context of gender is in the case of university professors. Efforts by unions to organize academic faculty often note the disparity in pay between faculty with similar training (a PhD) and years of experience (a particular rank) but different fields of research and/or teaching. Such disparities arise due to differences in the supply and demand in the markets for different types of professors. For example, economics or finance professors often earn relatively high salaries compared with sociology professors. This may be due to a higher demand for economics classes than for sociology classes, a smaller supply of economics professors due to more lucrative alternative opportunities in the nonacademic market, or a combination of both. However, unions and comparable-worth advocates would argue that the work performed by both types of professors is of equal worth, as both types of professors engage in teaching, research, and service activities, and so both economics and sociology professors should be paid equally. Opponents, however, would point to the negative effects of a decline in the employment of sociology professors, an increase in the unemployment of sociology professors, and the potential shortage of and corresponding decline in the quality of economics professors that would result if the wages of economics professors were set artificially low as a result of comparable-worth policy.

COMPENSATION

Compensation encompasses myriad schemes that organizations use for providing their employees money in return for their labor. When designing and implementing a compensation system, organizational decision makers must ask many questions and address many issues. How much should we pay our employees? Should pay be based on the job or on the person? Should employees be paid fixed rates, or should pay vary as a function of seniority or performance? What is the appropriate pay structure across the organization; that is, how much compensation discrepancy should there be between good and poor performers or between new and long-tenured employees? Researchers have studied compensation issues for many years and have generated a wealth of research evidence on some important issues, but other issues remain lightly researched. In this entry, a sample of this evidence is outlined and described. First, issues and evidence regarding base pay levels are addressed. Second, the types of variable pay and incentive plans are outlined.

Third, the evidence and issues concerning the structure of pay in the organization but within and across organizational levels are described.

The issue of how much to pay employees for their work has perplexed compensation decision makers for many years. An influential theoretical approach in economics, the *neoclassical theory approach*, suggests that market forces compel organizations to offer basically the same market rate for work and that any differences in base pay levels across organizations will be short-lived. Research evidence, however, suggests there are large differences in the rates of pay organizations offer for the same work and that these choices have a substantial relationship with important attitudinal and behavioral outcomes in organizations. Other economic viewpoints as well as theory in the fields of organizational behavior and human resource management provide interesting insights into these issues. In recent years, economists developed a theory known as the *efficiency wage theory*, which suggests that organizations may reap substantial benefits from paying higher-than-market rates to their employees. In establishing a very high base pay rate, an organization may garner several advantages over competitor organizations. Offering high pay rates may simplify recruiting processes by attracting a large number of applicants from the marketplace and perhaps a larger number of qualified applicants. Selection processes may also be simplified because it may take less persuasion to entice applicants to accept job offers. The organization may also realize advantages in terms of employee productivity. For example, organizations may be able to insist on or expect higher-than-average effort, efficiency, and performance levels in return for higher pay rates. From the perspective of the individual employee, a person may work harder because he or she realizes the advantages of higher pay in the given organization. Employees may also be more effectively retained in the organization because they realize that they cannot find a similarly paying job in the marketplace. Inducing employees to give more effort as a result of high pay levels is known as the *incentive effect of efficiency wages*, and the attraction of greater numbers of high-quality applicants is known as the *sorting effect of efficiency wages*.

Why do some organizations choose to pay efficiency or higher-than-market pay rates? One reason is that some organizations rely more on their employees to generate revenue. Organizations that require highly skilled or specialized employees to generate income

or those that are structured in unique ways may have a greater need to pay above-market rates. For example, some organizations have very few supervisory employees and make extensive use of self-managed work teams. Under these conditions, it may be necessary to pay employees high pay rates to ensure that they are performing at high levels. Research also suggests that the need to pay employees high rates may also be driven by the business strategy of the organization. Some organizations try to be successful by maintaining very low-cost structures, while other organizations focus on innovation or providing goods and/or services of the utmost quality. Low-cost organizations may pay low rates because employees are not as valuable in terms of creativity or quality, and therefore high effort levels and low turnover rates are minimized in importance. Innovative organizations require workforce stability and high skill levels among employees and often pay high rates as a result. Finally, organizations that have difficulty monitoring the behavior of employees because of the large size of the organization or the geographic dispersion of employees may pay efficiency wages to spur employees to work harder. Research also shows that organizations make several other important decisions about setting pay rates for their employees. For example, many organizations pay rates for jobs that are central to their functioning or core jobs (e.g., a baker in a bakery, a physician in a hospital, a logistics specialist in a freight-moving company) more than other jobs. That is, many organizations pay “efficiency” or special wages to only certain groups of employees, but average or below-market rates for other groups of jobs.

In addition to setting base pay or pay rate levels, organizations must also make decisions about whether or not to provide financial incentives for performance (e.g., merit pay raises, bonus). The use of financial incentives or pay-for-performance schemes continues to be hotly debated in the popular press and also among researchers. On the one hand, some researchers argue that providing financial inducements to individuals in return for good performance can reduce intrinsic motivation levels of employees. This argument is contained in a theory known as *cognitive evaluation theory*. According to this approach, if offered money as an extrinsic motivator, individuals will lose some of their basic interest in performing the tasks that are being rewarded. Perhaps more important, providing financial incentives for high performance may

lead employees to focus only on the tasks that are necessary to receive the reward, while ignoring other tasks that are important but not specifically rewarded. On the other hand, other theories suggest that providing financial incentives for performance is an effective means of increasing performance levels among employees and, in addition, has no negative effect on the intrinsic motivation levels of employees. Researchers pursuing this line of investigation often rely on the psychology models of B. F. Skinner, which suggest that individuals will repeat behaviors that are effectively rewarded. Several cognitive motivation models are also frequently used to explain a positive relationship between the use of financial incentives and employee performance. These models (e.g., the expectancy theory of motivation and goal-setting theory) suggest that individuals make decisions about behavior and effort levels as a function of their beliefs that (a) behaviors will lead to high performance, (b) high performance will be rewarded, and (c) the rewards for high performance are desirable. If financial incentives are properly administered, individuals will link these cognitions and perform at high levels in return for financial rewards.

There is considerable research evidence to support a positive relationship between financial incentives and individual performance, especially in terms of performance quantity, and virtually no evidence that financial incentives reduce intrinsic motivation levels. In a recent study that cumulated research findings across a 40-year time window, there was a strong positive relationship between the use of financial incentives and the quantity or amount of work that individuals produced. The relationship between the use of financial incentives and the quality of employees’ performance (i.e., how well they work), has rarely been studied. The aforementioned study found only six published investigations on this topic over the same 40-year period. While the average relationship in these studies was positive, it was not a strong positive relationship. Much more research needs to be conducted on the issue of financial incentives and performance quality.

It is clear that nearly all organizations in the United States use some kind of financial incentive or pay-for-performance program. Some surveys suggest that more than 90 percent of U.S.-based organizations state that they pay their employees based on performance. The question is this: What type of pay-for-performance program should be used? Clearly, the

most popular pay-for-performance program is merit pay. *Merit pay* is defined as permanent increases to base pay (a permanent pay raise) based on individual performance evaluations. Merit pay is what is known as a *behavior-based financial incentive* program. In these types of programs, a rater (or group of raters) evaluates the behavior of employees, compares and contrasts levels of performance among individuals in the group, and finally assigns pay raises based on the relative levels of performance. These types of programs offer several advantages to individual employees and employers: They can be used for any type of job, they allow for correction of factors beyond the control of employees when evaluating performance (e.g., faulty equipment), and they focus on the behaviors underlying effective performance. They also have several disadvantages. In particular, judgments of performance are often quite subjective, and employees may not believe that their ratings accurately reflect the quality of their behaviors.

Some research suggests that the key factor in the failure of merit pay plans is that employees do not believe that pay raises are accurately linked to performance levels. Another limitation of merit pay is that raters often fail to make clear or adequate distinctions among employees. Performance ratings tend to be biased upward; many decision makers are uncomfortable giving very low performance ratings to individuals who may deserve such ratings. Merit pay plans are also often limited by the small size of pay raises awarded. Some research suggests that pay raises must be as high as 7 percent before individuals will report that the pay raise is meaningful. Given that average pay raises in the United States over the past 15 years were typically less than 4 percent, most awarded merit pay raises are likely not effective in terms of encouraging high performance levels in the future. In general, although merit pay plans are extensively used by organizations, the research evidence concerning their effectiveness can best be described as “mixed.” There is clear evidence that the use of financial incentives relates positively to performance, but error and other failures in the administration of merit pay tend to reduce its overall effectiveness in practice. When administered effectively, merit pay raises tend to be positively related not only to individual performance but also to compensation satisfaction, or happiness with pay raises, and negatively to intentions to quit the organization.

Some organizations use what are known as *results-based financial incentive plans*. These types of plans, sometimes referred to as *piece rate compensation*

plans, provide rewards to individuals for results, rather than the behaviors that may or may not lead to results. Results-based plans are typically used when there is an available objective outcome (e.g., sales volume or units produced) and when behaviors cannot be monitored effectively. The advantages of these types of compensation systems include the clear link between the outcome (sales volume or units produced) and the incentive (e.g., a percentage of the sales volume or a certain amount for each unit produced). Although these advantages are clear, these types of plans are fairly rare in the current business environment, in part because objective outcomes are difficult or impossible to obtain in most modern jobs and because most of today’s work outputs are collectively rather than independently produced.

Although individual incentive plans are the most popular forms of compensation, many organizations also include seniority provisions in compensation packages for employees, use group, unit, or organization-based incentives, and a growing number of organizations use skill-based compensation plans. Research clearly demonstrates that providing pay increases based on tenure or seniority can lower turnover rates. There is consistent and clear evidence that workforces are more stable to the extent that pay is based on seniority, but there is little evidence that these workforces are high performing. Seniority provisions provide rewards for performance only in the broadest sense possible, that is, minimum performance necessary to avoid firing or discharge, and therefore provide primarily retention inducements.

Group- and organization-based incentives (productivity gainsharing, team-based pay, and profit-sharing plans) are gaining in popularity and offer several advantages over individually based incentive plans. These types of plans may encourage teamwork and collaboration across functional units and help develop a spirit of common fate in the organization, each of which may lead to increases in performance. These types of plans may also lead to mutual monitoring behavior among employees such that wasted time, effort, and resources are diminished when employees understand that their pay raises or bonuses are linked. There is consistent evidence that profit-sharing plans (bonuses awarded to employees based on organizational profitability) relate positively to organizational performance. These results, however, are not clear in terms of the causal direction of the relationship; perhaps only highly profitable companies adopt profit-sharing plans. A primary disadvantage of

group-based incentive plans is known as the *line-of-sight problem*. A given employee in an organization may not believe that his or her behaviors are related to the overall performance of the group, unit, or organization. In these cases, group-based incentives may encourage shirking or free riding because the person believes that the same reward will be received regardless of his or her effort level.

Skill-based pay, also called *pay for knowledge*, *pay for skills*, and *multiskilled compensation*, is a relatively new compensation innovation. Regardless of the terminology used, it represents a distinct deviation from traditional compensation systems that pay employees for the jobs, not the skills, they hold. Traditional job-based systems are concerned with the nature of the task, while skill-based pay is concerned with the nature of the attributes possessed by employees. Under these plans, an employee's pay level is set for the skills he or she holds at the current time, and the individual is given additional pay increases when he or she acquires a new skill and demonstrates competency in it. Moreover, pay increases are awarded whether or not individuals actually use the skills in the course of their day-to-day work. Multiskilled employees are desired by organizations because they can increase workforce flexibility and productivity. For example, an organization replete with multiskilled employees can more effectively handle periodic absences and unexpected quits than an organization using job-based pay, because many skills are essentially held in reserve in the workforce. The disadvantages of skill-based pay plans are that they are difficult to administer, involve a complete renovation and integration of the human resource management system, and can sometimes, although rarely, lead to prohibitively high pay levels in the organization. Although these types of plans are still fairly rare, there is evidence that they increase the flexibility and productivity of the workforce in general and that these types of plans are typically received favorably by employees.

The preceding review is but a brief sample of the types of compensation plans available to employers and employees, as well as a synopsis of the implications of adopting any given plan or combination of plans. Because compensation is one of the largest costs that organizations incur in doing business, often more than 70 percent of total costs, organizational decision makers are continually looking for ways to more effectively compensate their employees, and researchers are continuing to develop and test ideas

that may lead to more effective compensation management in the future.

COMPUTER-BASED CAREER SUPPORT SYSTEMS

Computer-based career support (CBCS) systems are information and communication technology (ICT)

applications aimed at assisting individuals in their careers through the provision of online career support services. CBCS systems include a mix of career support services that correspond to four general functions of "social support": informational, appraisal, instrumental, and emotional support. Informational CBCS is provided through information on occupational and career-related topics. Appraisal support consists of feedback from personality and skills assessments. Instrumental support includes, for example, e-learning, job vacancies, and career decision-making support. It has also been recently shown that emotional support can be provided through online communication functions, such as e-mail, chat, and discussion forums.

CBCS systems can be either (a) intraorganizational, with a restricted access, or (b) publicly available, Internet-based, or intraorganizational. CBCS can be offered as an independent career management application for employees or as part of an organization-wide e-HRM system. Public Internet-based career support is often associated with independent online recruiting and career counseling sites. Most Internet-based career support services are offered for free or at the cost of basic registration. Although both forms of CBCS are concerned with finding the best possible person-job fit, the key objective of intraorganizational career support is to maximize individuals' performance. The key objective of Internet-based career support is to improve users' careers.

Integrated CBCS systems are a fairly recent development. Thus far, few empirical studies have reported on such systems' usage and effects or on users' and providers' perspectives. The available studies point to an underutilization of integrated or all-inclusive career support systems. CBCS, no matter how sophisticated or integrated it may be, is often merely used as just another online recruiting service. The studies that focus on examining single CBCS functions, such as career counseling, career decision making, recruiting, and so on, however, report quite the opposite results. Some studies, for example, report a high popularity and positive reception of a Web-based career advisor application for medical students. Other empirical studies have demonstrated students' increased career decidedness after the use of an Internet-based interactive career-planning system and computer-based career guidance system. Also, there is evidence of an increase in the quality of selection outcomes and hiring, as well as job search process efficiency. Thus, current key questions in regard to the practice and

research of the integrated CBCS are as follows: Why does the provision of all-in-one career support appear not to be accepted by its intended users? How should the integrated provision of a CBCS be reconceptualized to get the system accepted and used effectively in the future?

Recent literature on the effective provision of interactive professional services, such as CBCS, distinguishes two approaches. One takes a sociotechnical perspective, and the other takes a social perspective. The sociotechnical perspective suggests that career support belongs to a range of professional services that are currently difficult to provide through the Web. Services of this group require high customization of highly advanced technologies that are only emerging. Recent literature notes the importance of gender, age, language, and ethnicity issues in the customization of such services. However, much more research is needed to identify all critical areas for CBCS customization.

The social perspective, however, is not constrained by technological developments and offers vast opportunities for new social science research. For example, studies of online communities suggest that CBCS may be conceptualized as a *virtual social structure* of relations or a virtual community, rather than a mere source of career service provision. From this perspective, the studies of CBCS would need to include the design principles of a traditional community. As several researchers note, virtual communities succeed not because of flashy graphics, but because they contain a number of requisite elements for a successful community, such as identity persistence, a coherent sense of space, and a sophisticated set of rituals. The incorporation of *social network* research on the various ways people operate within social networks may also determine who will use the CBCS and how it can be used effectively.

The social perspective calls for consideration of further study of *social career support processes* for making CBCS usable and effective. Recent empirical investigation of integrated CBCS systems suggests that the current process of virtual career support is quite different from what is provided by career counselors. The current CBCS systems allow selective usage of career support functions, or "cherry-picking," while the process of traditional counseling is more guided and prescribed.

Further research on the effectiveness of CBCS will need to question whether a single source of career support that includes career counseling services, on

the one hand, and recruiting, on the other, does not undermine the trust of users. If so, that could be a reason for poor usage of a CBCS. The basic idea behind this assumption is that very few users would be willing to expose their career uncertainties to a CBCS if it were part of an online recruiting agency's or an employers' e-HRM system and might be a vehicle to new career or job opportunities in the future.

In sum, CBCS is a novel and sprawling phenomenon that, in theory and practice, offers large potential efficiency gains. The efficiency gains to be had from a CBCS (at individual and organizational levels) appear obvious and perhaps, therefore, have not received much serious research attention. In terms of the perceived intrinsic value of the content of the offered support, much more research across both users and those who design and sustain the support will point to new ways of designing more effective and better used systems. Approaching CBCS from multiple and interdisciplinary research perspectives, including both the sociotechnical and social perspectives, would help to make it more accepted and effective.

CONTINGENT EMPLOYMENT

Contingent employment has become pervasive in contemporary society. It is a multifaceted phenomenon with significant implications for career development, occupational and economic opportunity, and employment security. The employment of people on a contingent basis is a trend found in all the advanced industrialized countries of the world. Understanding the many faces of contingent employment, therefore, is crucial to social science theories and empirical analyses of work, employment, and careers. While estimates of the extent of contingent employment vary, there is a consensus that it has expanded notably in the last two decades of the twentieth century and in the early twenty-first century. Estimates depend on how contingent employment is defined. In its broadest definition, contingent employment includes temporary, contracted, seasonal, day labor, and part-time jobs. Using these broad parameters, it is estimated that more than 30 percent of the American workforce is employed on a contingent basis. Excluding part-time jobs (many of which are permanent), the contingent workforce is estimated to be approximately 15 percent.

Part-time Employment

Part-time work has existed for many decades. Historically, employers hired people on a part-time basis to adjust the size of their staffs to shifts in business cycles. Hiring extra restaurant staff to serve customers during a lunch or dinner hour is one example of this type of adjustment. Increasingly, many corporations structure their jobs on a part-time basis to avoid having to pay benefits to workers, discourage workers from developing long-term attachments to firms, and minimize long-term relationships among workers that might lead them to mobilize against employers for better wages and working conditions. Part-time employment is widespread in the service sector, particularly in fast-food and retail service occupations, where training requirements are low and turnover is high. Many people who are able to find only part-time jobs may moonlight as well, holding down multiple part-time positions at any given time.

Temporary Employment

Similarly, temporary employment has existed for many decades, but the dynamics have changed

considerably in recent years, a period that has seen explosive growth in this form of employment. In the post–World War II era, many women took jobs on a temporary basis because it allowed them to adjust their paid work hours around their unpaid family obligations. When a woman worked in a temporary job, typically she filled in for a full-time, permanent worker who was temporarily ill or otherwise off the job for a brief duration. Today, researchers have discovered, many temporary jobs are permanent, continuous positions that managers staff with temporary workers on an ongoing basis. Thus, while a temporary employee in the postwar period might have worked for a few days or weeks to fill in for a permanent worker, today a temporary employee might work for months and, in some cases, years, carrying out job tasks much as a permanent worker does. While women continue to be the majority of temporary workers, this workforce is increasingly staffed by men who are able to find only temporary positions.

Companies use temporary workers for a variety of reasons, including increasing their flexibility to let go of a portion of the workforce when there is an economic downturn, externalizing the costs and complexities of handling the workforce, and cutting back on the size (and thus the costs) of the permanent workforce. Companies using temporary workers, or “temps,” often limit the length of time they can work in order to avoid “temp-initiated” legal actions that might require the company to hire them on as permanent workers or give them benefits. Temporary jobs on average pay lower wages than their permanent counterparts and usually are found in the lower levels of the occupational ladder, including clerical, assembly, and technical. Such jobs offer few, if any, benefits; in this “at will” contract, employers can let go of temporary workers without any advance warning.

For these reasons, social scientists and labor economists who study the spread of temporary employment worry that the institutionalization of this category of employment creates a second tier of workers who are disadvantaged economically, experience continual insecurity, and lack opportunities to develop careers. It can be difficult for temporary workers to develop and pursue careers because they lack the opportunities to acquire skills that would allow them to move up and out of the low-level “temporary ghetto.” Many temporary workers report feeling trapped in the cycle of temporary employment, wherein they must work so hard to survive in and obtain temporary jobs that they can’t

afford the time or the money to develop new skills or advance their educational credentials. At the same time, many workers hope that these jobs serve as a bridge for them to get a foot in the door of good companies and eventually gain permanent positions.

One indication that temporary employment poses a hardship to workers is that the majority who work on a temporary (or part-time) basis do so involuntarily: In other words, they would prefer to hold a permanent or full-time job if they were able to find one. Many observers argue that the growing pervasiveness of involuntary temporary employment is a key factor that undermines the stable-employment contract of the midtwentieth century, which offered workers stable and secure employment, as well as benefits. The explosive growth in temporary employment has been spurred by the symbiotic growth of temporary help and staffing agencies, which we discuss shortly.

Contract Employment

Contract work is another type of contingent employment. Importantly, it reveals the contradictory nature of contingent employment in the contemporary economy. Specifically, the experiences of contract workers reveal how contingent employment cannot be seen simply as a method for cutting back on costs, nor does it uniformly disadvantage workers. Contracting work in some ways resembles temporary employment: Contractors work for delimited periods of time for an employer, carrying out a project or a job only until it is completed. Contractors can be self-employed, or they can be deployed by staffing agencies. Like temporary workers, contract workers experience a great deal of uncertainty in their employment prospects and must absorb fluctuations in the economy and markets. For example, in the Silicon Valley, which has a large contract labor market, employees face intermittent periods of unemployment (“down time”) when high-technology firms experience economic downturns or lose their competitive edge in a product market, or when projects come to an end. Like temporary workers, contract workers usually pay for their own health benefits and design their own retirement packages. Unlike temporary workers, however, many contract workers experience greater advantages.

Contractors typically are highly educated professional and, to an increasing degree, managerial-level employees. Contract workers often earn higher wages

in a contract position than do their permanent counterparts. Researchers have noted with irony that it has become a common practice for firms to lay off their permanent, experienced information and technology workers, only to rehire them on a contract, contingent basis at a higher salary. Contractors possess technological or information management skills that put them in a highly competitive position on the job market and that they can use to leverage high wages. Firms employ these high-level contractors for different reasons than they employ lower-level temporary workers: For example, contractors may have unique technological or administrative skills that a company needs but lacks in its own permanent workforce.

With respect to career development, contractors experience a different set of issues than do temporary workers. Contract workers develop careers in their technological or professional niches, but their careers are not organizationally bound, as might have been more typical in the postwar era. Observers use the term *boundaryless employee* to capture the fact that specialized professional workers move from position to position, across a variety of organizational settings. Thus, their careers are fluid, not confined to one organization, and can even shift across different industrial fields. These skilled, well-paid employees, it is believed, choose to work on unpredictable terms, embrace the opportunity to work in new corporate environments and learn new skills, and eschew long-term relationships with one or a very few employers. In contrast, then, to those who are employed and even trapped in involuntary temporary employment, contractors are believed to work on a temporary basis by choice.

STAFFING AGENCIES: THE PRIVATE SECTOR

Contemporary staffing agencies, once commonly referred to as “temporary-help agencies,” are the dominant type of labor market intermediary that facilitates part-time, contract, and temporary employment relations. Although temporary-help agencies are not new, they have changed and grown dramatically in the last two decades. Today, staffing agencies often work directly with corporate human resource departments to help them manage a host of employment-related functions. And there is growing evidence to suggest that intimate partnerships between firms and staffing agencies are contributing to the outsourcing of significant portions of the human resource function.

Data on industry size and growth by segment indicate that temporary-help service agencies are still the largest segment of the staffing industry. Although revenues from temporary placement dominate the staffing industry, the character and scope of temporary-employment arrangements have changed dramatically as new staffing services have enabled firms to manage contingent labor in unprecedented ways. Whereas in the past temporary-help agencies primarily matched employers with employees, conducting a minimum of prescreening of less skilled workers who could fill the temporary needs of a company, today these agencies have expanded, changing their names and images to reflect the more diverse scope of their businesses.

Staffing agencies vary in both size and the types of services they provide, but most offer employers a range of services, including assistance with recruiting, training, prescreening or testing, and payrolling. They can take over the legal and administrative responsibility of managing a firm’s workforce through new types of employee-leasing arrangements (also known as professional employer services, or PEOs). Staffing agencies offer firms on-site management of their temporary workforces through vendor-on-premises arrangements (VOPs) as well as consulting services related to the development of human resource policies, organization and design, and communication strategy.

Often adapting their strategies to meet local labor market conditions, staffing agencies also provide a number of supplemental services for their client firms, including advertising for specific job openings, transporting workers, 24-hour staffing, and other services specifically designed for individual client needs. Historically, temporary agencies focused on recruitment and placement of temporary clerical and light-industrial workers. More recently, these agencies have expanded their market shares, reaching out to the technical, professional, and managerial workforces.

The staffing industry can enable employers by giving them an opportunity to either outsource functions or externalize the costs of their human resource functions. However, the use of staffing firms may complicate certain aspects of corporate human relations, creating hidden monetary and managerial costs. For example, *coemployment*, the term alluding to the relationship between staffing agencies and their client firms, can be unclear. Coemployment laws vary from state to state, often making the legal aspects of staffing agency involvement very confusing for firms and

workers. Grave uncertainty can arise out of the coemployment relationship, with consequences for both employers and employees. The legal, economic, and ethical obligations to employees on the part of the staffing firm, its customer, or both, depend on numerous complex factors.

Some researchers argue that today's staffing agencies actively shape labor markets rather than simply react to impersonal market supply-and-demand forces. Staffing agencies, through the various services enumerated above, are playing a critical role inside their client firms, becoming, in some cases, institutionalized actors taking on a range of functions that were once reserved for internal human resource departments or unions. They also work on behalf of workers themselves. Although evidence indicates that outcomes vary, it is well-known that employees are turning to staffing agencies for help with job placement, training, and career development as they search for help in navigating the complex terrain of contemporary labor markets. Many workers use these agencies to obtain the temporary positions they believe will be bridge positions into permanent jobs in a company.

NONPROFITS, UNIONS, AND PUBLIC AGENCIES

In addition to the private sector staffing industry, nonprofit, public, and union-sponsored organizations also provide services and/or advocacy programs for contingent workers. Some public sector employment agencies have partnered with private sector staffing agencies, channeling public funds to the private sector to provide workers with training or temporary employment opportunities. A number of researchers have criticized these partnerships because employment through the private sector staffing industry is often associated with low wages, bad working conditions, and lack of health insurance coverage and retirement benefits. There is a belief that public and nonprofit sector programs are by nature more oriented to the needs of employees. In recent years, a number of organizations have arisen to ensure that staffing agencies and corporations are accountable to the needs of the contingent workforce.

For example, Working Today, a New York-based organization, organizes contingent employees and independent contractors. This organization provides programs aimed at collectively solving the problem of health insurance and retirement pensions so that their members can more easily move from job to job while

retaining benefits. Unions themselves have moved beyond their traditional mission of primarily serving the needs of permanent employees and are now advocates on behalf of the contingent workforce. Several unions have extended collective bargaining conditions to temporary, part-time, and contract workers. A number of unions are operating their own staffing/employment agencies, placing temporary workers in positions with higher standards for wages and benefits packages than what the private sector offers.

Labor advocates have long documented the need to organize temporary, part-time, and contract workers to provide them with greater workplace protections, increased wages, better working conditions, and improved opportunities for career advancement. However, researchers have identified many obstacles to collective mobilization of the contingent workforce. In particular, because this workforce is very mobile and because contingent workers span a wide range of occupational groupings, efforts to organize the contingent workforce have been limited. Despite these obstacles, there is evidence that advocates for contingent workers are making progress in changing public policies and influencing corporate practices to better meet the overall needs of today's growing contingent workforce.

Contingent employment, a *mélange* of different corporate practices and lived experiences, shows all signs of remaining a dominant approach to staffing and hiring. Although many researchers worry that the size of the contingent workforce will grow, with deleterious consequences for American workers, the evidence to date suggests that the field is variegated and shifting; thus, the long-term implications remain inconclusive.

CONTINUING PROFESSIONAL EDUCATION

Continuing professional education (CPE), or continuing education, is the education of professionals in a variety of fields and practice that offers preparation for a particular career or extends the individual's knowledge and learning within a profession. CPE helps learners keep their knowledge current, build competencies, progress through a career, achieve promotions, and even shift into a different field. CPE is increasingly important in a context characterized by a boom in knowledge and technology coupled with public demand for accountability. In turn, these trends have increased the strain on continuing-education resources.

CPE certifies professional knowledge, skills, and abilities applicable to practice, while also addressing the professional's ongoing learning needs. It generally emphasizes the acquisition of individual competency and reflective practice. CPE assumes a continuation of prior training and that the professional has a formal body of knowledge, authority based on this specialized knowledge and expertise, and accountability to clients. Past research has suggested that four factors define quality in CPE: participant readiness to learn, relevance to practice, appropriateness of presentation, and relevance to the professional's needs.

THE HISTORY OF CONTINUING EDUCATION

Continuing education has been practiced throughout history, beginning with apprenticeships and guild systems of the middle ages. The field was named and

claimed by adult education in the 1960s. Throughout the 1960s and 1970s, the professions, occupations based on discrete information and competencies, began to establish professional organizations and regulatory agencies that monitored continuing-education requirements for becoming licensed, certified, or a practitioner. While required in many career fields, compulsory professional education guarantees neither professional compliance nor competence. The foundations of the field were solidified in the 1980s, with publications such as Cyril Houle's *Continuing Learning in the Professions*, and are grounded in adult-education theory.

In 2001, Ronald Cervero offered an assessment of 20 years of CPE, for the period from 1981 to 2000, noting five trends: (1) the amount of continuing education offered in the workplace dwarfs that offered by any other provider; (2) CPE is increasingly offered via distance education; (3) there are increasing collaborative arrangements among providers (i.e., universities and organizations); (4) the "corporatization" of continuing education has increased dramatically; and (5) continuing education is being used more frequently to regulate professional practice.

CONTROVERSIES IN CONTINUING EDUCATION

Controversies in CPE include compulsory CPE, market-driven CPE, and competency-based CPE. Although whether or not to make continuing education compulsory remains contentious, professionals continue learning throughout their careers. Proponents of compulsory CPE argue that it should be voluntary but believe this is an unrealistic goal. Proponents also argue that compulsory education will result in more efficiency and effectiveness, ensure equal access to a range of educational opportunities, and is a better alternative than periodic examination or review of practice. Opponents of compulsory CPE insist that it violates adult learning principles and that evidence is lacking that demonstrates that compulsory education improves performance, quality control, or practical relevance. It has also been noted that educational opportunities are not readily and equally available.

Other researchers have examined whether continuing-education programs should be market driven. Opponents argue that market-driven programs perpetuate inequality by ignoring the needs of those who can't afford to pay for the program, by meeting individual needs but not societal needs, and creating profit at the expense of educational benefit. The controversy

over market-driven CPE programs rests on three issues: who the market is, whether higher education's mission will change, and how continuing education is viewed within higher education. Some experts in the field advocate a market-driven orientation that is tempered with a socially conscious effort to balance profit with an ethical approach, while others believe that continuing-education programs should be demand driven, make a difference in the big picture, encourage learners to think critically, incorporate multiple perspectives, and change learners.

CPE's ability to maintain and enhance competence is an issue, as are enhancing accountability and relating to the context of practice. Researchers have argued that if CPE is to be effective in the future, educators must shift from a program mentality to developing professional competence. A fallacy of CPE is that participation automatically translates into professional competence. There is increasing pressure on CPE providers to demonstrate the value and impact of their work. Laura Bierema and Michael Eraut have observed that CPE harbors dysfunctional assumptions that diminish its effectiveness, including that CPE fails to pay sufficient attention to more complex representations of personal knowledge, skills, and competencies that have emerged during the past decade. CPE also tends toward the trendy and exaggerates formal learning over the more frequent and rich informal learning that takes place in the workplace independent of CPE. CPE is also individually focused, making it less effective than substantive changes in the collective practices of colleagues, administration, organizational structure, or culture. CPE also needs to better address issues of diversity through increasing self-awareness, examining diversity issues in the CPE teaching relationship (learner and educator), and developing more inclusive research and theory.

THE FUTURE OF CONTINUING EDUCATION

In the future, CPE must be regarded not as a program, but as a system of building professional competence. In this regard, Donna Queeney has observed that continuing education must address application of knowledge and skills within a practice context, must go beyond simply providing information and teaching technical procedures, and must help professionals build their collaborative, judgmental, reflective, and integrative capacities.

COOPERATIVE EDUCATION

Cooperative education is a structured educational model in which students alternate between periods of classroom study on campus and periods of paid work at job sites away from campus. Cooperative education relates to career development because it is a means of career exploration that is a comprehensive intervention, including self-assessment, feedback, general and specific information about work, and career testing for long-term periods in real-world settings. Educational goals in such programs include integrating theory and practice, testing career options, and learning from experience. Although the model has historical roots in feudal apprenticeships, as well as medical and legal clinical programs, the term "cooperative education" was coined by Herman Schneider in 1906 to describe a means for educating engineers at the University of Cincinnati with alternating study and work. At about the same time, a similar idea called a *sandwich educational program* was developed in the United Kingdom. Schneider and other early adopters of the model claimed a common rationale for the innovation: to smooth the transition from school to work for students, a need identified by employers, students, and educators.

Some full models of cooperative, or *co-op*, education exist within the K-12 and postbaccalaureate educational sectors; however, undergraduate programs are the focus of most scholarly materials on the topic. Co-op is a commonly used shorthand term for both the jobs taken by students and the students themselves.

The first half of the twentieth century saw a steady growth in the wider acceptance of the cooperative education model. Some important innovations included the adoption of the model for business students at the University of Cincinnati in 1919 and for students in all majors within a liberal arts program by Arthur Morgan at Antioch College in 1921. One way to cluster co-op programs is to differentiate *vocational* and *environmental* programs. In vocational programs, all co-op jobs taken are closely related to the student's major, with planned and evaluated learning outcomes being career-related. In environmental programs, students are encouraged to take jobs that meet a variety of personal developmental and professional goals, so that some co-op jobs will be major related and some purposefully not. The former type is more common in preprofessional programs, such as in engineering and business schools in the United States and abroad; the latter tends to be used in liberal arts programs primarily in the United States.

During the second half of the twentieth century, the prevalence of cooperative education programs grew in the United States from about 60 colleges and universities to a peak of about 1,000 programs in the mid-1980s. Much of this growth has been attributed to federal funding from 1971 to 1996. Reviewers of this period of co-op history generally surmise that more planful growth, that is, growth with a greater focus on structures to enhance learning rather than a focus on increasing student recruitment, might have allowed the federal funding stimulus to promote more stable programs that might be considered leading-edge educational models today. As it is, the number of programs has diminished to about 500 in the United States, the smaller of which struggle for legitimacy within their academic environments. Internationally, cooperative education is practiced in about 60 countries worldwide, and that number is growing more rapidly than in the United States.

There has been a concomitant growth of various forms of experiential learning since the 1960s. In fact, it would be difficult to find a U.S. undergraduate program that does not require or allow some type of internship, practicum, or service learning experience.

Should all of these models of work-integrated learning be called cooperative education? Some practitioners in the field see the generic use of the term as a negative, a clouding of the definition; others argue that it is useful for cooperative education to be inclusive of diverse models. There is not a strong research base to distinguish among the educational benefits of various amounts and types of work-integrated learning, but there have been several noteworthy attempts to publicize and use attributes that distinguish cooperative education from other models of experiential learning as credentialing criteria. These attributes include how thoroughly co-op is institutionalized (e.g., evident in institutional literature), whether there are productive and effective relationships with faculty and employers, and whether there are clear means of evaluating the work experiences of students and integrating them with their classroom learning.

Organizations that were created in the 1960s to promote cooperative education include the Cooperative Education and Internship Association (CEIA; <http://www.ceiainc.org>) and the National Commission for Cooperative Education (NCCE; <http://www.co-op.edu>), in addition to a variety of regional and state organizations. A more recent addition to the relevant associations includes the World Association for Cooperative Education (WACE; <http://www.waceing.org>), which promotes cooperative education and other forms of work-integrated learning internationally. These organizations promote co-op via professional conferences, research grants, awards, scholarships, and publications.

Although there is no single model of cooperative education programming, many programs share basic steps for job placement and crediting. Students are recruited into the program through internal marketing of the program; screened using GPA, year standing, or other criteria; aided with the development of résumés and other job application materials; advised about possible jobs that match their professional or personal goals; visited or supported in other ways while working; mentored at work by a job supervisor; and evaluated by the employer. The work term is reflected on and/or credited at the home campus through participating in a conference or focus group or submitting required written materials. Many co-op programs that follow the vocational model require students to return to the same employer for multiple terms, often with assignments of increasing sophistication; environmental co-op programs are more likely to encourage

students to take various work assignments to learn a wide range of skills and enhance the development of adaptability and flexibility.

There is a history of research on cooperative education going back to the 1960s, with early research focused on models, structures, enrollment, and earnings. More recent studies tend to focus on learning outcomes, as the field has acknowledged that describing learning outcomes is necessary to ensure that classroom faculty support these programs. Research in the area can be clustered by focus: on outcomes for students, employers, educational institutions, and society in general.

Research on student outcomes from cooperative education is challenging in several regards. In most cases, when a co-op is optional, students self-select into programs, making it difficult to set up quasi-experimental treatment and control groups that are equivalent. Also, a university education entails so many variables designed to impact student development and late adolescence involves such rapid developmental changes that it is challenging to specify what value is added by a co-op program. Research on student variables can be focused on outcomes (what is learned), on processes of learning (how learning happens), or on the linkages between the two (how program structures lead to outcomes). The type focused on linkages is important to the field in order to distinguish it from career services, service learning, and other approaches, and for program improvement. Despite such challenges, researchers have found co-op work to impact classroom performance, such as increased motivation to study, learning how to learn, more disciplined thinking, and persistence to graduation. Work-related student benefits from co-op include an improved work ethic, increased technical knowledge and skill, networking opportunities, organizational problem solving, and job-specific written communications. Personal development outcomes demonstrated in research on co-op include enhanced decision making, maturity, recognizing there are many ways to accomplish tasks, self-confidence, self-efficacy, and value development. Career development has been shown in terms of enhanced career identity, career planning, and postgraduation promotions and salary increases.

Co-op programs also benefit employers. Studies conducted both in and outside the United States have shown higher yield rates and lower costs for employee recruitment; lower training, wage, and benefits costs;

higher retention; and better work performance for employees who participated in co-op programs than those who did not. There is also some indication that employers can make more progress in meeting their affirmative-action hiring goals if they participate in co-op programs than if they do not. Some studies specify the traits of work supervisors that link to positive learning outcomes for students; for example, when supervisors take on the role of field faculty member, student learning is enhanced. Most of the benefits listed for students benefit employers indirectly as well. When the benefits demonstrated to students and employers are reviewed in concert, it appears that Schneider's original rationale for smoothing the transition from school to work has been met by cooperative education. There is an emerging debate within the field about how to balance employer benefits with student benefits, especially with regard to ethical values, creative thinking, social change, and the implications of the demand for global competitiveness for social welfare systems.

The benefits to educational institutions of including a cooperative education program have also been documented, including increased enrollment, aid in meeting institutional performance benchmarks, involvement by employers in curriculum development that is relevant to industry needs, and productive links with institutions overseas from international co-op placements. Benefits listed above to students and employers also benefit educational institutions. For example, when co-op students perform well in local industry, various economic benefits can accrue to the university, such as an enhanced reputation in the community, research collaborations, grants, equipment and other donations, and facilities sharing.

Societal benefits determined by research include less reliance by co-op students than by non-co-op students on government support during school and in postgraduation unemployment benefits due to high employability and increasing productivity via the development of human capital. For emerging economies, important benefits include the opportunity for students to develop technical skills needed by industries, the transfer of technology via international co-op placements, and the opportunity to replicate co-op models broadly due to government control of higher education.

A review of the research on cooperative education suggests that much of the work is atheoretical and may fail to present a coherent picture of the most

important processes and outcomes of work-integrated learning for career and personal development. The learning theory of David Kolb and the philosophy of John Dewey are most frequently invoked, if any theory is invoked at all. One recommendation for future research is to cast a wider net among the various disciplines that relate to cooperative education. For example, there is a long and deep history of research within the vocational counseling profession on *career exploration*. Other disciplines that should be considered include labor economics (e.g., theories of human capital); developmental psychology (e.g., theories about epistemological development); the sociology of education (e.g., theories about cultural capital); and management (e.g., theories about organizational behavior). By focusing only on theories about experiential learning, co-op researchers miss the opportunity for the kind of cross-fertilization that would allow for a broader range of measures, methods, and theoretical interpretations than are currently utilized. Research collaborations with faculty from these disciplines would allow two goals to be achieved: (1) broaden the knowledge about cooperative education and support of it by classroom faculty and (2) broaden the theoretical bases from which hypotheses can be generated and tested.

COPRENEURSHIP

With the growth and evolution of entrepreneurship research in recent decades, new terminology has emerged to describe various types and dimensions of entrepreneurship. *Copreneurship* is one such term. It is a new term for an old pattern of work: husbands and wives or couples with marital or marital-like relationships working together in the same business.

Work relationships between husbands and wives jointly in a business are well documented historically. Not until the late 1980s, however, was this working relationship described specifically in an entrepreneurial context. Frank Barnett and Sharan Barnett, themselves a husband-and-wife team, coined the term *copreneur* in 1988 by blending the words *couple* and *entrepreneur*.

Three basic types of entrepreneurial couples may be distinguished: a solo entrepreneur with a supportive spouse/partner, a dual entrepreneurial couple, and a copreneurial couple. A *solo entrepreneur with a supportive spouse* is a situation in which one person is fully committed to and involved in the operation of the business and the other partner supports that person. Often this support is psychological or emotional support and encouragement, though it might also involve a small degree of "helping out" with the business. The solo entrepreneur makes the running of the enterprise his or her career, and the supportive partner may be employed outside the business pursuing a separate career. *Dual entrepreneurs* are couples in which each partner is committed to and involved in the running of a separate business. In contrast with the former two types of entrepreneurial couples, *copreneurs* are partners who are both involved in a joint business, and neither one pursues a career outside this business.

Although similar, the term *coentrepreneur* is different from copreneur. Copreneurs are a subset of the wider coentrepreneur group. Coentrepreneurs are any combination of two or more parties involved together in the operation of a business irrespective of marital status, gender, and division of work tasks and functions among them. "Involvement" is predominantly taken to mean ownership and management; for instance, two sisters involved together in owning and operating a business would be considered coentrepreneurs, as would a separated or divorced heterosexual couple. The distinguishing characteristic of a copreneur is not only such coinvolvement but also the intimacy and marital or marital-like arrangement of two partners in a business venture. As Kathy Marshack has emphasized, the term copreneur represents more than the simple equation of marital partner plus business partner; it embodies the dynamic interface of the systems of love and work.

Copreneurial couples have chiefly been studied in the field of family business. Broadly and simply defined, a *family business* is owned or managed by one or more family members. Family businesses are regarded as the backbone of the global economic system and are estimated to contribute 50 percent of the U.S. gross national product, and around 67 percent to 90 percent of the world's firms are classified as family firms. Copreneurs are an important subset within this broad grouping. They are often identified as married or common-law couples who are in partnership in the business. In generic terms, copreneurs are couples in family businesses who share personal and work relationships.

Copreneurship is a fast-growing, if not the fastest-growing, segment of the family firm business format. The recent rise of new types of home-based businesses enabled by information and communications technology and the boom in franchising, helping franchisees grow with the help of the parent franchisor, are among the factors responsible for the rapid growth of copreneurship. Another reason for the rapid rise in the incidence of copreneurship is that it affords couples an opportunity for flexibility in their work and nonwork arrangements. Other contributory factors are the "glass ceiling," downsizing, and redundancies in organizations that have made corporate careers more uncertain. Copreneurship should not, however, be thought of solely in terms of small businesses and micro-businesses. It can also extend to the large-business sector. Typically, though, copreneurial businesses are small, and as with many family businesses, some are

structured as sole proprietorships. Nevertheless, a variety of organizational structures, varying degrees of partnership, and differing ownership patterns exist under the copreneur umbrella. This contributes to statistical difficulties in gauging the true extent of copreneurship. It is also often not easy to separate copreneurs from the larger family business data sets.

Today, in the entrepreneurship, family business, and small-business research literature, as well as the popular press, copreneurship has come to be an accepted, commonly used term. Despite this common usage, there is no single operational definition of copreneurship. Margaret Fitzgerald and Glenn Muske have listed the different characteristics that researchers have used to delineate copreneurs. These include various combinations of the following criteria: ownership, commitment, responsibility, sharing of risk and/or management, intertwined worlds of business and home life, egalitarian relationships, running a business together and/or sharing an entrepreneurial venture, and defined areas of work, partnership, and minimum hours of work in the business. Most definitions have a similarity to one another and focus on the business rather than on family connection.

Frequently, copreneurship constitutes couples who share ownership of, commitment to, and responsibility for a venture. Commitment and responsibility are often operationalized in terms of working in the business. This participation could include devoting time to work on business tasks and/or major decision making in the business. Some researchers specify the minimum level of such participation based on hours worked in the business. When Barnett and Barnett initially conceived the copreneurship construct, they specified joint ownership, commitment and responsibility to the business, as well as the blending of work and family worlds as the prerequisites for copreneurship. Work sharing in an egalitarian manner was also a feature of their notion of copreneurship.

When the literature interprets copreneurship in a mainstream manner, namely, couples in a marital and business partnership equitably sharing responsibilities, this might be described as *pure copreneurship*. An example of pure copreneurship is the case of the New Zealand fashion label "workshop" run by married couple Chris and Helen Cherry. Their work approach was described in terms of each of them equally engaging in all the tasks for the business: driving the van, invoicing, and designing. However, such an equal sharing of work is not necessarily what an

egalitarian model with regard to the division of responsibilities is all about. An egalitarian relationship involves nonadherence to a traditional conception of masculinity and femininity to define responsibilities within both spheres of work and home. There is equity, therefore, when an androgynous orientation prevails and tasks are defined according to capabilities and expertise rather than gender. Departures from pure copreneurship arise with other forms of copreneurship that are not based on the standard marital-coupling or egalitarian model.

Despite its growth and significance, the phenomenon of copreneurship remains essentially underresearched. Several possible reasons have been suggested for this relative paucity of empirical research on copreneurs. One explanation is that since there are several types and degrees of partnership, it is difficult to gather separate data on copreneurial partnerships. Another suggestion is that because copreneurs are so widespread, they are not recognized as a distinctive group. The belief that work and family are separate spheres and the invisibility of the contributions of women to businesses are other key reasons given for the lack of acknowledgment of copreneurship.

Recently, however, the presence of copreneurship has been highlighted by a number of in-depth investigations, notably those of Marshack. This has also led to the recognition that copreneurship can effectively be examined through lenses other than that of family business. Indeed, copreneurship investigations from a gender perspective are on the increase. This has stemmed from a twofold recognition. First, not to do so is to perpetuate the male-focused standpoint that has led to the important contribution of women in family ventures being frequently hidden. This androcentric perspective and the hidden dimension of women's involvement have characterized a significant portion of the academic debate on entrepreneurship to date. Second, there is the need to eliminate a cultural myth that views home and work domains as separate.

The emergence of copreneurship as a construct was seen to address many of the dimensions of entrepreneurial experience that were often negative for women. Its potential for sensitivity to egalitarian principles, mainly the division of tasks in the work and home domains not being determined along gender lines, was viewed as an affirmative step in this direction. Nevertheless, as research has pointed out, such equality and equitable division of responsibilities is often more perception than reality. For example,

Marshack's 1994 comparative study between dual-career couples and copreneurial couples found that decision making and responsibilities were not equal. In fact, work was arranged around conventional sex role orientations. Any change in task allocation also tended to be from husband to wife, rather than vice versa. Despite this situation, copreneurial couples expressed a high level of agreement between the actual and the ideal division of responsibilities. This, however, represents an interesting potential paradox in which the tenets of the standard copreneurship construct (e.g., equal sharing of responsibility and power) may be undermined by the actual experiences of copreneurs themselves. Importantly, since it is often the case that copreneurs rely on stereotypical gender roles to construct boundaries between work and home, the valuable and essential contribution of women to the functioning of the business continues to be concealed and underacknowledged.

JOINT CAREERS

There is a need for new career perspectives that can effectively convey the vital contributions of women, which might otherwise remain hidden when encompassed within a copreneurship or family business model. In addition, it may be argued that the copreneurship concept, traditionally grounded as it is in the marital or marital-like relationship, may not to be in keeping with contemporary patterns of intimacy and interfaces of love and work. The varied definitions and interpretations of copreneurship could also lead to inconsistencies, making generalization and comparability of findings on copreneurship difficult once the research in this area expands. There is also the possible confusion arising from the use of alike yet differently interpreted terms, such as coentrepreneurship. There is value, therefore, in extending the current conceptualization and research agenda on copreneurship to explicitly recognize a distinctive career typology for those who share both a similar work relationship, mainly in the entrepreneurial context, and a personal relationship. Such an explicit career focus is also in the interest of better understanding the experiences of the women who constitute half of copreneurial couples. The conceptualization of a *joint career* that has been recently put forward by Anne de Bruin and Kate Lewis is of merit in this connection.

Prior to the delineation of the joint-career idea, the common career classification that copreneurs might

be included in was merely a subset of dual-career couples. Nevertheless, as Marshack highlighted in her 1994 article, copreneurs are more than simply dual-career couples: They are dual-career couples who share business ventures. Inclusion of copreneurs within the dual-career classification is, however, highly misleading. Copreneurs generally do not pursue salient careers that are separate in their own right. Rather, copreneurs have an interdependent career or a unified career path. The less known symbiotic career type might be more meaningful than the dual-career category in portraying such a shared career. Explored in relation to the career of coentrepreneurial brothers of Spanish independent film fame, Pedro and Augustín Almodóvar, the symbiosis metaphor conveys the very close, mutually advantageous career relationship that can prevail between two people. The coentrepreneurial Almodóvar couple is in a committed relationship based on emotional ties and trust, and their united career is characterized by a marked functional division of labor and distinct responsibilities. Pedro focuses on the creative tasks of filmmaking and directing, while Augustín engages in the more humdrum responsibilities of producer and support of the creative talents of his brother.

While the *symbiotic career* usefully captures the nature of familial career interdependency and the compartmentalized division of labor that is possible in a coentrepreneurial context, it does not adequately address the dominant features of the copreneurial relationship. The symbiotic career of the careers literature is gainfully extended by de Bruin and Lewis to create the concept of a joint career and put forward the notion of a split between the primary and auxiliary career. The joint career also better accounts for the career profiles of copreneurs.

The joint-career formulation is based on the couple as a whole, interdependent system, not as two separate individuals. Each of the two (or more) parties in this integrated system is committed to a single career goal and trajectory, which is linked to the entrepreneurial activity in which they are engaged. There is a united (i.e., single) career path, which involves the organization and development of their enterprise, and with it they build a joint career. This joint career, however, progresses in association not only with the work sphere of the business but also through interaction of the personal relationship. There is an overlapping of the realms of work and family in the unfolding of an integrated career.

There is an increasing realization of the permeability of the work and home domains. The associated careers of individuals situated in the copreneurial context as well as other similar forms of familial entrepreneurship are interwoven in professional/work and personal/family relationships. The joint-career construct acknowledges this and suggests a binding of the careers underpinned by mutual interdependencies. It is thus potentially a useful framework within which to explore career trajectories that are not solely individual based but also more collective and cooperative. It is a unified career of two (or more) individuals with strong ties (usually spousal intimacy or familial-based trust and love) that can span the closely intertwined business and family spheres. It is a broader idea than couple-based copreneurship.

The united career trajectory encompassed by the joint career makes no attempt to imply an equal division of labor, as is usually implied by the copreneurship construct. Indeed, its point of difference is its acknowledgment of the possibility of an asymmetry in career contributions. The further division of the joint career into primary and auxiliary careers provides a dedicated recognition of the possibility of an imbalance in the functional division of tasks in the firm as well as in the household. The split into primary and auxiliary careers provides a fruitful avenue for discussion in relation to copreneurship and could usefully be discussed in the context of gender to add more depth to these arguments. It offers a framework for considering the working partnerships in entrepreneurship that neither depends on an equal division of responsibility nor relegates the women to a position of inferiority or subordination. Instead, this construct takes a middle ground that may be more akin to the empirical data being presented that point to the real inequalities of copreneurship experienced by many women than it is to the pure copreneurship ideal suggested by the literature.

When firm-family tasks are unequal, often when stereotypical sex role orientations prevail, the joint career might be subdivided into primary and auxiliary careers. The *primary career* is that linked to the openly acknowledged and visible partner, whose tasks focus on the business domain and its core aspects. The *auxiliary career*, by contrast, is not subordinate or inferior to the primary career, but rather supporting of it and the business as a whole. The auxiliary career could also be one that is simultaneously devoted to the main tasks in the family sphere. Both the primary and auxiliary

careers are a prerequisite for the resilience and success of the business as well as, in many cases, the efficient functioning of the family. The important point to note here also is that while there might be differentiation between the primary and auxiliary careers, together they make up the single entity of the joint career, which is pursued with a collective, cooperative, and committed movement toward shared goals. Indeed, it is feasible that the individuals involved in the joint career path may alternate auxiliary and primary roles dynamically within the career trajectory, perhaps in response to the needs and characteristics of the familial context.

Thus, the joint-career decomposition should not be interpreted as a static pattern. At different stages of the life course, or as a consequence of life events (e.g., sickness), the auxiliary component might merge into the primary, or there could be a switch with the persons occupying one or other of the component careers changing over. It is easy to envisage that once caring responsibilities subside as children grow up, an auxiliary career spouse can become dedicated to pursuing the common business vision of the joint career. This dynamic element of the concept thus can include work role transitions that may change with the altered contexts of work and home.

An important reason for distinguishing between primary and auxiliary components of the joint career is that a common theme in the family business literature from a gender-based viewpoint is the invisibility of the women involved. For instance, as Joanne Gillis-Donovan and Carolyn Moynihan-Bradt have emphasized, the contribution of women to the business and also the power and influence they wield in the business are largely unacknowledged and underestimated by families and even by women themselves. A typical case of a couple cited by these authors demonstrated that even the joint decisions made were presented by the woman as "his"; and though she was the one who had fostered the growth of the business that her husband had started up and she had played an active role in its operations during a 15-year period of his incapacitating ill health, she still remained invisible by being off the payroll and without a title. The invisibility of women in family enterprises, or what has also been described as the "hidden dimension" of women's work in family enterprises, is amplified by many of the typical data collection methods utilized by formal agencies and, indeed, by the nature of the work dynamics being engaged in by such women, thereby creating a self-perpetuating cycle.

A principal research finding in the literature is that careers, especially for women, are family responsive or family centric. Yet, as is often the case, it is usually the woman who plays (or is perceived to play) an ancillary role in the business domain, so much so that it might be reasonable to assert that when the spousal relationship is androgynous, with no gendered division of labor, the distinction between primary and auxiliary careers within a copreneurial joint career will cease to exist. This assertion is also realistic in the light of the findings of Marshack, which confirm the invisibility of copreneurial wives, in contrast to dual-career couples who have moved beyond rigid sex role stereotypes and in whom this androgyny contributes to an equal and an equitable division of responsibilities.

Studies of microbusinesses and self-employed people, as, for instance, the New Zealand data reported from the Labour Market Dynamics Research Programme by Patrick Firkin and colleagues and the United Kingdom's empirical research by Susan Baines and Jane Wheelock, often show women and wives in a typical support capacity for these businesses. Usually, the enterprises clearly have a principal with primary responsibility for the business, and this is in the majority of cases the male spouse or partner within the couple. Wives and partners of self-employed males almost always perform auxiliary roles, such as doing the bookkeeping and administration and answering telephones. Although these duties may appear mundane, they are essential for the viability of the businesses.

In contrast to the fashion label "workshop," which was cited earlier in the discussion of pure copreneurship, is the example of the internationally known New Zealand fashion label "Zambesi" and its creators, Liz and Neville Findlay. Liz concentrates on design and Neville on financial, retail, and marketing aspects. Thus, together they have a joint career path. Neither of them is in an auxiliary role in their joint career, which in their case is inextricably linked to the success and growth of the business. This example further illustrates the worth of grounding the concept of copreneurship in the careers literature as well as the entrepreneurship literature.

CONCLUSION

Copreneurship is a significant and rapidly growing form of enterprise that deserves further research attention. However, given that entrepreneurship and careers

are social constructions, it may be time to question a notion such as copreneurship that is rooted in a standard heterosexual marital relationship. Although marriage is an institution that is withstanding the evolution of society, it is not as relevant for some couples as it once was. Although copreneurship does account for informal life partnerships, other forms of intimacy, such as same-sex partnerships, have not usually been included within the copreneurship label and research agenda. Moreover, given the recognition of socially accepted alternatives, there is value in adopting new theoretical approaches that acknowledge the career trajectory as the main focus (for consideration in terms of entrepreneurship) rather than the relationship itself.

The apparent paradox of the essential contribution yet marginalization of women partners is seemingly reconciled within the construct of copreneurship, with its connotations of equality of opportunity and sharing of responsibilities. The actuality is, however, often not such an egalitarian outcome. Furthermore, perceptions of actual experience may be colored by an ambivalence by women themselves about the true worth of their contributions to the business—"helping out" or doing "odd jobs" often being used as descriptions of their contributions—despite their contributions being vital to the success of the business and the efficient functioning of the home. The copreneurship terminology, focusing as it does more on an egalitarianism in the division of labor and power within the business domain rather than the composite of both business and family domains, remains rather inadequate.

Indeed, the reality of the copreneurship notion may be a perpetuation of the relative invisibility of women—in particular those who are or perceive themselves to be within the periphery of responsibility and power of the business venture but may yet be core to its survival and success within the wider unit of activity of both family and business. Shifting the lens to focus on the nature of the career of entrepreneurial couples may thus represent a springboard that could facilitate greater visibility and recognition of varied family contributions to business ventures from a holistic perspective that encompasses both love and work. It can more accurately reflect the real experiences of partnered entrepreneurial women than the copreneurship concept currently does.

A joint career can apply to entrepreneurial pairs but can also encompass more people than such a dyadic relationship; strong ties may be substituted for marital type ties, and there is no insistence on a compartmentalized division of labor. Decomposition of the joint career

into a primary and auxiliary career provides for the possibility that at a particular time, one party involved in the composite career can play a lesser role in the entrepreneurial venture, yet this role constitutes an integral part of the unified career. Gender need not be at all influential in terms of who occupies the primary and auxiliary-career components respectively. Furthermore, even women in firm-family relationships who occupy the auxiliary position are explicitly acknowledged and have definite career paths and roles that are neither invisible nor inferior. Other partnerships based on strong ties (e.g., between siblings, or parent and offspring) and less traditional copreneurial relationships (e.g., same sex), can also be included within the joint-career framework. It is a gender-neutral, marriage-neutral, and power-neutral construct. Its theoretical newness, however, means that researchers must continue to refine and develop the idea and support it with empirical findings. Similarly, more research on copreneurship, in all its forms, should be undertaken. Only then will the building of cumulative knowledge on the interdependency of careers in a context of copreneurial involvement and other forms of coentrepreneurial intimacy gain momentum.

CROSS-TRAINING

Cross-training, also known as *multiskilling* or *multi-skill training*, is a movement in the training industry prompted by the increase in global competition and the need for workforce flexibility. The term cross-training applies to workers who are trained across a broad spectrum of an organization's work. Cross-training typically involves training employees to perform new tasks in addition to their usual duties. After being cross-trained, workers often possess the skills to fill the requirements of more than one position in an organization. In team-based work environments, cross-training refers to a strategy in which each team member is trained on the tasks, duties, and responsibilities of her or his fellow team members. The goal of the training is to provide team members with a clear understanding of the entire team function and how one particular member's tasks and responsibilities interrelate with those of the other team members. Cross-training has been identified as 1 of 10 training trends that are likely to be around for some time. Many cross-training efforts have been found to be highly cost-effective.

Beginning in the mid-1980s, organizations such as General Motors, John Deere, Motorola, Ritz-Carlton, Sheraton Hotels, and the University of North Carolina began cross-training selected groups of workers. The cross-training movement was spawned by environmental changes such as globalization, shorter production schedules, technological innovation, and limited labor availability. Cross-training efforts have often accompanied organization downsizings, mergers, acquisitions,

or other restructuring efforts. The major reasons for cross-training workers include the following: to obtain or sustain a competitive advantage; to increase business functions (speed, quality, efficiency, productivity); to counteract the effects of short-term and long-term labor shortages; to meet a need for a more flexible, multiskilled workforce; to utilize workers more effectively; to enrich jobs; to increase employee job satisfaction; and to enable the desire to embody more of a learning-organization philosophy toward sharing knowledge and continuous development.

While cross-training is often viewed as a strategic initiative relating to competition and business needs, it is also looked at as an effective career development strategy. Cross-training has been found to be advantageous to employee personal career development, increased employee morale and job satisfaction, enhanced job security, reduced job stress, and increased professional confidence. Compared with employees who are not cross-trained, cross-trained workers are reported to be more flexible and less vulnerable to unemployment, to be more likely to receive higher earnings and be promoted into supervisory positions, to have more possibilities for advancement, to be more apt to develop a career path, and to work more hours than their nonmultiskilled counterparts.

There are several steps to creating and implementing a cross-training program. They include the following:

- Checking to see that employees have been trained for their current positions
- Making sure that employees are functioning competently in their regular jobs
- Creating a list of all jobs in an intact work group
- Identifying individuals to serve as "backups" for each job in the work group
- Using current job descriptions or specific task analysis information to prepare a breakdown of job duties, responsibilities, and related skills for each position
- Preparing a training plan for cross-training each designated "backup" participant
- Setting up a training schedule for each designated "backup" worker
- Training employees in on-the-job training (OJT), so they can cross-train their designated "backup" participants
- Using OJT methods to cross-train the "backup" workers
- Having designated "backup" participants evaluate the training they received
- Periodically updating training according to evaluation feedback and revised job descriptions

Several factors are seen as being critical to the successful creation and implementation of a cross-training program. They include the following:

- Identification of organization objectives
- Analysis of the organization/project situation to determine whether cross-training is appropriate
- Assessment of the organization's setting, resources, and culture to ensure compatibility
- An organizational culture that supports cross-training efforts
- Obtaining union approval for training (in some instances)
- Identification of skill clusters (i.e., interrelated skills)
- Evaluation of employee proficiencies
- Supervisor support of trainees' learning process (e.g., time in training and practice)
- Management awareness of the skills possessed by multiskilled employees, so they can be placed in appropriate job functions
- Open lines of communication
- Linking of compensation and/or reward system to cross-training
- Giving sufficient time for trainees to learn, develop, and apply newly learned skills and behaviors

Reported outcomes of cross-training programs include an increase in worker motivation, enhanced employee recruitment and retention efforts, increased production, increased efficiency, improved customer service and support, reduction in overtime hours among workers, quality improvements, increased organizational flexibility and response to change, more effective problem solving, increased levels of interdepartmental cooperation, and improved relationships between job functions and coworkers. Reported drawbacks of cross-training include safety issues, a need for certification and credentials in some occupations, adverse reaction of unions to training programs, information overload of program participants, little opportunity to practice what is learned, and increases in human error.

CROSSOVER EFFECT

Recently, researchers have turned their attention to the phenomenon of stress contagion that has been labeled *crossover*, namely, the reaction of individuals to the job stress experienced by those with whom they interact regularly. An influential article by Niall Bolger and colleagues distinguished between two situations in which stress is contagious: *spillover*, when stress experienced in one domain of life results in stress in the other domain for the same individual; and *crossover*, when stress experienced in the workplace by the individual leads to stress being experienced by the individual's spouse at home. Whereas spillover occurs from home to work and from work to home for the same individual, crossover is conceptualized as a process occurring from one individual at the workplace to his or her spouse at home. This indicates that crossover can affect the dyad and the work group.

Crossover research is based on the propositions of the spillover model, recognizing the fluid boundaries between work and family life and noting that spillover is a necessary but not sufficient condition for crossover. The crossover model adds another level of analysis to previous approaches by considering the interindividual level and the dyad as an additional focus of research.

With the accumulated findings of crossover research, it is reasonable to posit that variables reflecting job and family demands are antecedents of the crossover process. Crossover research focuses on the individual's job and family demands that trigger this process.

A THEORETICAL PERSPECTIVE

A recent crossover model developed by Mina Westman integrates crossover research into a job stress model and anchors it in role theory, as outlined by Robert Kahn and colleagues. The usefulness of role theory as a basis for crossover research is that it underscores the interrelations between a focal person and his or her role senders in the work and family settings. Westman's model classifies a selected array of stresses and strains as antecedent influences of the crossover process. Furthermore, it posits personal attributes and interpersonal variables as possible moderators. The core assumption of the model is that one's stress has an impact on others in different settings, indicating a complex causal relationship between stress and strain in the individual arena and between stress and strain of the dyads. This model distinguishes between six dimensions of the crossover process: role stress, life events, strain, personal attributes, coping, and the interaction process.

Westman and Amiram Vinokur specified three main mechanisms that can account for the crossover process:

1. *Direct crossover through empathic reactions.* Accordingly, there is a direct transmission of stress and strain from one partner to the other as a result of empathic reactions. The basis for this view is the finding that crossover effects appear between closely related partners who share the greater part of their lives together. It has been suggested that the effect of the undesirable events one experiences on the significant-other's distress may be the result of empathy expressed as feeling the other's pain as one's own. Thus, when one spouse is depressed, this feeling crosses over to the other spouse because he or she empathizes with the partner.

2. *Common stressors affecting both partners.* The simultaneous effects of the common stressors on increasing both partners' strain result in a positive correlation between partners' strain, which may be erroneously interpreted as a genuine crossover effect. For this reason, Westman and Vinokur suggested viewing the effect of common stressors as a case of spurious crossover; that is, the common stressors merely represent the effect of a third variable (e.g., economic hardship) that independently but simultaneously increases the strain of each spouse.

3. *Indirect crossover of strain.* The crossover is mediated by personal attributes and the interaction between the partners. The explanation of crossover as an indirect process focuses on specific coping strategies and interpersonal transactions, such as social support, social undermining, and communication style. Most crossover research has focused on social undermining as an interpersonal factor. Social undermining consists of behaviors directed toward the target person that express negative affect and convey negative evaluation or criticism. Thus, one's distress may increase social undermining from one spouse to another, and this undermining behavior increases the depression of the other spouse.

The three mechanisms of crossover can operate independently of one another and are not mutually exclusive. Therefore, it is quite possible that some of the proposed mechanisms operate jointly.

Studies have focused on different variables in the crossover process. Some have focused on the crossover of job stress from the individual to the spouse; some have examined the process whereby job stress of the individual affects the strain of the spouse; and others have studied how the psychological strain of one partner affects the strain of the other. Crossover research has focused mostly on five major strains: physical health, burnout, depression, work-family conflict, anxiety, and dissatisfaction.

Westman has suggested broadening the definition of crossover into contagion of positive as well as negative events. If the crossover process operates via empathy, one would expect to find not only negative crossover, but positive crossover as well. Thus, empathy could just as easily involve the sharing of another's positive emotions and the conditions that bring them about. Positive experiences and feelings are not merely the absence of stress; they are qualitatively different experiences. Thus, positive events and emotions may also cross over to the partner and have a positive impact on his or her well-being.

PRACTICAL IMPLICATIONS

The findings of some crossover studies are based on a conceptual model with explicit pathways and therefore offer an important direction for the design of future interventions for couples experiencing stress and strain. From the organizational perspective, the ripple effect of stress and strain has far-reaching

implications. Some of the findings demonstrate that a distressed wife is likely to generate a process of social undermining that will have an adverse effect on the husband and then later, through the husband, on his team. Findings suggest that efforts to reduce the stress and strain of employees should also target their spouses. It would be advisable for management to provide assistance programs to individuals working in stressful conditions and their spouses.

CRYSTALLIZATION OF THE VOCATIONAL SELF-CONCEPT

People have self-thoughts about many personal attributes that together form a multifaceted self-view (i.e., self-concept). For example, a woman might think of herself as smart, caring, and dependable (her personal self-concept) but also as fiscally conservative and socially liberal (her political self-concept). The *vocational self-concept* refers to the subset of self-beliefs about vocationally relevant attributes. Thoughts about personality characteristics, abilities, and the types of jobs that would be satisfying are essential elements of everyone's vocational self-concepts.

Crystallization refers to the clarity and certainty of a person's self-beliefs. Clarity is the ability to say what "is me" and what "is not me"; certainty is the confidence a person has in those judgments. Clarity generally precedes certainty. Young children's self-beliefs about vocationally relevant attributes, such as interests and abilities, are tentative until additional life experience allows the child to develop certainty.

Self-esteem is a related concept that refers to how well individuals like their self-concepts. Self-efficacy, another related concept, refers to individuals' beliefs about their abilities to perform specific tasks.

In this entry, the major components of the vocational self-concept are identified. Next, the process of vocational self-concept crystallization is described; and the entry concludes with a brief explanation of the influence of the vocational self-concept on vocational behavior.

ELEMENTS OF THE VOCATIONAL SELF-CONCEPT

The self-beliefs that compose the vocational self-concept vary across individuals. For example, body type could be a component of the vocational self-concept for persons contemplating a career as a professional athlete or an actor, but people interested in most occupations might consider their physical appearance to be irrelevant. Nevertheless, at least four attributes are an essential part of everyone's vocational self-concept: personality, interests, values, and abilities.

1. *Personality* is the consistent pattern of mental, emotional, and behavioral attributes that characterize an individual.
2. *Interests* are salient and enduring preferences to engage in specific activities or behaviors.
3. *Values* are emotionally held beliefs, assumptions, and convictions that create expectations regarding moral behavior and provide guiding principles for personal behavior.
4. *Abilities* are talents or skills that enable individuals to perform the behaviors that are necessary for effectiveness in work, family, and community activities.

DEVELOPMENT OF THE VOCATIONAL SELF-CONCEPT

Significant contributions to understanding self-concept development have been made by Eli Ginzberg

and his colleagues in the Conservation of Human Resources Project at Columbia University; Donald Super, also at Columbia University; Harvard University professor David Tiedeman; Southern Illinois University professor Vincent Harren; and University of Delaware professor Linda Gottfredson.

CYCLICAL PROCESS

Although crystallization is sometimes used to refer to the ultimate goal of vocational identity development, the term more commonly refers to the process by which clarity and certainty develop. Crystallization involves a cyclical process in which the range of options under consideration alternately expands and narrows. Throughout the process, individuals seek information about themselves and the available work alternatives. An early task in the crystallization process is gaining an understanding of what self-knowledge will be helpful in making career decisions. Strengths, weaknesses, likes, dislikes, values, and priorities all must be considered.

Initially, this process expands the range of career options by drawing attention to previously overlooked possibilities. As more and more information becomes available, however, the individual begins to narrow the range of options by establishing priorities and eliminating less desirable alternatives. This process recurs repeatedly; options expand until some consolidation becomes desirable, then narrow until the new information is assimilated.

Gradually, the opportunities for new learning are exhausted, and priorities become well established. The end result of vocational self-concept crystallization is a clear understanding of self (clarity), a set of prioritized values the individual is confident will remain stable over time (certainty), and an understanding of the world of work and the implications of that knowledge for personal behavior. These prioritized values are used as a basis for making career decisions.

STAGE MODELS

Stage models depict development as a sequence of changes that occur during a specific age range; descriptions of vocational self-concept crystallization typically use a stage model. Stage models are useful for gaining a general idea of the developmental process, because biological maturation and universal social experiences (e.g., the educational system) exert

a major influence on development until the late teenage years.

Nevertheless, stage models oversimplify important features of the developmental process. Development is not linear; life experiences sometimes result in a return to a previous stage. Furthermore, the pace of human development is highly variable. Healthy individuals can and do develop at different speeds. Therefore, the broad age ranges specified in stage models are simplifications that are not true for all individuals.

CHILDHOOD

Children begin to express vocational preferences by age four. These early preferences typically ignore the child's potential talents and interests and focus primarily on the child's perception of the pleasure that would be derived from the activity. Pleasures derived as an unavoidable consequence of participating in an activity are intrinsic rewards; the desire to receive these rewards is intrinsic motivation. Firefighter, nurse, and cowboy are common occupational preferences of young children.

During childhood, vocational self-concept development is characterized by generalized exploration. Children are interested in learning more about themselves, but they have no coherent strategy for obtaining vocationally relevant information. Negative choices are absent or nearly absent, leaving the child with a broad range of alternatives.

As they gain life experience, children begin to identify with and emulate adults in hopes of developing their own potency. Adult roles are most clearly defined in the areas of work, leading children to begin internalization of a work orientation and ideas regarding sex-appropriate behaviors. This process results in a gradual increase in a preference for vocational activities that lead to rewards such as approval and money. Rewards that are not integral consequences of the activity are extrinsic rewards. The desire for extrinsic rewards is extrinsic motivation.

INTERESTS

Role-playing (e.g., pretending to be a firefighter or doctor) is one important mechanism children use for elaborating their vocational self-concept. By trying out a variety of adult roles, children gradually gain a clearer understanding of the activities they like and dislike. At about age 10 to 12, children begin to

narrow their range of choices on the basis of their potential to bring intrinsic enjoyment. University of Oregon professor Leona Tyler demonstrated that the early development of vocational interests is characterized primarily by recognition of the things we do not like. Children at this age recognize the tentative nature of their choices and the need for further maturation and experience. Nevertheless, their emerging understanding of their interests and their desire to avoid activities they dislike cause them to begin limiting their choices.

ABILITIES

Although parental influence remains strong, other models begin to exert a stronger influence on the thinking of the child around 12 to 15 years of age. Children at this age begin to form impressions of their abilities: the skills at which they excel and at which they do not. This process continues through the teenage years. Many children do not become clear about the implications of their abilities and talents for their choice of careers until their late teens or early 20s.

VALUES

Numerous changes begin as adolescents enter the second half of their teenage years (14-17 years of age). One important development is an emerging awareness that work offers more than a means of satisfying personal needs. For example, a child who was initially attracted to a career in medicine because of the prestige and financial security enjoyed by physicians may now begin to consider the humanitarian aspects of the medical profession. This expanded view of occupations ultimately leads adolescents to a consideration of their personal values and the implications of those for their vocational choices.

During this time, adolescents also become aware that occupations are associated with differences in the ways people live. People in different occupations tend to pursue different leisure activities, read different types of magazines, and participate in different social groups. This growing awareness of extra-work features associated with occupations leads to a consideration of lifestyles young people desire.

TIME PERSPECTIVE

During their later teenage years, adolescents' time perspective begins to mature. They grow increasingly

aware that a career involves a set of activities that are performed daily across the adult life span. Furthermore, they become more sensitive to the reality that they may be faced with the need to make life-altering decisions in a couple of years. The importance of these decisions and adolescents' lack of independence contribute to the sense of frustration and turmoil characteristic of the teenage years.

Adolescents' emerging sexuality creates additional pressures. Many adolescents experience intense emotional attractions for the first time, but their continued dependence and the necessity to delay commitment until they have established themselves in a career frustrates their desire to act on their attractions.

TAKING CHARGE

The timing of the vocational self-concept crystallization becomes more variable in the late teens and early 20s. Maturation no longer plays such a significant role in self-concept development, and the demands of alternative career paths are so variable that crystallization progresses at greatly differing speeds.

Around age 17 to 18, young people begin to have more independence of action. This allows them to take immediate, concrete steps toward realistic decisions. Whether headed toward college, the military, or jobs, they begin to assume greater responsibility for their career decisions. This lessens their turmoil considerably.

Adolescents' increased freedom allows them to choose new activities that provide opportunities to learn more about their skills and interests. Reality testing in the form of exams and other performance evaluations provides valuable feedback about the range of feasible alternatives. Significant others in their environments take cognizance of these performance-based activities and provide guidance and encouragement. This leads to a better understanding of the suitability of alternative careers and of the preparation that is necessary for the careers they are considering.

EMERGING ADULTHOOD

Young people typically begin to integrate an understanding of their likes, dislikes, and abilities and their own and society's values into a coherent self-view during the late teens and early 20s. They make tentative choices of career paths based on their two or three most strongly held interests and devise tentative plans that allow them to test the wisdom of their choices.

Although their goals are much narrower than in earlier years, they still have considerable flexibility and have not committed themselves irrevocably to the final decision.

Reality does not yet require (and often does not permit) a final decision at this point in the young person's development. Vocational interests begin to emerge around age 15, and a degree of stability is evident after age 20, but vocational interests still undergo substantial change until approximately age 25.

Despite the somewhat general and tentative nature of their commitment to a limited range of goals, this commitment brings feelings of satisfaction and relief. The pessimism of the previous stage is replaced by naive optimism about the future. Individuals begin to focus on aspects of the self that provide confirmation of the appropriateness of their decisions. Many express a singleness of purpose, an unswerving attitude of goal direction, and an eagerness and impatience to reach their career goals.

Despite this, many young persons at this stage have not yet begun detailed planning for realizing their career goals. Many are naive about the specific rewards of an occupation and fearful of a final commitment. Avoiding an unsatisfying occupation is still a powerful motivation. Nevertheless, time pressures are experienced as more acute, and youngsters whose abilities to make tentative career choices are limited by lack of progress in crystallizing their vocational self-concepts often seek the assistance of a psychological counselor at this point.

MAKING A VOCATIONAL CHOICE

Experience, societal pressure to make a decision, and a growing understanding of the occupational tasks they want to avoid all contribute to crystallization of the young person's vocational self-concept. Gradually, the young person moves toward a firmer commitment to a career path and begins planning in detail the actions that need to be taken to follow through on his or her commitment. This process involves an elaboration of the self-concept and of plans to implement it in the future.

DISSONANCE REDUCTION

Commitment is an internal psychological event: a self-statement of intention to follow a designated career path. As this internal decision becomes clearer,

individuals begin to seek additional information. Often this takes the form of telling important others what they are thinking. Positive feedback leads to a greater sense of confidence and strengthening of commitment, while negative feedback leads to doubts and may cause the person to recycle back through the planning stage.

Often the young person must wait until the environment permits implementation of his or her decision (e.g., admission to college or a training program, being hired by an employer). Some postdecisional dissonance (i.e., second thoughts) typically occurs during this time, and the individual becomes actively engaged in dissonance reduction and bolstering. *Dissonance reduction* involves seeking information that is consistent with the decision while discounting information that is inconsistent with the decision. Individuals also exaggerate the positive aspects of their chosen alternatives and minimize or deny the negative aspects. They bolster their decisions by reviewing their resources and assets and developing contingency planning for dealing with setbacks.

As a commitment becomes more and more firm, it begins to be incorporated into individuals' sense of who they are (i.e., self-concept). They begin to act in a manner consistent with their new sense of identity. This may affect external manifestations, such as how they dress and the type of leisure activities they pursue. Most people desire an interpersonal network of people having interests that are similar to theirs, so they may also change the people with whom they associate.

IMPLEMENTATION

Implementation of the vocational self-concept brings an individual into contact with a new environment (e.g., classmates or work colleagues). Adjustment to this new environment typically follows a pattern of conformity, reactivity, and integration. This series of experiences leads to further modification and clarification of the vocational self-concept.

Initially, the individual looks to the environment for cues regarding the values, goals, and expectations of the group and reacts primarily by trying to fit in (conformity). Once they begin to feel accepted by the group, they begin an active attempt to change the group's values and goals to bring them into greater congruence with their personal values and goals (reactivity). The resulting change in the group gives the

person a strong sense of self that is somewhat lacking in objectivity. Finally, the group members begin to resist the new member's emphasis on change, and a compromise occurs (integration). Both the group and the new member are changed during the implementation process.

LIFE SPAN DEVELOPMENT

The vocational self-concept continues to evolve across the life span. Vocational experiences (e.g., being promoted or fired, disliking a job one anticipated liking) provide information that is used to modify the vocational self-concept. Other life experiences (e.g., marriage, the birth of a child) also may influence the vocational self-concept. Eventually, everyone confronts the need to prepare for and enter into retirement.

IMPORTANCE OF VOCATIONAL SELF-CONCEPT CRYSTALLIZATION

The clarity and certainty of one's vocationally relevant self-views are critical determinants of one's ability to make satisfying vocational decisions. A body of clear and certain self-knowledge (i.e., a well-crystallized vocational self-concept) is essential to effective career decision making. Well-crystallized individuals are much better able to differentiate between alternatives that are and are not suitable for them.

Lack of a well-crystallized vocational self-concept causes a variety of career difficulties. Some people are troubled by chronic career indecision. Those who push ahead with a decision without gaining the necessary self-knowledge find it difficult to make decisions that lead to satisfactory career outcomes. As a consequence, they may drift from job to job without a clear career direction.

The desire to avoid an unsatisfying career is a strong motive. Individuals who lack well-crystallized vocational self-concepts are fearful that they will be trapped in unsatisfactory careers, and many feel generalized anxiety about their futures. As a consequence, they experience a great deal of stress whenever contemplating career issues. Prolonged stress can lead to physical and psychological problems unless the underlying causes are corrected.

The vocational self-concept is most susceptible to influence during childhood and adolescence. For this reason, it is important for parents and those involved in the educational system to understand the vocational

self-concept crystallization process and help children deal with developmentally appropriate tasks during their formative years.

Vocational experiences influence a person's self-concept across the life span. Vocational problems can create or contribute to psychological problems. Events such as being laid off or fired, failure to secure a desirable position, or job-related stress are only a few of the factors that have negative psychological effects and may cause lasting changes in an individual's self-concept. For this reason, the resolution of career dysfunctions may be instrumental in resolving more general psychological problems.

CULTURE AND CAREERS

Culture is defined as the beliefs and values that shape the customs, norms, and practices of groups of people that help them solve the problems of everyday living. Thus, culture influences the way groups communicate, the way they take care of and educate their children, how they provide food and shelter, and how they earn a living. *Culture and careers* refers to the way that culture influences the way people work, the way they make decisions about work, and how their career paths

are shaped. In other words, culture shapes individuals' identities and the context in which they work. All individuals have a cultural, ethnic, and/or racial heritage, and in some cases, individuals have multiple cultural identities that shape their contexts. For example, the cultural context for an African American woman who lives in the southern United States will be based on her race, gender, and geographic location. The cultural context in which she lives helps to determine her own and others' career expectations, her preparation for work, and the opportunities open to her.

The terms *culture*, *race*, and *ethnicity* are often used interchangeably, though this has also caused some controversy in the field. Race may be viewed as both a biological concept and as a social construct. Geneticists note that the biological concept is not very useful because although at one point in history it was possible to biologically distinguish individuals based on race, racial groups are no longer biologically distinct from each other. But it is also clear that race has a strong social meaning in the United States, and there are different social and psychological consequences for individuals based on their race. Thus, the term race continues to be used in research to help identify differences between individuals who identify as members of different racial groups. For more than three decades, researchers have examined various factors that contribute to the big differences across racial groups in the types of work chosen and the progress in those careers. Since there are no differences in ability patterns across groups, psychologists have focused on other factors that may lead to differences in occupational choice, such as career dreams, role models, work values, or interests in careers. More recently, researchers have examined possible reasons in the environment that may contribute to those differences, such as racism and discrimination.

In the United States, the largest racial groups are White, African American, Asian American, and Native American. *Ethnic group* refers to individuals who come from a common geographic area and share customs and ways of behaving. Hispanics/Latinos are referred to as an ethnic group and may encompass several different racial groups. The term *racial/ethnic minority group* is used to denote African Americans, Asian Americans, Native Americans, and Hispanic/Latinos, who are in the numerical minority in the United States. The term *culture* is used to broadly encompass the context for various groups. Cultural identity is considered to be shaped by racial and

ethnic identity; related concepts are gender and careers, sexual orientation and careers, and identity. While much of the following discussion will focus on differences between racial/ethnic groups, it is also critical to note that there are often more differences within a group than there are between groups. Thus, for example, there are often more differences between men and women, and adolescent and adult African Americans than there are between Hispanic, African American, and White men.

Culture influences careers in a number of ways. Since individuals work within a context shaped by the culture of the organization and the individuals within that organization, culture influences the type of work that is done, the rewards for various types of work, and the types of interaction that are valued. In other words, cultural values shape our perspectives of the importance of work and the type of work that is valued. Cultural values shape not only the decisions made by organizations and within the workplace but also the career and work decisions made by individuals. For example, individuals who place a very high value on family and the collective good of their racial or ethnic groups may make different choices than those who place a high value on individual achievement.

In the United States, the cultural context for the majority cultural group includes several assumptions about work. It is assumed, for example, that work decisions are made solely by individuals, without consultation from others. It is also assumed that individuals are affluent enough to have the resources to seek opportunities to prepare for work and that the work opportunities are available and open to everyone. Finally, it is assumed that the career development process is logical and rational and occurs in a linear, step-by-step fashion. However, many of these fundamental assumptions do not apply to individuals who are from racial/ethnic minority groups. In many cultures, the role of family is viewed as being important in decision making, and racial/ethnic groups differ in the availability of resources open to them. Work opportunities are often closed to racial/ethnic minority groups due to racism, and consequently the career development process is often not linear or rational.

Culture very clearly shapes the opportunities available to individuals. A review of the demographic diversity of occupations indicates that members of racial/ethnic minority groups are overrepresented in some occupations and underrepresented in others. Thus, it may be that for some, career and work decisions are a

result of a compromise between occupations available to them and what they really hope or want to do. This suggests that culture may interact with work and career in two ways. First, culture helps to influence individuals' views of what types of work are appropriate and of the role of work in their lives. Second, culture influences the types of work available to individuals, both for positive reasons (e.g., opportunities available to those in a family business) as well as negative reasons (e.g., racism preventing someone from being hired into a work setting). Cultural values, the demographic diversity of work, and the role of interests, dreams, and barriers to work are all explored more fully in the next sections.

CULTURAL VALUES AND WORK

Cultural groups have been found to differ on a number of variables, though most researchers discuss five major dimensions on which differences in cultural values influence career and work. The first dimension is that of individualism versus collectivism. Those who value individualism have a preference for working alone, avoid dependence on others, and prefer accountability as an individual. They tend to place a high value on competition. Their work goal is to maximize material wealth and well-being. Conversely, those who value collectivism have a preference for working as part of a group, subordinate their own goals for achievement to that of the group, and place a high value on group success and cooperation. European Americans tend to be high on individualism, while most members of racial/ethnic minority groups have a preference for collectivism.

Another dimension in which cultures differ is in their views of the purpose of work in individuals' lives. Some cultural groups have a preference for doing and achieving through work, and others prefer to work so that they can do other things. For the latter, who work to live, work is something to be tolerated to get to the "real" or "important" things in life. The former, who live to work, place a high value on work as a worthy end in and of itself; European Americans tend to value living to work. For many members of racial/ethnic minority groups, however, the role of work is less central in life.

A third cultural value is how much people believe they can control or shape their surroundings and how much they believe that life and consequences are predetermined. This has been referred to as *locus of control*: Is the control within the individual (internal

locus of control), or is it shaped by forces outside the individual (external locus of control)? Those with an internal locus of control tend to be more aggressive in achieving their own plans and also tend to be more optimistic about achieving those plans than those with an external locus of control, who tend to be more passive and accepting of fate. Research has found that European Americans tend to be higher in internal locus of control, and racial/ethnic minority group members tend to be higher in external locus of control. It is important to point out that often the circumstances of lives affected by racism and discrimination are, indeed, out of individuals' control.

A fourth dimension is that of avoidance of uncertainty. Cultures differ in how comfortable individuals are with ambiguity and unfamiliar tasks and how much risk is tolerable. Those high in uncertainty avoidance have a preference for highly structured environments and place a high value on individuals' conformance to rules and established norms. When rules are broken, a typical response is a high level of anxiety. Individuals' roles as women or men or as an elder or younger member of society are specified very clearly, and all members of the cultural group know what to expect from the behavior of others. The rules for behavior and relationships are clear, and conflict is avoided when possible. Cultures with low uncertainty avoidance have a much higher tolerance for outside-the-norm ideas and experimentation. Cultural groups with long ties to Catholicism, such as Latinos, tend to be higher in uncertainty avoidance, as are Asian cultures. Native Americans and African Americans tend to be lower in uncertainty avoidance, and European Americans tend to be in the midrange on uncertainty avoidance.

Finally, the fifth dimension focuses on differences across cultural groups in the way that time is perceived. Those who focus on the past place an emphasis on the traditional way of doing things; the future is an extension of the past. Asian Americans tend to have a strong sense of past traditions. Those with present-time orientations place an emphasis on spontaneity and living for the moment, and this orientation is more typical of African Americans, Native Americans, and Latinos. The last orientation, that of emphasizing the future, has a focus on future goals, and individuals with this emphasis are willing to make sacrifices for long-term goals. For those with future orientations, such as European Americans, time is viewed as a commodity to be "earned," "wasted," or "used."

It is important to note that while research has shown differences among racial/ethnic groups in

cultural values, there is no particular value in having a preference for one aspect of the dimension or the other. In other words, while European Americans place a higher value on individualism than collectivism, it does not mean that individualism is superior to collectivism. Cultural values for work, however, influence preferences for working style, and as will be seen in the next section, since European Americans occupy most of the positions of power and authority in the U.S. workplace, their cultural values become the norm on which work is shaped and evaluated.

DEMOGRAPHIC DIVERSITY OF WORK

The workforce in the United States has become increasingly more racially and ethnically diverse, mirroring the increasing diversity of the population of the United States. The 2000 census indicated this increase; in the 1990 census, one out of four individuals (or 25 percent) indicated he or she was a member of a racial/ethnic minority group. In 2000, the percentage of individuals identifying as members of racial/ethnic minority groups had grown to one in three. This was also the first census in which individuals were allowed to indicate more than one racial/ethnic affiliation. Of the third who identified as members of a racial/ethnic minority group, approximately 13 percent indicated they were African American, 1.5 percent identified as American Indian or Alaskan Native, 4.5 percent as Asian/Pacific Islander, 13 percent as Hispanic/Latino, and about 7 percent indicated "Other" race. Of those identifying as more than one racial/ethnic group, a large number were under 18 years of age, suggesting that the United States will become increasingly biracial in the future.

Since the 2000 census, Hispanic/Latinos have surpassed African Americans as the largest racial/ethnic minority group in the United States (13.85 percent vs. 12.9 percent). This increase and the increase in number of individuals identifying as Asian American/Pacific Islander are both due to higher immigration rates and higher rates of fertility. But while in 1990 members of racial/ethnic minority groups were most likely to be found in coastal or border states (e.g., California, New York, Florida, or Texas), the 2000 census showed an increase in diversity across the country in every state.

While there is an increasing number of racial/ethnic group members in the United States, there are marked differences in educational and occupational attainment across groups. The 2003 census, for example, indicated that Asian Americans had the

highest percentage of high school graduates (94 percent) by age 24, followed by Whites (86 percent), Blacks (81 percent), and Hispanics (65 percent). As might be expected, the levels of college graduation by age 29 mirrors this same pattern: 10 percent of Hispanics, 17 percent of Blacks, 28 percent of Whites, and 62 percent of Asian Americans had graduated from college by age 29. While these differences may seem striking, it is important to note that there is less disparity among racial/ethnic groups than ever; in 1940, the rate of high school graduation for African Americans was less than a third of that for Whites (7.7 percent vs. 26 percent), and the college graduation rate was similar (1.3 percent vs. 4.9 percent). Statistics are available only for African Americans and Whites during that time; data on Hispanics were not collected until the 1980s and on Asian Americans until the 1990s.

The differences in educational attainment may be due to a number of factors. Individuals may not have the financial resources available to them to finish high school or to attend and graduate from college. There may also be barriers due to lack of knowledge about educational opportunities, lack of parental support for education, and lack of role models to support higher educational attainment. Racism may also be a barrier for individuals in seeking opportunities for higher levels of education. Racism may play a role in equal access to educational and learning opportunities that are available to students from racial/ethnic minority groups, as well as discrimination in admission to institutions of higher learning. Whatever the cause of the educational disparity, it is clear that differences in education become magnified as employers require higher levels of education prior to employment, and with higher levels of education and employment come greater earnings. This can lead to a vicious cycle in which individuals from higher income levels have access to greater opportunities and resources for education, which leads them to have more occupational opportunities and income. They provide their children with more opportunities for education, and their children, in turn, have more occupational opportunities, and the disparity between groups grows. Recognition of this cycle has led a number of educational institutions to create specific programs to break this cycle and governmental programs to specifically address barriers that exist for racial/ethnic minority group members.

The increases in racial/ethnic diversity in the country discussed earlier have also resulted, as may be expected, in an increasingly racially and ethnically diverse workforce. A study by the National Research

Council showed increases in diversity in almost all occupational groups, though diversity was broadly defined to include gender, race, age, and educational level and did not just specify race or ethnicity. When occupational groups are examined specifically for diversity in race or ethnicity, however, it is clear that racial/ethnic groups are not represented equally.

The Bureau of Labor Statistics collects data from employers, and workers are identified as Black, White, Hispanic, or Asians; data are not collected on Native Americans. Blacks and Hispanics are each 13 percent of the population and would be 13 percent of workers across occupations if they were equally represented. However, they are underrepresented in many professional occupations and overrepresented in less skilled occupations. For example, Blacks and Hispanics are 7.9 percent and 5.1 percent (respectively) of executive, administrative, and managerial specialties; 5.3 percent and 3.5 percent, respectively, of engineers, architects, and surveyors; 4.8 percent and 2.8 percent, respectively, of natural scientists; and 5.0 percent and 4.1 percent, respectively, of physicians, dentists, and veterinarians. However, Blacks are 30 percent of guards, 36 percent of postal workers, 32 percent of licensed practical nurses, and 25 percent of dietitians, social workers, communications workers, correctional institution officers, and shoe sales workers. Hispanics are 38 percent of butchers, textile sewing machine operators, and concrete finishers and 40 percent of house cleaners. The implications of differences in occupational choice become more apparent when considering the differences in wages earned across the occupations. Across all occupational groups, Blacks earned 80 percent and Hispanics earn 68 percent of the median weekly wage earned by Whites. Men in all groups earned more than women in the same group, with the most extreme difference found for Hispanic women, who earned slightly more than half of what White men earned. Unemployment also differs markedly across racial/ethnic groups. In 2000 and 2002, the unemployment rates for Whites were 2.6 percent and 4.2 percent, 5.4 percent and 7.6 percent for Blacks, and 4.4 percent and 6.1 percent for Hispanics.

CULTURE AND CAREER DEVELOPMENT THEORIES

The statistics discussed above indicate that the educational and occupational landscapes are not equal.

Culture, or membership in a racial/ethnic minority group, appears to result in different pathways to careers, career choices, earnings, and the opportunity to work. What is less clear, however, is how that disparity occurs. A number of career theories help explain and predict the types of careers individuals will choose (e.g., Holland's theory, social learning theory, social cognitive theory, and Super's career development theory). Most of these, however, were developed to explain the career behavior of the majority culture and do not as adequately explain the career development of racial/ethnic minority individuals.

Most of the theories, for example, have been based on research conducted with White individuals (often the early research focused just on White men). Another criticism of these theories is that they have been based on the type of majority culture assumptions detailed earlier (individuality, centrality of work, open-opportunity structure, and linear process). Many of the theories note the role of interests in occupational choice, assuming a relatively straightforward path from having an interest in an activity to deciding to prepare to enter that occupational area. For example, an adolescent is interested in physics, math, and computers. Her teachers and parents encourage her to become a physicist; she learns about this field and decides to go to college and major in physics. But what if no one is there to encourage her interests? What if she does not know what she could do with an interest in physics or there are no resources available for her to go to college? What if she does not know that people of her race could be physicists and decides it is not a possible field for her? None of the theories explicitly addresses the external realities for many racial/ethnic minority groups. Thus, researchers and scholars have begun to call for theoretical frameworks that incorporate the realistic and perceived barriers experienced by members of racial/ethnic minority groups. These new theoretical frameworks will be based, however, on the research that has been conducted in the past two decades on factors related to career choice for racial/ethnic minority groups, described in more detail in the next two sections.

ASPIRATIONS, INTERESTS, AND CAREER CHOICE

As noted earlier, it is clear that there are differences in the occupations into which different racial/ethnic groups enter, though the reasons for that disparity in

occupational representation are not as clear. Is it possible that there are differences in the dreams or interests that individuals may have? In other words, do the variations in choices made by individuals stem from their aspirations or work interests? Investigators who have examined differences in students' responses to "What do you want your career to be?" have found that there appear to be very few differences between racial/ethnic groups. In fact, most studies showed greater differences between men and women than between ethnic groups. Differences have also been found between those whose parents are of higher social class even within the same racial/ethnic group. Thus, people of different cultures do not necessarily have different career dreams, and we cannot conclude that differences in career choices can be explained by the differences in hopes and dreams for careers.

Researchers have also examined whether differences in career choices can be explained by differences among groups in vocational (or work) interests. Interests may be viewed as a preference for an activity, and studies have been conducted to investigate whether culture affects the activities that different groups prefer. The research on vocational interests, for example, has found big differences between the interests of men and women, which may give a partial explanation for the different careers that men and women pursue. However, most research has found that the differences in interests between cultural groups is relatively small and is much smaller than the differences within the same racial/ethnic group. For example, differences are greater between men and women of the same racial/ethnic group or between older and younger members of the same group than between groups. As another example, one study found that Asian Americans who are less acculturated to the United States (i.e., those whose families are recent immigrants) are much more likely to choose an occupation that is consistent with occupations typically held by Asian Americans (e.g., scientist or engineer) and valued by their families than an occupation that is consistent with their own interests. This is consistent with the cultural value of collectivism discussed earlier, in that individuals chose an occupation that met family obligations rather than their own interests.

Investigators have also found that the structure underlying interests is the same across groups, such that it is clear that the world of work is perceived in the same way across racial/ethnic groups. Studies have also shown that individuals appear to be basing

their decisions on the same type of overall factors, though groups may weight those factors differently. In other words, while individuals from all racial/ethnic groups indicate that family is important in their career decision making, for some groups, family plays a much greater role in their decisions. It appears clear, then, that the differences in the occupational landscape are not a result of the interests expressed by individuals, by their career dreams, or by their incorporating different aspects in their decision making.

BARRIERS AND SUPPORTS

Some researchers have examined the career dreams or interests of individuals, and others have focused more on the effects of racism and discrimination on the choices that are open to individuals. In other words, they have focused less on whether the lack of equal racial/ethnic representation across occupations is due to individuals' choices and more on whether it is due to real (discrimination, racism) or perceived (perception of opportunities) barriers. Similarly, some researchers have also focused on the various factors that help to facilitate the choices of racial/ethnic minority group members.

Some of the same researchers that asked about career dreams also asked students and their parents what careers they expected to enter. They found that although there were no differences in aspirations, there were differences across racial/ethnic groups in careers they expected to enter. Parents from different racial/ethnic groups also did not differ in the types of careers they hoped their children would choose, but when asked what they expected them to eventually do, the responses of parents from different racial/ethnic groups were quite different. Those differences seem to mirror the types of occupations held by racial/ethnic minority group members, suggesting that students expected to do the types of occupations they observed others of their racial/ethnic group doing. Thus, for example, African American students may not feel that the occupation of "engineer" is open to African Americans because they do not have role models of African American engineers, either in their families or in their communities.

The history of racism and oppression for many racial/ethnic minority groups in the United States is long and has had a lasting effect, including the perception that discrimination will occur in the career process. This may help account for differences between

aspirations and expectations. It is clear, for example, that Blacks and Whites have very different perceptions of occupational discrimination, and studies have shown that in the same situation, Blacks will perceive more discrimination against Blacks than Whites perceive occurs against Blacks. Investigators have also shown that Black students' perceptions of discrimination are highly related to their perceptions of occupational opportunities. Further studies have replicated this finding across other racial/ethnic groups. In general, minority students are more likely than Whites to perceive barriers due to race or ethnicity.

Other researchers have examined supports for career and educational choices. In general, their studies have found that coming from a higher-income home, strong support from parents, exposure to programs that help to promote career exploration, and high expectations from parents and teachers facilitate educational and occupational attainment. Over the past two decades, schools have begun to develop programs both within the curriculum and outside the school setting to provide additional support for students. Government policies that emphasize high expectations in education and equal opportunities in employment also serve as support for career and educational opportunities.

CONCLUSION

The role of culture in careers is complex, and researchers have only begun to study various factors that explain differences between groups. Career development theorists are being challenged to be more inclusive in their theories to incorporate the realities of individuals from various racial/ethnic groups. Clearly, something occurs between the dreams that racial/ethnic minority group students and their parents have for their careers and the actual occupations they enter. We know that cultural values may play a role in that difference between aspirations and expectations, but we also know that racial/ethnic groups differ in their perception of barriers to accomplishing their educational and occupational goals. It appears that these barriers are also part of the reality of making career choices and thus are part of the cultural context for many individuals.

CUSTOMIZED CAREERS

Customized careers are unconventional patterns of workforce engagement by individuals who would

ordinarily be expected to adhere to traditional career paths. Customized careers differ from traditional careers on one or more of the following three dimensions: work time (e.g., working reduced hours rather than full time), timing (e.g., late entry into the workforce or taking time out of the workforce in the middle of one's career rather than maintaining continuous employment), and type of employment relationship (e.g., independent-contracting work as opposed to long-term organizational employment). Related concepts include the boundaryless career and the protean career.

Customized careers are defined by their contrast to the traditional or "orderly" career, a pattern of work involving intense commitment to and continuous engagement with the occupational world, along with a striving for upward mobility and achievement of external markers of success. Traditional careers involve full-time, continuous involvement in the workforce, typically starting in one's 20s following the completion of formal education and ending with total and permanent withdrawal from the workforce some 40 or 50 years later at retirement. The traditional career template rests on the assumption of an "ideal worker," for whom employment forms the basis of identity and work takes priority over other life domains. By contrast, the customized career assumes that personal identities are shaped by multiple life roles, including, but not limited to, work roles.

The customized-careers construct is most appropriately applied to employees who would ordinarily be expected to work on a full-time, highly involved, continuous basis throughout their working lives. Research on customized careers focuses primarily on managerial and professional occupations, which involve individuals for whom the traditional career pattern, with its strong emphasis on significant ongoing work involvement, constitutes a powerful cultural schema. Research on customized careers examines the work lives of individuals who choose to step off the traditional career track and craft careers that respond more precisely to their own and their families' needs and desires, even if this means rejecting the career expectations that are normative for their jobs, occupations, or organizations.

THEMES IN THE CUSTOMIZED-CAREERS LITERATURE

Four themes are central to the literature on customized careers. First, individuals pursuing customized

careers are seen as having and exercising choice and control in career decision making. Research samples are generally drawn from populations of individuals who are not forced to adhere to a traditional career pattern out of economic necessity, but have the option to customize. In other words, individuals with customized careers have the skills and labor marketability to work as intensely and continuously as do people following traditional careers, but they also have the resources and preferences that enable them to reject that pattern. By contrast, individuals who experience unwanted career interruptions or reduce their working hours or engage in nontraditional employment relationships because they are unable to secure traditional career arrangements, as opposed to doing so out of choice, are generally not considered to have customized careers.

Second, the longitudinal quality of careers is central to the study of customized careers. Customized careers are typically punctuated by intervals during which they look very orderly indeed (e.g., intense commitment, long hours, and upward striving during the early career). It is therefore necessary to compare the pattern of an individual's workforce engagement over time to a normative career template in order to classify that career as having been customized.

Third, the customized-careers literature acknowledges the inseparable connection between the work domain and other life domains. The traditional career model assumes near total separation between the work and nonwork spheres of life, with employment given the highest value and priority. In the traditional career, occupational success and advancement through a corporate hierarchy demand a nearly exclusive focus on work and a willingness to make sacrifices such as limiting time spent with friends and family, something that is difficult to do if one has multiple demands on one's time and no nonworking spouse to absorb those demands. Given that the modal U.S. family in the early twenty-first century is one with two working parents, adherence to the traditional career pattern is difficult for many. The desire to achieve a satisfactory integration of work and nonwork is a major factor leading individuals to pursue customized careers. The customized career allows people to forge lives between the two extremes of continuing to meet the normative expectations of traditional careers and dropping out of the workforce entirely.

Fourth, customized careers are less institutionalized than traditional careers. Individuals who pursue

customized careers challenge the prevailing norms of the traditional career path. From the traditional career perspective, striving for career success in the form of prestige, earnings, and upward advancement are both normal and noble. Making a decision to reduce one's working hours or take time away from one's career is often seen as deviant. Thus, persons pursuing customized careers bear the burden of justifying their choices, persuading others as to the feasibility and sensibility of their plans, and negotiating the specific arrangements that will allow them to fit work into their preferred life patterns. Pursuing a customized career means persuading and negotiating—with oneself as well as with one's family, organization, and occupational community.

CHARACTERISTICS OF CUSTOMIZED CAREERS

As indicated at the outset, three key characteristics differentiate the customized career from the traditional career. They have to do with schedules and time: the number of hours worked and the schedule that guides them, the timing of paid work throughout the life cycle, and the employment relationship.

Time. Customized careers often involve a reduction from standard full-time work schedules, either in the form of fewer hours per day on an ongoing basis, fewer days per week, or fewer weeks or months per year. Job sharing and part-time jobs are two vehicles for customizing. The desire to place some sort of boundary on the often seemingly limitless work time norms of the traditional career is one of the most potent forces leading people to seek customized careers. The work schedule modification is not necessarily permanent, and individuals may change their working time periodically over the course of their careers in response to personal preferences and to demands and resources emanating from other areas of their lives.

Timing. Timing refers to “biographical pacing,” or the patterning of work engagement across the span of a person's working career. The customized career is often marked by discontinuities. Women are more likely to participate in alternative timing than men, reflecting the “traditional” division of labor in households. Women are more likely than men to enter the workforce late or leave it temporarily to care for

children. Individuals who make this type of modification may find themselves in entry-level or early career stages when others of their age cohort are in more advanced career stages. Reducing work prior to retirement and/or returning to some form of employment after retirement are two more ways in which people customize their careers.

Employment Relationship. Customized careers may involve a variety of employment relationships that differ from the traditional career arrangement of long-term employment with one or a few employers. Customized careers are more likely to include work that is performed in the context of a temporary employment relationship or as an independent contractor or agency employee, as opposed to a regular organizational employee. For example, when professionals decide to essentially go into business for themselves by performing a variety of assignments for different clients rather than working exclusively for a single employer, they are moving away from the traditional career template into customized careers. The impetus to make this kind of modification may stem from the desire to avoid the politics that often accompany long-term organizational employment, to have more freedom over the conditions of work, or to stay active in one's field following retirement from a traditional job.

MAIN RESEARCH FINDINGS

Rationales for pursuing a customized career can be grouped into two main categories. The first has to do with care work and family or community engagement. For example, an individual (typically a woman) may choose to switch from a full-time schedule to a part-time schedule to care for children or to spend more time volunteering. The second type of rationale, which overlaps somewhat with the first, is the desire of people to bring their work careers into better alignment with their personal values. For instance, a corporate manager may decide to start an independent consulting business because he wants to have the freedom to take on only the projects that interest him most. Or a physician may decide to work a reduced-hours schedule in order to spend more time gardening.

Several factors are associated with the pursuit of a customized career. Having high levels of human capital (e.g., skills, credentials, experience) gives people the labor market power to demand the type of work arrangements that suit them best. (Curiously, however, human

capital is typically accumulated by spending some time in the traditional career mode.) Household-level resources give individuals the freedom to choose customization. For example, it may be possible to take time out of the workforce only if one has a working spouse who has a job with sufficient income and good benefits.

Customized careers are heavily gendered. At this point in time, women are much more likely than men to customize, particularly when it comes to working reduced hours or taking time off from work. These forms of customization are strongly associated with caregiving, which continues to be primarily the responsibility of women. Furthermore, it is seen as more acceptable for women than for men to customize in order to take care of children or to support a spouse's career. These findings highlight the theme of the inter-relatedness of work and family and emphasize the importance of taking the family context into account when examining the decision to pursue a customized career.

Customized careers are also associated with features of the employment context. Some jobs allow for greater flexibility than others. For example, emergency room physicians, who work scheduled shifts, have a greater opportunity to modify their working hours than do surgeons. The nature of an organization affects its employees' ability to customize. It is more difficult to customize in the context of an organization that has downsized its workforce and placed additional work on the remaining employees, for instance, than it is when there is more slack in staffing levels. Supportive supervisors, a flexible and accommodating organizational culture, and the presence of policies that lay out alternative career paths all facilitate customized careers. By contrast, employees have little opportunity to customize when they work in organizations with rigid, traditional cultures and when no alternative career policies have been developed and implemented. In such conditions, employees are often limited to two extreme options: stay on the traditional career path, regardless of the personal cost, or quit entirely.

Customized careers always involve costs and benefits. In general, people who pursue customized careers gain some control over their time and, in many cases, over the conditions of their employment. Individual productivity and satisfaction with work tend to be higher among individuals pursuing customized careers. They are also generally better able to integrate their work and nonwork lives, have less work-family conflict, and have higher levels of life

satisfaction. On the downside, they tend to suffer in terms of traditional markers of career success, including earnings, prestige, and advancement. They receive less support for career development from their employers and have fewer opportunities for promotion. They also frequently feel that they have made career sacrifices and experience some ambivalence about the state of their careers, reflecting the potent normative expectations of the traditional career they have chosen to customize and the extent to which career and identity are intertwined among professionals. The success of customized careers from the point of view of people who craft them appears to depend to a great extent on their own values and identities. For instance, people who are happiest in customized-career arrangements tend to value personal growth and family involvement more highly than pay, promotions, and prestige.

Although people who work part time have traditionally earned less than their full-time counterparts (even when compared on an hourly basis), received few or no fringe benefits, and had little or no opportunity for upward career progression, recent studies of reduced-hours work among professionals provide hopeful evidence of the existence of part-time jobs that are relatively permanent, have career potential, and provide salaries and benefits prorated on the basis of full-time standards. People who leave traditional employment relationships to pursue independent contracting work sometimes make substantially more money, particularly when economic conditions are favorable and there is high demand for their skills. Of course, there is no guarantee of increased earnings, but independent contractors do take on increased financial risk.

In summary, customized careers represent an individual adaptation of a traditional career pattern that does not fit the lives of many highly skilled working people. The increasing prevalence of this form of career is influenced by multiple factors, including demographic shifts (e.g., large numbers of dual-career parents in the workforce), the trend toward less employment security in U.S. corporations, and changes in lifestyles and values, with a decreasing emphasis on climbing the corporate ladder as the ultimate measure of success and greater emphasis on engagement in multiple life roles.

D

DERAILMENT

Derailment refers to the involuntary loss of promotional opportunity due to declining managerial effectiveness over time. In general, managers derail because their skills and perspectives are seen as a poor fit for the challenges they face, either currently, in the near future, or with additional moves to more senior-level jobs. While some derailed managers are fired from their jobs, many remain on the job but are no longer seen as promotable to positions of greater responsibility as a result of a perceived loss of effectiveness and poor performance.

Organizations often invest heavily in the development of individuals believed to have high potential for success at senior levels. For example, high-potential managers often receive special or accelerated job assignments, coaching, mentoring from senior executives, and access to leadership development programs. When an individual begins to lose his or her effectiveness when taking on the challenges of senior roles, much has been lost. While derailment can happen at any level in an organization, it usually represents the greatest loss at senior levels, in terms of an organization's investment in development, and frequently provokes the most questioning of existing selection and development processes. Therefore, the perceived causes of derailment have been studied primarily among senior managers.

Research indicates there are several key reasons why managers derail. One important factor is an individual's inability to adapt to changes in the environment. Many managers who derail do so because they

are unable or unwilling to develop new skills and perspectives as the demands they face change over time. Changing demands can come from added responsibilities in their jobs, promotions, organizational changes (e.g., mergers, globalization), environmental changes (e.g., market, regulatory environment), and the like. When managers are unable or unwilling to see that change is needed in their approaches or in their skill sets, to seek feedback from others on how skills might be improved, or to make the needed adjustments, their effectiveness as leaders can be increasingly compromised over time. Also, the inability to identify when new skills are needed and to develop new skills and perspectives makes it almost certain that an individual will be less likely to address any other derailment factors he or she may have.

Having problems with interpersonal relations is a second major factor leading to derailment. Derailed individuals are often seen by others as abrasive, arrogant, manipulative, demanding, or aloof. Although characteristics like these may be long-standing aspects of a manager's personality, they may not influence one's effectiveness early in career. Prior to being promoted into a management role, a lack of interpersonal skills may be overlooked in performance reviews if one's technical performance is good. As an individual takes on supervisory responsibilities, this characteristic begins to matter more, in that a lack of interpersonal skills can get in the way of motivating and developing others. At lower levels in the organization, despite having poor interpersonal skills, managers are often able to achieve good performance from people over whom they have direct authority. However, as an individual moves up to more senior levels, is responsible

for people who also have more organizational power and authority, and must achieve results from people over whom he or she has no direct authority, poor interpersonal skills can become a major obstacle to achieving high performance.

A third major cause of managerial derailment is the inability to build and lead teams. This factor has to do with poor performance in one or several aspects of team development and leadership, including choosing the right team members, securing adequate resources, and creating structures and processes for team innovation and high performance. The teams often described in the derailment literature are diverse teams, often cross-cultural in membership and geographically dispersed. They are also teams with urgent or high-priority tasks, working in a complex, global environment. The leadership role on such a team is demanding and often ambiguous for a manager and usually requires a significant degree of behavioral flexibility.

Other causes of derailment at senior levels include being seen as too focused on one's own agenda at the expense of organizational goals, not being trusted to follow through or to have high integrity, being too narrow and unable to assume a broader than functional orientation, being authoritarian in leadership style, and being too isolated from other key stakeholders in the organization.

Research shows that managers almost never derail for one reason alone. In fact, the causes of derailment are often closely interrelated in any one derailment event. An individual who is abrasive or manipulative (that is, has poor interpersonal relations skills) will not be one to whom others readily provide useful developmental feedback. So, as conditions change and new skills are needed, that manager is unlikely to get the information needed to develop new skills (and will be seen as unable to adapt to change). Someone with poor interpersonal skills will also be less likely to be able to effectively lead a diverse team of people he or she may rarely see when the team is geographically dispersed. In a rapidly changing world, the inability to adapt will get in the way of effectively leading diverse teams faced with complex or ambiguous tasks.

Finally, research shows that avoiding derailment also involves a strong ability to learn from one's experiences, both positive and negative. The ability to learn from experience has many components, including (a) the ability to recognize when new skills or approaches are needed; (b) the willingness to accept responsibility for one's own development; (c) understanding the

important aspects of one's personality, values, and commitments; (d) the willingness to intentionally try out behaviors and attitudes that do not feel natural or comfortable; (e) reflection on the process of one's learning in day-to-day activities; (f) persisting in the face of mistakes, setbacks, and lowered performance while learning something new; (g) using a variety of tactics for learning rather than approaching learning in one single way (for example, solely through hands-on experience, reading, or accessing others); and (h) the ability and willingness to seek regular feedback from multiple sources (for example, peers, bosses, and direct reports).

DIFFERENTIAL APTITUDE TESTING

An individual's career development and success are influenced by the attributes that differentiate that person from other people. These individual differences include interests, values, traits, motives, and intelligence. Perhaps the most powerful and pervasive individual difference influencing career development is *aptitude*. A person's aptitude can influence everything

from career choice to entry into a specific career to advancement within that career. This entry outlines what is known about the nature of aptitude, the relationship of aptitude to career development outcomes, and the current uses of aptitude testing in the workplace.

APTITUDE

Aptitude is defined as a person's natural ability or capacity for learning. It is also defined as talent within a specific domain. Aptitude testing uses a standardized test designed to predict an individual's ability to learn certain skills. Aptitude can be theoretically distinguished from the concept of achievement. *Achievement* is a result gained by effort or the quality and quantity of a student's work. Achievement testing involves a standardized test designed to measure an individual's acquired knowledge and skills in a specific domain. However, an individual's aptitude and achievement are highly related to one another. Aptitude predicts achievement, and achievement strongly predicts capacity for further learning. Thus, there is an inherent ambiguity between achievement and aptitude tests. No test can measure pure aptitude, because previous learning facilitates performance on any item type and all achievement tests act as tests of aptitude as well.

Aptitude and achievement are actually ways of describing individual differences in intelligence. *Intelligence* in this context can be understood as the entire repertoire of acquired skills, knowledge, learning sets, and generalization tendencies considered intellectual in nature that are available at any one period in time.

The most thorough understanding of the structure of intelligence is John B. Carroll's hierarchical model. He summarized the large body of intelligence research that spanned the twentieth century. Based on the data available at the time, Carroll applied factor-analytic methods to develop a model of intelligence that incorporated the relationships among the multitude of specific aptitude tests. The resulting model places general intelligence at the top of the hierarchy, with constructs including fluid intelligence, crystallized intelligence, memory, visual perception, auditory perception, retrieval, cognitive speed, and processing speed at the second level. The individual tests of attitude and achievement assess various facets of the third level. This model provides a framework by which the relationships between aptitude tests can be understood.

The presence of a general factor for intelligence has led some to suggest that only general intelligence or general mental ability is useful for predicting performance in most domains. However, highly related constructs can have quite different relationships with other variables. Because of this, different aptitude tests, such as the ones measuring the third-level constructs identified by Carroll, are useful for predicting various career outcomes. The specific aptitudes required in different careers can be discovered through job analysis.

APTITUDE OUTCOMES

Aptitude has been shown to predict a number of important work and career outcomes. These outcomes include career choice, training performance, job performance, and career advancement. Recent work by David Lubinski has revealed interesting trends in the career choices of extremely high-ability children. The area in which high-ability children are most able predicts the careers that they will later choose. This sample is especially interesting, because there are few limits on the careers such individuals can choose, since their aptitude is high in all areas. Philip Ackerman has developed complexes of aptitude, personality, and interests that tend to characterize individuals. These complexes also predict career choice. People tend to enjoy the things they do well and so gravitate toward careers that allow them to use the relative strengths they possess.

The definition of aptitude implies that it should influence an individual's training performance. Having high ability and capacity for learning in the area in which a person is being trained should lead to a faster and more complete knowledge of the area. This result has been consistently shown in the achievement tests that follow many training programs.

The effect of aptitude does not stop at training but extends into an individual's performance on the job. One of the most constant findings in the field of industrial/organizational psychology is that general mental ability (aptitude) predicts job performance. Frank Schmidt and John Hunter conducted a meta-analysis of all the major selection procedures used over an 85-year span, and general mental ability was found to be among the strongest predictors of job performance. The relationship between general aptitude and performance also reliably increases as the complexity of the job increases. The main way that aptitude

influences job performance is through the acquisition of job knowledge. Individuals with high aptitude learn more, and individuals who know more perform better. Recent work on understanding the multidimensional nature of job performance by John Campbell has led to a broader understanding of the nature of performance. The inclusion of various dimensions of job performance allows for differential prediction of those dimensions. Specific aptitudes influence performance in the dimensions of job performance that require the abilities and learning that constitute those aptitudes.

Aptitude also influences career advancement. Aptitude facilitates job performance, which typically leads to career advancement. Aptitude not only contributes to the performance that leads to promotions but also influences success within the new position, which leads to further advancement. Because of evidence showing the powerful effects of aptitude on performance, many organizations across a variety of fields and careers use information from differential aptitude testing as they make human resource decisions.

APTITUDE TESTING IN PRACTICE

Aptitude testing has been used for almost every sort of human resource decision faced by organizations. Many organizations include cognitive-ability tests to screen employees for selection. Even the National Football League uses an aptitude test to provide additional information about possible draft picks. Organizations use aptitude tests to manage their human capital. They identify the most likely candidates for future advancement so that they can invest extra resources into those individuals' development. Aptitude testing is not limited to traditional cognitive-ability testing. Recent development of tests of social or emotional intelligence and situational judgment represent attempts to measure individual differences in aptitude so that organizations can better use their human capital.

CONCLUSION

Aptitude testing has been shown to be effective for identifying individuals who will be successful across a broad spectrum of careers. Because of its power for predicting these vital outcomes in a competitive economic environment, it will most likely continue in its dominant position in human capital decisions and thus in successful career advancement. As our understanding of job performance and the aptitudes that influence it

increases, the form of differential aptitude tests will undergo changes. However, differential aptitude will continue to play a key role in our understanding of career development.

DISABILITIES AMONG COLLEGE STUDENTS

Over the last decade, the enrollment of students with disabilities in postsecondary education has increased dramatically. In 1978, just 3 percent of all incoming, first-time, full-time college freshmen reported having a disability. By 2000, a full 9 percent of incoming full-time freshmen reported having at least one disability. According to the 1995 to 1996 National Postsecondary Student Aid Study, the average age of all students with disabilities attending college was higher than that of their nondisabled peers (30 years versus 26 years); those with disabilities were less likely to be enrolled in public four-year colleges and universities

(25 percent versus 32 percent); and students with disabilities were more likely to attend public two-year institutions. The National Center for Education Statistics found that students with disabilities were about as likely as students without disabilities to attend private, not-for-profit, four-year institutions (14 percent and 15 percent, respectively).

Many postsecondary disability service providers believe that the 9 percent enrollment figure is an underestimate, as it includes only incoming freshmen of traditional age (18-22) and does not take into consideration older college students with disabilities, those who attend part-time, those who transfer to four-year institutions from community colleges, or those who discontinue their studies and later resume postsecondary education. Higher college enrollments among students with disabilities can be attributed to increased knowledge and advocacy while students are still in high school, teaching and classroom modifications in secondary education, and advances in adaptive technology, in addition to increased mainstreaming of students with disabilities in K-12 public education.

Despite this increase in enrollment, college students with disabilities persist to graduation in fewer numbers than their nondisabled peers and tend to secure employment in lower numbers. Beyond the routine issues of adjustment to the postsecondary setting, career assessment, and job-search skill development important for all college students, there exists a stigma attached to the disclosure of disabilities. Students still encounter stereotypes and bias when they enter college classrooms, and many students have not yet learned strong self-advocacy skills or developed a basic self-awareness of their own disabilities as well as what accommodations they may need. Despite legislation, students with disabilities still find many college science labs, clinical settings, and engineering facilities inaccessible, thus preventing access to and opportunities for training in higher-paying science, engineering, or other technology-based career fields. In addition, employers as well as internship and cooperative education supervisors remain relatively uneducated about the needs of people with disabilities in the workplace, as well as their legal responsibilities for accommodating applicants and employees with disabilities.

LEGISLATION INVOLVING INDIVIDUALS WITH DISABILITIES

Section 504 of the Rehabilitation Act of 1973 remains the legal cornerstone of the college student

disability accommodation process. Programs receiving federal financial assistance are not allowed to discriminate against people with disabilities. In particular, postsecondary institutions are required to make academic adjustments, modify nonessential academic requirements, and provide auxiliary aids and services to students with disabilities. Examples include priority registration, reduced course load, note takers, sign language interpreters, extended time on testing, alternative formats for printed material, and access to computer software and adaptive technology. Section 508 (Accessibility of Technology) of the 1973 Rehabilitation Act focuses specifically on expanding the access of software, equipment, and other technology for people with disabilities. Section 508 requires federal electronic and information technology to be accessible to people with disabilities, including employees and members of the public.

The Americans with Disabilities Act (ADA) of 1990 was later enacted to expand the 1973 legislation and earlier Civil Rights Act of 1964, which addressed discrimination on the basis of race, color, national origin, sex, and religion. In particular, Title I of The ADA prohibits employers from discriminating against qualified individuals with disabilities in the job application process, hiring, training, advancement, and other aspects of employment.

In public school settings, the Individuals with Disabilities in Education Act (IDEA) and its subsequent reauthorization of 1997 focus on K-12 education. This legislation added mandatory transition of students at age 14, to move students from being merely present in individual education planning (IEP) meetings to being active participants in planning for their needs after high school, in both college and employment settings.

Although these laws have increased protections from discrimination, attitudes and responsiveness to students' needs cannot be legislated. Thus, early career-planning activities for young people with disabilities provide the foundation for educating students regarding their rights and for students' requesting and using accommodations before entering the workforce. It is critical for career services professionals to develop their own awareness of disability needs as they assist students in taking advantage of part-time and summer employment, on-campus recruitment, externships, internships, and cooperative work experiences prior to college graduation. Career service professionals can also serve students by educating employers who recruit students with and without disabilities, so as to prevent

biases and personal stereotypes from adversely impacting their employment practices.

IMPROVEMENTS IN THE EXPERIENCES OF STUDENTS WITH DISABILITIES

As a result of legislation and improved transition from high school to college, students are becoming more knowledgeable about their rights and are more inclined to assert those rights to obtain their accommodations. In 2001, as a result of a physically disabled student's complaint, Duke University entered into an agreement with the Department of Justice to make its campus more accessible to students with disabilities. This landmark case was the first to deal with accessibility improvements on a wide-ranging basis (i.e., modifications of policies, practices, procedures; provision of auxiliary aids and services; and improvements to the accessibility of facilities). Duke went further than the legal requirements and developed a comprehensive campus disability management system, a model for many other universities across the country.

In another milestone for students with disabilities, the College Board has recently agreed to stop identifying students who take the SAT (Scholastic Aptitude Test) under nonstandard conditions. Colleges frequently (and erroneously) perceived such scores as having decreased value in students' applications, assuming that students who took the exam under nonstandard conditions were less likely to succeed in college. The original plaintiff had a physical disability (no hands) and used a computer and trackball to complete the test.

Another substantial improvement in students' experiences in college has been increased faculty awareness over the past five years. Under the Clinton administration, the National Science Foundation's Program for Persons with Disabilities funded over 20 demonstration grants to improve postsecondary education for students with disabilities by promoting accessible pedagogy, inclusive instructional materials, media, and educational technologies. "Universal design" for learning and instruction is a revolutionary concept in the field of disability services in higher education that focuses both on the diverse needs of learners and on ways of creating an accessible teaching environment on college campuses.

Distance education has exploded in the past decade, and adaptive hardware, accessible technologies, and inclusive teaching methods are critical if

students with disabilities are to enroll in online courses. Section 508 of the Rehabilitation Act also requires accessibility of instructional software, and more universities are stipulating that their faculties learn about access issues prior to teaching online courses. Information technology (IT) professionals are likely to be more aware of inadvertent barriers to students with sensory disabilities caused by college, departmental, and course Web pages, as well as courseware such as WebCT. Adaptive technology and software are increasingly available at institutions so that students no longer have to bear the huge costs of purchasing their own technology. Universities are now able to obtain software that allows students with visual disabilities to understand maps and graphs via tactile format. More colleges are moving to document conversion, where books in print are converted to audio or digital formats (e.g., eText), and some publishers provide printed materials in alternative formats. Medical professions use instruments such as auditory blood pressure machines and talking thermometers. Innovative equipment and technology are being created and improved each year to remove barriers students face in college and the workplace.

BARRIERS IN THE WORKPLACE

Despite many gains within the postsecondary environment, there continues to be a lack of understanding and awareness of disability issues among employers, human resource managers, and postsecondary career planning professionals. Stereotypes against employees with disabilities are still common. Employers are confused about the perceived correlation between ADA provisions and Family Medical Leave Act requirements.

Adults with disabilities continue to report barriers to employment, according to the Urban Institute of Washington, D.C. In a survey of 16,000 people with disabilities, respondents identified several workplace limitations that impacted their abilities to obtain and sustain employment. Respondents noted that barriers to obtaining employment included (a) lack of accessible transportation, (b) lack of appropriate information about jobs, and (c) inadequate training. The highest barriers within the workplace were listed as (a) lack of related experience, (b) lack of required skills, (c) supervisors' lack of knowledge about accommodations, and (d) negative attitudes and stereotypes. Finally, effective strategies needed to reduce employment barriers

included (a) visible top-management commitment, (b) staff training, (c) technical assistance, and (d) special budgets for auxiliary aids.

IMPLICATIONS FOR POSTSECONDARY FACULTY AND STAFF

Essentially, there are four modes of access that will increase the participation of students with disabilities in both college and employment: physical access, programmatic access, informational access, and attitudinal access. Provision of entrance ramps, wider doors, accessible bathrooms, braille elevator buttons, and accessible parking spaces allow for the first and most fundamental *physical access* to buildings, classrooms, offices, and employment facilities. Second, disabled people receive *programmatic access* when they obtain alternative formats of printed material and service animals to get to class or work. *Informational access* includes auxiliary aids and services (e.g., readers, interpreters), videos and films with closed or open captions, and TTY phones for deaf or hearing-impaired individuals.

Finally, the greatest difficulties faced by people with disabilities are perhaps related to *attitudinal access*. Although legislation easily mandates physical accessibility and provides legislative guidance on the technical specifications of accessibility as well as guidance on how to improve access to career programs, services, and information, the law cannot legislate attitudes. Faculty and staff need to carefully consider whether they may be more inclined to discourage students with disabilities from certain careers than students without disabilities; it is illegal to counsel a student out of a career field based merely on the presence of a disability. It is important that faculty and staff recognize their own biases and stereotypes and how these assumptions influence their behavior toward students with disabilities. Career professionals may be invaluable in helping students to accurately assess their strengths as well as weaknesses, the onset and nature of their disabilities, and what (if anything) they may need as accommodations that will equalize their chances to compete for employment.

There are several ways college/university professionals may address outdated attitudes about people with disabilities:

Take initiative in educating career services staff about the experiences of people with disabilities

Attend campus workshops, listen to speakers, and consult with career professionals at other universities to

learn more about different types of disabilities, employment issues for this population, and how staff can become allies of students

Consult with colleagues in the university office of disability services to learn more about the needs of students

Invite employers who utilize on-campus recruiting program to attend meetings with disability services staff to enhance their knowledge regarding disability issues

Provide training for employers (e.g., live and frequently asked questions) regarding how to interact with and hire people with disabilities

To further eliminate bias and stereotypes about people with disabilities, career professionals can provide accurate information to employers about the accomplishments of people with disabilities in different employment settings. For example, there is an increase in qualified students with disabilities who are enrolling and experiencing academic success in health care fields such as nursing and medicine. Unfortunately, many career professionals, medical school faculty, and employers may erroneously believe these professions are not realistic goals for students who have disabilities. Many advances in technology have led to the development of medical equipment that is more accessible to professionals (e.g., talking thermometers, adaptive blood pressure cuffs), thereby allowing qualified people with disabilities the opportunity to train and become employed in health care.

NEEDS OF STUDENTS WITH DISABILITIES IN THE CAREER-PLANNING PROCESS

Students with disabilities struggle with decisions regarding disclosure. Often they are caught between competing desires to be fully independent and to request accommodations that will facilitate their academic and/or job performance. When they meet with disability services professionals, they most likely are not seeking assistance for the job-search process. They are more likely to focus on achieving success in the classroom.

When students with disabilities do come into career services, they are not skilled in asking for specialized assistance regarding one or more disabilities. They may not know whom to ask for help regarding their disabilities and their implications for their career development. For this reason, career professionals must strive to establish a climate of support that will invite students to seek assistance. For example, adding

disability-related events to a Web-based office calendar conveys to students with disabilities that the office is aware of their needs. Similarly, the availability of disability-related material in print and via the office Web page gives much-needed information to a population of students frequently invisible to many campus personnel.

Internships, practica, clinical rotations, and co-ops are opportunities for students with disabilities to establish positive and successful work histories, whether or not they use the accommodations. The more students with disabilities experience positive job searches while in college, the more they will feel at ease when they enter the workforce. While still in college, people with disabilities are likely to benefit from practice conveying their skills, strengths, and aspirations, in addition to discussing their disabilities and requesting workplace accommodations as appropriate.

Career service professionals, on behalf of the students with whom they work, can be instrumental in training employers who come to campus regarding their responsibilities to students under the ADA. In some cases, this means creating partnerships and agreements, for example, regarding who pays for accommodations for a student at an internship or co-op worksite. While the ADA Title I identifies employers as being responsible for the costs of accommodating applicants and employees, sharing costs among the college, the co-op site, and possibly vocational rehabilitation will not only defray the costs of accommodating a student employee but also perhaps reduce the use of stereotypes. Career services professionals optimally will work closely with the campus disability services in coordinating the most effective accommodation(s) for an internship, practicum, or job site. The office of disability services often has the expertise and professional contacts to locate appropriate equipment, hardware, or software the student needs.

There are instances in which careers have essential job duties and/or training requirements that cannot be accommodated. For example, math is typically a necessary requirement for computer science programs and in many cases cannot be substituted or waived for a student with a disability involving mathematics. Similarly, foreign-language skills may be critical to some professions (e.g., translators), and substitutions to meet graduation requirements are not reasonable. Rather than counseling students out of a career field, it is imperative to help them assess their skills and needs in light of the essential nature of the field.

Career offices can actively partner with alumni, employment recruitment offices, study-abroad offices, and disability services to make programs they sponsor as accessible as possible to all students. Such coordination allows for planning ahead and prioritizing efforts before a disability is disclosed and accommodation request arises.

DISABILITY

Providing the necessary information to ensure sound, evidence-based public policy for those with disabilities has been more difficult than for other economically vulnerable populations. To do so, researchers need appropriate data: to identify the population with disabilities, to establish success measures for the public policies targeted on it, and to track outcomes of such policies. The U.S. Bureau of the Census, for instance, has developed criteria based on questions in the Current Population Survey (CPS) to measure the official employment rate, average household income, and poverty rates of the U.S. population by age, sex, race/ethnicity, and education.

The CPS has also been used to track the size, economic success, and government program participation of especially vulnerable populations, such as single mothers. But controversy over the conceptual and operational definition of the working-age population with disabilities has prevented any official counts of this population, its economic vulnerability, and employment outcomes. The failure of the federal government to establish an official measure of the economic outcomes of working-age people with disabilities may to some degree explain why their economic fortunes have languished while the fortunes of single mothers have greatly improved over the last two decades.

Both of these economically vulnerable populations had for many years been treated by policymakers as if they were "not expected to work." While this meant that they were the recipients of substantial federal funds, usually these funds were conditional on their not working. More important, since policymakers did not expect them to work, little was done to assist them to successfully compete in the labor market. Expectations changed for both groups in the 1990s.

The passage of the Welfare Reforms of 1996, along with a more generous Earned Income Tax Credit,

increases in subsidized child care, and better access to subsidized medical insurance and employment services, together with the devolution of greater responsibility for these programs to the states, were all based on the notion that single mothers, like other women, even those with children, were able to work in the marketplace and should not be discouraged from doing so. This change in public policy had a major effect on the behavior of single mothers. It increased their willingness to seek employment by consistently shifting program incentives to favor work over welfare benefits conditioned on not working. The consequences of these policy changes on the employment, income, poverty, and program participation outcomes of this vulnerable population were captured in the CPS and other national data sets. These data have been used to document the major success of these policies as well as what remains to be done to fully integrate single mothers into the labor market and out of poverty.

The Americans with Disabilities Act of 1990 marked a major change in disability policy away from the medical model of disability that stressed the role of a person's impairment on an "inability to work" to a model that better recognized that the social environment, including the economic, legal, and public policy environment, could have as much to do as the impairment itself with whether a person with a disability was employed. At the insistence of advocates and others, the government launched a multifaceted effort to more fully integrate working-age people with disabilities into society. While the passage of the ADA epitomizes this change, it is also reflected in other legislation, such as the 1998 Individuals with Disabilities Education Act, the 1998 Workforce Investment Act, and the 1999 Ticket to Work and Work Incentive Improvement Act. These pro-work policy initiatives focus on increasing investment in the market skills of individuals with disabilities, breaking down institutional and physical barriers to their use.

Unfortunately, the employment, economic well-being, and poverty rates of working-age people with disabilities appear not to have improved despite these changes in policy, although the evidence is controversial. The controversy is on two levels: quality of the data and interpretation of the data. With respect to the first, data quality, neither the U.S. Bureau of the Census nor any other branch of government has established an official measure of the economic success of this population.

Unlike age, sex, and to a lesser extent race/ethnicity, there is no well-established operational measure of the working-age population with disabilities. However, over the past two decades, a growing consensus has concluded that the old medical-based definition of disability is not satisfactory, that is, a model of disability that assumes that an inability to work is a direct consequence of a medically established pathology. For example, exceeding the medical listings of severity for a given diagnostic group (e.g., infectious and parasitic diseases, neoplasms, mental disorders) is still used by the Social Security Administration as sufficient cause for receiving disability benefits in the absence of work. However, there are people who have such conditions, do not apply for benefits, and continue to work. Hence, while disability begins with a pathology that causes a physical or mental impairment that subsequently limits one or more life activities, such as work, the social environments impaired people face can have as much to do with their work outcomes as does the impairment itself. For example, persons who experience deafness but are accommodated at the workplace with a TTY machine that permits them to use the telephone would not be considered work limited despite their impairment.

Unfortunately, no existing data sets fully capture this more general conceptualization of a work disability. Recent and still controversial research has, however, established that the CPS data, while imperfect, can be used to capture a work-limitation-based measure of the working-age population with disabilities and track its economic success both absolutely and relative to the rest of the working-age population with respect to employment, income and poverty outcomes. The results of this research suggest that in contrast to most vulnerable populations, especially single mothers, people with disabilities have not shared in the fruits of economic growth over the last 25 years, especially during the 1990s.

We now know that the United States experienced two major business cycles over the last two decades of the twentieth century: 1979 through 1989 and 1989 through 2000. Based on CPS data and confirmed with National Health Interview Survey and Survey of Income and Program Participation data, the employment rates of working-age people with and without disabilities were pro-cyclical over the first business cycle, falling over the recession years of the early 1980s and rising over the long period of growth from 1982 to 1989. The rise in employment for those with

disabilities, however, was not as great as for those without disabilities, so over the decade, the employment rate of the former fell relative to that of the latter. The case was the same for single mothers.

The relative employment rate of working-age people with disabilities fell even more over the 1990s business cycle. Although employment of those both with and without disabilities fell from the business cycle peak year of 1990 to 1993, during the growth years 1993 to 2000, employment of those without disabilities rose, while employment of those with disabilities continued to fall. The employment rates of those both with and without disabilities fell between 2000 and 2003, but the relative employment rate of those with disabilities continued to fall.

In contrast to working-age people with disabilities, the employment of single mothers grew dramatically over the 1990s, especially after the implementation of the Welfare Reforms of 1996. By the end of the decade, the employment of single mothers was, for the first time, higher than that of married women with children.

Between 1979 and 2000, the household income of working-age people with disabilities remained about the same. Their wage-earning declines were offset by increases in their disability transfers, Social Security Disability Insurance (SSDI), and Supplemental Security Income (SSI) and by the greater earnings of other household members. Their overall household income, however, fell relative to those without disabilities, whose income rose significantly over this period of substantial economic growth. In contrast, the income of single mothers, which fell relative to married mothers in the 1980s, grew both absolutely and relative to married mothers over the 1990s, especially after welfare reform. The overall increase in the average income of single mothers rose because their labor earnings and the government subsidies they received based on their work more than made up for the decline in their welfare benefits.

The ability of the average working-age persons with disabilities to at least maintain the same level of economic well-being while the income of the rest of the population was increasing, however, obscures what happened to the most vulnerable part of the working-age population with disabilities. This group has consistently faced a greater risk of poverty than working-age people without disabilities. In 1979, a working-age person with a disability was 3.2 times more likely than one without a disability to be living

in poverty. By 1989, their relative risk had risen to 3.5, and by 2000 to 4.1. Over these two business cycles, the poverty rate of working-age people with disabilities rose from 21.9 percent to 28.1 percent, while the poverty rate of those without disabilities remained about the same, 6.9 to 6.8 percent. In contrast, the poverty rate of single mothers rose during the 1980s but fell both absolutely and relative to married mothers in the 1990s, especially after welfare reform.

But what accounts for the failure of working-age people with disabilities to be more fully integrated into mainstream society? Although there has been controversy over the measures of economic success reported above based on CPS data, the controversy surrounding the interpretation of these data has been greater. To understand what is driving these outcomes, it is first necessary to recognize that most working-age people with disabilities experience the onset of their work limitations after they enter the labor market and remain in the labor force long after this initial onset of a work disability. Research shows that the average length of time before individuals apply for SSDI benefits following onset is 15 years and that only 72 percent of workers with disabilities will ever apply for SSDI benefits. The rest continue in the labor force until they exit onto the Social Security retirement program. The timing of SSDI application is affected (holding the seriousness of the impairment constant) by a worker's characteristics and the economic environment he or she faces. Younger and better-educated workers will delay application longer than older or less educated workers. But accommodation matters, and employees who are accommodated by their employers stay in the labor force longer than those who aren't. This is true across a wide range of accommodations. The most frequent firm accommodations, involving changes in job hours and job responsibilities, are not costly from an accounting perspective, although they may be from a work organization perspective.

Economic incentives also matter. Workers whose future earning streams are higher or who are less likely to be accepted for SSDI will delay applying for benefits and continue in the labor force longer than workers with lower future earning streams and higher likelihood of SSDI acceptance.

The employment experience of working-age people with disabilities is discouraging, especially since the passage of the Americans with Disabilities Act of 1990 was meant to usher in a new generation

of pro-work policies that would more fully integrate working-age people with disabilities into the mainstream of American life, including employment. Despite the increased duration in employment that accommodation brings and the likely rise in the percentage of workers with disabilities who were accommodated in the 1990s following the implementation of the ADA, their employment rates fell over the entire 1990s business cycle and has done so, relative to those without disabilities, since the mid-1980s. The causes of this decline in relative employment are controversial, but the preponderance of the evidence suggests that it was not caused by an increase in the severity of workers' impairments; and neither changes in the nature of work nor the availability of employer-provided health insurance were major factors.

The most likely causes of the decline in relative employment were the substantial reduction in the eligibility standards for entry onto the SSDI rolls that occurred in the mid-1980s and the increase in benefits relative to market wages. The unintended consequence of these well-meaning but antiwork policies was to discourage working-age people with disabilities from taking advantage of the strengthening of their legal right to work.

It has also been argued that the increased costs firms must bear to accommodate workers with disabilities have made them less likely to hire such workers and that this unintended consequence of the ADA offsets its positive impact via increased duration on the job for those who are accommodated. The evidence of a negative ADA effect on employment is more controversial and is sensitive to alternative definitions of the population with disabilities.

What is clear is that, as with those without disabilities, the employment of working-age people with disabilities is influenced by market forces. The skills that people with disabilities bring to the job will affect their chances of employment, their duration on the job, and the age at which they leave the labor market. The wage premium that those with more than a high school education can command has dramatically increased over the last two decades. This is true for those with and without disabilities. The best predictor of job market success is one's level of education; in the constantly changing American job market, the long-term rewards to well-educated workers demonstrate its value. Hence, those workers with good job skills and high education levels are the most likely to be retained by their employers during bad times and to

command higher salaries during both good and bad times.

Government policy can also influence the employment of working-age people with disabilities. Historically, the federal government's approach to providing economic security for working-age people with disabilities has been dominated by a caretaker approach, reflecting the outdated view that disability is solely a medical issue.

A glance at the federal budget shows that cash transfers and medical care expenditures (SSDI, SSI, Medicare, and Medicaid) dwarf expenditures for efforts to integrate those with disabilities into the labor force. And the eligibility rules for these programs discourage work and more than likely offset any pro-work effect of the ADA during the 1990s.

The dramatic improvement in the employment, average income, and poverty rates of single mothers after the Welfare Reforms of 1996 show that it is possible for government policy to shift from a caretaker to a pro-work priority and to have a significant impact on a population that was "not expected to work." To successfully integrate working-age people with disabilities into the workforce, however, it will be necessary to first establish an official definition of the working-age population with disabilities based on a currently available data set like the CPS and then use it to monitor the success of policy changes that are consistent with providing support for work, making work pay, and expecting people with disabilities to do what they reasonably can to support themselves. The recent experience of single mothers suggests that reforms with these three features can both improve the lives of many people with disabilities and achieve broad-based political support.

DIVERSITY IN ORGANIZATIONS

Workplace diversity continues to be both an interest and a concern to organizations worldwide. Efforts to provide greater access to corporate careers for groups that have been historically discriminated against is not new. However, what is more modern is the examination of how inherent and subtle biases, as well as privileges, may facilitate the movement of some groups up the corporate ladder—while constructing a glass ceiling for others. Managing diversity efforts that focus on more closely examining the organizational norms, values, and practices that enhance or impede diversity can therefore be met by appreciation as well as resentment and backlash by organizational members and the public at large.

This entry identifies reasons for continued interest in diversity matters and distinguishes workplace diversity initiatives from other organizational efforts to promote workplace equity, such as equal employment opportunity and affirmative action. The discussion then contrasts two different scholarly and

practical approaches to workplace diversity. Next, it focuses on career development and identifies some of the career challenges confronted by minority workers, even within the increasingly diverse workplace. Effective strategies for achieving equal opportunity in career development for organizations are summarized, and the entry concludes with a discussion of the benefits of workplace diversity.

WORKPLACE DIVERSITY: MORE THAN AFFIRMATIVE ACTION

Workplace diversity is a broad and complex phrase that means many things to many people, perhaps because as a larger society, we are continually challenged by what it means to have a diverse society. For example, changes in the demographic makeup of the American population have accompanied an evolution in how society thinks and even talks about diversity. The diversity metaphor has progressed from talking about the United States as a melting pot to discussing society as being a mosaic. The “melting-pot” metaphor reflected a time in which a large number of immigrants who came to the United States traveled in order to escape persecution and/or to seize the tremendous opportunities offered by the “American dream.” At times, immigrants were willing to shed their ethnic identities in exchange for the opportunity to call themselves Americans. Yet over time, for some groups, such as African Americans, the melting pot came to symbolize the lack of choice in becoming American for many of their ancestors and the sense that to be anything other than White, blond-haired, and blue-eyed was something to be avoided. The melting pot did not represent an equal blending of ethnic identities of both voluntary and forced immigrants; instead, for many citizens, it represented an avoidance and exclusion of their differences and identities.

Today, an alternative diversity metaphor portrays the American society as a mosaic, a picture made up of many different and unique parts that are able to retain their individual identities yet meaningfully contribute to the whole. The setting aside of the melting-pot metaphor in no way represents a dismissal of one’s American-ness, but rather signals the need to have both an American and an ethnic identity.

Given that the United States is largely a country of immigrants, workplace diversity in many ways is nothing new. The workplace has always been diverse, given that it has consisted of individuals with different

nationalities as well as values, personalities, perspectives, and ideas. However, *Workforce 2000* set into motion a growing concern about the future labor force and the roles of women, people of color, and older workers in the future of corporate America.

In 1987, the Hudson Institute released *Workforce 2000*, a major report that described the shifts the labor force was facing—namely, that as the population aged, so would the workforce. In addition, the report concluded that women would make up a greater percentage of new entrants to the workplace, as would racial minorities. Finally, this report also indicated that immigrants would make up the largest share of new workers since World War I.

Workforce 2000 served as a forecast for corporate America of the changes the labor force was undergoing. However, it also signaled to organizations that the old methods of recruiting, selecting, and developing workers might not be as beneficial with this new, more heterogeneous pool of potential workers as they had in the past. For example, the increasing gender diversity of the labor force has expanded ideas about employee benefits. Given many women’s responsibility for child and elder care, many employee benefits now go beyond health and life insurance to also include family and medical leave, as well as flexible working schedules and arrangements. Although these initiatives have been frequently considered by organizations in order to better attract and retain female workers, they benefit all employees as traditional gender roles for men and women (in- and outside the workplace) lessen.

Another example of how *Workforce 2000* challenged conventional notions of human resource practices relates to the increase in linguistic diversity, given the growing numbers of immigrant labor. The influx of immigrant labor has meant that organizations must consider the ways in which they communicate with current and future employees regarding recruitment, selection, and promotion as well as employee rights and responsibilities and, most important, safety. The surge of Spanish-speaking workers has made many organizations consider the relevance and legality of English-only norms and practices that could disadvantage this important and large segment of the workforce. The increase in immigrant labor has also meant that monolingual supervisors and managers who direct linguistic-minority employees must develop a working fluency of a new language as well as develop an understanding of the nuances of a different culture.

At the same time the United States and the world were coming to grips with the changing workforce, the nature of work was likewise changing. For the United States, an economy largely built on manufacturing was becoming increasingly focused on the service sector and the new information market. The workplace itself was becoming more and more streamlined as organizational charts flattened. Increasingly, the work of companies became organized around teams, thus increasing the relevance of the increasingly diverse labor force to the functioning of the workplace. Therefore, a concern of many organizations and researchers was the impact of cross-gendered and cross-racial teams on team cohesiveness and performance, as well as the potential for increased levels of conflict. However, all forms of diversity, not just demographic diversity, can potentially lead to conflict within the workplace. Some conflict may, in fact, lead to more effective team processes and outcomes.

The potential for conflict related to diversity has not been a function solely of group dynamics but also of differences in individuals' understanding of the implications of workplace diversity on their own careers, and these differences in perspectives have promoted both confusion and backlash. For example, most employees can agree on how to resolve *first-order conflict*, the type of conflict that results in overt and visible barriers and discrimination in the workplace, such as employment practices that directly discriminate against hiring members of certain ethnic groups. First-order conflict is easily recognized, yet differences over how it should be resolved may result in second-order conflict.

Second-order conflict represents differences in perspectives within the organization that center on definitions of fairness and achieving equity. These differences are rarely voiced and create heavy burdens for organizations that want to move forward in their diversity efforts. These hidden differences often manifest themselves in resistance and backlash. In large part, this backlash has been brought about by misunderstandings of what managing diversity efforts entail, in particular the relationship of diversity efforts to equal employment opportunity and affirmative action.

As a program or initiative, workplace diversity is often confused with equal employment opportunity and affirmative action. Given the continued backlash against affirmative action, many have considered workplace diversity programs and initiatives as "politically correct" disguises for affirmative action. These initiatives

can complement one another, yet are distinct. In fact, both workplace diversity programs and affirmative action can be considered as part of a larger strategy for accomplishing equal employment opportunity.

Equal employment opportunity comes out of U.S. federal law, and it promotes a goal for organizations so that everyone has an equal chance at employment regardless of race, sex, religion, or nationality. Title VII of the Civil Rights Act of 1964 established the Equal Employment Opportunity Commission (EEOC) to monitor and enforce the law that prohibits employment discrimination for the protected groups named.

Whereas equal employment opportunity policy reflects a goal for an organization, affirmative action involves proactive steps on the part of an organization to reflect the diversity of the local labor market. Affirmative action, therefore, is a tool to accomplish equal employment opportunity. Affirmative action came out of Executive Order (11246), signed by President Lyndon Johnson in 1965 (and extended in later orders), which required that federal contractors develop plans that would ensure that employment discrimination did not occur based on an individual's race or sex. Many people mistakenly confuse affirmative action with the use of quotas. Also dominant among the misperceptions of affirmative action is that it encourages organizations to hire unqualified women and ethnic minorities. In most circumstances, quotas are illegal. It makes very poor business sense to hire anyone who is unqualified. The only time the government forces organizations to hire anyone of a particular group is when that company (that contracts with the federal government) has egregiously discriminated against protected groups in the past. In fact, affirmative action is not just one program or initiative, but can involve a multitude of actions related to achieving diversity, in areas such as recruitment, training, and human resource development.

Perhaps the misconceptions of affirmative action reflect not only different levels of knowledge about equal employment opportunity, affirmative action, and workplace diversity but also differences in levels of awareness of the relationship of power and privilege to race, gender, and other forms of identity in and outside the workplace. The assumptions implicit within the inaccuracies regarding affirmative action as promoting unfairness and incompetence suggest a belief that discrimination is a thing of the past and that individuals regardless of race and gender have equal access to power and privilege throughout all sectors of

society. Consistently, data from the national census, the Bureau of Labor Statistics, and the EEOC suggest that minority group members lack the same level of access as majority group members to quality education and jobs and that they continue to confront discrimination (in many different forms) in and out of the workplace. Likewise, identifying any scholarly literature or research that explains the value of hiring any incompetent worker would be extremely difficult. Yet arguments exist to dismantle affirmative action based on these misperceptions. Perhaps, as one noted scholar indicated, affirmative action could be dismantled when *average* women and people of color have the same opportunities for education and employment as average White men.

Like affirmative action, managing diversity programs attempt to create organizational contexts that promote equal employment opportunity. Much of the focus of affirmative action programs has been on creating equity in regard to access to jobs and organizational careers. Although affirmative action is frequently successful in opening doors for qualified women and racial minorities, the organization must still find ways to ensure that support for these groups' performance and career development is available. At a minimum, organizations must strive to eliminate treatment discrimination once new minority workers have been hired. This is where managing-diversity programs come in. Like affirmative action programs, there is not a single defining characteristic of a managing-diversity program. Most are multifaceted and include attempts to not only attract diverse employees but also retain them.

INDIVIDUAL DIFFERENCE AND SOCIAL JUSTICE: APPROACHES TO UNDERSTANDING DIVERSITY

As organizations began to grapple with issues of diversity, organizational researchers have sought to understand the implications of the increasingly diverse workplace on organizations, work, and individual performance. Research has also sought to better understand the realities of diverse workers. There are two approaches to considering the relationship of workplace diversity to career development. The *individual-difference approach* takes a broad perspective about diversity and considers every form of difference as equally relevant and important to career development in diverse organizations. Therefore,

differences in personality and cognitive ability are equated to forms of difference that stem from race, culture, gender, or sexual orientation. The individual-difference perspective strives to be inclusive by expanding the criteria by which one falls under the diversity umbrella. The individual-difference approach is important in that it can attract majority group members, like White men, to diversity-related conversations and action planning. Although this approach may decrease resentment and backlash from the majority group, it may also antagonize minority group members, who may feel that their opportunities to be heard and seek justice are being co-opted in order to make majority group members feel comfortable.

In contrast, the *social justice approach* to examining diversity suggests that some differences are more socially significant and relevant to interpersonal dynamics in the workplace. The social justice approach considers the extent to which social and historical legacies have prohibited or denied some groups full participation in organizations and thus stifled opportunities for learning, training, and career development. The assumption guiding this approach is that the realities that minority groups face outside of organizations, such as discrimination, exclusion, stereotyping, and isolation, are transported into organizations through citizens who are also employees. From this perspective, differences based on characteristics such as race and gender are more important than diversity based on characteristics such as personality, because minority status due to demographic characteristics can be stigmatizing. These identities serve as social markers that create opportunities for access and treatment discrimination in organizations. That is why this entry places special emphasis on understanding the challenges for the career development of women and people of color. For members of these groups, a history of overt and modern forms of discrimination, exclusion, and isolation have limited their opportunities for personal career development and also their opportunities to meaningfully contribute to the healthy functioning of their organizations.

Therefore, a review of these challenges is necessary to fully understand how socially marked identities based on race, gender, and sexuality limit opportunities for career development. Organizations have differed in their perspectives regarding how they think and thus react to the challenge of developing a diverse workforce. A conversation regarding different organizational perspectives and actions regarding diversity will therefore follow, along with other

suggestions for successfully developing employees in a diverse workplace.

CAREER DEVELOPMENT CHALLENGES FOR MINORITY WORKERS

Despite equal employment opportunity goals, affirmative action, and even managing-diversity programs, minority workers can encounter significant challenges to their career development. Despite the federal laws and organizational policies against discrimination and harassment, these barriers to minority career development continue. Wal-Mart, for example, is currently defending itself against a class action suit that alleges gender discrimination. Female employees and middle managers claim not only that they encountered discrimination in regard to access to opportunities for development and promotion but also that gender discrimination exists in regard to pay. Black employees who work at Georgia Power have faced racial harassment and intimidation in their workplace. Racist graffiti and hangmen's nooses (reminiscent of the lynching of Blacks) have been found in areas occupied by Black workers within the company. These are obviously instances of overt forms of discrimination and harassment, yet minority workers also confront "microaggressions" and "everyday discrimination," which creates hostile work environments and likely interferes with employees' level of investment in their work and identification with their employers.

One way to think about the overt and subtle forms of discrimination that are confronted by minority group members in the workplace is to focus on the glass ceiling. The *glass ceiling* is a broad term that refers to the often subtle and invisible barriers confronted by minority workers as they attempt to develop their careers. Women, people of color, and gay and lesbian workers can confront both overt and covert forms of discrimination that derail their careers. Overt hostility and exclusion and subtle distancing prevent minority workers from forming healthy and developmental relationships at work and create very real barriers to their promotion and further professional development.

The glass ceiling limits opportunities for many minority workers to develop their careers and reach top-management positions in corporate America, an invisible barrier they confront as they attempt to move up the corporate ladder. There are varying explanations for why the glass ceiling exists, and they lead to

varying perspectives on what minority employees can do to overcome it.

A survey of chief executive officers in corporate America indicated that they felt that there are not many women in the upper echelons of corporate America due to the small numbers of women in the leadership pipeline and women's relative lack of experience. The same study also surveyed managerial women on track to upper-management positions. These female respondents provided different explanations for women's lack of visibility within the leadership ranks of many corporations. Rather than talking about the lack of women in the leadership pipeline and women's limited work experiences, these respondents largely pointed to the organizational culture as limiting women's advancement. Accordingly, executive women frequently describe organizational cultures as being highly patriarchal and hostile to women. The respondents suggested that another likely contributor to the glass ceiling is the method by which senior leadership is selected. According to this particular sample, it is likely that male leaders select future leaders based on the extent to which high-potential employees are most similar to themselves. These women felt that men select other men and that issues of equity and fairness in regard to leadership development are not critical when deciding who will and will not climb the corporate ladder.

Women who have broken through the glass ceiling and hold positions of significant leadership in the corporate world report using a variety of strategies to help promote their own career development and visibility. Studies of executive women across racial groups reveal that these women consistently try to exceed others' performance expectations. Exceeding expectations leaves little doubt or ambiguity regarding one's competence and credibility. Many female executives also report that they attempt to develop interpersonal styles that place male managers at ease. In addition, female executives look for stretch opportunities in order to develop new and valuable skill sets but also so that they can be successful in important and visible ways to top decision makers. Finally, they also attempt to gain the support of an influential mentor.

Especially telling about the culture of an organization and its contribution to the glass ceiling are the reported strategies that successful women use to break through the glass ceiling. Strategies that focus on exceeding expectations and using an interpersonal style that makes men comfortable reflect the prevalence of a

culture that privileges men and defines women as “the other” who must adapt to men’s preferences. A race-based privilege is likely also at work, given that Black corporate women make similar suggestions for strategies to break through the glass ceiling; these women recommend an interpersonal style that places White coworkers at ease. Again, this recommendation speaks to the prevalence of a “White racial privilege” in corporate America that defines non-Whites as “others” who must continually prove their worth and make people comfortable with their identity.

Workplace experiences of African Americans suggest that they confront a workplace dynamic similar to that experienced by women. A study of Black and White managers in various organizations found that compared with their White counterparts, Black managers had more negative career-related experiences in their organizations. Black managers felt less accepted by their organizations and saw themselves as having less job discretion than their White peers. In addition, Black managers received lower job performance and promotability ratings by their supervisors, and they expressed lower levels of career satisfaction. Black managers in the sample were also more likely to have reached career plateaus compared with their White counterparts.

A longitudinal study of Black and White managers’ careers revealed that managers identified early in the careers as being on the fast track or having high potential experienced very different career trajectories over time. White managers seemed to have a linear path to the corporate suite. Black managers, however, often experienced career plateaus prior to reaching high executive levels, and they also took longer to get there. Although Black managers experienced more promotions than their White counterparts, these promotions were frequently lateral moves and offered little opportunity for greater visibility and development. Black managers who did become high-level executives did so by moving past their career plateaus (and perhaps proving themselves to their coworkers) and by having an influential and diverse set of mentors.

A CONTEXT FOR CAREER DEVELOPMENT IN A DIVERSE WORKPLACE

Career development for an increasingly diverse workforce builds on older and standard organizational practices, such as career mapping, but must also reflect the unique experiences of minority workers. This section explores how differences in organizational perspectives

and paradigms are reflected in human resource practices that can impede or facilitate career development for a diverse workforce. Discrimination and fairness, access and legitimacy, and learning and effectiveness are three different diversity paradigms that have consequences for minority career development.

Some organizations embrace a *discrimination and fairness paradigm* or way of thinking in regard to diversity. For these organizations, managing diversity is mainly concerned with diversity numbers. Equal employment opportunity compliance and avoiding legal battles over employment discrimination are the primary diversity goals. Therefore, diversity efforts mainly center on the recruitment and subsequent selection of minority workers. Far less attention is paid to the issue of retention. These organizations lack efforts to support and develop minority workers, and so many of these workers will leave due to pressures to assimilate. Minority and majority employees in these organizations lack the opportunities to acknowledge and appreciate each other’s differences as an opportunity for learning.

Organizations following *access and legitimacy paradigms* view employee diversity as an opportunity to explore and serve new markets; the value of diverse workers is in the financial benefits organizations accrue by expanding their markets. From a human resource perspective, organizations with an employee base that reflects the diversity of the consumers they serve can provide better customer service. This is especially important within the marketing function, given that those who work in this area are responsible for understanding their potential market and making sure that new products have wide appeal. A classic pre-*Workforce 2000* example of a time in which an organization did not attend to the diversity of its potential markets relates to the marketing of the Chevy Nova. In the 1970s, the Chevy Nova was a somewhat popular midsized car that had broad appeal in the United States. However, marketing and sales of the Chevy Nova floundered in the Latin American market. Apparently, no one at Chevy had considered the role of cultural differences in the international appeal of the automobile. In Spanish, the word *nova* could actually be understood as “*no va*,” which, translated literally, means “It does not go!”

Although minority workers may feel valued within the access and legitimacy organizational context, they may also feel exploited, especially when they are not afforded opportunities to learn and demonstrate new or

non-identity-related skill sets. There is also a loss for nonminority workers in regard to their own development. Access and legitimacy organizations value the cultural knowledge diverse workers bring to the workplace; however, they fail to create opportunities for the wider dissemination of this knowledge for the organizational good. Nonminority workers therefore lose out on the developmental opportunity to enhance and broaden their knowledge of racial and cultural markets that may differ from their own. When minority workers leave these organizational contexts, the unique knowledge they bring to their jobs departs with them.

Organizations following *learning and effectiveness paradigms* view diversity as a strategic advantage and attempt to create a climate that values and recognizes diversity as an opportunity for learning, and therefore an opportunity for effectiveness. The integration of diversity is an organizational goal, and the appreciation for diversity and its value to organizational learning and effectiveness is a key part of these organizations' cultures. This type of organization creates opportunities for employees to learn from one another. The lack of pressure to assimilate to a defined norm within the organization frees all employees so that they can contribute to the organization in new and unique ways and accomplish their work most effectively.

CAREER DEVELOPMENT OPPORTUNITIES

Diverse workplaces that are able to facilitate the career development of all of their employees share some common mind-sets and practices. This entry concludes with a summary of common strategies used by diverse workplaces that promote career development.

Leadership: Organizations that reap the rewards of diversity have leaders who are committed to diversity and model that commitment. Leaders are accepting of diversity and value the variety of opinions and insights that a diverse workforce and top leadership team may offer. Leaders also recognize that challenges will exist due to the variety of perspectives that a diverse workforce can offer, yet they are committed enough to persevere during the shift in the corporate culture from one that may deny diversity to a culture that celebrates it.

Accountability: Leadership, managers, and all employees must be accountable for upholding the organization's values regarding diversity. This may mean enforcing antidiscrimination and harassment policies as well as ensuring that new employees are recruited, selected, developed, and promoted in ways that do not create systems of

disadvantage for minority workers. Likewise, organizations must monitor the climate for diversity in their organizations periodically to understand the opportunities and barriers that minority workers face.

Diversity training: Diversity training provides all employees with the opportunity to begin the journey toward developing multicultural competence, that is, the awareness, knowledge, and interpersonal skills required to work successfully with others who are different from oneself. For diversity training to be successful, it must have the full support and commitment of leadership, as well as be sensitive to the group dynamics that already exist within the organization. The perspective regarding training is that it is a long-term endeavor that evolves as employees develop in their own sense of identity and multicultural development. Effective training provides employees with a clear message regarding the organization's perspective and goals, as well as its commitment, related to diversity.

Mentoring and networks: Much of the mentoring research suggests that women and people of color confront barriers to accessing workplace networks and in gaining adequate mentoring. Mentoring by more senior personnel provides psychosocial and instrumental support to any employee. Therefore, the denial of mentoring opportunities because of a potential protégé's minority status due to race, gender, or sexuality places that employee at a severe disadvantage for career development. Organizations must create opportunities for mentoring (informal or formal) and reward effective mentoring. Similar strategies must be put in place in regard to networks. One option is to create affinity groups (such as a gay and lesbian caucus) or interest groups that are focused on supporting the organization's diversity goals as a way to enhance diverse networking opportunities for minority and majority group workers.

CONCLUSION

Increasing diversity in the workplace provides a valuable asset for organizational learning and effectiveness. Some research indicates that effectively managing diversity and committing to the development of a diverse labor force can save the money organizations lose when they have to remedy the problems of employee absenteeism and turnover. Committing to the recruitment and retention of diverse workers can also save organizations from the substantial financial costs of defending themselves against allegations of discrimination. Furthermore, organizations with a growth-oriented business strategy have demonstrated that workplace diversity can lead to higher levels of

employee productivity, organizational performance, and financial returns.

DOMESTIC-PARTNER BENEFITS

Employers around the globe are increasingly recognizing their employees' domestic partnerships as a basis for extending human resource benefits. The

practice has generated a number of human resource policy implications and has created a variety of legal, economic, and social issues and considerations. These issues and considerations have often created political and social controversy, which is beginning to subside at the beginning of the twenty-first century. This entry presents a brief look at what has now become a complex and broadly implanted practice in business, industry, education, and government.

DEFINITIONS

Domestic Partners. Individuals living in committed relationships but not legally married have recently been classified and recognized as domestic partners by many employers. This status is used to provide the domestic partner of the employee with benefits that historically had been provided only to married spouses or legal dependents of the employee. Companies vary in whom they designate as domestic partners. The domestic partner of an employee may be of the same sex (gay or lesbian) or of the opposite sex (straight), and some employers make this distinction in the granting of benefits. When employers recognize only one of these relationships as a domestic partnership, gay and lesbian domestic partners are usually the ones who are so designated and granted benefits. The rationale for some companies is that straight couples can get married if they so choose but in most states, gay and lesbian couples cannot.

Soft Benefits. When offered to domestic partners, soft benefits include the granting of discounted or free services, official recognition of domestic partners as equivalent to spouses in family and sick leave policies, free or discounted memberships in clubs, free or discounted use of employer facilities, and other similar policies or privileges.

Hard Benefits. Insurance for health, dental, and vision are considered hard benefits, because they involve direct expenditures by the employee for the benefit of a designated individual. They can include the children of a domestic partner as well. Hard benefits also may be granted for tuition coverage or remittance, day care, and retirement or survivor benefits that may designate the domestic partner as the successor beneficiary to retirement or survivor income.

Affidavits. Some employers require domestic partners to sign affidavits of the committed nature of their

relationships. Often these affidavits require proof of indicators of joint commitment, such as a joint account containing a substantial balance, joint ownership of major property, or proof of sharing a residence. Many individuals and civil rights organizations consider this a form of workplace discrimination because married couples often are not required to provide these proofs or affidavits.

BRIEF HISTORY

The first employers to start offering domestic-partner benefits (DPB) in the 1980s were among a small-but-growing group of gay-owned enterprises. In the early 1990s, larger corporations began offering these benefits. Within the span of that decade, there was a rapid rise in the numbers and types of employers that began offering DPB. The Human Rights Campaign (HRC) Foundation is one organization that tracks the changes in domestic-partner benefits among employers. The most recent figures reported by the HRC (<http://www.hrc.org>) reveal that nearly half of the Fortune 500 companies, hundreds of state and local governments and colleges and universities, and thousands of private employers now offer some domestic-partner benefits to their employees, usually a mix of soft and hard benefits. When hard benefits are offered to and obtained by an employee, the value of those benefits is now taxed by the federal government as income to the employee. Legislation has been introduced to eliminate this tax, which married couples do not pay when they receive these benefits.

ARGUMENTS FOR DOMESTIC-PARTNER BENEFITS

Economic Development and Diversity. Some have made the argument that respect and tolerance for diversity has benefits for the economic well-being of a region. It can improve the social environment, adding social capital. Diversity is believed to attract highly educated and talented residents who establish a skilled pool of employees for high-tech industries. The employment and consumer activity this generates could provide the foundation for local or regional economic development.

Fairness. A nondiscrimination policy that includes protection against discrimination on the basis of sexual orientation is often cited as a reason to extend domestic-partner benefits to those who are barred

from legal marriage to their partners. Most policies like this have been established by the employers themselves, some through collective bargaining and some through legislative action. Once in place, they establish a basis for the fair treatment of all employees.

Productivity. Antigay sentiments are increasingly believed to be counterproductive in today's business and social climate. They rob gay and lesbian employees of a sense of security in their employment, which can only dampen productivity. Antigay sentiments can promote a climate of discrimination and/or harassment that can be legally costly and further deprive employees of a safe and productive workplace. Offering domestic-partner benefits is one way that employers can attract the most talented and skilled employees in an increasingly competitive market. It can help retain employees who are the most competitive in that market, reducing recruiting and retraining costs that, in turn, boost productivity.

Changing Cultural Values. Changing social and cultural values that are more tolerant of diversity are partly responsible for the increasing numbers of employers offering domestic-partner benefits. It may be that the public image of a company is enhanced by embracing these social and cultural values, increasing their motivation to offer benefits. Domestic-partner benefits are likely to become more commonplace given legislative attempts by the U.S. House of Representatives at the start of the twenty-first century to establish domestic-partner benefits for federal government employees.

Defense of Marriage. Ironically, one of the driving factors in support of the provision of domestic-partner benefits is that it represents a counterposition to the legalization of same-sex marriages. More precisely, social conservatives, who might ordinarily oppose domestic-partnership benefits, now see these partnerships and the benefits they are now being offered as a possible solution to the constitutional problems raised by denying marriage to same-sex couples.

ARGUMENTS AGAINST DOMESTIC-PARTNER BENEFITS

Costs. When employers first started to consider domestic-partner benefits, one of the first concerns was the cost, largely driven by the fear that insurance costs for providing health care to an increasing

number of victims of AIDS among gay men would prove to be prohibitive. Several studies were conducted, and most revealed that these fears were unfounded. Experience gained over the years demonstrates that costs for offering domestic-partner benefits are low, largely because enrollments are low and actual expenditures constitute a very small percentage of total costs.

Prejudice and Discrimination. Many arguments against domestic-partner benefits are based on attitudes of prejudice that lead to discriminatory behavior. The prejudiced attitudes can be and often are simple extensions of *homophobia*, or the irrational fear of anything associated with anyone who is gay or lesbian. For example, in an early arbitration in which a faculty union sought domestic-partner benefits under its contract based on the nondiscrimination clause, the legal brief written by the employer's attorney relied on phrases such as "perilous trail," "thorny issues," and "administrative nightmare" to describe the impact of offering domestic-partner benefits (*KSU-AAUP v. Kent State University*). These fears were unsupported by evidence then and are recognized by experience today to be unfounded. However, in the early period, ignorance of the nature and fear of the relationships between same-sex couples generated fears that created discriminatory barriers to domestic-partner benefits. Even today, many other arguments against offering domestic-partner benefits (e.g., costs or legal/administrative technicalities) are made as an open opposition to the "homosexual agenda" or offered as a pretext for motivation rooted in homophobia.

Backlash. Some employers cite the imagined backlash from the community and consumers that could occur if they began to offer domestic-partner benefits to their employees. For example, university administrators might fear that state legislatures would withhold funding, donors and alumni would stop giving or terminate planned future gifts, or parents would choose to send their children to more socially conservative institutions. Retailers, manufacturers, or service professionals might fear that consumers would buy products and services from organizations that do not offer their employees domestic-partner benefits.

CAREER DEVELOPMENT

Prospective employers are increasingly aware that to remain competitive, they must offer domestic-partner

benefits. Experience has shown that employers who offer such benefits are more open to questions from job candidates and more supportive of employees in answering questions or administering benefits. Both job candidates and employees are encouraged by human rights groups to question their current or prospective employers about the availability of these benefits, and handbooks are available online to provide information to both employers and employees on how to implement these benefits.

DOWNSIZING

The term *downsizing* represents the broad variety of ways in which organizational leaders reduce employee ranks to achieve business objectives. Downsizing occurs through voluntary programs, such as early retirement packages; involuntary dismissals, such as layoffs; and the displacement of employees through outsourcing. No matter which method is used, the underlying objective of a downsizing is to reduce costs in order to contribute to the achievement of short-term financial objectives and/or long-term strategic shifts in response to the ever-changing global marketplace.

Corporate restructurings and downsizings have become deeply woven into the fabric of contemporary organizational life. What once were infrequent and, in some cases, unheard-of occurrences in most work organizations now have become regularly occurring actions. What once were managerial reactions to difficult market conditions now have become proactive tactics for attaining strategic and financial objectives. And what once were poorly managed events that

eroded the psychological relationship between employer and employee have become, at least in some organizations, opportunities to define or reinforce desired corporate cultures that reflect the realities of today's ever-changing business environment.

Downsizing activities have been implemented in organizations of all sizes, in all industries, and across all geographic areas. Many huge corporations headquartered in the United States have experienced multiple waves of downsizing. Smaller organizations are not immune from downsizing. In recent years, over 500 dot.com start-ups have undergone reductions in force. Practically every industry sector—telecommunications, manufacturing, financial services, education, health care, high technology, and retail, among others—has experienced a major displacement of employees during the past decades.

What initially was an American phenomenon has transcended national borders. Several large European and Asian organizations have experienced layoffs, divestitures, and closings in recent years. These downsizings are especially significant given the labor laws, worker councils, and national cultures that have traditionally supported lifelong relationships between employers and employees. In China, for example, mores were at one time so strong that this type of organizational activity was referred to as “taking away someone's rice bowl.” That is, the company would be removing an individual's means of income.

THE UNINTENDED IMPACT OF DOWNSIZING ON CAREERS

In principle, downsizing should enable an organization to improve its competitiveness without impairing its ability to execute its strategy. In practice, however, a downsizing can exact a heavy toll on organizational effectiveness and the well-being of both survivors and those whose jobs were eliminated. Organizational scholars assert that companies must change today to remain competitive, and they identify a wide array of organizational strategies (such as downsizing) to accomplish this change. Ironically, the term *organizational change* depersonalizes change. It suggests that “organizations” need to change when, in fact, organizations are composed of employees. Employees are the ones who need to change. Employees are the ones who need to bend and flex to the current demands of the work environment. Employees are the ones whose jobs, careers, and lifestyles are directly affected by a downsizing.

In general, downsizing threatens the self-esteem and sense of fair play of all employees. People can rationalize layoffs based on performance, for example, when an employee is repeatedly late to work or fails to meet production standards. However, people cannot rationalize the fact that hardworking fellow employees have lost their jobs because of an economic downturn. Downsizing victims blame themselves for not having seen it coming or not having done something to protect themselves. For victims and survivors alike, a downsizing eats away at the assumption of fairness in the workplace, as they wonder why leadership could not stave off the dreaded event or identify some alternative course of action. Survivors see the human carnage of lost jobs and destroyed careers and wonder, “How could an organization I want to dedicate my life's work to do this to people?”

Some executives believe that downsizing survivors should be grateful just to have a job in tough economic times—that employees should be ready to roll up their sleeves and get down to work. However, the real consequences are very different. Survivors of organizational transitions experience a broad range of psychological and behavioral reactions that begin with rumors of impending events, continue through the weeks and months of transition planning and implementation, and linger long after the dust settles. Downsizings have a lasting impact on employees' perceptions of their workplaces and their career opportunities.

In their research on human responses to major organizational events such as mergers, acquisitions, and downsizings, organizational psychologists Philip Mirvis and Mitchell Marks identified the *transition syndrome*. This process describes the set of expected employee responses to living through a major transition in a company. They found that the transition syndrome arises even when executives have taken some care to devise a downsizing plan designed to minimize upheaval and provide due consideration for its effects on people.

The following six symptoms of the transition syndrome occur in practically every downsizing and have implications for career expectations and progress:

1. *Preoccupation*. When first hearing of a reduction in force, employees become distracted from their work responsibilities and preoccupied with their personal situations. People often feel guilty for having been spared, similar to the psychological reaction of children who lose a playmate or sibling in a fatal

accident. Survivors also may become depressed at their inability to avert future layoffs or disruptions to their careers.

2. *Worst-case scenarios.* Not only do people become distracted, they focus on worst-case scenarios. Dire rumors spread throughout the downsizing organizations.
3. *Psychosomatic reactions.* The stress of living through a downsizing is manifested in a variety of ways. Sick leave increases as many employees are worried and others simply do not want to be around a dismal workplace. Many survivors and victims of downsizings report psychosomatic reactions, ranging from sleeplessness to increased tension and fighting with spouses and children.
4. *Constricted communication.* People often turn inward in a downsizing and restrict their communication. Trust can be eroded in the downsized organization, and people do not know the consequences of speaking up about their careers. Ironically, this occurs at a time when people need to reach out to one another and provide support, both emotionally (e.g., How do we get through this difficult time?) and practically (e.g., How do we minimize the adverse impact on our careers?).
5. *Crisis management.* Many employees lurch into a crisis-management mode. The high level of stress that accompanies every downsizing impairs perception and judgment. People may make rash decisions and jump at what may appear to be decent career moves when, in reality, they have not fully assessed their options.
6. *Loss of control.* What really concerns employees in a downsizing is the sense that they have lost control over their careers. They perceive that no matter how well they do their jobs, they could be hit in the next wave of layoffs. This feeling explains why they may jump at the first opportunity outside the firm or take other actions that initially provide some psychological satisfaction of exerting control but, over the long haul, may prove to be detrimental to their careers.

CAREER MANAGEMENT AND DOWNSIZING

Past research has indicated that employees who have been terminated due to downsizing should keep four perspectives in mind during the period after the job loss. These four perspectives include marketability, composure, standard of living, and attitude. To survive a downsizing experience, indeed, to capitalize on it, individuals will need to manage each of these areas effectively.

Maintaining Marketability

Downsizings have become an integral part of organizational life. The right time to start planning for the impact of a downsizing on one's career is well before it occurs, before the cuts and associated stress hit. This minimizes the likelihood that stress and uncertainty will color one's perceptions and actions. Individuals should develop a contingency plan of what actions would be taken if one's job were suddenly put at risk. A good place to start is with an honest assessment of the current situation. A number of key assessment questions should be asked, including "Do I know what I contribute to my company?" "If my job opened up today, would I get it?" and, finally, "What would I do if my job disappeared tomorrow?" With regard to these questions, it is important for individuals to keep an up-to-date record of achievements, and it is imperative to keep abreast of trends and developments in the field by reading trade publications, joining industry groups, and attending conferences.

In today's economy, whether an employee is laid off often has little to do with job performance and more to do with the turbulence and uncertainty in the global marketplace. It is helpful for individuals to know a few of the signs that a downsizing is likely coming in the organization. For example, is upper-level management having a lot of confidential meetings? Are middle-level managers being questioned more closely or simply turned down when asking for more staff or funding? Is your boss less and less willing to talk to you about the future, or does he or she avoid you as much as possible? Does your boss seem unusually stressed? Has your company's senior-management team changed suddenly? Has your company merged with or acquired another company? Has your company's stock price fallen greatly or its debt rating been substantially downgraded? Has senior management's focus shifted from competing in the marketplace to attempting to cut costs wherever possible? Do Wall Street analysts appear to know more about what's going on in your company than employees do?

It is important for employees to be proactive in this instance. If there is a lack of information coming from leadership, individuals should set up a meeting with immediate supervisors to ask for more details on company plans. If one's supervisor is eliminated in a downsizing, the individual should take the initiative to sit down with the new superior to talk about contributions and get direction for setting new priorities.

Maintaining Composure

When individuals are laid off, it can be a shock, producing feelings of demoralization, fear, frustration, anger, and resentment. Past research has shown that one of the best ways for individuals to effectively cope with job loss is to spend a half hour or so a day writing about the trauma of being terminated. Penning one's thoughts actually can speed up the chances of landing a new job. In a study of 63 men who were laid off by a computer firm, researchers Stefanie Spera, Eric Buhrfeind, and James Pennebaker found that employees who wrote down their thoughts daily found jobs sooner than those who did not. It appears that translating events into words diminished the stress those men experienced and enhanced their understanding of the downsizing process. According to the authors of this study, the writing forced the employees to address their emotions and cognitively reappraise their situations, which prevented negative emotions from resurfacing during job interviews.

Losing one's job is a traumatic event for most people. However, it can be helpful to realize that the typical college graduate today will have several *career* changes during his or her lifetime; a *job* change can be perceived as simply an interlude in one's lifelong employment journey. Maintaining poise and confidence during this unemployment phase will help enable downsized employees to more effectively reposition their skills, talents, and experiences into the next job.

Maintaining Standard of Living

When a downsizing occurs, employees should consider all aspects of the company's actions to be negotiable (e.g., severance pay, outplacement services, medical insurance, stock options). It is important for individuals to know their rights during a downsizing. For instance, although no law requires an employer to provide severance pay, it is a common practice in companies today. A widely used rule of thumb is to offer employees two weeks' pay for every year of employment. If an individual is earning more than \$100,000 a year or is 50 years or older, it may take a little longer to find a comparable new position. A frequently used benchmark for individuals seeking reemployment is to figure one month of job-search time for every \$10,000 in salary earned at the previous position. Consequently, two weeks of pay per year might not be sufficient for many individuals. In this case, individuals should not

hesitate to negotiate a better severance with the direct supervisor or the human resources director. In addition, it may be possible to negotiate a "stay-on bonus" if one commits to remaining on the job until a current project is completed.

Approximately 80 percent of U.S. companies provide outplacement services to downsized employees. Typically, a standard package includes résumé-writing and job-interviewing skills workshops, temporary use of office space, career counseling, and, in some cases, one-on-one coaching sessions. By law, employers must provide COBRA (Consolidated Omnibus Budget Reconciliation Act) coverage. This provision means that individuals have the option to pay a health insurance premium that is much lower than what they would have to pay on their own. However, an employer is legally required to offer COBRA for only 18 months. If one anticipates that the job search might take longer, it might be appropriate to negotiate an extension. Stock options should be considered as well. Usually, an individual has 90 days after a layoff to exercise vested options before losing them. However, most companies, when asked, will agree to extend that period to as much as a year.

In return for providing the above services to the employee, the company will require the signing of a legal waiver of some sort. This document precludes the individual from suing the employer for unjust termination and often includes a clause that the individual will not "bad-mouth" the company to employees or customers.

Maintaining a Positive Attitude

A downsizing can be a stimulus for revitalizing a dead-end career. Most people avoid change at any cost, even when they are unhappy with the current state of their careers. A downsizing, from the perspective of either a victim or a survivor, can be the impetus required to rethink one's career progress and career strategy. It can be a launching pad for exploring new industries or even new occupations. Employees often get so accustomed to functioning within one company that they cannot see their way to "reinvent" themselves. The loss of a job can be the impetus to finally get that dream job, buy that franchise you have been talking about all these years, or to set up that small business. Furthermore, the Trade Adjustment Act (TAA) offers money for many downsized workers to seek retraining (refer to <http://www.doleta.gov>). Besides such retraining funds from the federal

government, many states provide additional money for retraining opportunities.

It is important for downsized individuals to stay busy while seeking new employment. Becoming involved in civic organizations, volunteering for youth sports programs, or becoming more involved at school are all ways to stay active while seeking reemployment. Moreover, individuals should take advantage of the opportunity to spend more time with family.

Overall, downsized individuals must recognize that it is ultimately their own responsibility to manage their careers after a layoff, and they should not forfeit the responsibility to a company or another person. On the positive side, a downsizing can lead to a new career and a brighter future. Downsizing can be the stimulus for a more challenging, more invigorating, and more rewarding career and provide individuals a second chance at victory.

E

EARLY CAREER STAGE

One of the most important milestones in an individual's life and career is the transition from school to work. Much research has examined how individuals come to understand who they are by the work they perform and the occupations they choose. Early psychological theories examined the importance of work, especially as measured by hierarchical rank and income, to the process by which a child becomes an adult. One of the most influential of these models was developed by Erik Erikson, who proposed that an individual must pass through eight stages, each with its attendant requirements or "dilemmas" determined by age and social demands. Erikson's fifth stage (identity versus role confusion) is the time when young adults (approximately age 19-25) begin to focus on career concerns by contemplating what occupations to prepare for, while creating sexual, religious, and political identities. The formation of an adult identity and separation from one's parents are associated with career decidedness, exploration, confident decision making, and the ability to engage in career-related tasks.

Drawing on the works of psychological life development, Donald Super devised perhaps the best-known model of career stage development. Super suggested that individuals implement their self-concept through vocational choices. This process of choosing an occupation that permits maximum self-expression occurs over time and can be summarized in four career stages: (1) *exploration*, a period of engaging in self-examination, schooling, and the study of different career options; (2) *establishment*, a period of

becoming employed and finding a niche; (3) *maintenance*, a period of holding on to one's position and updating skills; and (4) *disengagement*, a period of phasing into retirement. The exploration and establishment stages constitute the *early career*.

EXPLORATION STAGE

One key developmental task of the exploration stage is choosing an occupation. Career scholar John Holland argued that individual traits, parental preferences, and childhood experiences create natural preferences, which, over time, lead to the development of interests and coping styles as well as occupational preferences. Holland's model of vocational choice suggests that individuals will seek out work environments that match their skills, abilities, attitudes, and values. He identified six personality types: (1) *Realistic*, who prefer to work with objects, tools, machines, and animals and are persistent, practical, and asocial; (2) *Investigative*, who chose to observe, understand, and control the physical and social environment and are curious, independent, and introspective; (3) *Artistic*, who prefer ambiguous, unsystematic tasks that use physical and verbal materials to craft new ideas or products and are expressive, imaginative, and nonconforming; (4) *Social*, who like to inform, teach, and develop others through human relations skills and are friendly, empathic, and understanding; (5) *Enterprising*, who exercise leadership, use persuasion to achieve goals, and are ambitious and self-confident; and (6) *Conventional*, who like to organize and handle data and are conforming, efficient, and practical.

Holland's theory and its related measure, the Holland Vocational Preference Inventory, have been used by career counselors in a variety of settings and, as such, have been the subject of much research scrutiny. Holland's six types, along with the Myers-Briggs personality measure, are often used to assist college students in making early career decisions.

Holland contended that failure to work in a situation with good personality-environment fit would create role conflict, whereas congruence between personality and the environment would result in high satisfaction and performance. The process by which individuals match themselves to organizations was detailed in John Wanous's book *Organizational Entry: Recruitment, Selection, Orientation and Socialization of Newcomers*. During the job search process, individuals seek out firms that will meet their needs, while organizations simultaneously seek out individuals with required qualifications. Once a match is made, the new employee learns the firm's culture and norms through formal organizational methods, such as orientation programs and the employee handbook, as well as informal processes, such as hazing and office gossip.

Wanous suggested the use of "realistic job previews" (RJPs) as a means of reducing the likelihood of a person-organization mismatch and decreasing employee turnover. In contrast to the seduction recruitment method, which creates inflated expectations or false impressions, RJPs provide potential employees with the positive as well as the negative aspects of the organization and job. During the recruitment and selection process, individuals who perceive a mismatch between their needs and values and what the organization has to offer can self-select out of the process, choosing alternative job offers that better fit their needs. Those who are eventually hired by a firm providing an RJP should be aware of—and "vaccinated" against—the potential negatives of the workplace. They should have more realistic expectations that can be more easily met, as well as a better understanding of job requirements. Employees exposed to an RJP are more likely to have developed coping mechanisms for managing the realities of the workplace and to be more committed to the firm after having made a meaningful choice among alternative job offers. Because the highest turnover rates are reported among the newly hired, the use of RJPs, as well as other methods of reducing unrealistic expectations, can help organizations lower replacement costs.

ESTABLISHMENT STAGE

In the early career stage of establishment, individuals become employed and try to discover their niches. Individuals become regulated to the work world, learning how to interact effectively with coworkers and superiors within cultural norms. They develop expertise and responsibility for improving performance and seek to reconcile the desire for independence and the demands of organizations. Being proactive, managing office politics, and finding a mentor or establishing a network of mentors are all means by which newcomers can help increase the effectiveness of the socialization process that occurs during the establishment stage.

As individuals navigate through the establishment and other stages, career anchors, which are internal to the person, act as both driving and constraining forces of career decisions. Edgar Schein defined a *career anchor* as the pattern of an individual's self-perceived talents, values, and motives. If an individual is placed in a situation incongruent with his or her values that fails to meet his or her needs or is unlikely to produce success, that person will be "pulled back" by his or her anchor to a situation more likely to produce success.

During the establishment stage, individuals may also make significant decisions regarding marriage, the fit between work and nonwork, and the achievement of goals. Individuals may differ in the amount of commitment and participation they devote to roles, with some individuals engaging in perhaps only two roles (e.g., homemaker and worker) and others at the same age and stage engaging in many roles. The choices young adults make regarding commitment to these roles can cause various levels of role conflict, stress, and self-fulfillment. Daniel Levinson's well-known model of life development suggests that whereas men develop relationships that complement their career goals (e.g., the special woman and mentor or advisor who support his career), women often struggle with marriage or other relationships that are obstacles to their development. Research has found a number of factors affect men and women differently as they try to build and progress through their careers, including social norms regarding time expectations related to child-rearing and household duties, the importance of job characteristics as they relate to work/family balance, the relative influence of a partner on career saliency and financial rewards, and the impact of organizational cultures that discourage

work/family balance and impede career advancement through discriminatory practices.

EARLY CAREER TASKS IN CHANGING TIMES

The linear career stage models, as exemplified by Donald Super's model, mirror the rise of tall, organizational forms and their related structures and policies. Linear stage theories continue to dominate the research on careers, despite the changes that have occurred in the work environment, including increased globalization, rapid technology advances, increased diversity, and evolving organizational forms (e.g., flatter, more flexible). Some scholars, however, have proposed newer models and theories to recognize these changes. For example, instead of one set of career stages, as depicted by Super's model, Tim Hall and Philip Mirvis have suggested multiple shorter learning cycles over the life span, which are driven by constant learning and mastery rather than by chronological age. Thus, an individual's career will be characterized by a series of ministages of exploration-trial-mastery-exit across functions, organizations, and other work boundaries rather than just one period of exploration or establishment.

Moreover, under the old career models, success was often based on winning "tournament style" (i.e., win a round and advance to the next round; lose a round and out of the game). Early career failures, disruptions, and deviations from the linear career path were thought to have long-term negative effects on the career. Under newer, nonlinear careers models, success is defined by the individual, and focus is placed on continuously learning, intrinsic as well as extrinsic outcomes, and the increased ability to make physical and psychological changes throughout life. For example, Lisa Mainiero and Sherry Sullivan suggested a kaleidoscope model of careers, in which women change the facets of their lives to best match their life situations, even if those choices run counter to typical definitions of success. Moreover, unlike the stage theories, the kaleidoscope career model values gender and context rather than making it invisible in the examination of careers. In sum, these newer career patterns may place less pressure on individuals in the early career stages to make permanent career decisions and avoid early career mistakes at all costs, thus reducing stress and encouraging more entrepreneurial endeavors.

Career counselors and educators should examine new ways to assist individuals in early career stages to

develop the skills and mind-sets necessary for achievement and personal success in these changing times. Such methods for enhanced early career development include high school guidance programs that facilitate public career exploration and the discussion of clear occupational choices; helping young adults set early career goals that provide a framework for making the many decisions they will face; experiential learning and other creative educational experiences, including university-sponsored service learning and entrepreneurial activities; and emphasis on part-time employment, structured internships, and co-op positions that foster the learning of new skills, interactions with more established workers, and meaningful work experiences.

EARLY RETIREMENT

There is no strict legal definition of *early retirement*, as a mandatory retirement age is illegal for most occupations in the United States. Individuals can begin receiving Social Security benefits from 65 to 67 years of age, depending on year of birth. Therefore, early retirement is often defined as choosing to leave the workforce prior to the age at which one is eligible for Social Security benefits. Individuals in their 30s and 40s are considerably less likely to retire early than those who are 50 and older. The concept of early retirement as a transition into unemployment is misleading, since many individuals who “retire” early continue to participate in the labor force, at least part time.

Individuals may choose to retire early for a number of reasons. Obsolete skills, job dissatisfaction, or chronic health problems may contribute to the decision to retire early. People may retire early because they wish to travel, spend more time with family, do volunteer work, or pursue alternate careers. If they are unable to find other jobs, older workers who have been laid off from jobs may retire sooner than they had planned. The choice to retire early is facilitated by having adequate financial reserves or attractive alternatives to work.

Employees may retire early because they have been offered generous financial incentives by their employers to do so. Some employers, in an effort to cut costs, offer employees the opportunity to retire early on a voluntary basis. Although a company’s up-front costs associated with an early-retirement program are high, payroll costs are decreased over time. Because voluntary job cuts are seen as more humane than involuntary cuts, companies sometimes offer early retirements to avoid bad press and negative employee reactions associated with forced layoffs. Early-retirement incentives are generally offered only to employees who meet certain age and length of service requirements, such as a minimum age of 50 years and 10 years of service. Early-retirement incentives, sometimes called “buyout packages,” might consist of lump-sum payments, monthly retirement benefits over a period of several years, full pension payments ahead of schedule, Social Security bridge payments, and health and life insurance.

When offering early-retirement packages, companies must follow guidelines set forth by the Age Discrimination in Employment Act (ADEA), which prohibits discrimination against employees who are 40 and older.

The Older Workers Benefit Protection Act, an amendment to the ADEA, permits early-retirement incentive plans as long as they are voluntary. The company cannot coerce, threaten, or pressure employees into accepting an early-retirement offer. Eligible employees must be given adequate information about the terms of the offer and a reasonable period in which to make a decision. Early-retirement incentives must be offered to groups of employees rather than an individual employee but can be targeted to specific departments or facilities. A drawback of voluntary early-retirement programs, in comparison with involuntary job cuts, is that the best employees might choose to leave while more poorly performing employees stay.

For individuals, drawbacks to early retirement are largely financial and health related. Because of increases in life expectancy, retirees, especially women (who live longer than men), require significant financial reserves. Health insurance costs may rise dramatically if the retiree’s former company provides less generous benefits or charges higher premiums in comparison with regular employees or drops coverage altogether. Early retirees should seek financial planning to ensure adequate cash reserves and insurance coverage following retirement.

It is important to recognize that early retirement does not always mean going from full-time employment to being unemployed. Increasingly, the trend is for individuals who retire early to seek *bridge employment* and work longer after retiring early. Early retirees may work in part-time or temporary jobs, become self-employed, or be rehired by their former employers as consultants. Retirees may seek bridge employment to provide income to compensate for lower wages in retirement, although bridge employment tends to pay less than the retirees’ previous jobs. Individuals whose identity is strongly tied to work are less likely to retire early, but if they do so, they are more likely to seek bridge employment, which can help smooth the transition from career to retirement and offset social isolation that may occur in retirement. A form of bridge employment is *phased retirement*, in which longer-tenured employees, rather than leaving their companies entirely, are given shorter work hours and less responsibility as they gradually phase into full retirement.

Some experts believe that the trend toward early retirement is ending and that the twenty-first century will be characterized by later, not earlier, retirement. The average retirement age for men in 1950 was 70

and decreased to 62 in 1985. In 1985, the trend toward early retirement began to decrease, and labor force participation for men 60 and older increased significantly more than earlier trends would have predicted. Women's retirement patterns have followed a similar trend. One factor in later retirements is the shift away from a manufacturing economy with jobs requiring heavy physical labor toward a service economy with jobs that can be done by employees with more diverse physical abilities. Another factor in the trend away from early retirement is the increasing use of defined-contribution pension plans, such as the 401(k). Traditionally, employers have offered defined-benefit plans, in which an employer promises to pay retirees a guaranteed amount. In a 401(k) plan, the retirement benefits received depend on the investment performance of the stock market, so that employees cannot accurately predict their retirement incomes. Therefore, employees may be reluctant to retire early if they perceive that their future retirement benefits are less secure and reliable.

Early retirements are less prevalent when the labor market is strong and unemployment is low. Because of this, some experts believe that the trend away from early retirements is temporary, resulting from the rapid economic growth of the 1990s, and that the average age of retirement will again decline in the future.

—Kelly A. Mollica

frail or disabled elders, including aging parents, grandparents, spouses, other relatives, or friends. Elder care involves care at the person's home or in a care facility that may be nearby or miles away.

Many informal caregivers to elders have jobs and careers and thus find themselves juggling their work and caregiving. The most common types of assistance provided by working caregivers include helping an elder with instrumental activities of daily living, such as transportation, shopping, making care-related decisions, managing money, housekeeping, and chores.

Some of the work-family issues faced by working caregivers of elders are similar to those of working parents, including the difficulties posed when the elder is sick and other care arrangements must be made or when the elder must be taken to the doctor, dentist, or other appointments that generally must be scheduled during the workday. Often, caregivers of elders must also meet the needs of more than one household, because most do not live with the elders. Also, care must sometimes be coordinated among multiple caregivers of the elder (e.g., several adult children). Moreover, elder care differs from child care emotionally, in that the elder generally will become more, not less, dependent over time. Finally, the power and authority dynamics differ when an adult child is caring for an aging parent or other elder versus when a parent is caring for a dependent child.

Providing elder care can yield a sense of great satisfaction and pride and enhance caregivers' skill sets and sense of competence. At the same time, it can have deleterious effects on caregivers' work performance and careers and also their personal and financial well-being, such as when one must quit work or reduce the number of hours worked, resulting in costs to employers and employees alike.

PREVALENCE OF ELDER CARE

Estimates of the proportion of employees in the U.S. workforce who have informal elder care responsibilities range from 10 percent to 25 percent, and the numbers are increasing. Most working caregivers, especially those who are married, are providing care to more than one aging parent, stepparent, parent-in-law, or other elder. Moreover, later child-bearing has meant that more than a third of working caregivers of elders are also caring for dependent children. These caregivers have been called the "sandwiched generation."

ELDER CARE PRACTICES

The term *elder care* describes the unpaid help provided by family members, friends, and/or neighbors to

FACTORS CONTRIBUTING TO EMPLOYER INVOLVEMENT

Employers have developed workplace supports to help employees manage their elder-care duties and reduce work-family conflict, due to growing awareness of the increased numbers of workers providing elder care, management's personal experience with elder care, and research findings concerning the possible negative effects of caregiving on employees, their work performance, and worker retention and recruitment. For example, many working caregivers of elders have been found to experience an increase in time lost from work, including missing days, arriving late or leaving early, and being interrupted during the day by caregiving responsibilities, such as making or receiving telephone calls concerning the elders in their care. Some take unpaid leaves of absence to provide care. Some caregivers experience a decline in their performance or effectiveness at work. Some quit their jobs to provide elder care, or they take early retirement. Others refuse promotions, travel, or training, thus forgoing career advancement opportunities and decreased lifetime earnings. A greater risk of depression among working caregivers of elders also has been found, as have greater stress and fatigue and more health problems.

TYPES OF EMPLOYER SUPPORT

Three basic types of support have been offered by U.S. employers in an attempt to reduce working caregivers' work-family conflicts and maximize employees' abilities to provide informal help to elders while continuing to perform optimally at work: policies, benefits, and direct services or programs. Key caregiver needs that have been addressed through these mechanisms include time to deal with family issues, emotional support, and tangible assistance.

Specifically, policies that maximize flexibility in the scheduling of work hours, the place of work, the number of hours worked, and the ability to take time off from work when needed, including leaves of absence, have been implemented by employers. For employers with 50 or more employees, offering such leave is mandated by the federal Family and Medical Leave Act (FMLA) of 1993, which allows an employee to take up to 12 weeks of leave, with the guarantee of being able to return to his or her same or similar job at the same pay and benefits. This leave,

however, is unpaid, except where state law stipulates otherwise (e.g., California). Supervisor support for work-family issues, reinforced through management sensitivity training, is another policy that contributes to perceived flexibility in the workplace and reduces work-family conflict.

In addition to paid time off to deal with family-related needs, other benefits that can be useful to employees with dependent-care needs include full or partial payment for health and long-term care insurance, legal expenses, and dependent-care services. Offering a *cafeteria*, or flexible, benefits plan allows maximum flexibility and can address employee needs across the life span. In such plans, the employer pays a major portion of the costs of the benefits by establishing a "flexible benefit allowance" of a certain dollar amount, and employees choose the benefits that best meet their needs. Flexible spending accounts, such as dependent care assistance plans (DCAPs), are a benefit of particular use to employees with dependents. DCAPs may or may not involve direct employer contributions but are available only when set up by employers for their employees. Another form of assistance is the Dependent Care Tax Credit, which is a federal, and also sometimes a state, tax credit for employment-related dependent care expenses. Employers have no direct role in providing these credits, but they can publicize their availability. Finally, because long-term care is not covered by health insurance plans or by Medicare, some employers have begun offering long-term care insurance at reduced, group rates, generally with no employer subsidy.

Direct services are the last general type of support offered, typically only by large employers, to aid employees with dependent care responsibilities. Some employers establish a library of educational materials, distribute newsletters, and/or provide seminars concerning caregiving, health conditions, and where to turn for help. Some make computers available so that employees can access information electronically through company intranets or the Internet, and some offer caregiving fairs, where local service providers set up tables or booths so that employees may obtain information at one time in one place.

Although there is a wide range of public, nonprofit, and for-profit services in the community, the service system is fragmented and difficult to negotiate. Therefore, some employers offer information and assistance or referral services, and some offer assessment and case management to assess the elder's

needs, determine eligibility and payment options, and then package together the needed services. Psychological counseling and support groups are offered by some employers to help employees deal emotionally with their elder-care responsibilities. Other direct services include take-home dinners from the company's cafeteria, employee convenience centers that handle grocery shopping, laundry, dry cleaning, shoe repair, and so on or provide door-to-door transportation in employee-driven vans. The benefit consists of the time and travel costs saved; employees pay for the actual services. A few U.S. companies provide services for elder care recipients themselves, such as day-care facilities, or offer subsidies, vouchers, or discounts for such services provided in the community. Sometimes services are offered through an employer's employee assistance program; other times, they are provided by a separate contractor (with both venues representing career opportunities for those trained in gerontology).

Finally, some employers have determined that the best way to help their employees is to contribute funds, either solely or jointly with other employers, to expand the supply and improve the quality of elder (and child) care services in the local community.

ELECTRONIC EMPLOYMENT SCREENING

Electronic employment screening (EES) is preemployment assessment using any electronic hardware or software, including the Internet. EES is typically conducted by employers or others with whom the employer contracts. For practitioners, EES includes electronic applications, résumé scanning and tracking, online interviewing and videoconferencing, and electronic database access for inquiries into applicants' backgrounds. These background assessments include, but are not limited to, identity checks (Social Security number and fingerprint verification), credit and criminal histories, workers' compensation claim history, and specialty database queries, such as antitheft lists.

The use of EES has expanded geometrically primarily due to the widespread availability and increasing number of preemployment services. EES offers speed, thoroughness, efficiency, impartiality, and significantly more information. Human resource screening, electronic or not, is receiving increasing attention in all sectors. Organizations have found that a competitive advantage can be achieved through human resource strategies designed to recruit, select, and hire the best candidates for available positions, while eliminating those that pose potential risk or liability. Global competition ensures that the necessity for thorough screening will continue to offer challenges for practitioners.

Research indicates that many, if not most, applicants provide some degree of false information. In fact, the Society for Human Resource Managers estimated that from 40 percent to 70 percent of job applicants enhance their personal work histories. The experience of September 11, 2001, brought to the forefront the seriousness of screening—and not just for airlines. Traditional, nonelectronic screening for security clearances can take as long as one year. Using electronic systems significantly shortens this time delay and reduces backlogs. All entities involved in transportation plus those traditionally charged with scrutiny, such as security, health care, youth-related, and residential management organizations, are obliged to expand their background investigations of both prospective and current employees. The relatively

recent proliferation of negligent-hiring lawsuits and attendant damages also elevates the value and necessity of thorough screening. Consequently, *credentialing*, the process of screening and evaluating applicant qualifications and credentials, including required education and training, licensure, and certifications, is receiving well-deserved attention.

As more and more organizations develop Web sites, they are increasingly offering—and sometimes require all job seekers to complete—electronic job applications. The purpose of this requirement is twofold. First, paperwork is significantly reduced. Second, integrated human resource software systems can be updated immediately and background investigations begun.

Whether or not résumés are submitted electronically or in hard copy, many organizations are increasingly utilizing résumé scanning and tracking systems. Résumés are scanned into computer databases, which can later be queried for applicants with specific qualifications. That is, organizations are accumulating inventories of résumés that are immediately accessible. Some companies use text searching or artificial intelligence software to track the résumés. Key words from job descriptions can be matched with applicants' scanned résumés, identifying and often even ranking the job candidates. Current descriptions of these processes in the popular press note the advantages of impartiality and reduction in human errors and/or omissions. Job applicants are cautioned to adhere to certain design restrictions in developing their résumés; they can be scanned most accurately on plain white paper, without bolding, italics, or underlining formats.

Although most job applicants' references are checked via telephone or in writing, some organizations do visit the Web sites of companies listed as previous employers to identify and find other sources that might have valuable information about job candidates.

Increasingly, companies are conducting interviews and testing electronically. Work simulations and other tests for both job skills and honesty are often conducted electronically via the computer. Some computerized honesty tests record not only the job applicant's choice but also the time it takes to make that choice (response time). The inference is that if faced with an ethical dilemma, hesitation might indicate dishonest tendencies. There are also national antitheft databases containing names of workers who have been prosecuted for theft or who have admitted to it.

In the last 10 years, organizations have increasingly outsourced background investigations to firms

specializing in preemployment information and/or fraud detection services. These third-party companies conduct background searches for job applicants in varying depth and do so relatively inexpensively and quickly. However, it should be noted that legal liability for accuracy and depth is not alleviated through this outsourcing. Electronic databases are queried regarding workers' compensation claims, credit histories, conviction and traffic records, and identity confirmation. Only government agencies and selected private sector industries such as transportation, banking, brokering, and gambling have access to the Federal Bureau of Investigation's Information Center for fingerprints and known terrorists.

Federal and state laws regulate the inquiry into and the use of information regarding criminal histories. Employers should seek information only about the conviction of felonies. The Federal Aviation Administration and the Food and Drug Administration require criminal checks to prevent bioterrorism.

All employers should pay close attention to some caveats about the use of electronic databases in employment screening. Databases are often inaccurate and incomplete. Experts in the field recommend that Web searches be backed up with telephone confirmations. For instance, a person may have been found not guilty of a crime but the court-ordered expunging of the alleged criminal activity failed to take place. Thus, a candidate might improperly receive a negative search report. There is a dearth of reliable national and state criminal databases necessitating access to county court records, many of which are not available electronically. Job applicants often move out of the county in which they encountered difficulty, thus requiring background checks to query multiple counties. In all of these cases, organizations that make decisions based on inaccurate or incomplete information can be held liable.

The recent increase in identity theft makes credit checks of employment candidates suspect at the very least. The Fair Credit Reporting Act requires that applicants be informed as to whether a decision not to hire is made on the basis of a negative credit history, and the applicants must be given the opportunity to dispute the report. Preemployment information service companies vary significantly in their attention to detail. Therefore, some screening tools should be used only postoffer, and it is wise for employers to have knowledge of employment and privacy laws.

EMOTIONAL INTELLIGENCE

Emotional intelligence (EI) is a concept that has caught the attention of researchers, practitioners, and the general public over the last decade. The idea that career development involves not only a cognitive but also an affective component has been promoted in recent years. Popular books discuss the importance of EI for success in academic and occupational settings, as well as how it determines success in current jobs, promotions, and other important life outcomes. Claims abound that successful negotiation of relationships in a career depends on the perceptions and management of emotions in oneself and others. This entry covers three areas associated EI. First, there is a review of the competing conceptualizations (and associated measurements) of EI. Second, there is an overview of empirical studies that attempt to link EI to successful career development. Finally, there is an identification of some critical future research needs and potential applications.

CONCEPTUALIZING EI

Although *emotional intelligence* as a distinct term has been in use for only a little over a decade in the industrial, work, and organizational (IWO) psychology literature, researchers have been exploring alternate intelligences since the beginning of the twentieth

century. The notion of interpersonal and intrapersonal intelligences had previously been put forth. Research on the role of affect in explaining organizational behavior has a lengthy past, and the recent emphasis on EI has built on these traditions.

The current literature on EI can be grouped into two rather distinct camps, based on differing conceptualizations of the construct. The correlation between measures of the two conceptualizations has been in the low .10 range, suggesting that the two assess distinct concepts. That is, an individual who scores high on one conceptualization of EI need not score high on the other. Instead, the assessment of an individual depends on the measure used. For clarity of communications and practical use, it is necessary that the two constructs be separated. In this entry, we will focus on each of the current conceptualizations and their links to career success.

One conceptualization of EI, often termed *trait-based* or *mixed EI*, views it as a conglomeration of personality traits. Emotional stability, agreeableness, sociability, and empathy are among the traits considered to be central aspects of EI. Given that this model places EI close to the domain of personality characteristics, EI is assessed using self-reports similar to those employed in the assessment of personality. It has been argued that since most of the affective processes underlying EI are not observable to outsiders, self-reports may be the most appropriate method for measuring it. The writings of Reuven Bar-On, Daniel Goleman, and others can be broadly grouped in this camp. However, during high-stakes testing (e.g., selection into highly competitive positions, admissions into educational institutions), there is a concern that such self-reports could be distorted by motivated faking. In fact, it could be argued that individuals with good EI skills are the most capable of such distortion. Individuals high on EI are probably better able to perceive what kinds of answers or behaviors are expected of them in a social context and would thus better be able to distort their responses.

The actual dimensions that constitute EI have varied across writers. Furthermore, some authors have shifted the defined content domain of EI over the years. It is in part this lack of consensus among EI researchers that has generated criticism and the perception that EI is a fad instead of a valid psychological construct. For example, Goleman has conceptualized EI as consisting of five dimensions or core competencies described by self-awareness, self-regulation,

self-motivation, social awareness (empathy), and social skills. This model is primarily driven by its relationship with personality-based variables. Others have claimed that self-awareness is the key to EI. *Self-awareness* refers to one's ability to know and monitor one's feelings on a regular basis. This enables one to be aware of one's preferences, internal states, and intuitions. These descriptions mirror the definition of private and public self-consciousness that psychologists have studied in preceding decades. The second core competency in this model refers to self-regulation. *Self-regulation* refers to managing one's internal states and impulses. This competency includes elements of self-control, conscientiousness, adaptability, and so forth.

The third competency, *self-motivation*, is the force behind being goal oriented and taking an optimistic point of view regarding outcomes. To complete work successfully, the individual should experience a feeling of *self-efficacy*. This competency appears to include achievement, drive, commitment, and so forth. Awareness of others' feelings and emotions, *social empathy*, is construed as the fourth basis for EI. This element of EI encompasses empathy, a variable that has been studied extensively by psychologists. Given that careers of the twenty-first century increasingly involve work in teams and thus necessitate interpersonal skills, this component of EI is viewed as a critical aspect in studying career success. The last component of this conceptualization of EI, *social skills*, refers to a person's adeptness in interpersonal relations.

In addition to this five-competency conceptualization of EI, several other trait-based models exist. One of the popular models, developed by Bar-On, conceptualizes EI as consisting of five main factors: intrapersonal, interpersonal, stress management, adaptability, and general mood. The *intrapersonal component* is based on an individual's self-awareness and expression. This requires individuals to be aware of their emotions and effectively express them toward others. The *interpersonal component* involves an individual's social awareness and adeptness at social relationships. A key aspect here is the ability to empathize with how others experience social situations and the feelings they experience, as well as the ability to build and maintain relationships. *Stress management* deals with a person's ability to manage and regulate his or her emotions. Individuals high on this dimension control their emotions instead of allowing emotions to control them. *Adaptability* revolves around a person's capacity

to adjust his or her feelings in order to effectively deal with emotional situations, whether internal or external. The last dimension, *general mood*, is based on a person's degree of happiness or overall feeling of well-being. This dimension has been described as a key facilitator of emotionally intelligent behavior.

These five dimensions are further broken down into 15 components that are said to describe EI. Interestingly, 5 of these components have recently been described as "facilitators" of EI rather than actual subdimensions. The scales assessing this conceptualization of EI generally demonstrate small correlations with cognitive ability and considerably larger correlations with personality as described by the Big 5 factors. It should also be noted that a number of EI scale names have been directly adapted from facets or compound traits of the Big Five personality factors (e.g., well-being).

The second major conceptualization of EI has been termed the *ability-based model* of EI. In this model, EI is described as a set of cognitive abilities involving the perception of emotions in oneself and in others, as well as understanding and using emotions effectively. Peter Salovey and John D. Mayer have popularized this conceptualization and, over the last decade, have developed several measures to assess this model. A characteristic of this conceptualization is the notion that because EI is considered an ability, performance-based measures should be the preferred means of assessment instead of self-reports. It has been known for some time that self-reports of ability do not necessarily correlate with actual performance-based measures of ability. Because the ability-based model of EI is conceptualized as a specific cognitive ability, its measures should correlate positively with those of general mental ability but not so high as to be redundant with it.

According to the ability-based model, there are four dimensions of EI: perception and expression of emotion, assimilating emotion in thought, understanding and analyzing emotion, and reflective regulation of emotion. Salovey and his colleagues have referred to these four components as "branches" of EI. It is not yet clear whether there is a hierarchy among the four dimensions or even some kind of temporal sequence or developmental-age patterns across the four dimensions similar to those found in developmental models of intelligence (i.e., Piagetian notions of concept development). The *perception of emotions* involves the ability to recognize emotions in oneself, other people, and stimuli, such as music, scenery, and art. *Emotional facilitation* of thought allows a person to

use emotions in a rational and adaptive manner to guide judgments and actions. An actress, for instance, may use emotion to enable herself to fully immerse herself in a character she portrays.

As the branch name suggests, *emotional understanding* involves the capability to comprehend emotional information and to realize how emotions can change, whether across situations or people. The final branch, *emotional management*, is proposed as the highest level of emotional functioning. Here, people not only recognize and understand emotions but also know how to properly regulate and utilize emotions effectively in different situations.

Unlike trait-based models, which overlap with personality, the ability-based model manifests greater correlations with cognitive ability. Other researchers have postulated similar models of EI and have designed measures to assess the construct. However, the instruments typically attempt to measure ability-based EI using a self-report methodology, which differs from the performance-based scoring techniques.

Suzy Fox and Paul Spector have conceptualized EI as a set of competencies that could be utilized by individuals to effectively use emotions to attain desirable outcomes. They measured three components of EI, described as empathy, self-regulation of mood, and self-presentation. Fox and Spector have acknowledged a serious weakness in EI measurement because of the lack of a clear operationalization of the construct. *Empathy* consists of several components, including being able to relate to another person's point of view and to experience emotions as others would in a given situation. *Self-regulation* of mood is based on a person's ability to identify his or her feelings and those of others and to use this information effectively. The third component, *self-presentation*, involves a person's ability to create a desired impression, often using non-verbal cues.

The many alternate conceptualizations of EI have generated skepticism about the concept itself. Some argue that if one were to wait long enough or read widely enough, one will come across a conceptualization to one's liking. This hodgepodge of models has also generated the criticism that there is nothing new in the concept of EI. Hans Eysenck, for instance, argued that EI should be dismissed as an amalgamation of emotional stability and intelligence, just as physicists will dismiss the concept of "hot lengths" as a muddled mix of the concepts of temperature and length. At times, these criticisms of the field of EI

have overshadowed recent work that has been empirically grounded and conducted independently from commercially interested parties, such as test developers and publishers.

For clarity and usefulness in research and practice, the following steps should be undertaken to clear these skepticisms. First, factor-analytic studies with representative (large) samples and measures should be undertaken to distill the dimensions that constitute the concept of EI. On a related note, temporal or hierarchical relations among the different dimensions should be clearly delineated. As a result of this process, some of the existing conceptualizations will undoubtedly no longer be considered as EI. Second, the relative independence of this newly distilled EI construct from more traditional constructs, such as personality, interests, and intelligence, needs to be documented. It is true that even decades of research have not resulted in a consensus on what constitutes constructs such as stress or general intelligence. Thus, a quick resolution of these issues should not be expected with EI, but it is hoped that future work will at least clarify the nature of the construct to a significant degree. In a short period of time, EI research has covered a substantial amount of ground, but more remains to be investigated if EI is to be widely accepted as a viable construct.

The popularity of EI in career counseling and other areas depends partly on the expectation that (a) EI is distinct from other traditional predictors, (b) EI adds incremental predictive potential beyond what is provided by traditional predictors, (c) EI is developable through interventions (unlike interests or intelligence, which are more biologically based and inherited), and (d) there are minimal group differences in EI, so that the use of EI measures in selection and personnel decision making results in a more egalitarian society. As will be elaborated on in the final section of this entry, the empirical research base to support these assertions is weak in many areas. The EI bandwagon is fueled by myths that may fail to withstand empirical scrutiny and, if so, may cause the enterprise to come crashing down. Careful research is needed to prevent this occurrence.

COMPONENTS OF EI LINKED TO CAREER OUTCOMES

This section reviews some of the research findings that support the role of various components of EI (e.g., self-control, empathy) in predicting career

success, career commitment, and career satisfaction. Career success can include successful job performance, doing well in academics, and having career commitment and satisfaction with the chosen career. Several theories on effective career counseling have stressed the importance of self-observation and regulation. The concept of self-efficacy has been central in these accounts. EI, with its emphasis on accurate perception and management of emotions, is likely to be a critical component in many career endeavors. For example, in the exploratory stage of Super's model of career development, accurate perceptions of environmental cues are critical for proper career choices. Differential progression of individuals across the developmental career stages is likely a result of individual differences in EI. The theory of work adjustment postulates that people will gravitate to jobs commensurate with their abilities and interests, a pull that might be fueled by the EI levels of individuals (as well as contextual pressures). Social learning theories applied to career counseling emphasize the need for accurate perception of emotions in oneself as well as in others. Thus, EI is likely to be useful in explaining career choices and could serve to enhance the explanatory power of these different approaches.

Before discussing specific empirical findings, some boundary conditions need to be specified. A long tradition of research has linked the components of EI that reflect personality variables to occupational outcomes such as job performance. In fact, multiple quantitative summaries of these empirical studies have amply documented the relationship between certain personality characteristics and job performance. For example, the personality traits of conscientiousness and achievement striving have been linked to successful performance in almost all jobs. Other personality traits, such as emotional stability, have been linked to performance in specific occupations. As an example, emotional stability has been linked to performance in stressful jobs, such as security personnel. Agreeableness has been found to be a determinant of career success in jobs involving teamwork, whereas extraversion has been linked to success in sales and managerial jobs. Similarly, a voluminous literature supports the notion that general mental ability or intelligence is predictive of performance in all jobs.

To the extent that EI is conceptualized as a construct comprising these traditional personality variables and intelligence, any review that links the components of EI to job performance will also have to demonstrate

the added utility of this new construct over those already well established as valid predictors in occupational domains. Thus, the goal here is not to comprehensively review all research linking any component ever conceptualized as constituting part of EI to job performance. Instead, we focus on research that claims to link EI to job performance as an independent predictor of valued outcomes (independent of the traditional and more established predictors, such as personality and intelligence).

Recent studies have stressed the need to combine personality, interests, and abilities when investigating career choice, career commitment, and career success. However, within each of these predictor domains, several competing models have also been provided. For example, books on personality discuss theories postulating as few as 3 personality dimensions to as many as 16 distinct dimensions. Multiple cognitive abilities have also been proposed, and several factor-analytic studies have come up with different clusters and models of these abilities. Although there is a positive correlation across the different abilities, which suggests the presence of a general factor, the career counselor is as likely to be interested in the profile of specific abilities as in the general factor. Given the different interest clusters, it is cumbersome to combine models of personality, interests, and abilities in investigating career choice, career commitment, and career success. The idea is that EI could be a bridge across the domains linking the rational-cognitive and affective as well as conative aspects of career choice, career commitment, and career success.

Although it is possible to summarize the attempts to measure the construct of EI explicitly and link it to career success, it should be noted that a more profitable research approach would be to first develop a theoretical framework that clearly delineates the content domain of EI and how it relates to career success. There is, at present, limited theory-guided research that tests processes that have been hypothesized a priori. Furthermore, the incremental validity that EI components yield over traditional personality and ability measures is seldom assessed. We hope such research will receive more attention in the future.

A recent meta-analytic review of 59 studies found that EI can be useful for predicting performance. In particular, subgroup meta-analyses based on criterion type demonstrated that EI predicted workplace performance and to a much lesser degree could be used to help explain success in academic settings. Since that

time, more studies have begun to review the link between EI and success in the classroom. A study of 372 undergraduate students found that highly successful students scored higher on several components of EI than did their less successful counterparts. In a study of 650 British students, trait EI was found to be related to scholastic achievement. In particular, high EI was associated with improved academic performance across individuals who scored low on cognitive ability. Yet in another study involving 180 students, a different trait-based measure was unrelated to academic success. A youth version of the same trait measure, however, was found to be related to academic performance in a study of 667 high school students. Overall, findings are still equivocal, and more research is needed in this area. Given a stronger cognitive component, ability-based measures of EI appear to have more potential in this area than the more affectively laden trait-based measures.

One theoretical framework that focuses on how EI should relate to career success is the contextualized action theory of career development. Richard Young and his colleagues proposed that emotions play a central role in how individuals develop coherent narratives of their careers. Emotions energize people to take and sustain action, help individuals decode feedback, and so forth. Career management includes appraisal of one's goals, present conditions, strategies for achieving goals, and career exploration. Components of EI such as understanding and managing emotions should therefore be important in the different stages of career management. It has been reported that those who trust and use their feelings effectively achieve success in their careers. In fact, career success can be described either in objective terms (e.g., levels promoted) or, more subjectively, in terms of internal psychological satisfaction. Effective use of EI has been postulated as a precursor for attaining feelings of psychological success. In a study involving 288 college students, it was found that a measure of EI (assessing empathy, utilizing feelings, handling relationships, and self-control) was positively related to career decision-making self-efficacy, career choice commitment, and vocational exploration. Career commitment has been linked, in turn, to successful job performance, promotions, and satisfaction.

EI has also been linked to career choice and satisfaction. A study of 295 business majors showed that individuals scoring low on a measure of EI (assessing self-awareness, self-regulation, and social awareness)

were likely to choose accounting majors. Career satisfaction has been predicted by personality traits such as emotional resilience across different occupational groups. Neuroticism, agreeableness, and conscientiousness have been related to the career satisfaction of executives. In a database involving about 6,000 individuals from 14 different occupations, it was reported that emotional resilience, optimism, and work drive predicted career satisfaction in all the occupational groups assessed (e.g., accounting, clerical, customer service, engineering, human resources). Thus, available empirical research suggests that EI has potential in the arena of career counseling. However, it is likely there are some critical gaps in our knowledge about the viability of EI in career counseling, which must be addressed to enhance our understanding of the construct's utility in this domain.

FUTURE RESEARCH NEEDS

This section addresses the issue of clarifying the concept of EI and the relative independence of EI from traditional predictors (e.g., intelligence, personality traits, interests). Perhaps the foremost research need is conceptual work clarifying the content domain of EI. In this process, it could be argued that some current conceptualizations should be discarded as EI (but perhaps resurface as important determinants of occupational outcomes, albeit under new names). Such clarification will help the advancement of science and practice. One approach is to factor analyze the different measures to identify common factors. Furthermore, multiple measures of the same construct should be developed to allow for the assessment of convergent validity through triangulation. At present, there is really only one measure that is claimed to measure EI as a specific cognitive ability. Other ability-based instruments do exist, but their foci are narrower and do not cover all postulated EI components. Thus, it is currently difficult to infer whether existing research findings are more a reflection of the EI-as-ability construct or of the one specific measure of it. Whereas test developers prosper by developing a unique measure, science progresses by analyzing constructs, not measures. The proprietary nature of most of the measures and their scoring keys is also a problem in that it hinders the free exchange of information between research groups, which makes comparison of results difficult.

Related to the need for conceptual clarification is the issue of measurement. The predominant question here

is the role of self-report methodologies. Self-reports can be used to assess EI whether EI is conceptualized as an ability or as a personality trait. However, self-reports of ability do not necessarily correlate highly with performance-based, objective measures of ability. On the other hand, if EI were to be conceptualized as a personality trait, some aspects would be best assessed by self-reports. When self-reports are used in high-stakes assessments, the potential issue of motivated response distortion needs to be addressed. In personality assessment, there is a voluminous literature on impression management, response distortion, faking, dissimulation, socially desirable responding, lying, and the like. Most personality inventories include scales that detect (or at least flag) potentially distorted responses and invalid test profiles. Several indices have been empirically developed to assess when faking should be a concern. Even though the validity and utility of such indices themselves are still under heavy debate in the scientific community, similar efforts should be considered when using EI inventories employing self-reports. Several of the self-report measures (e.g., the Bar-On EQ-i and the Emotional Judgment Inventory) have already taken this step.

A related measurement issue is the appropriate scoring method employed. The accuracy of individual responses can be determined by comparing them to (a) consensus criteria obtained from responses across a representative sample of respondents, (b) target criteria (self-reports of individuals who created test items or item stimuli of their actual emotions at the time of item generation), or (c) responses generated by experts in the domain of emotions. The use of consensus scoring presents a dilemma: The emotionally intelligent individual could be penalized for choosing a response that is better than that of the majority (which, by definition, should score about average), as his or her response will then most likely deviate from the mean response obtained from the standardization sample. The use of target scoring may not be justifiable, as there is no strong empirical evidence that the creators of stimuli or the so-called targets of EI test items (e.g., the person depicted in a task of emotional facial expressions) have insight into the stimuli they are creating that would constitute a sound criterion allowing for an accurate comparison. The use of experts in generating scoring keys to EI inventories raises multiple concerns, such as how to determine who should constitute the expert group (e.g., are researchers in the domain of emotions necessarily emotionally intelligent?) and the potential of cultural

biases. More important, the scant empirical research that exists to date that has assessed the convergence across the different scoring methods has found little convergence and/or problems of psychometric equivalence of scoring procedures (e.g., differences in distributional properties of scores and levels of reliability). In fact, the convergence between self-reports of EI and peer reports of EI is often lower than the convergence between self-reports of EI and measures of traditional personality variables (e.g., emotional stability).

Although several conceptual links have been made between individuals' EI and their success at the different stages of career development, the actual empirical research supporting these links is primarily restricted to academic and job performance. A recent meta-analysis found support for the hypothesis that EI has validity in predicting performance in both settings. More empirical studies are needed to assess the link between individual differences in EI and outcomes such as leadership emergence, successful handling of stress, and career satisfaction. Furthermore, it is important to demonstrate that EI helps explain career choices and career success beyond traditional variables such as abilities, interests, and personality variables.

Along these lines, future research is needed to assess the boundary conditions associated with these links and the potential moderators influencing these relationships. For example, it is possible that EI is more likely to be a predictor of academic performance in educational settings in which interpersonal skills are important than in those in which hard learning criteria are used to evaluate success. In addition to moderating influences, process mechanisms by which EI contributes to success need to be tested. As an illustration, it is possible that individuals high on EI could handle conflict and stress more effectively, either of which may enhance their performance in certain settings. Such mediational tests necessitate the need for longitudinal data collection and knowledge of the temporal effects of EI on performance. Consider one implication of the inattention that has so far been paid to such effects. At present, we do not know whether the difference in performance (academic or job) between high- and low-scoring individuals on EI measures attenuates over time and whether performance differences dwindle as relative experience increases. Alternately, the difference could magnify over time, in that the initial advantage in EI allows individuals to gain more resources and disproportionately better

their performance over time. Of course, there is also the possibility that performance differences will be stable over time.

One of the appealing features of EI for social policy is the supposed lack of ethnic group differences in EI scores. In the case of mean score differences, the group displaying the lower mean is likely to be underrepresented in the job or position selected for when such selection is done top-down using EI scores. Such disparities could potentially result in adverse impact (legally defined by the four-fifths rule in the United States) when EI is used for selection purposes. This may not be a problem as long as EI is used only for counseling, but given the widespread claims that EI predicts performance, leadership, and other valued criteria, it is imperative to assess ethnic group differences on this construct. Limited empirical research currently exists on this issue.

On a related note, an implicit claim is made in many trade books “selling” EI to the general public that EI can be developed by anyone. The idea that EI can be developed or schooled through interventions raises the hopes that every individual can be successful—a very promising alternative to the view that general mental ability is rather stable throughout one’s life and also highly heritable. However, such hopes at this point remain exactly that: only hopes. There is no cumulative empirical research unequivocally demonstrating that EI can be developed to any level or that the heritability of EI is low. In fact, given the correlations EI demonstrates with ability and personality variables, it is likely that the heritability of EI will prove similar to those found for such constructs, though possibly not to the same extent as with general mental ability.

In summary, although the empirical research base is just beginning to accrue, several models of career development and success suggest an important role for EI. Career counseling researchers and practitioners need to stay tuned for developments in this area. However, at present, the empirical research on the criterion-related validities of EI is limited to selected criteria such as academic and job performance and certain aspects of life success. More research on the validity of EI for predicting diverse criteria such as stress management is still needed. A better differentiation of the criterion domain of interpersonal skills is necessary if there is to be a better understanding of the processes through which EI influences success in this important area of career success. The incremental gains from using EI over traditional predictor variables,

such as abilities and interests, need to be demonstrated. The concept has to be clarified and its theoretical underpinnings more clearly and consistently defined. The moderating and mediating influences have to be empirically tested in more detail, and longitudinal research should be employed. Ethnic group differences and the heritability of EI need to be documented before expectations of successful interventions are encouraged.

The intent here is not to paint a pessimistic picture of EI but, instead, to draw attention to the need for independent and focused work on the construct. Findings have at times been encouraging and at other times nebulous and conflicting. Replication of sound research studies is a necessity, and careful examination at this time is warranted and recommended to provide a more thorough understanding of EI. This would include further clarification of the diverging models as well as the continued assessment of their predictive and incremental validity.

EMOTIONAL LABOR

When employees regulate their emotions in order to display the emotions that are expected of them in workplace interactions, they are performing *emotional labor*. They may do this by suppressing or hiding their real feelings and, instead, expressing emotions that they do not actually feel, that is, *surface acting*. Surface acting involves putting on an "emotional mask" and creating a sense of emotional dissonance, a feeling of discrepancy between felt and expressed emotions. Employees may also express the socially expected emotions by working to actually feel the emotions they need to express, that is, *deep acting*. For example, in a customer service situation that requires pleasantness, they might try to generate the necessary emotions by thinking about how they feel when they are with friends. Thus, in contrast with surface acting's focus on external displays, deep acting's focus is primarily on creating inner feelings that are aligned with appropriate external displays. Employees may also simply express their genuine emotions in workplace interactions. If these emotions don't fit with situational requirements and expectations, employees may be engaging in emotional deviance.

Occupations can generally be classified on the basis of their need for physical, mental, and emotional labor. The extent and nature of the emotional labor performed by employees may depend on the norms that exist for emotional expression and suppression in a particular occupation. For example, although grocery store clerks are expected to be friendly and cheerful, funeral directors are expected to be somber and reflective. Also, occupations in which employees express a variety of emotions with high intensity in frequent interpersonal interactions of lengthy duration are most likely to involve high levels of emotional labor. Although

emotional labor tends to be associated with service occupations in which there are frequent interactions with customers, it is likely that employees in all occupations perform some amount of emotional labor. For example, research indicates that workers in a wide range of occupations, such as program managers, secretaries, nurses, and golf course maintenance workers, report that they regulate the emotions they display to others.

In addition to these situational predictors, there may be individual differences in how emotional labor is performed. For example, research indicates that workers who hold collectivist values are more likely than those with individualistic values to perform deep acting and hide their feelings. Also, workers who easily adapt their behaviors according to the demands of the external environment (i.e., high self-monitoring) and workers who tend to experience sadness and low levels of energy (i.e., high negative affectivity) tend to engage in high levels of surface acting. Interestingly, the ability to manage emotions in oneself and others, two elements of emotional intelligence, tend to predict higher levels of surface acting but are unrelated to deep acting.

Since emotional labor has been conceptualized in a variety of ways, a multitude of measures of emotional labor also exist. For example, it has been measured by considering (a) the result of dichotomizing occupational categories into high- and low-emotional-labor jobs; (b) the emotional tone of occupations; (c) the emotional requirements of occupations, such as the frequency of emotional display; (d) the emotional dissonance associated with surface acting; and (e) the emotional regulation involved in surface and deep acting. A growing number of researchers appear to be adopting the emotional regulation perspective of emotional labor.

Initially, researchers assumed that performing emotional labor was universally draining and alienating for employees and a cause of burnout. However, research suggests that the way in which emotional labor is performed influences its effects on employees. Employees who express emotions that they do not really feel (i.e., surface acting) tend to experience a lack of authenticity and, as a result, report high levels of emotional exhaustion. In contrast, employees who try to align their felt and expressed emotions through deep acting tend to feel a sense of authenticity and, consequently, relatively low levels of emotional exhaustion and high levels of personal accomplishment. Surface acting has also been associated with reduced levels of job satisfaction and higher turnover levels. Researchers have found that emotions can be

passed from one person to another, such that, for example, customers feel enthusiastic as a result of being served by enthusiastic salespeople. However, there is still little research that considers the relationship between the way in which emotional labor is performed (i.e., surface or deep acting) and customer emotions, attitudes, and behaviors.

The concept of emotional labor has implications for career development. In particular, when considering alternative career directions, individuals are advised to select occupations that require emotional displays that fit with their emotional temperaments. For example, an individual with a tendency to be bubbly, friendly, and enthusiastic is more likely to be able to express genuine emotions as a flight attendant than as a bill collector. This is important, since a mismatch may require more effort on the part of employees to display the required emotions and result in feelings of emotional exhaustion. Employers should be mindful of applicants' emotional temperaments and other relevant personality characteristics during the process of selecting employees. They should try to hire employees whose emotional temperaments match the job requirements. This means that employers should develop a thorough understanding of the emotional tone and requirements of occupations. Employers may also want to provide employee training and performance feedback that helps employees learn how to perform emotional labor in a way that does not have detrimental effects on their health.

EMPLOYABILITY

Historically, the majority of *employability* research and practice pertained to vocational rehabilitation or to the attractiveness and selection of job candidates. Employable individuals are able to demonstrate a fundamental level of functioning or skill to perform a given job, or an employable individual's skills and experience fit some predetermined set of job requirements. Conceptually, both streams emphasize the degree of person-job fit in terms of the knowledge, skills, and abilities (KSAs) required to perform effectively on a job. Employability literature utilizing this fit perspective suggests that necessary KSAs are known and stable, which is incongruent with the highly uncertain employment environment and current employee-employer relationships.

As demands confronting employers rapidly change, their strategies morph, which necessitates that employees continually update their KSAs to execute these strategies. Thus, framing employability in terms of rigid KSAs is a liability to both employers and employees, in that it suggests that employees are valuable only to the extent that their current skill sets match their employers' current strategic objectives. Instead, the new employer-employee relationship requires organizations and the employees that populate them to be flexible and adapt strategies, services, products, knowledge, skills, abilities, and behaviors as needed to realize organizational and individual goals. In short, both employers and employees must adapt in order to compete successfully and avoid obsolescence. Therefore, rather than maintaining a traditional KSA perspective, it now seems reasonable and appropriate to frame (and measure) employability in terms of individual characteristics that foster active adaptability at work.

Mel Fugate, Angelo Kinicki, and Blake Ashforth's conceptualization of *dispositional employability* follows this lead and provides an interesting alternative to more traditional employability research and practice. They have defined employability as a multi-dimensional constellation of individual characteristics that predispose employees to (pro)actively adapt to

their work and career environments. Employability facilitates the identification and realization of job and career opportunities both within and between organizations. Conceived this way, employability is a disposition that captures individual characteristics that foster adaptive behaviors and positive employment outcomes, and it more accurately describes the action-oriented, proactive, and adaptive qualities that employers now widely espouse and seek. This perspective is also consistent with more current research that views employees as proactive rather than reactive agents. More employees now initiate change and create opportunities, rather than reacting to change after the fact or waiting for opportunities to present themselves. Moreover, conceptualizing employability as a disposition seems appropriate, given the high level of uncertainty inherent in today's career landscape. According to social psychology, highly uncertain situations can be characterized as "weak situations," and thus one can expect individual characteristics to be primary determinants of behavior.

A dispositional perspective of employability also has the added benefit of being explicitly anchored in the work context, which overcomes a prevalent operational (measurement) shortcoming of previous research related to adaptability at work. Recent reviews of literature related to adaptability at work has revealed that researchers typically used broad dispositional measures as indicators of adaptability. For instance, research has shown that various measures of personality are positively related to work adjustment, openness to change, innovation and career initiative, and job satisfaction and performance. Despite the benefits of this research, the generalizability of results is limited because the measures of personality were not anchored to the work context. A greater alignment of context and content between indicators of employability and adaptability at work enhances predictive power, more precisely captures the true essence of employability, and is consistent with Fugate and colleagues' conceptualization of employability. To further highlight the importance of contextualization, the following section briefly explicates the component dimensions that constitute dispositional employability.

COMPONENT DIMENSIONS OF DISPOSITIONAL EMPLOYABILITY

Workers must parlay personal factors to identify and realize opportunities within today's work environment

(i.e., to be employable). Although many individual characteristics potentially support these endeavors, only a few deemed critical and representative of the active and adaptable nature of employability are discussed here: openness to changes at work, work and career resilience, work and career proactivity, career motivation, social and human capital, and career identity. Because dispositional employability subsumes all component dimensions, it represents an overarching construct that contributes to proactive adaptability at work. The individual component dimensions are explained next.

Openness to Changes at Work

Openness to changes at work supports flexibility in uncertain situations and facilitates continuous learning. For example, in the context of organizational change, open individuals exhibit more positive attitudes toward changes, greater job satisfaction, and lower intentions to quit. Open people also are likely to perceive change as a challenge rather than a threat and be receptive to new technologies and processes. Therefore, people who are open to new experiences and change are adaptable in dynamic work and career environments, which enhances their employability.

Work and Career Resilience

Work- and career-resilient individuals tend to have high self-evaluations and be optimistic in their work and careers. Cognitive adaptation theory and research show that these qualities are highly adaptive. Positive self-evaluations precipitate positive and productive attitudes, and optimism fosters positive expectations about future events. Consequently, work and career resilience affords individuals confidence in their abilities to handle the objectives and affective challenges associated with their work and careers. Accordingly, work and career resilience fosters the identification and realization of career opportunities (employability) in turbulent environments.

Work and Career Proactivity

Work and career proactivity is a hallmark of adaptability at work and is similar to proactive coping. Proactive coping consists of individual efforts to identify potential stressors and to acquire the skills and resources necessary for dealing with stressors, should

they occur. In terms of employability, work and career proactivity subsumes the acquisition of information related to possible opportunities and challenges associated with one's current position and future opportunities. It also includes preparatory actions for coping with and/or exploiting said opportunities and challenges, should they occur. This may involve actions such as considering the implications of a possible downsizing or merger or exploring the benefits of taking an international assignment. Moreover, individuals with high employability periodically assess their value in the marketplace, comparing their skills and experience with current job opportunities and requirements. One benefit of this activity is that it may serve as market feedback, per se, informing the individual of the value of his or her current skill set and experience in the eyes of the market. Thus, work and career proactivity has important implications for identifying and realizing opportunities.

Career Motivation

Career motivation relates to career goals, planning, and an orientation toward learning. As such, it draws on the concepts of motivation control and learning goal orientation. Career motivation provides many benefits to workers: enhanced drive for work-related endeavors, persistence during periods of boredom or frustration, and sustained effort in the face of challenges. Individuals with high levels of career motivation are also interested in mastering new skills and approach new situations as opportunities. As a result, career motivation is a critical determinant of continuous learning—a critical aspect of employability.

Social and Human Capital

Social capital and human capital are important elements of employability. Social capital consists of the resources available in social networks that can advance a person's interests. One's ability to identify and realize career opportunities is greatly influenced by such capital. The size and diversity of an individual's social networks are directly related to the amount of information and influence available. Similarly, employability is influenced by human capital. *Human capital* refers to a host of more traditional factors that influence a person's career advancement, such as age and education, work experience and training, job performance, and organization tenure.

Together, investments in these types of capital contribute to employability.

Career Identity

Career identity is the cognitive basis of dispositional employability, as it describes one's self-definition in the career context. Career identity provides direction for future opportunities and behaviors, while at the same time organizing past experiences. It coheres the plethora of career-related elements both for the self and for others. For example, people's career identities are often revealed when they answer the question "What do you do for a living?" The answer to this question often communicates an individual's interpretation of his or her career past, present, and future. As such, career identity assembles past, current, and future career experiences and aspirations into an understandable whole, and it also acts as the cognitive glue that integrates the other dimensions of employability. In a sense, it is the cognitive canvas on which the other dimensions of employability are painted. Moreover, career identity gives employability particular relevance for career development, in that career identities help fashion career trajectories in the absence of traditional career tracks. Now that the dimensions of employability have been explained, the following section explores the influence of employability on career development.

EMPLOYABILITY AND CAREER DEVELOPMENT

It is important to illustrate the utility of the new conceptualization of employability, as it is dramatically different from historical perspectives. This section thus briefly describes how a dispositional perspective of employability influences two important career development topics: career exploration and job search.

Career Exploration

Due to substantial changes in the employer-employee relationship, the onus of career management resides increasingly with the employee. In response, some researchers and vocational counselors propose career exploration as a means for employees to manage this responsibility and cope with the increased complexity in careers today. Through career exploration,

employees learn important information about themselves and their career opportunities. Such internal and external information gathering has been linked to increased job search intensity and job search effectiveness. Thus, career exploration has important implications for career choices and experiences. This has led other researchers to examine a wide variety of predictors of career exploration, such as ego identity status, goal directedness, and vocational decision-making style. Unfortunately, however, identification of powerful predictors has been disappointing; that is, those investigated have explained relatively little variance in ultimate career outcomes. A dispositional approach to employability helps fill this void.

It is reasonable to assume that employability is a powerful predictor of career exploration, as it influences the two fundamental foci of information gathering: internal/self and external/environmental. For instance, consider the internally focused activity of inventorying and evaluating one's career interests (i.e., desirable characteristics of a job or career). Those with high employability are likely to have both a broader and a clearer array of interests and possibilities. They are predisposed to identifying more opportunities that are consistent with and motivated by their career identities and supported by social capital. Furthermore, the active orientation inherent in employability means that these individuals are more likely to engage in self-exploration activities in the first place. In addition to the internal influence, employability also has implications for externally directed career exploration and job search.

Job Search

Job search has become an increasingly important and frequent endeavor for workers. The U.S. Bureau of Labor Statistics states that American workers now often make a dozen or more transitions during their working lives. In response, researchers have identified and investigated numerous individual difference factors that influence both job search behaviors and employment outcomes: personality traits (five-factor model), generalized expectancies (locus of control and optimism), self-evaluation (self-esteem and job search self-efficacy), motives, social context, and biological variables (age, gender, education, race, and tenure in the workforce and in one's current job). These nonability individual differences have been shown to affect self-regulatory processes that influence

both job search behaviors and ultimate job search outcomes.

Employability not only subsumes many of the individual differences noted above but also presumably affects the self-regulatory job search process and associated outcomes. Employability makes unique contributions to job search behaviors, job choice, and job search outcomes. For example, individuals with high employability are likely to proactively identify reemployment goals (opportunities) when job loss is anticipated or advance notice provided. Moreover, the opportunities identified are directed and driven by the career identity dimension of employability. Employability also connotes confidence with and the active use of multiple search modalities, and it likely enhances job search self-efficacy. Therefore, employability is likely to influence not only the choice of employment goals and enhance ultimate reemployment outcomes but also the ultimate quality of reemployment, as they both likely align with one's career identities.

CONCLUSION

To be employable, it is important to possess baseline KSAs that fit a given job. However, this traditional approach is inadequate in today's turbulent career landscape. Because competitiveness is a moving target for employers, they must adapt in order to compete and survive—and likewise their employees. Therefore, now it is more accurate and appropriate to expand our perspective of employability beyond KSAs (person-job fit) to include individual characteristics that facilitate individual action, proactivity, and adaptability. The construct of dispositional employability presented here does just that. As such, a dispositional approach to employability has important implications and predictive power for career development and other aspects of organizational behavior.

—Mel Fugate

EMPLOYEE ASSISTANCE PROGRAMS

Employee assistance programs (EAPs) function to treat a variety of work- and nonwork-related problems that may interfere with an employee's job performance and/or productivity. EAPs were originally developed in the 1950s to treat employees whose job performance was negatively affected by alcohol abuse, but they have evolved greatly over the past several decades. The scope of the problems addressed by EAPs varies from plan to plan, with some plans covering only issues closely related to work stress and others covering a much broader range of work-life and mental health issues. Some plans offer services solely to employees, and other plans also cover treatment of family members. Although counseling is still the focus of most EAPs, a few progressive plans include financial and legal advice and resources to assist in locating child care or elder care programs. As a result of receiving assistance with these work-life issues, an employee may find that he or she has an increase in time and energy to focus on being productive at work.

Whether offering concrete advice or providing counseling, EAPs strive to address the personal problems of employees so that they can function to their full capacities in both their work and their home lives. EAP counseling services may be provided on-site by an in-house provider or off-site by an external

contracted provider. EAPs offer a certain number of sessions (determined by the plan) to the employee. Typically, if an employee's issues cannot be resolved in the allotted number of sessions, the EAP counselor refers the employee to a counselor through the employee's health plan for continued service.

A growing number of worksites in the United States now offer EAPs to their employees. Most of these are large companies: 100 percent of Fortune 500 companies have EAPs, and 90 percent of Fortune 1000 companies have them. In 2001, 28 percent of companies with 1 to 24 employees and 86.3 percent of companies with 500 or more employees had EAPs, compared with 22.4 percent of small companies and 73.9 percent of large companies in 1993. These statistics not only show the growth in the number of companies with EAPs but also highlight the vast difference in prevalence of EAPs between large and small companies. This may be due in part to the cost involved in offering EAP services.

Despite the cost of maintaining these programs, many companies find that EAPs are mutually beneficial to the company and the employees. Using EAPs, employees are able to benefit from free (or low-cost) services they otherwise may not have chosen to utilize. Employers who offer EAPs send the message to their employees that they care. Employees may feel an increased sense of investment in their companies because they feel that their companies are invested in them. This sense of feeling "cared for" can greatly increase morale in an organization.

It would be neglectful to discuss EAPs without mention of the role of stress in today's society. Stress has become quite common and almost expected in many work environments. Employees work long hours and often feel overwhelmingly pressured to be productive. This, coupled with increasing demands in their personal lives, may leave employees feeling frustrated, anxious, or depressed. Without the appropriate skills to manage these symptoms, people may experience a variety of manifestations of their stress, including physical illness, substance abuse, and marital problems. EAP counseling can provide employees with the skills to cope with stress in both their work and their personal lives. As a result, they can enjoy improved functioning in both arenas.

Clearly, having employees who are efficient at managing their stress is not only a benefit to the employees. Many managers feel that their departments run more smoothly as a result of their EAPs. They feel that it makes good financial sense to support their employees.

One expected result of an EAP is reduced absenteeism. Depression is a leading cause of missed workdays, and undoubtedly, stress-related medical conditions contribute to absenteeism as well. Furthermore, disability claims caused by depression and stress-related illnesses are costly to an organization and may be avoided by addressing these issues before they become debilitating. Studies have shown that substance abusers are more likely to become injured on the job and are more likely than their non-substance-abusing counterparts to file workers' compensation claims. EAPs can even lower health care costs, as they may result in fewer claims being filed. In addition, a company invested in helping its troubled employees realize their full potential will avoid the time-consuming and costly process of hiring and training staff to replace those who would otherwise be terminated.

Theoretically, an EAP sounds as if it would be an asset to any company, but is it really worth the cost? It is first important to note that for an EAP to be effective, it must be utilized by the employees. Employees need to know about it and how to access it. It should be marketed as a useful and substantial benefit. It should also be marketed in such a way that employees do not view accessing these services as a sign of weakness. Employees must feel confident that information discussed with EAP counselors will be kept confidential.

There is not a wealth of information regarding the actual effectiveness of EAPs, and the existing studies show inconsistent results. Self-reports of people who have used their EAPs indicate a high level of satisfaction with the services they received. Other studies note improvements in job performance and attendance as a result of EAPs. Conversely, some studies do not promote EAPs as a valuable commodity. As far as the actual cost-effectiveness of these types of programs is concerned, the numbers vary greatly. Different studies have shown that for every dollar spent on an EAP, the return is as little as \$2 or as much as \$15. Other studies have found EAPs not to be cost-effective at all. Many employers believe that regardless of the dollar-for-dollar return (or lack thereof), EAPs are worthwhile investments. The improvement in morale and productivity among the employees and the generally positive work environment that an EAP achieves are well worth the cost of the program.

EMPLOYEE PARTICIPATION IN ORGANIZATIONAL DECISION MAKING

Employee participation in organizational decision making allows employees to have a say in decisions that affect their working lives in some way. Nevertheless, this apparently benign definition masks a number of complexities. The main problem is that different parties in the employment relationship may differ on the procedure by which employee voice is expressed and on the substantive content of the participation. For this reason, the history of employee participation (EP) is long and tortuous, with no simple, uncontested objective.

Many managers see EP as largely job centered, established as a means to offer expanded task discretion to individual employees as a way to enhance their fulfillment and hence job performance. Employees may accept these prescriptions, but under conditions of insecurity or hostility (e.g., following downsizing exercises), they may interpret these initiatives more negatively as being orientated toward satisfying primarily employer, rather than employee, needs. Managers may also adopt EP principally as a means to disclose information of managerial intentions or decisions, which they hope will engender employee trust and goodwill.

Unions, on the other hand, through their representative functions, may seek a broader and more active vision of gaining a voice in organizational decisions, which managers might believe could undermine their authority or subvert optimal corporate performance (e.g., by seeking higher pay awards). While some

economists do point to a negative association between union participation and organizational performance, other authorities contend that the same process of representative EP can actually strengthen employee commitment to the company by providing them with an authoritative collective voice, which also encourages managers to sharpen their performance in dealing with staff. Allied to this, a third perspective suggests that rather than representing conflict over divided interests, employee participation, correctly applied, can benefit the ambitions of all stakeholders. This approach has been reinforced through studies and research by authorities such as Jeffrey Pfeffer and Mark Huselid, who have argued that employees represent the principal source of performance enhancement and that encouraging employees to exercise autonomy and discretion fortifies both their motivation and their performance. There is certainly evidence by these and other authors that the combined use of commitment-focused EP can positively impact employee contributions. These observations are especially relevant for the growing numbers of knowledge workers in advanced economies, whose commitment is vital to organizational success.

What emerges from these different perspectives is that EP can be represented by a host of varied practices, applicable at different levels within the organization. Basically, though, EP can be classified into *direct*, *indirect*, and *financial* forms. Direct forms tend to derive from management instigation and provide for personal involvement for individual employees or work teams with no representative intervention. Involvement by employees in decision making is restricted to task or workgroup issues or to reactive communication exercises. Examples include direct communication between employees and managers through both downward and upward routes. Performance appraisal can be seen as a means of direct EP, requiring upward communication from employees (e.g., factors influencing their performance or requests identified for future development) and downward communication from appraisers about appraisee success in meeting targets, allocating performance-related pay awards and setting future personal objectives. This focus on direct contact between manager and managed can have important implications for managerial and career development. As an assessed part of their performance and indicator of advancement potential, supervisors and managers may need to acquire a range of facilitative and communication

skills as a demonstration of their managerial competence. At the same time, the appraisal process offers opportunities to different ranks of employees to enhance their employability through the acquisition of skills and qualifications.

Personnel skills may also be practiced in facilitating two other prominent approaches to direct EP, namely, employee empowerment and teamworking. Research has indicated that these processes are especially relevant to today's increasingly sophisticated and flexible work regimes and educated workforces. Empowerment, which aims to project greater decision-making autonomy on individual employees and supervisors at the task level, can provide opportunities for career advancement for both managers and the managed that are in contrast to more rigid and hierarchical work regimes. Teamworking, a form of group empowerment, requires competence in communication and facilitative leadership from both team leaders and their supervisors.

Indirect EP through representatives can be demonstrated through collective bargaining (or negotiation) and works councils and, in Europe especially, by worker directors and, more recently, European Works Councils (EWCs). In contrast to direct EP, indirect EP has a regulative function and may actively engage with organizational or corporate issues (such as restructuring), which may require the organization to become more accountable to employees and their representatives. Especially in the more regulated European economies, these approaches can be supported by national or supranational legislation within a social justice framework that acknowledges that in an era of giant and multinational corporations, employees are often at a market disadvantage in negotiating and protecting their terms and conditions of employment. For the same reason, not all companies welcome these interventions into their decision-making powers and may oppose recognition of trade unions and resist, organizationally and politically, the imposition of forms of indirect EP, which are considered inimical to their economic interests.

Collective bargaining is probably the most commonly adopted form of indirect EP and, unlike other forms, requires recognition of an independent trade union by the employer. Collective bargaining involves the joint regulation of terms and conditions of employment between the employer and trade unions acting on behalf of employees. Works councils and EWCs can exist independently of trade unions (and, indeed, may

be regarded by unions with suspicion), and rather than joint regulation assumed by negotiation, they are designed for managers to inform and consult over organizational decisions with representatives of the workforce. The role of EWCs is tightly circumscribed by European legislation to inform and consult about company international issues at formal council meetings held at least annually. Evidence from the operation of EWCs suggests, however, that employers have little to fear from the establishment of these institutions.

Financial participation or employee ownership is most advanced in the market economies of the United States and United Kingdom. In both countries, over a third of employees in the private sector have access to acquiring stock in their companies through employee share ownership plans (ESOPs). Although the intention of ESOPs can be to support retirement incomes, their more general purpose is to create a tangible sense of ownership, which advocates like Joseph Blasi, Douglas Kruse, and Corey Rosen have argued feed into both employee and organizational performance. Although the evidence is mixed, research tends to confirm that the presence of a positive “ownership effect” is directly associated with higher proportions of shareholdings held by employees. The other positive finding is that synergy between employee ownership and other high-commitment human resource policies has been demonstrated.

As organizations attempt to become more competitive, effective deployment of human resources is becoming an essential feature of organizational strategy. The role of employee participation in this process of human resource development is vital. Research will continue to explore the approaches and conditions that can be best associated with enhancing employee capabilities and managerial performance.

EMPLOYMENT ADVERTISING

Employment advertising is a medium for posting employment opportunities through ads that appear in public media, most notably newspapers, magazines, and Internet sites. Ads appear in all countries in the Western world and to a lesser extent in other parts of the world, generally in dedicated sections of newspapers, typically in proximity to sections covering business and economic issues. Ads for specific professions sometimes appear in other sections (e.g., employment in medical professions is sometimes posted in newspaper sections dedicated to medicine). Labor economists and labor policymakers often consider the number of employment ads appearing in a country at a given time to be a key indicator of unemployment and the degree of economic vitality of the country.

Ads can be posted and paid for by a potential employer, by a recruiting firm, or by a placement agency and are often designed by marketing or public relations firms as a part of organizational efforts intended to promote the organizational image. The costs of employment advertising vary widely, depending on size (number of square inches), complexity (e.g., with or without color), and status and market reach of the newspaper in which an ad appears. There are many guides to effective product or service-marketing advertisements, but little research has been done on effective employment advertising, perhaps because the cost of employment advertising is typically significantly lower than that of product advertising.

Research on employment advertising has typically compared ads with other sources of employee recruiting, such as college placement, employee referral, or placement agencies. Employment advertising is usually found to be less effective than other sources, most notably employee referral. Advertising is identified as a formal recruitment vehicle (as opposed to an informal vehicle, such as employee walk-in) that relies on

external information (as opposed to relying on internal information, such as employee referral).

Employment ads are strikingly similar in structure, regardless of the newspaper or region of the world in which they appear. Historically, ads were structured as a rectangle with some embedded text; today, they include elaborations in both text and visual elements, such as fonts, logos, color, pictures, or borders. The content of most ads includes a “skeleton,” that is, a job title and contact information. Most include additional information, or “embellishments,” on the skeleton, including marketing information about the organization, the physical or social work environment, or the legal issues pertinent to the posted job or the posting organization. There is significant variation among ads in the content of embellishments, and there seem to be some systematic differences in the nature of embellishments employed in different countries and different professions, but little research has been done on the rationale behind them or their effects.

Employment ads serve functions other than connecting employees and employers. Job seekers and people actively employed are encouraged by career advisors to read ads as a means of learning about the job market, and many report that they read them for reasons other than finding specific jobs. Managers and technical people report that they read ads for the purpose of learning about competitors, about new projects, and about new developments in their fields.

EMPLOYMENT CONTRACTS

Unlike many years ago, when employers and employees began the working relationship with a simple

trusting handshake, today’s employment often begins with lengthy *employment contracts* and careful scrutinizing, discussion, and negotiation. Such contracts are often necessary to reduce the potential for expensive litigation on a multitude of issues, although in many cases, it is advantageous for an employer not to have to deal with the restrictions and obligations that a contract may create. For this reason, not every prospective employee will be successful in obtaining an employment contract. Until recently, employment contracts were used almost solely for executives. Today, many employees, particularly managers and professionals with special expertise, look to employment contracts as a hedge against job loss brought on by mergers and corporate “housecleaning” and as a way to negotiate greater predictability in their work lives.

This entry provides a checklist of some of the more important issues to consider at the time of establishing an employment contract. It is not intended as legal advice. The law pertaining to employment contracts and the enforceability of particular provisions vary substantially from one state to another. Therefore, an individual should seek the advice of a knowledgeable attorney before deciding on the content and language of an employment contract.

A well-drafted employment contract clearly states the agreement between employer and employee and reduces the potential for future litigation. It should start with the basics, such as job title and a description of the level of responsibility the employee will assume. If the employee wants to remain in a particular location or desires to avoid extensive travel, these issues should be addressed in the contract. Generally, employees are hired for an indefinite period of time. However, in many states, a contract is unenforceable if a definite term is not stated. The parties should consider whether extensions to the contract term will be permitted and under what conditions.

The salary and total compensation package should be addressed in an employment contract. This would include the following: base pay, bonus, commissions, cost-of-living salary adjustments, pension, life/medical/dental/disability insurance (address who pays what percentage), 401(k), stock, profit-sharing, incentive pay, expense account, company car, vacation, parking, use of company property, associations/club memberships, mobile phone, tuition (self, dependents), moving costs, low-interest loans, severance pay, tax/legal/financial counseling, child care, and employee discounts. Just

because an employer does not state that a particular item is available as a benefit does not mean that a well-qualified applicant cannot use his or her qualifications as leverage to negotiate for and receive that benefit.

In an individual employment contract, there is often a clause listing the specific reasons that will justify termination. If the contract does not address valid reasons for termination, the employee is generally considered to be an *employee at will*. The doctrine of employment at will holds that unless there is a contract stating otherwise, employers have the legal right to terminate an employee for any reason as long as the basis for termination does not violate state or federal law. This doctrine is generally followed in all states, subject to some exceptions that vary from state to state.

If an employee desires some protection beyond the minimum required by law, the employment contract should state, for example, that the employer cannot terminate the individual unless there is just cause. Also, the parties may wish to specify that termination may occur only after the occurrence of certain specified events. The contract should specify what the consequences would be for the parties in various scenarios. For example, misconduct, particularly gross misconduct, normally does not entitle an employee to severance pay. If the termination is for something less than the agreed-upon standard of misconduct or if the employer breaches the terms, the contract should state how, when, and how much the employee is to be compensated.

One of the most often used provisions in employment contracts is a clause that prohibits the employee from working for a competitor during the term of the contract and after leaving the employer. Noncompetition agreements have long been used in the employment contracts of top executives, sales representatives, and research/technical personnel. As employers have become more competitive and more concerned about trade secrets and other proprietary information getting into the hands of their competitors, covenants not to compete are being included more often in contracts involving employees who will have access to customer lists, business and marketing plans, pricing and financial data, research and development, production methods, product formulas, and any other information that would be of value to a competitor.

A prospective employee should give this issue serious consideration before agreeing to a restriction on future employment. Most states enforce noncompetition

agreements. As with most other matters related to employment contracts, state laws control how these agreements are interpreted and the extent to which they may be enforced. State laws dealing with such agreements vary significantly.

A noncompetition agreement often includes other restrictive covenants, such as a nondisclosure agreement prohibiting the former employee from using or disclosing the employer's confidential or proprietary information. Also, a nonsolicitation agreement may be used to prohibit former employees from soliciting the employer's customers and prospects, and a non-raiding provision can prohibit former employees from hiring the employer's other employees. Employers often include a provision in employment contracts to protect their interest in intellectual property created while the employee is employed. Employees should be careful not to give up ownership of patents or copyrights already obtained prior to joining employers.

Many employers include compulsory arbitration clauses covering all employment-related claims in their employment contracts. Giving up one's right to seek a legal remedy in court is a serious issue and should be given due consideration by the employee.

If the employee will be assigned to work outside the United States, it may be wise to consider such issues as cost-of-living adjustments, minimum number of trips home (at company expense), and travel and moving expenses back to the United States upon termination of the contract.

Many other types of provisions are often used that may place additional restrictions on either the employee or the employer. The parties are limited primarily by their imagination and their particular needs when determining what should be included in the employment contract. Both parties would be well-advised to have knowledgeable employment attorneys assist them in this process to avoid unpleasant surprises in the future.

EMPLOYMENT-AT-WILL DOCTRINE

The *employment-at-will doctrine* governs employment contracts of an unspecified duration. The doctrine's classic formulation holds that absent a clear intention to contract for a term or other employment protections, the employee-employer relationship can be severed for any reason. As the Tennessee Supreme Court famously declared in *Payne v. Western Atlantic R.R. Co.* in 1884, an at-will employee may be dismissed for "a good reason, a bad reason, or no reason at all." The rule is of course symmetric: Unless specified otherwise, an employee may leave without liability. The doctrine is a common-law rule, meaning that it was adopted by judges without legislative intervention.

SCOPE OF THE DOCTRINE

Though it is now circumscribed by statutory and judge-made limitations, the rule remains one of the most important legal doctrines in employment law, governing the contractual relationships of almost all nonunion, nongovernment employees (roughly 85 percent of the labor force). The doctrine, which is unique to the United States, emerged in the late nineteenth century and is widely regarded as a legacy of the *laissez-faire* attitudes prevailing at the time. By the early twentieth century, it was adopted in every state with surprisingly little controversy.

The employment-at-will doctrine is a judge-made rule; its purpose is to fill in gaps when the terms of the relationship are unspecified. Courts frequently face contracts with gaps that must be filled in during the course of litigation. The general rule is that courts will read in terms (or "default" to terms) that represent a best guess as to what the contracting parties would have wanted had they thought to contract for it. When faced with an unspecified employment contract, then, courts assume that the parties wanted an at-will relationship and place the burden on the plaintiff (almost always the employee) to show that a contract for term or just-cause protection was intended.

If a term of employment is specified, either in writing or orally, courts presume that the contract contains a promise of employment for the duration specified, provided the employee performs satisfactorily. In some cases, the employer could offer an indefinite-term contract in which dismissal may occur only for just cause, creating just-cause employment for life. Prior to the recent innovations discussed below, these cases were limited almost solely to well-specified contracts for academic tenure. Courts were once unwilling to find that oral assurances or statements in employee handbooks created a just-cause relationship. Since the 1970s, the trend has been toward a more liberal interpretation of assurances and a greater willingness to find just-cause employment.

In the case of a term contract, the employee must show only that the dismissal occurred within the covered term, and then the employer may defend by showing that he or she had a good reason to dismiss the worker. Courts have been careful to note that provisions stating salaries on a yearly or monthly basis do not create a term of employment and are therefore insufficient to rebut the presumption of employment at will. In addition, an employee may also be liable if he or she leaves the relationship prior to the expiration of the term, although courts will require greater clarity in this regard. Litigation in this vein is far less frequent, likely because employers do not wish to retain employees who want to leave and damages may be harder to calculate. Of course, employers can also protect themselves by delaying compensation until the end of the employment term, in the form of a bonus.

Courts did not adopt the at-will rule because no other default was tenable. Indeed, the at-will rule, when adopted, was a rejection of an English rule that held that employment contracts for an unspecified duration would generally be read as a contract for one year of employment. The rule was often justified by the courts with reference to seasonal variations in labor demand and the fear that employers would opportunistically dismiss workers when agricultural conditions were unfavorable. The rule, however, was not limited to farmhands but applied generally, although English courts would impute a shorter term if the situation seemed to call for it.

EROSION OF THE AT-WILL RULE

The first chips at the rule came in the form of statutory limitations on specific "bad reasons" for dismissal.

The National Labor Relations Act of 1935 forbade discharge (and other discriminatory practices) based on an employee's participation in collective action. In addition, it facilitated the creation of explicit labor contracts to govern the employment relationship, and these contracts typically provide a term of employment or just-cause provisions for dismissal and a procedure under which dismissals are to be governed.

The next major limitations on the actions of employers came in the form of antidiscrimination laws, most prominently Title VII of the 1964 Civil Rights Act, which forbids discrimination in employment on the basis of race, sex, national origin, and religion. Age discrimination (in 1967) and disability discrimination (in 1990) were later prohibited under separate statutes. With the exception of disability discrimination, which requires employers to make accommodations for the disabled, the most common cause of action under these statutes is for wrongful termination, and hence they operate as a check on the at-will rule. Other federal statutes also limit dismissal, and many state statutes offer employment protection along similar lines.

The federal government and the states have provided a cause of action to at-will employees dismissed for specific reasons, but the legislatures have generally not altered the employment-at-will default rule. Only Montana has a statute that mandates a just-cause presumption, and recovery under the statute appears to be fairly limited. Courts, however, have been much more active, and most states now recognize at least one of three exceptions to the at-will rule.

Public Policy Exception

In 1959, California became the first state to recognize a common-law exception to employment at will, in *Petermann v. International Brotherhood of Teamsters*. Petermann, an employee of the Teamster's Union, sued for wrongful termination, alleging that he had been fired because he refused to perjure himself for his employer's benefit. The union claimed that there were no grounds for recovery because Petermann was an at-will employee, and the trial court agreed. The appellate court reversed, declaring that some terminations are limited by public policy considerations. The court relied heavily on the fact that perjury is illegal.

Roughly 42 states have recognized the public policy exception. Most of the claims involve some sort of

illegal action on the part of the employer. Many states require that the public at large be affected by the motive behind the discharge or that the employee was trying to assert a statutory or constitutional right. For example, courts have held that the exception applies when the discharge resulted from the refusal to participate in a price-fixing scheme, the assertion of workmen's compensation claims, or complaints to the employer about inappropriately labeled products. It should be noted that many states have codified at least part of the public policy exception in the form of so-called whistleblower statutes. For example, New York courts reject the public policy exception, but New York has a very narrowly tailored whistle-blower statute.

Because it relies on particularly egregious conduct, the public policy exception is limited in scope. Two much more important exceptions sprang into existence in the 1970s and 1980s: the good-faith exception and the implied-contract exception.

Good-faith Exception

Courts will read a "duty of good faith" into most commercial relationships, mainly as a weapon against opportunistic behavior by one party. It is interesting, then, that only 11 states have accepted good-faith limitations to the doctrine of employment at will.

The paradigmatic case here is one in which an employee is terminated prior to the receipt of a bonus or a commission. For example, in the case of *Fortune vs. National Cash Register* in 1977, the Massachusetts Supreme Court held that it was a violation of an implied agreement of good faith when an at-will salesman was terminated after making a large sale for which he would have received a commission. Thus, the good-faith exception focuses on whether or not the termination was opportunistic—an attempt to prevent the employee from obtaining benefits to which he or she would have been entitled had he or she remained employed. (As a side note, federal statutory claims may exist for a termination motivated by a pension vesting.)

Implied-contract Exception

Perhaps the most important exception to the employment-at-will rule is the implied-contract exception, which is recognized in 42 states to varying degrees. Under the exception, courts will allow the statements in employee handbooks, oral assurances of employment, and even the conduct of the parties, such

as an employee declining other job opportunities, to constitute evidence of a just-cause relationship. Prior to the exception, these factors, even though not in dispute, would have been insufficient to rebut the presumption of employment at will.

Of course, state courts vary in how willing they are to recognize the implied-contract exception. For example, California courts tend to construe the evidence liberally to find an implied contract. On the other hand, New York courts emphasize that the implied-contract exception is narrow, requiring that an employee handbook contain a clear just-cause provision and that the employee relied on that provision in some way, for example, by leaving his or her previous job.

Damages

In general, contract damages are limited to the value of the contract itself (the so-called expectation interest). Thus, under the implied-contract exception, employees may receive the value of back wages and benefits plus interest, as well as the going-forward loss caused by the termination, known as *front pay*. The law requires that the employee mitigate by trying to find comparable employment, and if the employee finds a comparable job, his or her recovery may well be limited to back wages and benefits. Front-pay awards are also subject to attack as being too speculative, and courts have reduced them accordingly.

On the other hand, courts have often characterized the public policy exception as a tort action. A tort is an action that exists independent of a contractual obligation; thus, the characterization of the action as a tort helps the court avoid the at-will designation. In tort, back pay and front pay are available, as well as punitive damages and pain and suffering. In some states, claims under the good-faith exception may proceed in contract or tort, depending on the factual situation. Others, such as California, have limited tort claims to public policy exceptions.

EMPLOYER RESPONSE TO EXCEPTIONS TO THE AT-WILL RULE

Employers are famously sensitive to employment litigation, and the at-will rule provides them with cover. On its face, the implied-contract exception is easiest for employers to get around, because they may simply require workers to sign at-will statements or insert at-will provisions into employee handbooks.

Almost all contract rules are simply default provisions from which the parties may contract out. Survey evidence indicates that over half of all employers insert at-will provisions into handbooks or other writings such as offer letters.

Such alterations do not amount to blanket protection for employers, however, if courts allow later oral assurances or conduct of the parties to trump the handbook provisions. In addition, courts have split over whether an employee hired under a just-cause handbook can later be turned into an at-will employee when the handbook is amended to include an at-will provision. Employers can limit their liability to some extent by providing severance packages in consideration for an employee's waiver of legal claims. Arbitration clauses in employment contracts have also become increasingly popular and are generally enforced.

Employers can also respond by decreasing their use of labor or favoring states that have stronger at-will presumptions. Law and economics scholars have provided evidence that this has, indeed, happened. Among the findings are that in states that adopt at-will exceptions, employers retain current workers longer and offer lower wages to new workers; employers hire more temporary help employees; and there is slower employment growth. These findings are all consistent with the argument that exceptions to the at-will rule make employers less likely to both hire and discharge workers. As with many employment protections, they benefit those currently with jobs; those on the outside are damaged. The implied-contract and good-faith exceptions are the most salient in these studies. The public policy exception is generally found to have little or no effect, which is not surprising given its limited scope.

IMPLICATIONS FOR EMPLOYEES

Employment at will is widely regarded as a harsh doctrine because it leaves the employee with little recourse in the courts. To escape this doctrine, an employee must have a statutory claim or meet the burden of demonstrating that he or she fits an exception. A few states do not recognize any exceptions, and others have very narrow exceptions. In addition, survey evidence indicates that the rule comes as a surprise to most workers, who have very different understandings of their legal rights. Some have argued that courts should flip the default rule and presume employment for just cause or revert to the old English rule. Employers could

still contract for an at-will labor force; they would just have to place employees on notice by explicitly stating that the relationship is at will.

There is a contrary view, however, that argues that the law is fairly unimportant to the employment relationship. First, employees do not in general rely on legal protections. Indeed, even when employees have well-known statutory protections, as in the case of Title VII, the conventional wisdom is that they are hesitant to assert these rights. Second, the market disciplines employers who dismiss workers (or permit supervisors to dismiss workers) arbitrarily. They lose valuable employees. They face the cost of replacing employees. They demoralize their workforces, making other employees more likely to leave. Third, America's consistently low unemployment rate provides a built-in protection for workers. When they are dismissed unfairly, they are likely to find new work, which makes it harder for employers to replace good workers with those equally qualified.

Whether the market's regulation may be improved on is a tricky issue. For example, there may be times when the benefits to firing an employee for a bad reason are large enough to overcome the market-imposed costs of such an action. Consider again the example case of the dismissal of an employee prior to a large pension or bonus vesting. Even more complicated are cases of so-called implicit labor contracts, in which the employer offers lower wages at the start of employment but high seniority-based pay later on. These contracts are offered in the hopes of retaining workers and encouraging good performance. The extra effort and retention are valuable to the employer, who gets a more productive workforce and saves training and recruiting costs. Even though the employer profits from this deal over time, longtime employees may eventually earn more than they are currently "worth" to the firm (similar to the case of dismissal motivated by a pension vesting). The firm has an incentive to terminate this employment opportunistically. Some have argued that the regulation of such arrangements is a justification for limiting the at-will rule. But any of these benefits must be weighed against the empirical evidence that alterations to the rule make employers less willing to hire, which in the long run is not good for employees.

CONCLUSION

The doctrine of employment at will remains surprisingly intact, even after the creation of many

important statutory and judge-made exceptions. After the revisions to the rule during the 1970s and 1980s, many predicted its demise. In the end, the nineteenth-century doctrine, though modified, appears to have survived into the twenty-first century, and it remains a distinguishing feature of the U.S. labor market.

EMPOWERMENT

One of the most frequently discussed topics in contemporary management literature is the notion of employee empowerment. *Empowerment* is generally taken to mean the delegation of decision-making authority and responsibility to lower-level employees

in a process of directed authority. However, this traditional top-down approach to empowerment is no longer viable, as the shift to a knowledge service economy in the United States, as elsewhere, gives rise to the growing transformation of twenty-first-century workplaces. Emerging knowledge services, such as business-to-business services, high-tech, medical/health care, advertising/marketing/public relations, accounting/financial services, engineering services, management consulting, legal services, educational services, and the like constitute the most rapidly expanding segment of the labor force. The movement to knowledge services has had a profound impact on the nature of work and the people who work within these organizations. In a very real way, the shift to a knowledge service economy has given rise to the “professionalization” of workplace and the structural empowerment of people who work within these organizations. Structural empowerment, unlike traditional approaches to empowerment, is customer- and client-centered empowerment in which the decision-making prerogative of employees, along with the discretion to act on their own, is market driven.

The fundamental unit of production in knowledge service organizations is the direct relationship between service employees and their customers or clients through which a product or service is delivered. This is called the *customer alliance*, a partnership or collaboration between knowledge-intensive organizations and their customers for generating problem solutions and mutual gain. Customers have important roles to play in these organizations and have long been recognized as “partial” employees. The notion of worker empowerment is at the core of customer alliances in knowledge-based services because it makes it possible for the organization to more effectively utilize the customer’s contribution and thus increase the quality of services produced.

There is an ongoing dialogue in both academic and popular press concerning the so-called empowerment of employees. This issue is particularly important in knowledge-based services, in which employees in direct encounter with customers are often required to perform as independent decision units in the generation of responses or solutions to customer priorities. The delegation of structural empowerment has traditionally been used to provide frontline employees with the authority for spontaneous, creative activities that are often required in high-involvement customer relationships. Much is known about this type of

formal employee empowerment in organizations. There is increasing recent attention, however, to the nature of empowerment in customer alliances that emerge outside the formal authority structure and how knowledge service employees actually empower themselves to more effectively render quality problem solutions to customers and contribute to organizational effectiveness.

THE NATURE OF CUSTOMER ALLIANCES

The output of knowledge services emerges from transactions or exchanges between customers and service employees, often referred to as *engagement personnel*. These relationships are coordinated efforts by both parties in the exchange of resources to generate solutions to customer problems or strategic priorities. For the customer, an adequate, or better, exchange would include satisfaction with the solutions rendered; for the knowledge worker, a satisfactory exchange might include direct payment, a sense of accomplishment, or the generation of new knowledge to the organization. Since valued resources are being exchanged and allocated between the knowledge worker and the customer for mutual gain, the exchange is anchored in a market context.

Implicit in the exchange of resources between knowledge workers or engagement personnel and customers is a social and psychological contract, which consists of a set of mutual expectations involving the rights and obligations of the participants. From this perspective, customer alliances in knowledge-based services can be meaningfully explored through what are generally called *agency relationships*; that is, customers of knowledge service organizations engage workers in performing deeds on their behalf and also give the workers the right or authority to act on the customers’ behalf.

KNOWLEDGE WORKER EMPOWERMENT

It has long been acknowledged that customers perform salient roles in service operations. In recognition of the important task activities performed by customers in knowledge services, it has been argued that these participants should be included within the boundaries of organizations as “partial” or temporary employees. Such an inclusion within the boundaries of the organization, however, renders customers’ roles essential but subordinate to the knowledge workers or

engagement personnel with whom they directly interact in the alliance.

The customer's subordinate position is primarily based on customer alliances being viewed, as previously noted, as agency relationships, in which clients delegate some decision-making authority to knowledge service workers or engagement personnel. This kind of relationship is a germane and unique feature of knowledge service organizations. Fundamentally, the customer in knowledge-based services hires the service worker or engagement personnel and delegates to the engagement personnel the responsibility for gathering and processing information for generating solutions to customer problems or needs. In so doing, the customer surrenders a delimited set of rights to the knowledge service employee. This process is an important form of employee empowerment because it is thought to provide a framework that encourages employees to exercise initiative, spontaneity, and imagination. Consequently, within knowledge service customer alliances, there is a disparity in status between the customer and the knowledge service employee or engagement personnel based largely on the greater legitimate power or right to make decisions bestowed on the employee by the customer. Further disparity in status may also emerge from the unique body of expertise or knowledge possessed by the empowered worker.

It seems clear that engagement personnel in customer alliances not only are boundary spanners for the firm but also, more important, represent first-line managers for the organization, assisting in the coordination and control of customer activities. Thus, customers enter into the service boundaries as "temporary" members of these organizations and become the responsibility of knowledge service employees.

It is also recognized that knowledge service employees are empowered by an employment contract when they join work organizations. This empowerment is tied to the formal authority structure that would entail, among others things, the governance of customers. As partial members of the organization, however, customers cannot be completely under the jurisdiction of the firm or its representative, the engagement personnel. Exclusive reliance on traditional structural empowerment would restrict the employee's ability to manage customers effectively, because the empowerment of an employee emerging from the employment contract may often be at odds with the "market-based" empowerment provided by the customer. Market- or customer-based authority is a primary

source of employee empowerment in knowledge-based service organizations. The paramount issue for engagement personnel in these services is managing the customer alliance within a market authority: an empowerment structure that is customer provided and thus outside the traditional empowerment structure inherent in the employment contract.

ESSENTIALS OF MARKET-BASED EMPOWERMENT

To a significant degree, knowledge workers in customer alliances are "mini-factories" because they are in a unique position to simultaneously produce and deliver their problem solutions to customers. Engagement personnel in knowledge-based service organizations are thus in possession of resources simply because they occupy formal and informal positions within these organizations. Whereas the traditional structural empowerment in organizations is widely viewed as top-down delegation of decisional power to employees, market- or customer-based empowerment is a bottom-up approach to worker empowerment. In customer-driven empowerment, employees accumulate resources and rights to act in the customer's best interest. In consultation with the customer, employees jointly create services or solutions to problems in order to add value to the organization. Customer-empowered workers, unlike traditionally empowered employees, generally make claims over a unique body of expertise, knowledge, and skills that confers on them the right to develop solutions to problems. Equipped with empowerment from the customer alliance, engagement personnel are capable of interpreting knowledge and rules, as opposed to merely applying them. This is essential for generating creative solutions for customer needs in knowledge-based service organizations. Furthermore, customer-driven empowerment makes it possible for workers to engage in continuous learning and development in service organizations, with specific features for service excellence.

An important component of customer-driven employee empowerment in knowledge services is the potential for workers to engage in laterality. *Laterality* means the lateral interests of the customer, entailing the various aspects of the customer as a total product that have to be addressed by engagement personnel in order to render quality services. For example, teachers may have to take into account students' emotional states and their physical, environmental, and financial

situations because these factors might affect the learning process; brokers in a financial planning organization might need to consider not only the customer's financial status but also factors such as the client's physical health condition, familial situation, desires, consumption patterns, and personal relationships because these factors may affect the quality and effectiveness of long-term investments, insurance, or other services.

As the knowledge service worker's laterality in the customer increases, a greater variety of alternative solutions will be possible. Empowerment bestowed on the employee by the customer suggests that the employee in these services is capable of determining the activities that can be performed legitimately in acting in the customer's interest and modifying the rules when necessary. Worker empowerment within this context represents the acquisition of resources, mainly knowledge, and opportunities required or desired by employees in rendering solutions to customers.

To a great extent, market-based or customer-driven empowerment is a loose understanding of or psychological contract around a set of rights that is bestowed by the customer on engagement personnel in customer alliances. In knowledge-based service organizations, customers are sometimes unable to establish the quality and quantity of solutions. This may lead to reducing contract specificity and providing knowledge service workers with a relatively open contract. The existence of customer authority, as a dimension of customer alliances, transforms engagement personnel activities to sanctioned efforts that are undertaken in the interest of the customer. Customer authority of this kind, therefore, gives rise to empowerment and creates the potential for control gained by the knowledge service worker in a boundary-spanning role. Thus, by right and by the resources possessed, engagement personnel in customer alliances occupy an elevated empowered position in role and in stature relative to other employees in knowledge service organizations.

Customer- or market-based employee empowerment arises out of uncertainty surrounding the generation of solutions to customer needs. Customers' central role in the uncertainty issue of worker empowerment occurs in response to their difficulties in measuring performance outcomes. While empowered knowledge employees may be certain about the appropriateness of their actions in addressing a customer's needs, they may be uncertain as to how that

customer will value their performance. In knowledge-based services, customers might have difficulty evaluating the worth of activities performed by engagement personnel. Under these circumstances, both the employee and the customers implement mechanisms to understand and gauge the effort and performance of others and their intent in the generation of solutions. Customers may invoke their authority, inherent in their hiring rights, to align the interests of empowered workers and reduce potential opportunism in customer alliances. Thus, customer- or market-based authority focuses on the effects of empowerment, not the causes.

CONTROLLING EMPLOYEE EMPOWERMENT

In customer-based empowerment, knowledge service employees are advantaged as to the potential opportunities and threats in achieving the optimum solutions to customers' priorities. Empowered employees may be certain about efficiency or the appropriateness of their performance or efforts, but they may be uncertain as to how the customer values such performance. An important question is "What control mechanisms are there to maintain the stability of a customer alliance?"

The misuse of empowerment can be tempered by mutual agreement between the participants on certain solutions or outcomes. Clients, for example, may base the effectiveness of their lawyers on contingent arrangements, in which lawyers receive bonuses if the litigation is successful. The lawyer has a vested interest in the outcome and all the consequences ensuing directly or indirectly from the compliance with the client. Given the emphasis on examining the effects of empowerment in customer alliances, this approach of contracting on the outcome establishes a framework for reducing goal incongruence while fostering the accumulation of resources for both the customer and the knowledge service employee. Within this context, both parties would be empowered. By sharing in the outcome, the employee will be motivated because the outcome creates an incentive to be efficient on activities he or she can most efficiently control. Thus, by having a vested interest in the outcome, empowered employees will be less motivated to exploit their advantages.

Several other mechanisms are employed by knowledge services that may serve to temper risks in potential market- or customer-based empowerment: monitoring, bonding, and the normative system. Monitoring

activities are undertaken by customers to reduce the loss of utility. They entail costs as customers attempt to gather and process information about employees' abilities to adhere to expected contractual agreements. As an example, students often seek information on instructors before signing up for a class.

Bonding activities are undertaken by empowered service workers to assure customers of some minimum level of performance and reduce the perception that they are taking advantage of their position. Bonding activities supplant the need for the customer to engage in monitoring engagement personnel. Typical bonding activities include those associated with obtaining credentials (e.g., certification for completing training programs, awards for outstanding performance, advanced degrees) and guarantees. The reputation of the knowledge worker emerges as an important credibility factor and serves as a bonding mechanism. It gives customers some idea of how to evaluate the potential performance of employees and the amount of probable risk that they are assuming.

A third important mechanism that serves to temper customer- or market-based empowerment is the organization's constitution. This is the value system within the organization consisting of a set of rules, which, over time, evolves into an ethical code of acceptable or unacceptable behavior. The organization's constitution serves to monitor and guarantee the integrity of customer alliances.

CONCLUSION

Traditionally, there has been an overemphasis on empowering service employees through formal organization authority. The organization gives the frontline employee in direct encounter with customers a voice in how they believe activities should be performed. Although such formal mechanisms may provide knowledge service workers the autonomy to make decisions that may influence organizational direction and performance, such organizational mechanisms present only a partial or truncated perspective on knowledge service employee empowerment.

This entry has addressed the issue of empowerment of first-line engagement personnel in knowledge-based service organizations from the perspective of how employees empower themselves. A fundamental assumption of the discussion is that an alliance between customers and engagement personnel is crucial to the generation of solutions in knowledge

service organizations. Customer alliances exist to facilitate the exchange and distribution of resources necessary for the development of solutions to customer needs and strategic priorities. Rather than focusing on the empowerment of employees through the delegation of authority from the organization, this analysis has concentrated on the effects of empowerment that emerge from the customer's authority and are outside the formal organization authority structure.

ENTREPRENEURSHIP

Entrepreneurship is the recognition and exploitation of market opportunities. Recognizing that an opportunity exists is not enough; to be entrepreneurial involves the pursuit of that opportunity. Therefore, being an entrepreneur involves both cognition and behavior. As a state of mind, entrepreneurship is valuable within existing organizations as well as in the

establishment of new ventures. Sometimes referred to as *creative destruction*, entrepreneurship has been viewed as the engine of progress in capitalistic societies and is inseparably linked to innovation and competitive advantage. Evidence of the importance of entrepreneurship exists in public policy initiatives that encourage new business development and also within established organizations that actively encourage the development and pursuit of new opportunities.

Entrepreneurs possess the ability to identify and capitalize on opportunities to start new business ventures, whereas *intrapreneurs* apply these same skills to venture creation within an existing organization. Often when one speaks of entrepreneurs, images of individuals such as Bill Gates, Oprah Winfrey, and Donald Trump come to mind. Yet in reality, these cases are more the exception than the rule. In fact, research has shown that it is virtually impossible to “stereotype” the typical entrepreneur. What is common to entrepreneurs is their proclivity to recognize and capitalize on market opportunities. Not all entrepreneurs become successful, rich, and famous. What prompts some people but not others to become entrepreneurs and what makes some people but not all successful have intrigued businesspeople and academics alike. The past 10 years have seen a proliferation of research dedicated specifically to understanding entrepreneurs and their careers.

Distinguishing characteristics that separate entrepreneurs from nonentrepreneurs is an important part of gaining an understanding of entrepreneurship as a career. Initially, these efforts included studies of demographic characteristics and personality traits. Demographic characteristics thought to distinguish entrepreneurs from others include socioeconomic indicators, educational background, and influences in an individual’s family of origin (e.g., parents/siblings owned businesses). In general, entrepreneurs tend to come from middle- to upper-class families with one or more parent considered an entrepreneur, self-employed, or owning his or her own business. Educational levels and backgrounds of entrepreneurs vary, and therefore the role that education plays in entrepreneurial career choice is inconclusive.

Other research focused on individual traits, such as need for achievement, need for autonomy, internal locus of control (individuals who believe they have control over their own lives), gender identity (masculinity versus femininity), proactive personality (individuals who take action to influence their environments), risk-taking

propensity, and tolerance for ambiguity. While some entrepreneurs are likely to exhibit some of these personality traits, there is no conclusive evidence to suggest that only entrepreneurs exhibit these traits, and therefore personality traits alone do not seem to distinguish entrepreneurs from others.

More recent research suggests that some people become entrepreneurs not because they have distinct traits but because they perceive situations and opportunities differently than others perceive them. More specifically, cognitive factors for entrepreneurs differ from those of nonentrepreneurs. Although there are many cognitive factors that affect thinking, in particular the perception of risk, several specific cognitive biases have been suggested to influence risk perception as they relate to entrepreneurs: overconfidence, illusion of control, and belief in the law of small numbers.

Overconfidence is the belief that one knows all there is to know about a particular topic. Recent research has shown that entrepreneurs may be more susceptible to overconfidence than are other individuals and are more optimistic in their assessments of business situations. Overconfident individuals are less likely to perceive risk in business situations because they believe they know what they need to know. More specifically, entrepreneurs are more likely than nonentrepreneurs to overestimate the accuracy of their predictions of uncertain events. For example, new competitors surface even in the mature, uncertain environment of the airline industry because entrepreneurs believe they have an inside understanding of how the industry works.

Illusion of control refers to an overestimation of one’s skills in situations and a belief that one’s skills can control outcomes. Like overconfidence, an illusion of control also decreases risk perception. This suggests that individuals starting ventures might not acknowledge that certain factors important to a venture’s success are beyond their control. Individuals who believe that their skills are the primary determinant of the success of their businesses have strong illusions of control.

Belief in the law of small numbers occurs when an individual uses a limited number of informational inputs (a small sample of information) to draw firm conclusions. Some entrepreneurs have a tendency to use limited information in decision making. Entrepreneurs typically find themselves in circumstances of information overload, high uncertainty, novel situations, strong emotions, time pressure, and

fatigue. In dealing with these tense circumstances, entrepreneurs may (a) focus on limited amounts of information to gain support for risky actions and (b) focus on recent success stories or positive outcomes that relate to the situation at hand. Generalizing from a small sample can effectively reduce the perception of risk for a particular opportunity.

In addition to the personal characteristics that help explain why some individuals become entrepreneurs and others do not, a number of career factors also play into this phenomenon. Entrepreneurs prefer to be innovative or to accomplish something new. In addition, they are intrinsically and extrinsically motivated. Intrinsic rewards such as autonomy, personal challenge, learning and growth, and the ability to influence organizations are appealing to entrepreneurs. Extrinsically, financial independence and success, status, and recognition drive individuals to choose entrepreneurial careers.

In general, individuals often choose careers they believe will match their talents, skills, abilities, needs, and preferences. For example, individuals who believe they have strong analytical skills and prefer to work with numbers seek jobs or careers that allow them to do so. Entrepreneurs are no exception. Many entrepreneurs attribute their prior work experience as a major influence on their desire to start new ventures. A major drive for many entrepreneurs is the desire to create something new. Therefore, entrepreneurs are likely to seek opportunities to explore and nurture their preferences for creating new products, services, or businesses.

The image of an entrepreneur as a rugged individualist who forges his or her own path is another myth about entrepreneurship. One key and consistent research finding is that networks are critical to entrepreneurs and to the success of new ventures. Networks and the social capital inherent in them are essential to entrepreneurship. Social capital, sometimes referred to as *network resources*, consists of the goodwill that can be obtained from the web of relationships developed by individuals and can be mobilized to facilitate action. Social capital theory proposes that networks of relationships are a valuable resource for the conduct of social affairs and economic action. It has been applied to individuals, familial relationships, communities, and organizations. Social capital is a resource that brings a higher rate of return on investments and creates an advantage by fostering entrepreneurial opportunities for some and not for others.

Not only do individual, personal, historical, and psychological factors influence the decision to become an entrepreneur, but contextual factors also contribute to this type of career. In the following sections, we describe two categories of entrepreneurship that derive from both individual characteristics and environmental circumstances: *serial entrepreneurs* and *second-career entrepreneurs*.

Although the concept of serial entrepreneurs has come into greater prominence in the past few years, certainly there have always been particular groups of people who are seemingly addicted to starting one business after another. Recently, however, with the prominence of venture capital firms and the popularity of start-ups, particularly in the technology sector, more individuals are getting into business with the idea that they will exit sooner, rather than later, and start other businesses. Serial entrepreneurship is an identifiable occurrence and extends into many different industries. Approximately 43 percent of the chief executives of current Inc. 500 companies indicate their intentions to start other companies after they leave the ones they are running now.

Some make the distinction between serial entrepreneurs and *portfolio entrepreneurs*. The former group of people creates and becomes involved in a business; that is, they manage it, improve it, sell it, and then move on to another business, whereas the latter group operates several businesses simultaneously.

Despite the semantic distinction, both types of entrepreneurs get tremendous personal satisfaction out of taking an idea to market and making it happen. They are more devoted to the creation of something than to the actual business idea. Once they establish a new venture, it is almost as though boredom sets in and they are ready for the next challenge. Serial entrepreneurs focus on the creation of something new. They possess the drive to overcome obstacles, the readiness to take risks, and the need for personal prominence in whatever is accomplished.

Second-career entrepreneurs are sometimes referred to as *older entrepreneurs*, *senior entrepreneurs*, and *third-age entrepreneurs*. All terms refer to individuals who decide to start their own companies after they have been employees for most of their professional lives. Demographic profiles in the United States point to the fact that the number of individuals between the age of 45 and 64 will grow significantly by the year 2006. Many of these people will likely begin new ventures in this life stage. A recent survey

of the American Association of Retired Persons (AARP) found that 80 percent of this group planned to work beyond retirement age and 17 percent intended to start their own businesses.

Corporate layoffs, shifting values (i.e., flexibility in working hours to pursue family obligations and/or nonwork interests) and rising life expectancy have contributed to this phenomenon. Aside from these specific factors, reaching midlife is historically a time of change for people, and the midlife transition often spurs adults to change careers. Individuals reach midlife and realize that the dreams and passions of youth have been subjugated to economic obligations and early career choices. Facing the reality that they still have half a lifetime to live provides individuals with the courage to venture out on their own and pursue their passions and interests. Many of these individuals launch their ventures from their homes.

Technology has facilitated a proliferation of home-based businesses to accommodate the lifestyles of second-career entrepreneurs. Powerful software applications combined with the Internet technology have allowed home-based businesses to compete with larger firms. Home offices can be furnished and wired for under \$5,000, a relatively small amount for starting a new venture. The Internet allows for reaching a potentially global customer base that brings home-based businesses into a competitive realm. While second-career entrepreneurs (like first-career and serial entrepreneurs) are most often men, the proportion of self-employed women increases from 6 percent among women age 25 to 54, to 9 percent among women age 55 to 64, and 16 percent for employed women 65 and older. Since women are more likely to be primary caretakers of children, they have in the past, been less likely to pursue entrepreneurial opportunities until reaching midlife.

In the United States, this trend seems to be changing. Many younger women, particularly those with school-age children, are giving up corporate jobs to start home-based businesses. These career choices are a response to the “glass ceiling” in the corporate world and the need for more flexible work arrangements. More than likely, many more women will become second-career entrepreneurs much earlier in life than did their older counterparts.

As of 2002, women were responsible for 6.5 million businesses in the United States, a 20 percent increase since 1997. The current state of women’s business ownership in the United States is quite

strong. The number of women-owned businesses continues to grow at twice the rate of all U.S. firms, and these firms are increasing in economic influence. One in 18 women in the United States is a business owner. Prior to 2002, most of the companies started by women were in the service sector, including industries such as health care, professional services, real estate, and finance. Since 2002, women-owned businesses have been expanding into nontraditional industries, such as construction, manufacturing, agriculture, and transportation. Growth rates are higher than average among women-owned firms with \$1 million or more in sales and 100 or more employees. Ongoing studies that focus on the characteristics of women entrepreneurs indicate that women take substantial business risks, use technology to achieve growth, and seek advice from multiple sources.

Despite the remarkable growth in women-owned businesses, most women-owned firms are very small—with no employees or fewer than 10 employees—and continue to face challenges, including access to capital, access to markets, access to training and technical assistance, access to networks, and the need for legitimacy, in other words, to be taken seriously as business owners, employers, and contributors to economic growth.

Minorities are another fast-growing group of U.S. entrepreneurs. Sometimes starting businesses as a response to the glass ceiling encountered in corporate America, minority entrepreneurs account for 3.9 million businesses, or 14 percent of the total number of businesses in the United States. Of this number, 39.5 percent of businesses are Hispanic owned; 30.0 percent are Asian owned; 27.1 percent are African American owned; and 6.5 percent are Native American owned. Most Hispanic-owned businesses are in administration and support, waste management, health care, and construction industries. African American ventures are primarily health care, retail, and other service-type businesses.

Challenges of minority entrepreneurs are similar to those of women, with limited access to financial resources being the number 1 reason for minority business failures. Most minority business owners seek financing through family rather than seeking commercial capital opportunities. With the entrepreneurial landscape changing, women and minority entrepreneurs are more able to rely on role models and mentors who can offer access to financial and market resources. As with the factors that influence second-career entrepreneurs, the Internet, because it tends to be

gender and race neutral, has opened markets and opportunities to minority and women entrepreneurs that were previously closed.

Like the American economy, the economy of the European Union relies heavily on the “creative destruction” of entrepreneurship as it continues to evolve toward more capitalistic principles. Small-and medium-sized enterprises (i.e., employing 10 or fewer employees) constitute 90 percent of the private businesses in Europe (28 countries of the European Economic Area plus candidate countries to the European Union). The challenges of underrepresented populations of entrepreneurs (women, ethnic minorities, and young people) in Europe are similar to those faced by their American counterparts. Government-sponsored programs that help encourage and fund women and minorities with small businesses are in place in Europe, as they are in the United States.

Finally, no discussion of entrepreneurship would be complete without a description of *social entrepreneurs*. A social entrepreneur crafts innovative, long-term solutions to social problems. Just as traditional entrepreneurs create and transform whole industries, social entrepreneurs act as societal change agents, recognizing and exploiting opportunities others miss in order to advance sustainable solutions that create social value. Unlike traditional entrepreneurs, social entrepreneurs primarily seek to generate “social value” rather than profits. And unlike the work of the majority of nonprofit organizations, their work targets long-term reform rather than small-scale change.

The concept of social entrepreneurship has been in existence for a long time but has recently reached a new level of prominence as a field of study and career choice. The social sector has increasingly relied on the business skills of entrepreneurs to increase awareness and generate funding. Mission-based businesses have traditionally been nonprofit organizations. The marriage of solid entrepreneurial principles and the need to effect sweeping societal change have resulted in the transformation of many societies, particularly in developing nations. The trend to making money and contributing to the social good continues to increase, and as it does, so will career opportunities for social entrepreneurs.

In sum, entrepreneurship as a career alternative is becoming more and more popular across age, gender, and ethnic origin. Being an entrepreneur is not limited to certain personality types or stereotypes; there is possibly an entrepreneurial spirit in all of us. As the global economy grows and changes, there are more and more opportunities for individuals to become entrepreneurs and

adopt careers that fit their lifestyles. Entrepreneurship is a vital part of any national economy.

ENVIRONMENT AWARENESS

Awareness has been defined as a relatively complete and accurate perception of individuals’ qualities and the characteristics of their environments. It can be of two types: self-awareness and environment awareness. *Self-awareness* refers to the realistic and accurate perception of one’s interests, values, skills, limitations, and lifestyle preferences. *Environment awareness* has been characterized as the accurate and realistic perception of opportunities, constraints, and challenges relevant to the individual’s work and family environment. The two types of awareness are important for successful career development and career decision making.

Both self-awareness and environment awareness are closely interlinked and share a variety of common stimuli that trigger the process of self-exploration and environment exploration. For example, self-assessments

and environment assessments are triggered when individuals experience greater ambiguity about environmental demands, such as those brought on by organizational or job changes or by other evolutionary life changes. Furthermore, the two types of assessment have been identified as important components of the self-regulation process that enable individuals to achieve their personal, organizational, and career goals. In this respect, these assessments may be driven by individuals' curiosity, self-determination, and other volitional processes. Finally, there are a number of barriers to effective exploratory behavior common to both self-assessments and environment assessments. Hence, to get a true picture of the role of environment awareness in career development, it is important to first discuss the relationship between self-awareness and environment awareness.

RELATIONSHIP BETWEEN SELF-AWARENESS AND ENVIRONMENT AWARENESS

It has been suggested that there is a reciprocal relationship between self-awareness and environment awareness. For example, the more individuals understand themselves, the more likely it is that certain insights about jobs, organizations, or occupations will become relevant to them. Similarly, the greater the amount of information gathered about the different facets of one's work environment, the greater the likelihood of its triggering insights about one's values, lifestyle preferences, and personal aspirations. It has been acknowledged that the process of gaining self-insight can often be fragmented and that it may be advisable to engage in environmental exploration before the task of self-analysis can be deemed complete.

Furthermore, it is believed that self-exploratory activities influence the direction of environment exploration, because individuals' careers are embedded in the larger context of jobs, organizations, and occupations. Self-awareness provides the framework for engaging in environment exploration. Thus, individuals' awareness of interests, values, abilities, and lifestyle preferences guides their search for information regarding potential occupations, organizations, and jobs.

IMPORTANCE OF ENVIRONMENT AWARENESS IN CAREER DECISION MAKING AND CAREER DEVELOPMENT

Awareness plays a central role in numerous theories of career decision making, career development,

and career management. The study of both self-awareness and environment awareness is rooted in the concept of career exploration. *Career exploration* has been defined as the collection and analysis of information on a variety of career-related issues. Career exploration is oriented toward providing information about oneself, such as values, interests and talents, as well as providing information about different aspects of one's environment, such as occupations, jobs, organizations, and families. Career exploration is oriented toward helping individuals develop a greater awareness of themselves and their environment so they can establish realistic career goals and be prepared for career changes and disruptions whenever they occur. The need to be prepared for and adapt to rapidly changing work conditions is especially critical in managing a "boundaryless" career.

It has been noted that individual careers are increasingly characterized by a variety of transitions, such as involuntary job losses, lateral movement within and across organizational boundaries, and career interruptions. Furthermore, scholars have acknowledged that individual careers are no longer confined or "bounded" to a single organization and instead are characterized by membership and experiences that span across organizational, functional, and job boundaries—hallmarks of a boundaryless career.

Just as the nature of careers has undergone a fundamental paradigm shift, so have the criteria that define career development and success. It has been argued that career development and success in such a competitive, unstable, and volatile work environment calls for increased levels of awareness and skills. Researchers have emphasized that individuals need to continually learn about themselves and their environments and expand their personal identities to succeed in today's rapidly changing workplaces. It has been shown that individuals oriented toward learning are likely to seek additional career-relevant information that helps them become aware of their developmental needs, engage in organizationally sponsored developmental activities, and avoid becoming plateaued in their jobs.

Other researchers have investigated the role of environment awareness in terms of the "knowing why" competencies that individuals need to possess for effective career decision making and management. "Knowing why" competencies refer to individuals' motivational energy for understanding themselves, exploring different possibilities, and adapting to constantly changing work conditions. These competencies have been found to be associated with perceived

career success and individuals' beliefs that they are valuable to their employers.

Awareness has also been identified as a critical component of effective career decision making and career management. Effective career decisions are preceded by thorough exploration of oneself and various facets of one's environment, which is reflected in self-awareness and environment awareness. Likewise, the literature on career indecision suggests that a lack of self-awareness and environment awareness may lead to a state of indecision.

The underlying assumption in career decision-making and development theories has been that the better people understand themselves and their work environments, the more likely they are to make career decisions that are compatible with their needs, values, interests, and talents, that is, decisions that reflect a high level of person-job fit. In other words, people need to be cognizant of their abilities, values, and beliefs as well as the demands, opportunities, and constraints of their environments—the dimensions of self-awareness and environment awareness—to achieve a better fit between themselves and their work environments. Research has also borne out the view that individuals, over the course of their various employment experiences, try to seek out jobs that are compatible with their interests, values, and abilities, that is, jobs that reflect good person-environment fit. Compatibility between the person and the work environment has important implications for individuals' career development. For instance, person-environment fit has been found to be positively associated with job satisfaction, organizational tenure, and career success.

In sum, environment awareness plays a critical role in helping individuals make optimum career decisions and successfully develop and manage their career plans. The next section highlights various facets of one's environment that are particularly important for environmental exploration.

ENVIRONMENT FACETS RELEVANT FOR EXPLORATION

Many facets of an individual's environment need to be explored and understood to develop a comprehensive sense of environment awareness. The specific aspects of the environment that need to be explored depend on individuals' particular life situations, the career development tasks they need to address, and their salient life roles. Combinations of these factors

determine the extent of exploration engaged in and the types of resources that will be helpful in building individuals' environment awareness. In addition, it has been noted that self-insight is critical in directing this exploratory behavior. Unless individuals have sufficient self-insight and ask themselves the right questions, they will not be effective in utilizing various environmental resources to gain the requisite environment awareness.

The literature on career development and career management has identified four facets of an individual's environment as being particularly important for environmental exploration and building environment awareness: occupations, organizations, jobs, and families. These facets are closely interlinked, and learning about one dimension often leads to insights about other dimensions. However, not all facets of one's environment need to be explored to the same degree; the relevance of a facet depends on the type of career decision that the individual has to make. For example, an individual contemplating a midcareer change will need to explore various organizations as well as alternative occupational fields. The following section describes different aspects of an individual's environment and their relevance for enhancing environment awareness.

Occupational Exploration

Scholars have defined an *occupation* as a group of similar jobs found in several organizations. These jobs share a certain set of unique requirements and rewards that serve to distinguish them from other jobs in other occupations. To explore an occupational environment, it is important to understand the nature of tasks and activities that are characteristic of a particular occupation as well as the ability and training requirements necessary to perform those tasks. In addition to task differences, occupations differ in the types of rewards and job security they offer and in the physical and social settings they provide.

Two features of occupational exploration that merit special examination are the occupation's time demands and work-related stresses and strains. Understanding the nature of these occupational demands and stresses has important implications for individuals' lifestyle preferences. An impressive amount of research shows how extensive time commitment to work can interfere with individuals' abilities to meet the demands and obligations of their other life

roles. Similarly, research has shown that extensive work-related stress can produce conflicts between individuals' work and family roles and impair their well-being.

Understanding various facets of an occupational environment also has implications for individuals' self-exploration. That is, individuals need to be aware of their abilities, interests, and values in order to explore different aspects of an occupation and make appropriate occupational choices. Most psychologically oriented theories of occupational choice share a common assumption that people prefer and choose occupations that are compatible with their self-concepts. In other words, it is believed that individuals, consciously or unconsciously, choose occupations that match their skills, abilities, needs, values, and talents. The same view holds for individuals seeking to explore various facets of their jobs. The following section describes environmental exploration as it relates to a job context.

Job Exploration

Over the course of various employment experiences, individuals "gravitate" toward jobs that are compatible with their interests, values, and abilities. This concept of person-job fit also guides individuals' search for information regarding various facets of their job environments. Seeking information about occupations entails learning about the various tasks and activities that constitute that occupational field. Hence, in their pursuit to learn more about various occupational fields, individuals also end up learning a great deal about particular features of specific jobs. For example, in understanding the ability and training requirements for different occupations, an individual gets a general idea about what the requirements are for a particular job within an occupation. However, occupational exploration cannot and should not preclude job exploration.

Jobs within the same occupation may vary substantially from one organization to the other in time demands, financial rewards, job security, and physical and social settings. Jobs may also vary between two units within the same organization, particularly in terms of mobility prospects and autonomy in decision making. Hence, a thorough job exploration entails learning about all these features of the job environment as well as understanding how they fit in with one's lifestyle preferences.

Jobs are embedded not only in occupations but also in organizations. In reality, exploration of jobs and organizations cannot be independent of one another. A thorough search for information about a particular job reveals important features of the organizational environment just as a search for information about an organization inevitably provides information about specific jobs in the organization. The next section discusses how exploration of an organization can affect one's environment awareness.

Organization Exploration

Individuals undertaking exploration of an organization as a potential employer are also, consciously or unconsciously, driven by a desire to achieve a fit with their goals and values. The two prominent models of organizational choice, expectancy theory and unprogrammed decision making, emphasize that individuals choose jobs in organizations that will help them satisfy their important values.

An individual exploring an organization typically seeks information about the organization's job opportunities, culture, strategy, administrative practices, and financial performance as well as different pay and benefits practices. In exploring various facets of an organization, an individual often develops expectations about the organization's capacity to provide valued outcomes. The accuracy of these expectations can have a profound influence on that person's job experiences, job satisfaction, and, ultimately, the decision to continue with or leave his or her employer.

Exploration Related to the Family Environment

Regardless of the extensiveness of individuals' exploration of their work environments, effective environment exploration involves paying attention to one's family environment as well. The literature on both identity formation and career development has emphasized the important role that family relationships play in facilitating career exploration and development. In addition, organizational scholars widely accept the view that individuals' work and nonwork lives are closely and inextricably intertwined. They also recognize that individuals' career decisions are strongly influenced by their family roles, demands, and obligations. Hence, to develop an accurate awareness of one's total environment, it is important to

consider and understand the members of one's family: their emotional and financial needs, their career aspirations, and their desired lifestyles.

Tools and Techniques That Promote Effective Environment Exploration

There are a variety of resources available that facilitate the gathering of information about various facets of one's work environment. Some of the commonly recommended sources of information include industry profiles and summaries, such as those available in standard industrial classification (SIC) guides, organizations' annual reports, the Department of Labor's *Occupational Outlook Handbook*, and Occupational Information Network (O*Net). Additional resources are available through career information centers housed in state public libraries. Individuals are also increasingly turning to the World Wide Web in their pursuit of information regarding various aspects of the work environment.

In addition to the above resources, one's family, friends, and former coworkers employed in different organizations can be sources of information regarding specific occupations, organizations, and jobs. Last but not least, individuals' mentors play vital roles in providing not only career-relevant information but also feedback, guidance, and support—which can all serve to enhance individuals' levels of environment awareness.

Extensive exploration does not always produce an enhanced awareness of one's environment. The obstacles to gaining an accurate insight into the various facets of one's environment are very similar to the ones encountered in the process of self-exploration and self-assessment. For example, anxiety, fear, and defensiveness over the exploratory activity can prevent a person from obtaining the right type of information and accurately and constructively processing it. Similarly, interventions that are useful for overcoming the barriers to self-exploration can also help overcome obstacles to successful environment exploration.

In sum, environment awareness in conjunction with self-exploration plays an important role in helping individuals make appropriate career choices and manage their careers. Self-assessments help individuals understand the nature of their preferred work environments, and effective environment assessments help individuals understand the types of jobs, organizations, and occupations that are compatible with their

interests, talents, and lifestyle preferences. Both types of awareness are important for individuals' career development and progress.

EQUAL EMPLOYMENT OPPORTUNITY COMMISSION (EEOC)

The *Equal Employment Opportunity Commission* (EEOC) is a five-member commission appointed by the president of the United States and confirmed by the Senate. The EEOC was created by Congress to be the primary enforcement mechanism of Title VII of the 1964 Civil Rights Act. Title VII prohibits discrimination in hiring, terms or conditions of employment, union membership and representation, and the referral of applicants by employment services. It was passed in June 1964 by

strong bipartisan majorities in both houses, and signed into law by President Johnson on July 2, 1964. Title VII specifically forbids any employer to fail to hire, discharge, or classify employees or discriminate with respect to compensation, terms, conditions, or privileges of employment in any way that would deprive any individual of employment opportunity due to race, color, religion, sex, or national origin. Title VII also prohibits retaliation against individuals who file charges with the EEOC or participate in EEOC investigations. Title VII applies to private employers, state and local governments, and educational institutions that employ 15 or more employees. The federal government, private and public employment agencies, labor organizations, and joint labor-management committees for apprenticeship and training also must abide by the law.

The primary mission of the EEOC is the elimination of illegal discrimination from the workplace. In addition to enforcement of Title VII of the 1964 Civil Rights Act, the EEOC is charged with enforcing the Age Discrimination in Employment Act (ADEA), the Equal Pay Act, Section 501 the Rehabilitation Act of 1973, the Civil Rights Act of 1991, and Title I, the employment provisions of the Americans with Disabilities Act. Under Executive Order 12067, the EEOC is also charged as the lead agency on all the civil rights employment enforcement activity for the federal government. The members of the commission do not decide individual cases, and the primary enforcement operations are carried out through its regional offices and through agreements with state fair employment practices organizations (FEPs). Congress gave the EEOC litigation enforcement authority in 1972, and the General Council to the EEOC is responsible for conducting EEOC enforcement litigation in the courts.

The EEOC uses an integrated approach to remedy allegations of discrimination, including the use of conciliation, education, technical assistance, and litigation. The time limitation for filing charges with the EEOC is 180 days after the occurrence of the alleged discriminatory act. If the charging party is required to file first with a state or local FEP, the time limit for filing charges is increased to 300 days after the occurrence of the discriminatory act or 30 days after receiving notice that the FEP has terminated its processing of the charge, whichever is earlier. After the conclusion of proceedings before the EEOC, an individual claiming a violation of Title VII has 90 days after receipt of a right-to-sue letter from the commission to file a civil lawsuit in a federal district court.

EEOC charge processing begins with the filing of a complaint by an individual alleging violation of one of the statutes the EEOC is responsible for enforcing. The individual filing the charge is interviewed by an equal opportunity specialist, who assists the charging party in writing and filing a charge of discrimination if warranted. The EEOC classifies incoming charges by letter-designated priorities, designating "A" charges as worthy cases for immediate handling, "B" charges as those requiring further investigation, and "C" charges as those that have a low likelihood of success or merit. If the EEOC concludes that discrimination probably occurred (an "A" case), the agency will first undertake efforts at conciliation. This involves the EEOC's working with the employer and employee to try to reach a settlement. If the EEOC's conciliation efforts are unsuccessful, the commission will either issue the employee a reasonable-cause notice of right to sue or sue the employer itself.

In recent years, the EEOC has implemented a strategic plan that emphasizes proactive prevention. The commission has initiated efforts to prevent discrimination from happening in the first place by offering technical assistance seminars to employers, making more effective use of technology and the media, and encouraging both employers and alleged victims of discrimination to make more use of arbitration as an alternative to litigation. On February 1, 2001, President George W. Bush announced his New Freedom Initiative to promote the full integration of people with disabilities into all aspects of American life. EEOC activities associated with this initiative include free workshops on the ADA for small businesses and individuals with disabilities. These workshops, which include information on tax incentives, community resources, and the rights and responsibilities of employers and employees, are aimed at (a) encouraging businesses with 15 to 100 employees to hire individuals with disabilities and (b) assisting individuals entering the workforce in understanding the ADA. Other recent initiatives include special efforts to respond to the sharp increase in the number of complaints alleging employer discrimination against Muslims and people of Middle Eastern descent since the attacks on the United States on September 11, 2001. In 2004, the EEOC also announced the start of a yearlong campaign to protect teenage workers from discrimination and sexual harassment on the job. Youth at Work is a program designed to educate teenagers about their rights and encourage employers

to voluntarily comply with federal rules forbidding harassment and abuse on the job.

The EEOC's Web site (<http://www.eeoc.gov>) contains a wide range of information, including historical information about the commission, enforcement guidelines, statistical data on charges filed, and litigation initiated by the EEOC under the act. The EEOC continues to update and make its Web site more user-friendly both for individuals attempting to exercise their rights under the laws enforced by the EEOC and for employers attempting to provide workplaces free of discrimination.

EQUAL PAY ACT

The *Equal Pay Act*, which passed into law in the United States in 1963, requires that employers provide female and male employees an equal amount of pay when both perform the same jobs. When a female worker on a job alleges a violation of the act, she must prove that (a) her work was "equal" to the work of the male employee, (b) the work of both the plaintiff and the comparison male employee were performed in the same "establishment," and (c) the complaining female's rate of pay was less than the rate of pay of the comparison male employee's pay. An employer might justify the pay differences by showing that they reflected a valid seniority-based pay system, a merit- or performance-based pay plan, a pay plan that bases pay on the quality or quantity of production, or any pay plan giving different levels of pay to workers doing equal kinds of work where the pay difference is based on *any factor other than sex*.

For several years prior to the 1963, the U.S. Congress had considered versions of a bill that would have prohibited unequal pay for comparable work. *Equal-pay evidence* is primarily based on job descriptions, whereas *comparable-work evidence* requires the much more expensive and complex job evaluation process to quantitatively evaluate the worth to the employer of different jobs. Comparable work requires equal pay for males and females for different jobs of equal worth to the employer. During World War II, the National War Labor Board used the comparable-work standard in its decisions, but the equal-work standard prevailed in the Equal Pay Act, primarily because the Congress did not wish to mandate job evaluation for employers.

Labor Department guidelines for the Equal Pay Act define jobs as being equal on the basis of four required factors: (1) equal skill of the workers, (2) equal mental or physical effort to perform the job, (3) equal responsibility for performance, and (4) equal working conditions, that is, equal hazards and physical surroundings in which the work is performed. When evidence supports the charge of unequal pay, an employer must prove that one of these four factors was actually unequal.

The courts have insisted that the relevant work evidence must be the *actual work performed* and that the work must be *substantially equal*, not exactly equal. However, equal pay for different but comparable jobs is not required.

The courts have decided several cases with the charge of unequal pay between females and males on unequal work. For the most part, these cases have alleged violations of Title VII of the Civil Rights Act, not of the Equal Pay Act. In general, these cases showed that the employer had maintained a general pattern of sex discrimination against females in regard to hiring, placement, or promotion, as well as pay discrimination. The courts did establish that charges of pay discrimination on dissimilar (not equal) jobs could be brought under Title VII, but they did not consider what might constitute pay discrimination in dissimilar jobs. In these EEOC cases, a group of females would need to prove (a) a general employer pattern of discriminatory personnel practices; (b) that the employer improperly used market survey data to justify the lower pay for females than males (though in one case, the court concluded that market disparities were not what Title VII tries to prevent); or (c) that the employer established a comparable-worth plan and

continued to discriminate against females by paying them less than males on comparable jobs and less than the employer's own plan called for.

In essence, the requirements of the Equal Pay Act do not call for comparable-worth pay approaches for men and women. A comparable-worth approach would require comparable pay for jobs that require similar job skills, effort, and responsibilities, even if the exact content of the jobs were different. Various attempts to establish comparable-worth payment laws in the United States have failed, and comparable-worth pay has not become established as the law in the United States.

ERIKSON'S THEORY OF DEVELOPMENT

Erik Erikson set forth a *theory of ego identity development* to account for the interactions between psychological, social, historical, and developmental factors in the formation of personality. Perhaps no single theoretician has had a greater impact on the way we perceive adolescent identity development than E. H. Erikson. His writing seems timeless, and ideas from his classic book *Identity: Youth and Crisis*, published in 1968, are still pertinent to this day.

Originally, Erikson was concerned with the difficulties some World War II veterans encountered upon reentering civilian life, and he became interested in problems associated with acute identity diffusion. Over time and through clinical experience, he came to believe that the pathological difficulties some veterans experienced in leaving one role (soldier) and entering another

(civilian) were psychologically similar to the problems some adolescents experience as they leave childhood and move through the transition of adolescence into adulthood. From this experiential framework, along with observations of Native American populations, he constructed a theory of psychological and social development with a focus on identity formation.

Erikson's academic training was originally based on psychoanalytic theory, but he turned his attention to ego development: the portion of personality that serves the executive function of directing, guiding, and selecting thought and action. In his writings, there are many different definitions of *identity*. At times, he refers to the consistency and sameness that a person uses as a style of individuality and its meaning for significant others in the immediate family and community. He often stated that identity is a form of persistent character one shares with others.

Throughout his many writings, Erikson proposed that self-sameness and continuity are expressed through a conscious sense of individual identity; a coherent and stable, yet evolving, character; and the solidarity one develops with a group's ideals and social identity. He focused most strongly on occupational, religious, and political aspects of identity formation, because each of these emerges from the interaction of the individual with the social institutions that offer a form of ideology. For example, occupational identity emerges within a communist, socialist, or capitalist ideology; religious identity is formulated within Protestant, Catholic, Islamic, or other forms of ideology; and political identity is constructed within party, state, or group ideologies, such as Republican or Democratic ideological platforms in the United States.

LIFE STAGES

Erikson proposed an eight-stage theory of human development. These stages are set by societal expectations to accomplish specific developmental tasks. Each task, when successfully resolved, provides a particular strength to identity development. Erikson referred to each stage as a *crisis*. For each crisis, the individual can take one of two opposing resolutions. However, crisis is not meant to be a calamity or catastrophe. Rather, a crisis refers to a necessary turning point, a critical and crucial moment in development in which the individual moves in one direction or another. In the adolescent stage (Stage 5), this normative crisis stimulates identity consciousness, which

compels the individual to explore life alternatives (with occupational or vocational choices being of great concern) and make a personal ideological or career commitment. However, it is important to restate that all crises associated with the eight stages in the life span make contributions to the nature and quality of identity. A brief description of the eight stages follows.

Erikson proposed that the eight major dilemmas of the life span are universally experienced; that is, in one form or another, an astute observer of culture can find these eight stages. Indeed, he argued that many so-called cultural differences were due to *pseudospecification*: the creation of an illusion that differences exist when, in reality, things are more similar than different. In the first crisis, the infant establishes a sense of basic trust through social and physical care by an effective caregiver. If not, the child will mistrust others. During the toddler years, the child explores the world and is given secure psychological space to find a sense of autonomy. If not, the child will experience shame and doubt. During childhood, the child is supported in his or her initiative to master new learning tasks and develop a sense of initiative. If not, the child will experience guilt. In early adolescence, the child is encouraged to strive toward competence, mastery, and achievement and develop a sense of industry. If not, the adolescent will feel inferior. During adolescence proper, the adolescent must search and explore the question "Who am I?" Failure to answer this question results in role confusion. During youth or emerging adulthood, the individual either finds someone to engage in mutual sharing and trust to develop a sense of intimacy or, if not, feels isolated and alone. In middle and late adulthood, the crisis focuses on generativity versus feelings of stagnation, with the positive resolution of the crisis resulting in the ability to care for others. In the final adult stage of old age, the crisis centers on integrity versus despair and depression, with resolution resulting in wisdom.

EGO STRENGTHS

Each of the eight stages in life provides an opportunity to enhance the psychological outcomes (ego virtues) of identity formation. That is, positive resolution of each stage provides ego strengths that bolster and support a healthy personality in the form of a maturing identity. To develop trust is to provide a sense of hope for life and a positive future. To feel autonomy

and openness to exploration is to promote the virtue of (free) will. To encourage the resolution of initiative is to help internalize a sense of purpose. With a sense of industry, a youth acquires the ego strength of competence. To find an answer to "Who am I?" provides the strength of fidelity. To feel capable of intimacy is to promote the ability to love. During the adult years, generativity promotes the strength of caring, and integrity promotes a feeling of wisdom.

Each virtue reflects either forward or back on the fifth stage of identity formation. Therefore, although identity is stable over relatively short periods of time, it is also transforming and growing stronger with each life stage. However, the fifth stage of life is the one in which the most obvious and visible identity "work" is evident. This is because each society provides a scheduled time period for the completion of an identity. Although he recognized tremendous cultural variations in the duration, intensity, and ritualization of adolescence, Erikson proposed that all societies offer a period of *psychosocial moratorium* wherein the adolescent is expected to make an initial commitment for living and to establish a firmer sense of self-definition. The psychosocial moratorium period focuses heavily on career and occupational choices, educational preparation, and vocational identity formation.

MATTERING

Erikson acknowledged that like all personal knowledge, the self is constructed in a relational context. In particular, he recognized the importance and power of societal institutions, such as religion, culture, work, politics, and family. The ideologies of each institution set the structure around which identity choices are made. His most observant thoughts focused on biographical accounts of individuals such as Gandhi and Martin Luther, in which he discussed the psychological and social processes surrounding their identity formation and the importance of recognition from others about personal choices that are made by the individual. Essentially, Erikson argued that socialization processes that enhance imitation, identification, and internalization of societal values, goals, and directions are the building blocks of identity formation. In addition, socialization processes demonstrate direct feedback to the individual that his or her identity *matters* to others, which provides the "glue" between the individual's identity and social approval. This bond is made up of social recognition for values and goals

selected, institutional support for endorsing particular ideological viewpoints, and daily recognition by family members, teachers, peers, and others that one's identity is a good fit with the community and culture within which one lives.

EXECUTIVE FUNCTIONS OF IDENTITY

Erikson's writing focused on the interconnection between identity and ego mechanisms. In particular, he believed that the ego operated to provide a self-regulatory function in the development of self and the choices in behaviors and actions from moment to moment. Researchers have inspected the writings of Erikson and concluded that he essentially discussed five basic functions of identity and self-regulation. Identity offers the following five self-regulation mechanisms:

1. The structure for understanding who one is
2. Meaning and direction through commitments, values, and goals
3. A sense of personal control, free will, and self-regulatory abilities
4. A consistency, coherence, and harmony between values, beliefs, and commitments
5. The ability to recognize potential in the form of future possibilities and alternative choices

To give operational substance to Erikson's self-regulatory mechanisms, Toni Serafini and Gerald Adams developed a scale to measure each of the mechanisms proposed by Erikson's theory of identity development. In attempting to build scale items that were true to the nature of Erikson's theoretical ideas, the researchers first operationalized the five self-regulatory functions associated with identity. Next, items were constructed that reflect each of the operational definitions. These items were then used to develop what the authors call the "functions of identity scale." Each of the definitions is given below, with three items that measure the nature of each ego mechanism that Erikson proposed in his theoretical writings.

To Provide Structure for Understanding Who One Is

Definition: Identity provides an awareness of the self as an independent and unique individual. It is most apparent

when it is about to transform or change, when change is accompanied by extreme identity consciousness. A sense of understanding "who one is" provides the structure for self-certainty, self-esteem, and a foundation for an emerging and unfolding self.

Items: I have a clear awareness of myself as a unique individual. I am most conscious of my sense of identity when I must face change. I accept who I am.

To Provide Meaning and Direction Through Commitments, Values, and Goals

Definition: Identity is based on the capacity for faith that commitments or chosen values or goals will receive institutional confirmation. The commitments or goals of identity direct or channel behaviors and actions.

Items: The values I have developed influence my behaviors. I set goals and then work toward making them happen. I believe my values and goals are congruent with my actions.

To Provide a Sense of Personal Control, Free Will, and Self-regulation

Definition: Identity is based on the distinctions between passivity or compliance and an active or willful nature. Passive forms of identity are based on compliance, imitation, and identification. Active forms of identity are based on self-expression, independent construction, and a sense of free will and autonomy.

Items: I am an independent and autonomous person. I have actively constructed a strong commitment to my values and goals. My sense of who I am is based on self-expression and a feeling of free will.

To Provide for Consistency, Coherence, and Harmony Between Values, Beliefs, and Commitments

Definition: Identity formation is based on the organizing agency of synthesis or integration at one point and across time. Identity offers a sense of coherence between values, beliefs, and commitments. This sense of coherence is accompanied with harmony and low anxiety and a sense of peace with oneself.

Items: My values and beliefs are consistent with the commitments that I make in my life. I feel a sense of peace with myself and my identity. I believe my values, beliefs, and commitments fit together.

To Provide the Ability to Recognize Potentials in the Form of Future Possibilities and Alternative Choices

Definition: A sense of identity is in part based on self-initiative and a sense of purpose that offers the promise of fulfilling one's range of capacities. Thus, self-initiative, purpose, and capacities offer the promise of a tangible future.

Items: My sense of purpose in life will help guide my future. I have what it takes to make my future a reality. The decisions I make today about myself build the promise of my future sense of self.

Erikson wrote that passive identities based on imitation and identification will result in less strength in the form of these functions. He argued that active identity forms are associated with all five functions and that furthermore, these functions will provide the ego mechanisms that enhance personality and ego strengths.

IMPLICATIONS FOR CAREER DEVELOPMENT

Erikson viewed human development as being influenced by culture, social and historical events, and economic, religious, and familial forces. In industrial societies, adolescents and emerging adults are allowed a period of psychosocial moratorium to find or construct their identities. As an individual's identity emerges, in either a passive or active form, support from family, friends, and community members determines whether the identity is acceptable to society. In turn, as adolescents are supported by society, they develop a growing sense of fidelity: faith that they matter to people who are significant in their lives. Identity formation enhances the use of ego mechanisms that provide powerful self-regulation systems. These functions of identity, then, enhance the ego virtues of the individual in this stage of life.

The implications for career development are clearly discussed in Erikson's writings on occupational identity. Indeed, Erikson viewed occupational identity as the most central domain of identity formation, followed by religious and political identity. During the psychosocial moratorium, much attention and energy are directed at defining or constructing one's work interests and building skills in the technology of the selected occupational choice.

To summarize, identity formation, such as occupational identity, is constructed within a broad contextual environment of culture, institutions, family, and friends.

As occupational identity emerges, certain important self-regulation mechanisms emerge to direct the individual in regard to values, beliefs, and commitments to work. These mechanisms promote the formation of ego virtues or strengths that enhance one's personality. Furthermore, these factors help an adolescent emerge into adulthood with a commitment to work, occupation, and ego strengths that enhance self-esteem and mental health, and a stable and achieved sense of direction that is supported by society. However, when this important set of events is not encouraged in a psychosocial moratorium or the youth fails to meet the challenge of identity versus role confusion, there will be considerable emotional angst, anxiety, and lack of direction in the youth's life and future.

—Gerald R. Adams

ETHICS AND CAREERS

Individual and group behavior is governed in part by *ethics*, the moral principles or values on which judgments are made as to whether actions are right or wrong, good or bad. The minimum ethical standards in a society are codified in law, but ethical behavior requires going beyond mere adherence to the letter of the law. The ability to engage in commercial and other types of relationships is dependent on trust and general acceptance that standards or codes of behavior will be upheld. Community agreement regarding acceptable and unacceptable behavior enables transactions to take place with some sense of order and predictability.

This entry first examines the organizational context in which choices about ethical behavior take place and then discusses sources and career effects of ethical values. The stages in development of moral reasoning are then examined and also the types of ethical issues

associated with specific career stages. The special case of organizational whistle-blowers is considered. Finally, the bases for making ethical decisions and opportunities for careers in the field of ethics are discussed.

ORGANIZATIONAL CONTEXT

In the late twentieth and early twenty-first centuries, a number of highly publicized events concentrated negative attention on ethics in public life and in private and public organizations, such as WorldCom, Enron, Tyco, HealthSouth, and Arthur Andersen. Consequences for individuals held responsible for these legal and ethical failings were career ending in many cases.

A plethora of potential ethical issues faces individuals at all organizational levels: discrimination, sexual harassment, falsifying financial information, insider trading, confidentiality and privacy violations, lying (to managers, colleagues, or customers), stealing, bribery, undercutting coworkers, claiming credit for work done by others, misrepresenting credentials, covering up unsafe working conditions and products—to name just a few types of ethical violations that occur in organizations. Most individuals can expect to face and handle many ethical issues throughout their careers.

As organizational changes accelerate, new situations with uncertain ethical overtones require action: downsizing, outsourcing, employability replacing career ladders, use of contingent workers, technological changes, and the increasingly global nature of competition. These changes impact careers at all organizational levels and present new challenges to those trying to balance their own career development and the needs of the organizations that employ them. The changing nature of workers' psychological contracts introduces new tensions between individual career considerations and obligations to employers. As job security fades and individuals recognize a lack of commitment from their organizations, they reciprocate with less commitment to their employers. The accepted exchange relationship between employer and employee has eroded, and individuals must now take responsibility for maintaining and updating their skills and managing their careers.

SOURCES AND CAREER EFFECTS OF ETHICAL VALUES

Individuals develop ethical standards as a result of socialization in their families, community, religious institutions, and professions. When they join organizations, the contexts in which they work become a

powerful determinant of ethical choices. In fact, organizational context is a stronger determinant of ethical behavior than individual moral reasoning ability or espoused ethical standards. Individuals have been shown to use lower levels of ethical reasoning when making decisions in business settings than they do in nonbusiness contexts. Organizational culture, the presence and strength of a code of behavior, role-modeling by managers, the reward system of the organization, and personal career consequences of ethical choices may override the individual's code of behavior or ability to reason ethically.

Ethics impacts careers in a number of ways. Personal beliefs about work that is valuable to society and consistent with the individuals' values influence the choice of a career. Decisions to join, stay with, or leave a particular career or organization may be made on the basis of congruence between the individual's moral beliefs and those enacted by and required of members of the profession or organization.

One criterion for determining whether a profession exists is the presence of a generally accepted code of ethics for those working in the area. Professions thus socialize their members into the behaviors regarded as ethical by their practitioners; however, these professional ethical standards may come into conflict with expectations for employees of particular organizations. For example, certified public accountants must pass an examination on the ethics of accountancy. If their employers request that they falsify accounting records or violate generally accepted accounting practices, the ethics of their profession will be in conflict with the expectations of their employers—and possibly with their own ethical standards.

DEVELOPMENT OF ETHICAL REASONING ABILITY

Movement through stages of ethical reasoning occurs as individuals mature. At the lowest levels of moral reasoning, *preconventional*, individuals make choices based on hedonistic consequences for themselves: They do what gives them pleasure or what allows them to avoid punishment or pain. At this level of cognitive moral reasoning, individuals are concerned about the consequences of their actions for themselves. As people mature, their ethical choices are influenced by the standards of the groups to which they belong. Conformity to rules and laws of peer groups govern ethical choices at the *conventional* level. At the highest level of moral reasoning,

postconventional or *principled*, individuals' ethical choices are made by reference to principles they have accepted or developed for themselves. Here, the concern is for consequences to society at large, not just to individuals and their reference groups.

ETHICAL ISSUES AND CAREER STAGES

Different types of ethical dilemmas are faced by individuals at different career stages. Using Donald Super's career development framework, researchers have found different types of ethical issues faced by those in the exploration, establishment, maintenance, and disengagement stages of their careers.

In the aptly named *exploration career stage*, individuals focus on acceptance from peers and also may be most vulnerable to pressure from superiors. If achieving performance norms is critical to peer acceptance, this need for acceptance by peers can lead to ethical shortcuts. If the organization rewards goal achievement, the individual in this early career stage may feel pressured to achieve those goals using any means, ethical or unethical. The potential for ethical shortcuts is increased if superiors themselves do not model ethical behavior.

When individuals enter the *establishment stage*, they have made some commitment to a particular profession or career and are increasingly concerned with career advancement. High levels of competition may result in individual ethical compromises to achieve promotion. In individuals with high success drives, this temptation may be intensified. In the establishment stage, the pressure to take ethical shortcuts may be mostly internal, in contrast to the exploration stage, in which pressure comes from peers and superiors.

During the *maintenance* and *disengagement stages*, both external and internal pressures to violate personal ethical standards in pursuit of organizational goals can be expected to lessen. With established track records, decreased competition, and more personal acceptance of one's achievement levels, both internal and external pressures for unethical behavior can be expected to decrease. In addition, as individuals become more focused on their work legacies, they may gain more incentive to help others achieve their life and career potential and also further integrate their own careers into their whole life systems. On the other hand, individuals in the maintenance stage are expected to be at the top of their careers, often in positions that may lead to temptations to encourage

subordinates to use ethically questionable means to achieve organizational goals. Furthermore, individuals who have reached upper-management positions may face external pressure from stockholders as well as from their boards of directors to do whatever it takes to increase share price.

Thus, the nature of the pressure to behave unethically, the types of ethical issues faced, and the motivation for ethical/unethical behavior can be expected to vary over the course of a career, but no career stage immunizes individuals from the necessity of handling ethical issues.

Whistle-blowing

In extreme cases, individuals may choose to become whistle-blowers, even though the consequences of such actions are almost always detrimental to the individual's career. Whistle-blowers speak out about illegal or unethical behavior in organizations. They may blow the whistle internally or, after exhausting internal reporting systems, publicly report organizational wrongdoing. At the other extreme, individuals who remain in positions or organizations that require some violation of their personal ethical standards may disconnect their emotions from the work situation and therefore reduce commitment to the organization and fail to engage in organizational citizenship behaviors. Perceptions of ethical culture are strongly related to both job satisfaction and organizational commitment and thus to organizational citizenship behaviors.

Issues differ in their levels of moral intensity. Moral intensity is higher—and whistle-blowing is more appropriate—when consequences are greater, when there is general social consensus that an action is wrong, when it is highly likely that the harmful consequence will actually occur, when the event is imminent and proximate to the individual, and when the effect is concentrated rather than diffuse. Enron whistle-blowers Sherron Watkins and Maureen Castaneda felt the legal and ethical violations at Enron justified their going public with the company's lapses. In another case, the *Challenger* disaster might have been avoided had the engineer, Alan McDonald, who disagreed with the judgment regarding the safety of the O-rings, taken his concerns outside NASA.

Being a whistle-blower frequently carries heavy career consequences. Most whistle-blowers lose their jobs as a result of their reporting legal or ethical

violations. They may also be unable to find employment in their professions after the event. Most suffer financial and/or personal reverses as they pursue cases, which frequently drag on over a number of years. Nonetheless, whistle-blowers feel a moral imperative to expose organizational actions that endanger others, even at the cost of their own careers.

Integrity, honesty, and a strong work ethic are high on employers' lists of traits and skills they seek in employees. However, many employees fail to see a positive relationship between ethical behavior and career advancement. In fact, they believe they must choose between adhering to their personal ethical standards and their own career progressions. Concerns for organizational profit and/or survival often trump individual concerns about honorable behavior. Ethicists thus recommend that early in their careers, individuals make decisions about the lines they will not cross. If these decisions are not consciously taken when there is time for thoughtful consideration, individuals may find themselves unwittingly compromising their integrity as they respond to the organizational pressures of the moment.

BASES FOR MAKING ETHICAL DECISIONS

Philosophers have suggested prescriptive approaches to ethical thinking. The *utilitarian approach* judges whether an action is ethical by examining its likely consequences. Among the alternatives available, the ethical choice is the one that creates the greatest good or the least harm for the greatest number of people. This approach, with its roots in economics, is embraced by the majority of businesspeople and by many in other fields. Using utilitarian reasoning, for example, management fires some workers in an attempt to improve profits, attract investors, and retain other jobs, or they close a plant in one town because its inefficiencies have a negative impact on profits of more efficient plants in the same organization. Utilitarianism works well for those in the majority, but minorities do not fare well under this philosophical approach to making ethical decisions. That many others benefited from the decision may offer small comfort to those who lost their jobs or to the town whose economy was decimated when the plant closed. In addition, the likely consequences of all alternatives cannot be known with certainty. Information about some consequences or even about some groups or individuals who will be affected by the decision may be unavailable.

A second approach to ethical decision making is the *rights approach*. A decision is considered ethical if it avoids violating the basic human rights of any stakeholders affected by the decision. Difficulties with this approach include the impossibility of getting universal agreement on what basic human rights are. To some, these rights include the right to a livable wage or health care; others recognize fundamental rights to life and freedom, but to little else. Furthermore, rights can conflict, and there are no clear rules for determining which rights take precedence in a particular case.

In the *justice approach* to making ethical choices, decisions are considered ethical if the same procedures apply to all who are affected by the decision (procedural justice) or if those who are similarly placed receive similar outcomes (distributive justice). Thus, those with similar professional qualifications, workloads, and performance levels should receive similar compensation; those with lesser credentials, workloads, and performance levels should be compensated less than those in the first group, but all members of the same performance class should receive similar outcomes.

The *virtue approach* focuses on the integrity of the decision maker or moral actor. Intentions and motives as well as actions themselves are considered in judging whether or not an action is ethical. This approach relies on community standards of behavior. In professions, these standards are encapsulated in codes of behavior accepted by practitioners in the field.

ORGANIZATIONAL CAREERS IN ETHICS

Career opportunities in the field of ethics are increasing. Growth in the demand for ethics officers in corporations is partially a response to changes adopted in 1991 by the U.S. Sentencing Commission. The sentencing guidelines reduce penalties for corporations found guilty of violations if they can demonstrate that they have comprehensive ethics programs in place. Having a high-level executive with direct responsibility for ethical behavior in the organization is a strong signal that companies take ethics seriously. More recently, the passage of the Sarbanes-Oxley Act of 2002 has reinforced the pressure for compliance officers who are held responsible not only for ensuring compliance to ethics laws but also for the development of an organizational climate and culture that support ethical behavior.

The responsibility for compliance with employment laws, ensuring nondiscrimination in hiring and

treatment of employees, and setting programs in place to prevent sexual harassment is generally housed in human resource management departments. Thus, careers in human resource management also require a thorough grounding in law and ethics.

Ultimate responsibility for ethical behavior in organizations, however, still rests with individual employees. Company titles that include the word *ethics* may be limited, but the necessity of considering the ethical implications of organizational decisions permeates the entire organization and affects careers at all levels.

EXECUTIVE COACHING

Executive coaching involves one-on-one discussions between an executive and a behavioral science professional on topics involving skills and style in a professional setting. Coaching has several advantages over

other types of executive development options, such as class activities, group facilitation, and consulting advice. Convenience, relevance, and the self-directed nature of executive coaching are important advantages that one should consider in deciding to use coaching over other ways of achieving professional growth and greater organizational effectiveness. Central to executive coaching are the notions that the objectives are jointly determined by the executive and the coach, that it involves observation and assessment of behaviors related to these objectives, and that these observations and assessments are shared. Coaching takes place in small increments, often separated by weeks, and must be both intimate and flexible. While coaches may offer perspectives on substantive issues and the coaching agenda, executives must determine learning goals and issues around which they desire to be coached.

Three different perspectives are relevant for an executive coach to consider in conversations regarding executive performance: the individual executive, the work unit, and the organization. An initial consideration is to explore the executive's self-awareness. A first step is to compare the individual's self-perception of his or her relevant strengths, weaknesses, and suggested areas of development with the perceptions of those around him or her. These comparisons provide a context and basis for further dialogue and exploration. The agreement of the executive's self-perception and others' perceptions on strengths and weaknesses capitalizes on an executive's established talent and social/professional network. Examining strengths and weaknesses provides insights into the habits of the executive's business interactions, as most people tend to repeat the patterns of behavior that come most easily to them, leading to both positive and negative outcomes. This repetition is the basis for defining one's style and exploring whether there is a need for more flexibility in approach. For example, an outgoing and verbally fluent executive may be coached to deliberately hold back in discussions to allow less articulate counterparts to expound on their viewpoints.

The second perspective focuses on the interpersonal interactions of the executive within his or her work unit. A coach must look at the quality and impact of an executive's interactions with subordinates, peers, customers or clients, and those in more senior positions. The gap between the executive's intentions and the impact of his or her behavior on others is a key point of analysis. For example, an executive may believe that providing a casual or superficial comment about an issue will

stimulate others to think, whereas those on the receiving end of the communication may view the comment as an inflexible opinion. In this case, the gap between the executive and others would result in fewer challenges to the executive's decision, because others believed that the opinions were less flexible than they were intended to be. Coaches must examine the widely held perceptions about the executive for the purpose of considering the impact of these perceptions on the executive's effectiveness.

The third perspective assumes a broader, longer-term view as the coach and executive examine the executive's relationship with the firm over time. Specifically, the coach should guide the executive in addressing issues of *fit* between the executive and the cultural and political environments within the firm. Differences between the cultural norms and an executive's style provide a basis for possible misperceptions by those within the firm. For example, in a firm with a strong task focus, an executive who openly discusses emotional issues may be judged to be less effective. The coach's role is to help diagnose such situations to stimulate the executive's interest in attending to the issue.

TOPICS OF FOCUS: STYLE AND SKILLS

Two topic areas provide a focus for much of the multilevel analysis suggested above: personal style and strategic management skills. *Personal style* is one's preferred way of interacting with others or pursuing a goal. One's style is rarely inherently good or bad. A style may be advantageous or a hindrance when considered in the context of a firm's cultural environment or the specific expectations and needs of the immediate team of peers, subordinates, and bosses. The norms and values of a firm are reflected in the way business is conducted, and executives are expected to conform to the expected behavioral norms.

One approach to understanding differences in interpersonal styles was developed by Will Schutz, who created the Fundamental Interpersonal Relations Orientation Behaviour Questionnaire. The questionnaire, known as FIRO-B, provides measures of the extent to which one expresses and wants from others three interpersonal needs: inclusion, control, and openness. Each interpersonal need is measured on the basis of how likely the respondent is to express this need and how much the respondent wants to have the need expressed toward him or her. The six measures

can be applied to many executive positions and often help to explain differing perspectives in situations involving interpersonal friction.

For example, consider how behaviors demonstrating a low need to express inclusion may be interpreted by others with a high need to be included. The executive with a lower need to express inclusion may avoid interactions with others unless there is a defined need for communication. Others may view this task-driven frequency of contact as a sign of lack of interest or commitment to them or to the team. The executive demonstrating low expressed inclusion may be attempting to respect the time of others by limiting interaction to only the most essential issues. An executive with a low need for inclusion may view the repeated invitations by associates to interact as unnecessary or assess the interactions as superficial if they do not lead to a completed task. In issues relating to style, the role of the coach is to assess the behaviors, challenge the executive to consider alternative patterns of interaction, and help identify and clarify the potential alternative interpretations of personal style.

While style and skills are acknowledged to be distinct and measurable arenas by the research community, the distinctions between style and skill are sometimes not recognized by executives. Identifying the distinction can be an important contribution of the executive coach. The blurred distinction is often a result of attributing skill, or lack of skill, to a preference in style. For example, an executive with a high need to express control may assess another executive who has a lower need in this dimension as lacking "leadership" because of a belief that "leaders provide direction"—when, in fact, the latter executive may think that he or she has already provided direction.

The definition and importance of different skills are determined by the organization with respect to the executive's position. Many firms have defined skills by level and have performance appraisal systems based on these competencies. The role of a coach is to reach agreement on a defined goal of targeted skills, with measurement criteria that are observable and accepted by the relevant players in the work unit. A plan of action includes advisement on creating opportunities to demonstrate the skill and a plan to seek feedback from colleagues so as to determine whether or not the new behaviors are successful.

The six skill sets identified by Stephen Stumpf are relevant to many senior executives: knowing the business and markets, managing subunit rivalry, finding

and overcoming problems, staying on strategy, being an entrepreneurial force, and accommodating adversity. For example, demonstrating the skill set of being an entrepreneur would involve a clear articulation of a vision, communicating the vision with clarity and getting others excited about it, and influencing others to take the desired actions toward execution. The executive and coach would discuss the need for this skill, where it was most needed, and how the executive might proceed to exercise this skill to improve the performance of the unit and organization.

The field of executive coaching is relatively young and just beginning to be broadly accepted as a topic for academic research. Although executives have been “coached” by peers, friends, and mentors for decades, hiring individuals with extensive behavioral science knowledge and experience in working with senior executives is still limited to those firms with substantial resources to fund the effort. One factor that supports the continued growth of this field is that executives want more customized and convenient opportunities for growth. In addition, executive coaching has gained support within executive suites because it is believed to be of significant value by those being coached. Finally, there is a growing body of research to support the relationship between executive coaching and leadership effectiveness.

EXIT INTERVIEW

An *exit interview* is a discussion between a departing employee and a representative of the organization that

occurs in the last days of an employee’s tenure. The interviewer is typically a manager or a human resources professional. The interview usually takes place on company property during work hours. Exit interviews are widely believed to be helpful to organizations that wish to better understand why people leave their jobs. Recent research has found that more than 80 percent of large organizations use exit interviews. More than 90 percent of the executives in firms that use exit interviews believe that they provide useful information.

Exit interviews serve a number of beneficial purposes beyond providing information about why people leave. Some organizations use the interviews to persuade employees to stay (e.g., by offering improved wages, working conditions, transfers, or promotions). Other organizations use the interviews as a public relations exercise to ensure that the parting employee leaves the company on a positive note. The exit interview can serve as a last opportunity to inform employees about their remaining obligations, rights, and benefits packages. It can be used to remind employees of their responsibility to protect the organization’s intellectual property. A final purpose might be to protect the organization from legal proceedings by providing information about incidents of discrimination, sexual harassment, or other inappropriate activities.

Notwithstanding the many perceived benefits of exit interviews, researchers who have studied them are much less enthusiastic. One approach to studying exit interview validity highlights the costs to departing employees of telling the truth. Some of those potential costs include (a) the risk of burning bridges with the former employer, (b) the risk of conflict with individuals in the former organization, (c) the risk of incriminating or otherwise hurting friends and coworkers who remain with the organization, and (d) the risk of repercussions from the former employer (e.g., poor references). Not surprisingly, research shows that employees are more likely in exit interviews than in employee surveys to give non-job-related factors as their reasons for quitting. Another approach to assessing the validity of exit interviews questions the ability of interviewees to accurately recall their reasons for quitting—a problem compounded when the actual time of departure lags significantly behind the time of decision making.

Additional concerns about exit interviews exist. One study suggests that only about 50 percent of organizations that conduct exit interviews actually use the

information. Other studies emphasize the need to use qualified interviewers; however, relatively few firms have qualified interviewers conduct exit interviews, because of cost, timing, or other constraints.

Researchers have identified a number of ways to improve the quality of exit interviews. First, they recommend the use of structured interviews. In short, that means the interviewer uses a set of open-ended questions and a standardized tool for reporting answers (e.g., computer template or tape recorder). Second, researchers advocate the use of neutral, trained interviewers. Such an interviewer would not have had prior contact with the employee, would follow the interview protocol closely (e.g., avoid probing questions that could bias the responses), and would take detailed notes. Third, researchers point to the need to guarantee confidentiality and anonymity to the departing employee. Practically speaking, the interviewer should state that confidentiality will be maintained unless legal obligations prohibit such confidentiality (e.g., Title VII of the Civil Rights Act of 1964).

Organizations that wish to better understand why some employees stay and others quit have many additional tools available to them. One is the exit questionnaire, which is completed by employees before they leave. Such a questionnaire might be especially helpful in the context of organizations in which there is low trust between employees and their supervisors. *Exit questionnaires* or surveys may also be less costly in time and energy to implement. Furthermore, they may generate more reliable, valid, and specific information. Another tool is the use of *external consultants*. The consultants can use either interview or survey techniques to obtain information from departing employees. The primary advantage of external consultants is their independence from the firm. As an added layer of protection for respondents, the consultants frequently promise to report only aggregate data, thereby protecting individual employees from the costs associated with telling the truth.

An alternative approach to understanding reasons why people stay and why they leave is an *employee morale survey*. Such surveys usually solicit employee attitudes such as job satisfaction, organizational commitment, perceived job alternatives, and job involvement and then relate them to reported job search behaviors, intent to leave, and actual leaving over an extended period following the survey collection. Such prospective research designs have proven more

reliable and valid than exit interviews. They have the added benefit of providing information for acting immediately on issues to curb turnover, rather than waiting for the turnover to occur and then commencing action, when, for all practical purposes, it is too late. A driving analogy is that employee morale surveys represent a forward-looking approach (i.e., looking through the windshield), whereas exit interviews represent a backward-looking approach (i.e., looking through the rearview window).

Recent research has identified exit surveys as useful means of gathering ethics-related information within an already-existing framework in most organizations. The same research found that organizational members were willing to freely discuss five areas in an ethics exit survey: illegal organizational activities, unfair administrative actions, illegal human resource activities, dishonesty, and mistreatment of organizational constituencies. Such data can be used in ethics training, policy evaluation, assessment of ethical climate, and identification of specific ethical (or legal) issues. Based on these findings, future research is likely to focus on exit interviews as a source of valuable information about ethical issues.

In sum, while the use of exit interviews is pervasive in organizations, human resource professionals and managers concerned about employee retention will use many other tools to complement them. Performance appraisals, counseling, career-planning interviews, and employee morale surveys will help provide perspective on issues of concern to employees as well as actionable ideas for improving the organizational environment. Such activities ideally reduce employee turnover—and the need for exit interviews.

EXPATRIATE EXPERIENCE

From ancient times through the colonial era, expatriation was a means of enhancing political and economic influence to dominate new frontiers. Today, business expatriates are performing similar functions. A *business expatriate* is a citizen of the country in which the parent corporation is located but works in a foreign country at a subsidiary or branch office of the parent company. Expatriating parent country nationals has become a significant means for the transfer of the philosophy and strategy of an organization's headquarters from the parent to the foreign operations. By linking the use of expatriates to a corporate strategy of globalization, expatriation could be seen as a way to establish control and coordination, at the same time creating international informal personal networks between managers in the corporate organizational structure. By assigning trusted managers from the parent organization to the foreign operations, greater control is made possible. Through a process of organizational acculturation, the expatriate, who identifies with the policies of the headquarters, transfers the culture of the parent organization to the foreign subsidiary. The parent company greatly benefits from such internationally mobile managers, who have proven themselves successful in handling relationships with the head office, host country relations, and the management of foreign operations.

The development of the careers of expatriate managers is crucial for many organizations. Without world-class managers in the global marketplace, many international firms would not be able to effectively compete against major global competitors. Expatriation leads to a competitive advantage in creating a pool of cosmopolitan executives sensitive to international opportunities and threats, representing an international education that cannot be replicated in any classroom.

Five broad categories of attributes of expatriate success have been identified: job factors, relational dimensions, motivational state, family situation, and language skills. These attributes can be potentially enhanced by career development activities available to international corporations for assisting expatriate careers.

Job factors have traditionally been considered as important components for expatriate success, and an overwhelming majority of firms use technical expertise as their main criterion in selecting expatriates. Although functional competency is a relevant initial requirement,

other job factors such as managerial skills and administrative competence are also important considerations in selection. *Relational dimensions* include a number of factors associated with individual characteristics, such as personality, more-transient socialized value systems, and more-incidental traits and behaviors that might result from an individual's interaction with immediate environmental conditions. This category most often accounts for the expatriate's success or failure. Relational attributes are especially important for expatriates, such as top management and sales executives, who have many contacts with host country nationals. *Motivational states* encompass a number of factors that may operate as expatriation incentives. *Family situations* involve critical characteristics of the expatriate's spouse and children and the nature of the family relationship. A mutually supportive family is necessary for living overseas, and it provides the resilience that the expatriate needs during a time of stress and daily life challenges. Finally, *language skills* include factors essential for effective communication by the expatriate in the host country.

Among the career development activities for expatriates, job postings allow expatriates to remain aware of internal job vacancies elsewhere within the parent company's operations. Corporate online job-posting systems can often be accessed through intranet sites. Career path information provided by the organization offers expatriates the opportunity to assess their own plans against those reflected in the corporate career paths. Annual performance reviews can serve developmental, evaluative, and administrative purposes for the expatriate. It is evident that domestic performance appraisal systems must be customized to become effective for expatriate situations. Fast-track programs make expatriates aware of proposed organizational plans for them, often involving rotation through different divisions or areas of the corporation. Information on career planning provided by the organization simply means the organization reveals its specific plans to the expatriate, which is the general case for fast-trackers. Professional career specialists can help expatriates manage their own careers and also provide individual career counseling. Such services can be offered face-to-face, over the telephone, or online. Career testing might include the use of interest inventories, personality profiles, and aptitude tests. The results of such tests are assumed to help the expatriate understand and articulate important personal determinants of career direction and satisfaction.

Expatriates can often benefit from coaching and/or mentoring. Mentoring can be undertaken by senior peers or superiors or simply a person the expatriate trusts. A good mentor is not there to provide the answers but to assist an individual in developing his or her skills in resolving career-related complications. Assessment centers include multiple independent evaluations, often providing a conclusive indicator of a participant's potential for success in a range of alternative careers and leaving little doubt for the individual as to what future options are available or possible. However, assessment centers could also be used for developmental purposes and are, as such, a very versatile tool in helping expatriates with career management. Career-planning workshops are purposeful learning experiences emphasizing self-assessment and development of planning skills. Effective workshops help expatriates analyze their interests, values, goals, and capabilities; consider their options; make decisions related to their present jobs; and establish personal development plans.

Not much academic research has been undertaken on expatriate career development, but studies suggest that the availability of corporate career development activities seems to be low, indicating little interest on the part of parent organizations to assist in the development of their expatriate managers' careers. As indicated above, this contradicts the best interests of globalizing firms, which are dependent on a pool of cosmopolitan managers for their business expansions.

Large parent organizations with substantial interests in international business operations generally assist their expatriates' career development more than other firms. This is intuitively justifiable and, indeed, serves their best interests. However, it poses a problem with regard to small- and medium-sized enterprises with less resources and little experience to cater to their expatriates' career-development needs.

Experienced expatriate managers generally use more of the available corporate career-development activities than do less experienced managers. Such a tendency might complicate the procurement and

advancement of new generations of expatriate managers. Since expatriate careers could take shape at an early stage, it is most unfortunate if junior managers do not make much use of available means to guide their international careers. Maintaining a sufficient corporate pool of cosmopolitan managers over time helps compensate for resignations and managers choosing to settle down in foreign locations. Developing international expertise this way is a long-term undertaking, and a company must invest substantial resources and efforts to develop such a group of cosmopolitan managers.

Regarding gender differences, corporate career development seems less available to female than to male business expatriates. This may demonstrate a gender bias in corporate support for expatriates. For reasons of talent maximization, international firms cannot afford to limit their pool of talented human resources by excluding particular groups of employees. Business firms may unintentionally create a considerable disadvantage for women in their struggles to internationalize, since women may not be attracted to or motivated for international careers to the same extent as men.

FAIR LABOR STANDARDS ACT (FLSA)

The distinction between *exempt* and *nonexempt* employees, a familiar dichotomy indicating exemption from certain federal labor regulations, was created through the *Fair Labor Standards Act* (FLSA) of 1938. The act instituted many taken-for-granted characteristics of employment in the United States: the five-day workweek, the 40-hour workweek, and overtime pay. The written intent of the act was to guarantee a minimum wage, regulate working hours, establish a premium for overtime pay, and prohibit child labor. Because of prior legal battles regarding the constitutional limits of federal labor legislation, the FLSA was written to cover interstate commerce. Even so, challenges to the authority of the act continued into the 1940s, with a range of industries challenging the new law. The restriction to interstate commerce left ample opportunities for exempting labor in enterprises with predominantly intrastate sales; this and industry-specific exemptions from the law left a considerable number of workers uncovered. The categories of exempt and nonexempt workers are often associated with specific occupations, but they constitute only part of the detailed rules and amendments that have been used to establish coverage.

Historically, four general rationales have been used as the bases of sector and establishment exemptions. For seasonal or irregular work, it was argued that legislation meant for weekly year-round employment presented an undue burden. Second, due to the lack of economic resources (by virtue of economies of scale or the capacity to substitute capital for labor), some firms

(those with sales below a set minimum) and sectors (services) were exempt from the provisions. Third, in some cases, exemptions were based on the characteristics of the workers. It was argued that minimum wages were not needed when the labor force was predominantly young, when the individual workers tended to have other primary employment, and when the earnings were not likely to be the primary household earnings, clearly implying age-based career stages and gender-based careers. Finally, in cases in which wage and hour conditions had already been established by collective bargaining between labor and management (for example, transportation in the late 1930s), coverage by the FLSA was seen as unnecessary.

A lack of need also formed part of the rationale for exempting outside sales, administrative, professional, and executive employees. These occupations are not typically vulnerable to low wages. Furthermore, workers in these occupations tend to have good benefits and opportunities for advancement, which are seen as compensating for longer-than-standard workweeks. Even so, to classify as exempt, these workers must make a minimum salary and be engaged in occupation-specific duties and tasks for most of their time at work, or they must be certified or licensed by the state in order to do their work (e.g., teachers).

The FLSA has been amended many times, not only for the purpose of updating values—such as salary limits and the minimum wage—but also to alter exemptions and coverage. Current debates regarding the act involve recent changes in the criteria used to exempt workers from overtime regulations.

FAMILY AND MEDICAL LEAVE ACT (FMLA)

Recognizing the difficulties that an increasing number of workers face when they combine job with family responsibilities, many lawmakers and activists fought for and won the passage of *the Family and Medical Leave Act* (FMLA) of 1993. Moving beyond prior legislation that allowed maternity leave, the FMLA mandates that employers provide up to 12 weeks of unpaid, job-protected leave for a worker's own serious medical condition, maternity disability, care of a newborn or newly adopted child, or care of seriously ill children, parents, or spouses. The act also guarantees the continuation of any existing health insurance coverage during the leave.

More than 35 million women and men have taken job leave under the FMLA since its passage, averaging about 10 days. Although opponents decried mandated leave as potentially costly and harmful to productivity, a bipartisan congressional committee (in both 1996 and 2001) found that 90 percent of companies subject to the FMLA experienced no negative impact on productivity, growth, or revenues.

The passage of the FMLA in 1993, proudly claimed by President Clinton as the first bill he signed into law, was the culmination of more than a decade of political negotiation. It was vetoed twice by President George H. W. Bush and opposed (then and now) by business interests, including the Chamber of Commerce. Advocates of the bill included members of Congress, led by Senator Christopher Dodd (D-Connecticut) and former Congresswoman Patricia Schroeder (D-Colorado), to whom Dodd gives credit

for conceptualizing the act. Unions, such as the AFL-CIO, 9 to 5, and CLUW, provided critical support for the passage of the act by testifying before hearings and lobbying Congress.

The FMLA moved beyond prior federal legislation, specifically, the 1978 Pregnancy Disability Act (PDA), which required only that maternity leave be covered under the provisions of any existing temporary-disability leave policy. The PDA did not require the establishment of any maternity leave in cases in which temporary disability leave was not available, nor did it allow use of such leaves for non-pregnancy-related family needs. Furthermore, there were no provisions for men to take any job leaves for parenting.

In contrast, gender neutrality in family leave taking was a primary goal of the FMLA, as stated by the early sponsors of the bill. In a 2003 Supreme Court ruling, the majority opinion reiterated this initial view.

LIMITATIONS OF THE FMLA

Albeit an important advance over prior policy, the FMLA does not provide universal protection for employees who need leaves to provide care for their family members. Employees are eligible only if they have worked for an eligible employer for at least one year and for at least 1,250 hours in the previous year. Eligible employers are public agencies or private employers with 50 or more employees working within a 75-mile radius. Those who work for small employers are uncovered, and the act also does not provide leaves for temporary workers, whose numbers are growing. Employers excluded from these provisions, about 90 percent of establishments, employ approximately 40 percent of the workforce. Furthermore, as Jane Waldfogel has reported, almost one-fifth of workers for covered employers do not meet eligibility requirements, leaving approximately 53 percent of the workforce ineligible for FMLA leave. The FMLA was clearly a major victory for those interested in promoting family-friendly laws, but a substantial portion of the workers who took leaves after the passage of the FMLA could have taken these leaves before its passage, because of state-level laws or leave policies enacted voluntarily by employers.

Although the FMLA theoretically provides gender-neutral access to leaves, actual leaves taken post-FMLA remain far from gender neutral: Women (especially married) take the overwhelming number

of leaves. A large number of men take leaves, but typically when they themselves get sick or occasionally to care for some other family members (especially a seriously ill wife or newborn child). Women are more likely than men to say they need leaves, to take leaves, and to take longer leaves.

These enduring gender differences suggest that access to unpaid leaves is not enough to counter other influences that shape men and women's leave taking. Why do such gender differences persist? A key problem is that leaves are unpaid. Even though both men and women are now allowed to take leaves to care for their families, men still earn substantially more than women; this means taking an unpaid leave is more expensive for them and their families than it is for women. The FMLA cannot seriously counter the inequalities rooted in the wage gap between men and women, a gap sustained by preexisting policies. Moreover, the FMLA was introduced in the context of existing legislation (the PDA) that provided paid disability leaves for some women. Thus men and women do not have similar access to useful family leaves, at least for infant care, because some women (but certainly not all) have paid leaves, but almost no men do.

Consequently, because leaves mandated by the FMLA are unpaid, such policy exacerbates rather than alleviates certain forms of inequality. At the same time, it helps stabilize the unequal division of family work—where women do far more than men—still so characteristic of families in the United States.

In addition to perpetuating gender inequalities, the provisions of the FMLA result in, or at least bolster, other inequalities among workers—by race, class, marital status, and sexuality. Although the FMLA does not specifically address racial or ethnic inequality, some research suggests that race and ethnicity play a role in the need for and ability to take family leave; that is, African Americans and Latino(a)s, whether because of greater health problems or greater exchanges with relatives, may need leaves more than Whites. At the same time, they are, on average, less able to afford unpaid leaves.

Moreover, race and gender operate jointly in their effect on people's leave taking. Amy Armenia and Naomi Gerstel found that although there are no significant differences in leave taking between White women and women and men of color, White men are significantly less likely than any other group to take family leaves. This intersection of race and gender may be connected to cultural factors, such as the

centrality of children or kinship more generally in men's and women's lives or economic factors such as wage differentials. There is some evidence that African Americans, especially women, are more involved with kin than Whites. Moreover, a larger wage gap exists between White spouses than between African American spouses. Both these differences may lead to more gender equality in leave taking among people of color than among Whites.

Given the provisions of the FMLA, marital status and sexuality also affect leave taking. Having a spouse or partner improves women's and men's financial abilities as well as their need to take family leaves. Because the provisions of the FMLA include spouses but not unmarried partners, lesbian and gay employees, like cohabiters more generally, can legally take leaves to provide care for their children but still in most states cannot take leaves for their partners or their partners' children.

Research to date, although limited, suggests that class position affects both the ability of workers to take family leaves and the length of their leaves. Because leaves are unpaid, the working poor, whose numbers are large and growing, cannot afford to take leaves. And these are the workers most likely to have sick family members or to have no other paid-leave options. Research shows that although women with lower household income are more likely to perceive the need for family leaves, they have less access to family benefits in general and take less time off after childbirth than do women from higher-income households. When they do manage to take leaves to provide care for their families, the loss in income is often enough to push them below the poverty line. Approximately 9 percent of FMLA leave takers report that they go on public assistance to cover lost income. Furthermore, poorer employees also are significantly more likely to face pressure from their employers to return to work.

The FMLA provides a minimal level of benefits for many workers. For many workers, the availability of leaves, however, depends not only on the federal mandate provided by the FMLA but also on the policies and practices of their individual employers. Some research has examined whether different kinds of employers vary in the amount and kind of job leaves they provide. A number of authors contend that relatively privileged workers, especially union members and those working in large organizations with salaries rather than wages, are in better positions to negotiate

with their employers for family leaves. Studies have provided mixed results. Some have found that large employers are more likely to offer leaves, either because of cost-effectiveness or greater social pressure. In contrast, comparing national (Current Population Survey) data from the pre-FMLA (1992-1993) with the post-FMLA (1994-1995) period, Jane Waldfogel found an increase in leave taking concentrated in “medium-sized” firms (100 to 499 employees) among working mothers with children under one year of age.

Inequalities in official provisions of leave taking are increased by organizations’ responses to those who ask for leaves. Employers may discourage family leaves, especially in large firms. Research shows that employers discourage lower-level employees from taking time off to care for their families. They also discourage men employed in the upper reaches of management: Mindy Fried found these men were particularly susceptible to informal pressures to keep working. As a result, many did not take parental leaves even when entitled to them. Many scholars suggest that workplaces that deny the validity or even the existence of family needs may have more influence on employees’ options than does official policy that supports such needs.

Finally, knowledge is crucial, but often lacking: Many workers are simply unaware of possibilities for leaves or other job benefits provided by employers. This is why many union leaders not only worked to get the FMLA passed but also continue to put much effort into telling workers about their legal rights and making sure that employers give workers the family leaves to which they are now legally entitled.

PAID FAMILY LEAVE POLICIES

The limits of the FMLA become especially clear when we look at the policies in other nations. All European countries and Canada provide paid leave benefits to working parents. Most are universal. Most are funded by a variety of methods, including direct state funding and employee contributions to disability insurance funds. Providing not only job protection but also substantial income replacement, generous programs are common throughout Europe (although the length, flexibility, and level of payment they provide vary). In Sweden, for example, parents receive a full year-and-a-half paid parental leaves for each child (including 12 months at 80 percent of prior earnings).

Because so many parents—mostly mothers—use family leaves, fewer than 200 children under one year old in the entire country are in day care. In Norway, employed parents are entitled to leaves of absence of 42 weeks. Furthermore, the “fathers quota” reserves four weeks of this leave for fathers only. If the father does not use them, these four weeks of paid leave are lost to the family. The fathers quota, instituted to change the gendered division of caring labor, is being used by almost 70 percent of the eligible Norwegian fathers. Sweden and Italy have instituted “fathers quotas” as well, creating nontransferable leaves for fathers only. Although the U.S. welfare state clearly differs in many other ways from its European counterparts, these policies can help us understand ways to be responsive to the needs of families and the inequalities maintained by the FMLA.

Many groups in the U.S. are still working hard to introduce and implement policy that covers a broader range of workers and ensures that workers will receive at least some pay when they take time off to care for their families. The National Partnership for Women and Families is currently joining with others around the country to advance family leave insurance plans; they hope to expand current unemployment or disability insurance to provide some pay during periods of unpaid family and medical leave.

In 2004, the state of California enacted the first paid family leave policy in the United States. The California Family Rights Act went into effect in the summer of 2004, making workers eligible for six weeks of partially paid family leave. The leaves are funded by an employee payroll deduction, expected to average \$27 per worker per year, that will go into a fund similar to the one used for unemployment insurance. The law is not a mandate for all companies; businesses with fewer than 50 employees do not have to hold a leave taker’s job open, and managers can deny an employee’s request for leave. Still, many see the law’s passage in California, home to one-tenth of the nation’s workforce, as a watershed; many states now have bills pending that are similar to California’s. Many are now working for the expansion of such paid leaves to the federal level so that more workers who must combine work and family responsibilities will be able to do so.

FAMILY BACKGROUND AND CAREERS

Family background and *careers* are robust constructs, each of which subsumes a complex network of conditions and behaviors. They are interconnected; that is, the definition of one construct in isolation is somewhat limited because it depends on the other construct for complete meaning. The workings of a career are embedded within the workings of the family, and the workings of family are embedded within careers. Definitions of the linked constructs are complex and involve complicated webs of interactions. Family background and careers are applicable to all individuals. Indeed, all persons, notwithstanding their locations within cultures or nations, experience family and career, although the particular manifestations may vary across cultures.

Some authorities believe that families differ from other social units in that new members enter only by birth, adoption, or marriage and leave only by death. Like schools, workplaces, and communities, families have differentiated roles and functions, but they are

unique in the social-emotional importance ascribed to interpersonal relationships. If family members die or depart, others can perform the lost members' roles and functions, but the relationships cannot be duplicated. The emotional intensity of the parent-child relationship has a distinctive influence on a person's life.

The *family background construct* definition herein is limited in scope to the single-generation family of origin, not the intergenerational family of the familiar family tree. Family background is further limited to psychosocial conditions and behaviors within the family and will not include the cross-generational transmissions of psychobiological features through genetic inheritance. The focus is on nurture, not nature. This limiting assumption is typical in social science literature about family and careers, though not always acknowledged.

Family background has a time-extended influence on careers. The family of origin is the principal agent of socialization during childhood and, as such, exerts a pervasive and durable influence on long-term psychosocial development. This influence extends to experiences associated with the transformation from a dependent, nonworking child into an independent, working adult.

A general definition of *careers* was chosen from among many used in the social sciences because it has acceptance in most disciplines: A career is the evolving sequence of a person's work experiences over time. The definition's essential features are (a) its focus on work experiences rather than simply employment, thus including homemaking and other productive efforts; (b) limitation of experiences to those of one person; and (c) dimension of time required to encompass an "evolving sequence" of work experiences and thus necessitating historical or longitudinal conceptualizations. Careers thus defined are essentially *occupational careers*: literally, the work that occupies a person's time and efforts, whether remunerated or not.

Careers, as sequences of work experiences, can be thought of as one strand in life span development that is interwoven with, among things, social experiences, cognitive experiences, and emotional experiences to form a person's psychosocial life history. Careers are described as behavior patterns and sequences rather than single acts (e.g., choice or entry into an occupation).

Careers are most strongly connected with family background during the first decade of life, and therefore emphasis will be given to the early emergence of

two broad activity patterns: habits of industry and occupational aspirations. Both activity patterns are recognized in psychology and sociology; both are multidimensional constructs; and both are believed to be shaped through social interactions within the family unit.

Habits of industry are the attitudes and behaviors that are exhibited on jobs required within a social system, whether it is the family, school, or workplace. For example, the nonworking child develops habits for organizing time and energy to complete tasks. Some theorists add that the child learns to habitually manage aggression and frustration, to put work ahead of play, to meet externally imposed standards for achievement, and to follow verbal instructions. Taken together, these behaviors form a pattern acceptable to community and employer norms. The family is instrumental in inculcating and shaping habits of industry.

Occupational aspirations refers to a broad construct that has multiple meanings in social science theory and research. Aspirations relate to several psychosocial functions:

- Goals, intentions, or orientations
- Manifestations of personality traits, such as interests, values, abilities
- Cognitive interactions among values and expectancies
- Reflections of past social experiences
- Representations of the self, self-concept, or identity

For purposes of this discussion, occupational aspirations will subsume all these functions. The content of occupational aspirations is often analyzed along three dimensions: (1) a status hierarchy, (2) an array of fields of work, and (3) role typing (occupations peopled by gender or racial/ethnic groups). Aspirations are dynamic, and the content changes frequently over time; that is, people aspire to a certain occupation at one time and another occupation at some other time.

Occupational aspirations are first formed within family social interactions and are clearly associated with the quality of interpersonal support and perceived societal norms, both of which may emanate from the family background. Aspirations formed at an early age shape later educational and occupational attainments. Some have argued that a feature of aspirations critical to their fulfillment is that they be “realistic,” that is, “aligned” with the education planned. Families are also instrumental in fostering the values and expectancies that are central elements in independent, self-directed choices among occupational roles.

Habits of industry and occupational aspirations also represent forms of coping with social system demands peculiar to an age/stage in the life cycle, that is, following society’s timetable for growing up. These age-graded social expectations are called *developmental tasks* and capture the predictable, socially impinged adaptive challenges within each stage. The major career developmental tasks to be mastered in childhood are often depicted as the acquisition of habits of industry and forming an identity as a worker, commonly expressed through occupational aspirations. The family is the primary setting in which children are first introduced to the demands of career development tasks and then taught how to cope with these tasks.

The complex mechanisms for transmitting the influences of family background experiences on a person’s early career are generally grouped by two dominant family characteristics: (1) family structure, the internal organization of the family unit, and (2) family functions, the intrafamily unit relations and interactional processes required to carry out normal family responsibilities and duties. These two characteristics will be considered both separately and jointly.

Family structure characteristics linked to careers can be explained by describing three publicly observable differences among family units. The first difference occurs in *family composition*. Examples are the number of siblings and caretakers (i.e., family size), whether or not members are biologically related, and children’s birth order and spacing. The second difference occurs in the *physical surroundings*. Examples include domicile space considerations, such as shared bedrooms, noise level, and the family-related circumstance of geographic location. Third are *material differences* among families, including conditions such as family wealth, prestige of caretakers’ education and occupations, and number and type of media in the home. In summary, family structure characteristics set the parameters for children and youth to broaden and deepen experiences essential to careers.

Some would argue that the examples of material differences are simply indicators of the venerable sociological construct *socioeconomic status* (SES). The influence of family-of-origin SES on the offspring’s entering high-status occupations, especially when educational achievement is controlled, has been demonstrated in several large-scale longitudinal research studies. In brief, more material and social resources enable families to provide opportunities for

education, skill development, and social “contacts” that influence hiring. Conversely, less material and social resources can result in biases and barriers that reduce these opportunities.

Family functions are fulfilled through family interactions, and are the overt and covert communication processes both within dyads of family members and within the family unit as a whole. For example, family members communicate work habits and attitudes to a child, which, in turn, the child generalizes to school and job settings. Consequently, these communications are sometimes called the *initial social learning mechanisms* for socialization into work roles.

These communications are further clarified by differentiating three family interactions in which they commonly occur: (1) activities that are taught, encouraged, or disciplined; (2) interpersonal relations among family members; and (3) social roles as taught directly and conveyed through models. These three opportunities for children’s socialization experiences have obvious parallels with three adult experiences in occupational careers: work tasks and duties, worker relationships with bosses, coworkers and customers, and differentiated roles within work organizations.

Family activities, such as intrafamily games and household chores, allow children to learn about family social norms such as competition and cooperation, rewards and penalties, and the general “rules of the game”: attitudes that serve as important foundations for a socialized worker. As children grow up, they engage in more complex activities that teach advanced lessons about worker roles and attitudes as preparation for the habits of industry.

The family also directs activities at the person, such as parental child-rearing practices that train children both overtly and covertly in work habits and values. Some research evidence supports the proposition that parent child-rearing orientation and behaviors, for example, the kind of activities parents reward, influence children’s developing interests and values and thus indirectly influence their occupational aspirations and the directions their careers take later in life.

Familial interpersonal relations are the fundamental qualities of the parent-child dyad, parent-parent relationships, and sibling relationships. Family conversations are important to the child’s developing ideas and attitudes about careers. Some theorists argue that security and safety in relations with others as first experienced in the family are essential for coping with later developmental tasks. The content of these communications has been

classified as either *supportive* (i.e., affective enabling) or *challenging* (i.e., cognitive enabling). Parental support and encouragement are manifested through showing appreciation, respect, and special attention. Such communication, sometimes portrayed as parental affirmation, strengthens the connectedness or emotional bond between parent and offspring. Support may also convey positive attitudes about the child’s aspirations. High familial support has been shown to be critical for young women and lower-SES offspring who are forming and realizing nonnormative occupational aspirations. Conversely, low support and low challenge may impede the learning of habits of industry and occupational aspirations.

Parental challenges directed toward the child usually occur in purposeful, self-conscious, and goal-directed activities and take the form of stimulation, discipline, or training. Challenge is communicated through competitive games and expectations of achievement, effort, and efficiency.

There has been considerable debate about the place of separation and individuation of offspring from parents in relation to careers. *Separation* is a part of the child’s self-reflective processes, particularly how the child sees himself or herself as separate and distinct in the parent-child relationship. Some believe that adequate separation from parents is a necessary condition for adult independence and self-direction, which are the hallmarks of careers in Western societies. Some believe that separation is valued only in particular cultures and that it can be the source of tension in families and in offspring growing up in dual cultures. Parental attachment, or close contact with parents, also seems to be associated with enhanced development. Although the evidence is mixed and largely retrospective and correlational, thus making the direction of causation unclear, there is a tendency for both separation/individuation and connectedness/attachment to be associated with mastery of adolescent and adult career-development tasks.

Sibling relationships are likely to be instrumental in careers, although there is little research or theory about these relationships. Commonly accepted examples are that older siblings may provide younger siblings with challenges and support much as parents do, and younger siblings may offer opportunities for older siblings to practice nurturing skills.

Social roles and role expectations are communicated through family power relationships, family “rules,” and family traditions. Roles are learned within the family

setting directly through instruction and vicariously through work role and sex role models. Some authorities suggest that parents'/caregivers' workplace conditions have an indirect influence on their children's career development. Their argument is that the conditions of parents' jobs (e.g., degree of self-direction) shape parents' personalities and values (e.g., value of independence), which, in turn, influence parenting behaviors (e.g., arranging and rewarding independence). Whether or not the female caregiver works outside the home has been shown to influence daughters' aspirations and subsequent career directions.

Although often studied in isolation, family structure characteristics and family functions interact in everyday life to produce the essence of family background experiences that are linked with career experiences. For example, family material wealth distributed according to family size (two structural qualities) may set constraints on the transmission of occupational aspirations and habits of industry that takes place through family functions such as child-rearing practices and role models.

Empirically validated relationships between and among family background variables and career variables are extremely complex owing to several conditions. First, many family-career links are indirect; that is, family influences on career are mediated by a third set of factors. For example, the influence of family structure on an individual's career is not direct, but rather is enhanced or limited by the amount of education the individual attains. Second, the purported causation is not always unidirectional; that is, the child influences the family, and the family influences the child. For example, the influence of parents' activity interests on children's interests may be reciprocated by adaptation of parental activities to accommodate the child's interests. Third, the sheer number of variables involved makes data gathering and analyses complicated. When the necessity of longitudinal designs is added to study "experiences over time," research on family background and careers becomes an expensive and formidable venture.

Two specific examples of frequently studied family occupational socialization mechanisms that influence careers are called occupational inheritance and occupational linkage. *Occupational inheritance* is the general notion that a parent's occupation "begets" the child's occupations. Social scientists refer to occupational inheritance as the social induction mechanism by which offspring are prepared to enter the particular

occupation of the parent. Families are believed to be instrumental in shaping the direction of the child's occupational aspirations. For example, professional entertainers provide their offspring with performance models, training, and "personal contacts" that prepare the child for work in the entertainment field. Evidence suggests that relatively few children enter the specific occupation of either parent; for example, in general, entertainers' children seldom become entertainers, though children tend toward broad fields of work similar to their parents'; for example, entertainers' children are more likely than other children to enter occupations in the arts.

Occupational linkage is a social induction mechanism for explaining the perpetuation of the occupational value structure across generations. Parental work values, such as valuing achievement or material wealth, are transferred to children through social learning experiences and, as a consequence, influence children's choices of occupations. The evidence is mixed; some studies have revealed a tendency for children to reflect their parents' occupational values and to apply these values in selecting occupations, but evidence from other studies is equivocal.

In summary, family background is linked with careers in powerful ways that are not completely explicated by theories or by research evidence. Families and careers each demonstrate wide-ranging interconnected qualities that, in turn, are linked with the other construct in a tangled, complicated fashion, analogous to the convergence of two nets. What seems irrefutable is that each touches the other to shape human and societal development.

FAMILY-RESPONSIVE WORKPLACE PRACTICES

Family-responsive workplace practices are employer-sponsored programs and practices designed to help employees manage the demands of work and personal life. Such practices are intended to help organizations in their recruiting efforts, enhance their employees' work-related attitudes and job performance, and encourage their employees to remain with the organization, all of which can ultimately improve an organization's productivity. In other words, both employees and their employing organizations experience a "win-win" situation in offering and using these practices. Perhaps because of their greater resources, large employers are more likely than small ones to offer family-supportive practices, and because of their desire to improve their recruiting effectiveness, firms in industries with a high percentage of women in the labor pool also tend to offer family-supportive programs.

Family-responsive workplace practices include programs such as dependent care support (including child

care and elder care), flexible work schedules (such as flextime and four-day workweeks), and other forms of flexible work arrangements, such as part-time schedules, job sharing, and telecommuting. Jeffrey H. Greenhaus and Sharon Foley have observed a number of trends in the way that researchers have classified the type of family-supportive practice, the ways in which family-responsive practices are measured, and the type of employee most likely to use such practices.

For example, the practices may be formal or informal, and they may attempt to fit an employee's family responsibilities around a strong focus on work (segmentative) or focus on integrating an employee's work and family life (integrative). In addition, whereas some studies examining the effectiveness of family-responsive practices focus on the presence or absence of a practice or the number of practices offered by an employer, other studies examine the actual use of a practice or the employee's level of satisfaction with the practice. Moreover, it is not surprising that employees most likely to use family-responsive practices believe that the practice can meet their needs (e.g., women, employees who place importance on spending time with their families) and that their supervisors and their organizations are supportive of their family and personal lives. Although some employees may be hesitant to take advantage of family-responsive practices because they believe that their coworkers will resent them, employees generally seem to react favorably to family-responsive workplaces even if they do not personally benefit from the practices.

Do family-responsive practices accomplish their aims? Comprehensive reviews of the research, by Sharon Lobel in 1998 and by Jennifer Glass and Ashley Finley in 2002, have reported generally positive results. The availability and/or utilization of such practices has been associated with enhanced recruitment, positive work-related attitudes (such as job satisfaction and organizational commitment), low work-family conflict, and reduced withdrawal tendencies (that is, low levels of absenteeism, lateness, turnover intentions, and turnover behavior). Family-responsive practices have also been associated, although not as consistently, with improved individual and team performance. In addition, bundles (or groupings) of family-responsive workplace practices may be a source of sustained competitive advantage for organizations that offer them.

Despite the positive trends noted above, the effectiveness of family-responsive practices has not always

been observed. Moreover, specific practices may be effective in some respects (e.g., reducing absenteeism) but not others (e.g., improving job performance). Further research is needed to determine the conditions under which particular family-responsive practices improve specific individual and organizational outcomes. Research along this line has shown, for example, that flexible work schedule policies and practices are more likely to enhance work attitudes (e.g., organizational commitment, job satisfaction, feelings of loyalty to the employer) for employees of childbearing ages and those with dependent children. However, additional research is required to understand when certain types of practices have their most potent effects on employee and organizational well-being.

A partial answer as to the effectiveness of family-responsive practices may rest with the family supportiveness of an organization's culture. Family-supportive work environments not only provide family-friendly practices but also encourage supervisors to be supportive of their employees' family and personal lives by being understanding and flexible when their subordinates face challenges in juggling their work and family lives. Moreover, supportive supervisors enable their employees to use the family-responsive practices provided by the organization. It is probably due to these reasons that individuals who report to supportive supervisors tend to be loyal and committed employees who experience relatively little work-family conflict and stress and intend to remain with the organization.

A concept similar to a family-supportive work culture is what Tammy D. Allen has called "family-supportive organization perceptions" (FSOPs). These refer to overall perceptions that employees hold about the extent to which their organizations support employees' participation in their family lives. Employees who perceive their organizations as supportive tend to use the family-responsive practices their employers provide, experience relatively low levels of work-family conflict, and hold positive attitudes toward their jobs and their organizations. Therefore, although the provision of family-responsive practices is certainly important, they are most likely to be used, and therefore useful, when the overall culture of the organization is supportive of employees' lives outside of work and when the supervisors who work in the organization are supportive of their subordinates' family and personal lives. In fact, research indicates that a supportive culture promotes positive

work attitudes above and beyond the effects of the family-responsive practices provided by an organization.

It is reasonable to ask whether men and women differ in the utilization of family-responsive workplace practices. There is evidence that women react more positively than men to such practices and are more likely than men to use them. Although it is possible that men, as a group, have less need than women for the assistance provided by these practices, men's reluctance to take advantage of the practices may also be due to their fear of being stigmatized as uncommitted to their careers if they seek help from their organizations to meet family responsibilities. Men also have been found to make informal arrangements with their managers to juggle work and family responsibilities rather than rely on more formal organizationally sponsored practices.

Because much of the research on work-family issues in general and family-responsive workplace practices in particular has been conducted in the United States, the role of national culture in work and family life has emerged as an important topic in recent studies. A number of these studies have examined similarities and differences between countries in the extensiveness of government policies provided to help employees juggle work and family responsibilities. Although a high proportion of women in the workforce is associated with extensive family-supportive practices and legislation, national culture, in particular the availability of extended kinship systems, seems to determine who is thought to be responsible for helping employees balance work and family responsibilities. For example, in countries in which the extended family is expected to provide care for children and elders, dependent care is seen as a private responsibility, and there is little government support. Other countries rely more heavily on legal solutions to dependent care, as witnessed by the European Union's Parental Leave Directive and the 1993 Family and Medical Leave Act in the United States. Additional research is required for understanding how culture affects the extent to which families, governments, and employers assist employees in balancing work and family responsibilities.

In summary, the literature indicates that family-responsive workplace practices can help employees meet the challenges of managing their work and family responsibilities and can help employers become more productive as well. However, further research is necessary for understanding the mechanisms that explain why and when different family-responsive

workplace practices promote individual and organizational well-being across a variety of national cultures. One useful concept studied by Susan Eaton is the “perceived usability” of family-responsive workplace practices, which refers to employees’ belief that they can use formal or informal practices without damaging their careers. The provision of family-responsive practices will be of little help if employees fear that using these practices will contribute to “career suicide.” It is likely that the culture of an organization and the supportiveness of its supervisors enable employees to take advantage of the practices that the organization offers—and become satisfied and committed employees in the process.

FAST-TRACK CAREER

A *fast-track career* offers advancement opportunities to top-level positions based on a series of developmental experiences provided by the organization. Stated differently, high-potential individuals are given accelerated development opportunities, with the idea of their reaching senior-management levels more quickly than those who are not on such a track. There are individual (e.g., needs, personality, education) and organizational (e.g., staffing, structure) characteristics and processes associated with the “fast track.” High achievement-motivated individuals seek environments in which a path to the top echelons of the organization is explicit, with identifiable career benchmarks. This is the traditional upwardly mobile career path, also known as the *linear career*. Related concepts include upward mobility and high-potential managers.

Fast-track career paths are widely accepted in organizations as a means of attracting and retaining a pool of highly capable future leaders. Such programs are typically called *leadership development* or *leadership continuity programs* and provide the requisite experiences deemed necessary to prepare the participants for top-management positions. The underlying assumption is the competitive advantage an organization achieves by investing in leaders who will ensure the continued success of the organization. In reality, there is no single path that will lead to success, and the contemporary organizational environment characterized by mergers and acquisitions, reduction in organizational levels, global competition, and outsourcing have significantly increased the complexity of routes to top management. Organizations are rethinking “succession planning” models, and individuals have no guarantees that top management is attainable even when they appear to have such potential.

The literature has identified two types of fast-track individuals: the *apparent fast track* (AF-T) and *real fast track* (RF-T). To an observer, both types would look pretty much the same in the early career stages: highly energetic, bright individuals who know how to get things done. There would be also be differences,

although they may not be observed as easily. The AF-T is characterized by rapid promotions and salary increases, with a lesser emphasis on developing the skills and relationships that are needed to make the executive transition (i.e., from middle to top management). Such individuals have a higher probability of derailing from the fast track because of their inability to handle the interdependence and diversity of higher-level management. RF-T individuals progress a bit more slowly, but they invest the time in honing the requisite skills and cultivating long-term relationships that increase the likelihood of reaching top-management positions. Such individuals understand that quick promotions are not the ultimate goal and that lateral moves can also be an effective path to the top.

Derailment from the fast track has become a major issue because of the resultant personal and organizational consequences. Individuals can become disillusioned and bitter because additional promotions are denied them as others continue to progress. The major factors associated with derailment include interpersonal relationships, team leadership, performance, and coping with change. Some managers find it difficult to make the transition from being task-based managers, the key to earlier successes, to becoming relationship leaders, which is required at higher levels. Such managers can be seen as manipulative by others. Performance issues often center on being overly ambitious with a lack of follow-through on promised results. Team leadership has become a critical aspect of top management. Building, developing, and leading an effective team may be difficult for managers who are individualistic, primarily concerned with task performance, and insensitive to the participative aspects underlying team dynamics. Finally, the inability to deal with change can manifest itself though unwillingness to learn new skills, work effectively with a new boss, or, more broadly, change as the business evolves.

The literature suggests a new psychological contract that emphasizes employability rather than vertical movement (promotions). In essence, organizations assist employees with development (rather than a path to the top), while individuals enhance their market value as a result of such opportunities. However, research also indicates that few organizations have modified their fast-track philosophies or behavior. This is a testimony to the importance of top leaders to organizational success. From a retention perspective, one of the true organizational shortcomings is clearly communicating

expectations to individuals about their career progress. Some highly capable managers leave because they are unsure about their value to the organization.

Concerns have also been advanced that current fast-track models do not include sufficient diversity in the high-potential equation. The current cadre of primarily White male CEOs may be more comfortable promoting and encouraging White males on the fast track. Minorities and women may have to work harder to achieve equivalent levels of recognition regarding promotional opportunities to top management. The literature suggests that line managers be rewarded for achieving diversity in their staffing plans.

The fast track continues to generate significant interest from individuals and organizations. Much of the literature centers on the organizational perspective, with significantly less research on the individual perspective. Nevertheless, recent research has reexamined the role of an individual's personality matching a fast-track career path and the role of work in the individual's life space, particularly with reference to family and activities outside of work. It is also important to understand the paradoxical situation in which early career behaviors that were recognized and rewarded (e.g., AF-T) may, indeed, be the very same behaviors that ultimately prevent some fast-track individuals from attaining top-management leadership positions. Enhancing fast-track opportunities for women and minorities continues to be a concern in the literature. Organizations need to remain focused on recruiting, motivating, and retaining top leadership talent, while realistically communicating expectations and opportunities to the leaders of the future.

FIRO-B

FIRO-B (rhymes with “Cairo”) is an acronym for Fundamental Interpersonal Relations Orientation-Behavior, a psychological instrument developed by William C. Schutz and fully described in 1958. The *FIRO-B* was originally developed to support the use of interpersonal compatibility as the basis for work group design in military settings. Since its original development, the *FIRO-B* has been widely used in the United States, Europe, and Japan for team development, leadership training, executive coaching, career counseling, and relationship/family therapy. Career-development professionals have predominantly used the *FIRO-B* to facilitate self-awareness, explore incompatibility with particular work settings, stimulate effective performance management, and assess interpersonal coping strategies during job transitions (e.g., networking, support groups).

The *FIRO-B* instrument focuses on only one aspect of Schutz’s broader *FIRO* theory, but it is the most recognized and popularly used element. Drawing on the work of psychologists Mortimer Adler, Erich Fromm, and T. W. Adorno, Schutz proposed that interpersonal behavior can be understood by examining three interpersonal needs: inclusion, control, and affection. Like biological needs, these three interpersonal needs represent a condition that if not satisfied leads to a state of discomfort or anxiety.

Given that these needs are likely to operate outside of daily consciousness, the purpose of the *FIRO-B* is to bring clients into sharper awareness of their needs and to guide them in selecting and managing behaviors used to satisfy their needs.

The realm of Inclusion (I) represents the need to seek out and sustain interactions with others, including the extent to which one seeks communality, belonging, participation, involvement, and prominence in social interactions. In the workplace, a person with high levels of Inclusion would enjoy the recognition, contact, and attention provided by interacting with others. The realm of Control (C) represents the need for structure and purposeful direction with others, including the extent to which one seeks responsibility, consistency, and decision making in social interactions. Individuals with high levels of Control would be oriented in their work to the nature of influencing, leadership, dominance, and competitiveness when interacting with others. The realm of

Affection (A) represents the need for closeness and supportiveness in social interactions, including the extent to which social interactions provide intimacy, openness, warmth, and encouragement. A person with high levels of Affection would enjoy working with others who show a high degree of concern for each other, expect and reward loyalty, and function with each other like a “second family.” Each need area can also be associated with characteristics that define low levels of the need. For example, a person with low levels of Affection would be comfortable in work environments characterized by cool and businesslike relations, little interaction outside of work, and more open, direct expressions of disagreement and conflict.

The *FIRO-B* provides measurement of these three interpersonal needs along two dimensions. For each need, the first dimension is called the Expressed Need. Expressed Needs are the extent to which a person actively initiates toward others those behaviors associated with the need area. For example, a high level of the Expressed Need for Control could be demonstrated by a person’s need to try to influence others, take a leadership role, and direct others on tasks. A low level of the Expressed Need for Control could be demonstrated by an aversion or passivity toward those same behaviors.

The second dimension is called the Wanted Need, which also can be manifested in each of three need areas. Wanted Needs represent the extent to which a person will be comfortable receiving another person’s Expressed Needs. It is difficult to observe Wanted Needs as a passive dimension. For example, if supervised by a person with high levels of Expressed Control, a person with low levels of the Wanted Control may exhibit resistance, insubordination, and avoidance. Absent the presence of such a supervisor, the same person may simply seek out ways to work autonomously. Conversely, a person with high levels of Wanted Control may ask many questions and seek guidance and feedback from others. Absent a person to provide such direction, the same person may become demanding and highly frustrated.

Table 1 shows the resultant six-cell framework used by the *FIRO-B* to understand interpersonal behavior. Using 54 items (9 per cell), the *FIRO-B* asks individuals to report the frequency and selectivity of interpersonal behaviors. Individuals receive six numerical results between 0 and 9 indicating the level of their interpersonal needs, with the 0 to 2 range considered “low,” 3 to 6 considered “medium,” and 7 to

Table 1. The FIRO-B Framework

	<i>Inclusion</i>	<i>Control</i>	<i>Affection</i>
Expressed Behavior Wanted	<i>Expressed Inclusion (eI)</i>	<i>Expressed Control (eC)</i>	<i>Expressed Affection (eA)</i>
Behavior	<i>Wanted Inclusion (wI)</i>	<i>Wanted Control (wC)</i>	<i>Wanted Affection (wA)</i>

SOURCE: Schnell (1993).

9 considered “high.” Client interpretive materials elaborate on the meaning of each result and provide explanations for additional results obtained by adding together different variations of the six cells.

Administration of the FIRO-B (approximately 15 minutes) is much briefer than for other instruments, with the same psychometric strength and interpretive flexibility. The psychometric properties of the FIRO-B indicate that it is reliable and valid. Norms for age, race, educational level, and organizational level, as well as for several countries, are available. The FIRO-B has convergent validity with other instruments commonly used in career-development settings, such as the Myers-Briggs Type Indicator (MBTI), California Psychological Inventory (CPI), and Strong Interest Inventory. Understanding these relationships can improve interpretive clarity. For example, there appears to be an association between the extroversion preference and higher levels overall on all FIRO-B results. Other relationships may prove useful to the career-development professional, such as a finding that individuals with higher levels of Wanted Control will rely more on religious beliefs when facing problems and transitions.

Research on the FIRO-B has included findings about occupational groupings and preferred workplace characteristics. Interesting findings include an association between high levels of Expressed Inclusion and a preference for diversity in the workplace, between high levels of Expressed Control and a preference for greater opportunities for advancement and high pay (even if job security is lower), and between high levels of Wanted Affection and a preference for workplaces that emphasize workplace loyalty and offering a job for life.

FLEXIBLE WORK ARRANGEMENTS

Flexible work arrangements refer to employer policies or managerial practices designed to give employees greater flexibility in influencing the time (duration), timing (when), or location (place) of work. Typically, these practices permit greater individual autonomy in self-managing work-role enactment in relation to family and other nonwork demands. Flexible work arrangements can be based on formal corporate policies and also on informal use permitted by the immediate supervisor or work group peers. According to the Bureau of Labor Statistics National Compensation Survey conducted in 2000, which includes employers of all sizes in the United States, 5 percent of U.S. employers provide flexible workplace schedules. Most research on flexible work schedules has been conducted in large employer organization.

Time flexibility (duration of work) policies and practices permit employees to have control over the number of hours they work. *Reduced-hours or*

part-time work is an example of time flexibility practices that allow individuals to work less than full time with a commensurate decrease in salary or workload. Such practices allow individuals increased flexibility in the amount of time that is allocated between work and nonwork. Another example of time flexibility is the *leave of absence*, in which employees are allowed time off for maternity and paternity leave military service, education, elder and child care, and other life pursuits and are able to return to their jobs or similar jobs when they come back to work. *Job sharing* involves two employees working part time to share a full-time job.

Timing flexibility (scheduling of work hours) refers to policies offering temporal flexibility or freedom to influence the time at which work occurs. Under *flex-time*, employees can vary their beginning and ending times (often within a given flex range and established core hours) but generally work full time. Under a *compressed workweek*, employees typically work a full-time week of work but are allowed to work longer or extra hours on some days of the week in order to have part of a day or a whole day off at another time. Under *compensatory time*, employees working long hours are allowed subsequent time off to recoup.

Policies and practices offering *place flexibility* (location of work) allow employees to choose to work outside of the office or main worksite (all or some of the time). Employees may *telework*, working part time or full time at an off-site location, using technology (e.g., e-mail, fax, mobile phone) to communicate with others. Some avoid long commutes by teleworking, and others may obtain blocks of time without interruptions from coworkers.

Although more well-designed research is needed on the outcomes associated with different forms of

flexibility, studies suggest that employee use of flexible work practices can result in lower turnover intentions, less work-family conflict, and greater organizational commitment, job satisfaction, and attraction. More research is needed on how different types of flexibility are linked to different work and family outcomes. Studies on work-family policies also need to examine relationships between policy use and the supportiveness of supervisors and the climate of the organization.

G

GENDER AND CAREERS

Gender influences a wide range of career-related attitudes, behaviors, and outcomes. This includes career choice, career experiences, occupational health, work attitudes, other people's perceptions, and career outcomes. Therefore, to understand individuals' careers, it is important to consider gender.

GENDER AND CAREER CHOICE

Men and women differ considerably in their career choices, and many factors contribute to these differences. *Socialization experiences*, which refer to the lifelong social learning experiences that people have when interacting with others, play a major role here. Parents, siblings, teachers, school guidance counselors, other adult role models, peers, the media, and many other sources greatly influence how individuals view themselves based on their gender.

From an early age, parents tend to treat boys and girls differently and encourage children to engage in gender-appropriate play (e.g., boys play with trucks; girls play with dolls) and extracurricular activities (e.g., football for boys, dance for girls). Teachers and other adult role models such as guidance counselors, extended family members, and family friends also act differently toward boys and girls and hold different expectations for children based on their gender. Boys are expected to be more rambunctious and physically active, whereas girls are expected to be more sensitive and sociable. Thus, people in children's social environments reinforce and send

consistent messages as to what is expected of them according to their gender.

Materials used in primary educational settings also contribute to the socialization experience. For instance, textbooks often depict men and women in stereotypical occupations (e.g., men as doctors and women as nurses) and social roles (e.g., working fathers and stay-at-home mothers). Furthermore, children's stories are more likely to use men than women as story characters. The media plays a role in its portrayal of men and women in sex-typed occupational and societal roles, television shows, movies, and advertisements. Peers also exert considerable influence and contribute to the socialization process, particularly during adolescence. Because adolescents want to fit in with their peers, the decision to pursue activities that are not consistent with sex-role expectations is a difficult one. This might include choosing to participate in activities that are gender typed (e.g., a boy choosing to pursue art, a girl choosing to join the wrestling team) or expressing vocational interests that are viewed as less appropriate for one's gender (e.g., a boy interested in nursing, a girl interested in auto repair).

Although such socialization experience influences both genders, it is presumed to have greater negative effects on girls because it tends to limit and restrict their options and achievements more so than boys'. For example, healthy adult men are expected to work, but the decision to enter the labor force is presented as a choice for girls. In this way, gender influences the initial decision of whether or not to pursue paid work outside the home. Likewise, socialization experiences strongly influence vocational interests and career

choices. Both adolescent boys and adult men report greater interest in scientific, technical, and mechanical pursuits. Adolescent girls and adult women indicate greater interest in social and artistic endeavors. Thus, it is not surprising that men are generally encouraged to pursue careers in engineering, business, and science, whereas women are encouraged to pursue careers in social and helping occupations. It is also noteworthy that male-typed careers tend to offer higher status and pay than female-typed careers, contributing to the observed gender inequities in pay.

The availability of same-sex role models also influences vocational interests and subsequent career choice. Due to the differential representation of men and women in various occupations, girls are less likely to have female role models in male-dominated occupations, such as engineering, police and detective work, and construction trades. Girls are more likely to have role models in traditionally female occupations, such as education, nursing, and social work. The opposite is true for boys. Parental role modeling also influences occupational preference and career choice, since children tend to identify most with their same-sex parents and working adults are also segregated occupationally to some extent. Maternal employment also relates to career choice. In particular, working mothers can facilitate their daughters' career aspirations by providing female models of career pursuits and by demonstrating how women can successfully integrate work and family roles.

Another reason for male-female differences in career choice relates to career-related self-efficacy perceptions, or beliefs in one's ability to be successful in a wide range of career pursuits. Women have less access to the types of experience necessary for developing strong beliefs in their abilities to master career-related tasks, particularly tasks in male-dominated occupations and majors (e.g., math, science). Individuals develop career-related self-efficacy through vicarious experience (role models), verbal persuasion (encouragement from others), and actual experience (having opportunities to master tasks). Women tend to have less opportunity for these experiences and therefore tend to report lower career-related self-efficacy than men. These lower self-expectations can lead to further occupational sex segregation, as individuals are less likely to pursue certain jobs and/or careers if they believe that they will not be successful. Interestingly, there are few consistent differences in actual ability between men and women, and when differences are

found, they tend to be small in magnitude. Moreover, there is greater within-gender than between-gender variability in abilities such as overall intelligence, verbal ability, mathematical ability, and visual-spatial ability.

GENDER AND CAREER EXPERIENCES

Gender also influences individuals' career experiences. Women face unique barriers in the workplace, which, in turn, shapes their work and organizational experiences. One barrier consists of practices that intentionally or unintentionally exclude women from jobs and developmental experiences based on gender. This includes overt sex discrimination in hiring, being overlooked for high-visibility or high-stakes job assignments, and not being targeted for domestic or international relocation opportunities. Gender differences are also found in developmental assignments after individuals are hired by organizations. Women are more likely to be hired into staff positions and have less access to line experience, which is often a steppingstone to higher-level management positions. Women tend to report that their initial job assignments are less challenging than men's assignments. In addition, unlike jobs that tend to be held by women, jobs held by men tend to exist in job ladders that lead to positions of greater power and influence. Gender also influences access to information within organizations. Men tend to be more politically connected and have access to more powerful organizational members than do women. This is important since managers develop impressions about an individual's career potential through both formal and informal interactions. There is also some evidence that men receive more favorable performance feedback than do women and that the quality of such feedback provided varies by gender (e.g., more specific and developmental feedback tends to be provided to men). All of these factors can influence the availability and quality of career opportunities in an organization.

Another way in which men's and women's career experiences differ is that women are more likely to experience career interruptions, and gaps in employment can slow down their career progress. Men and women also tend to interrupt their careers for different reasons, with women being more likely to temporarily leave the workforce for family reasons and men being more likely to do so for job-related reasons (e.g., inability to find suitable employment). Interestingly,

career interruptions for family-related reasons have less negative impact on one's career progress than interruptions that occur for other reasons, such as gaps in employment due to temporary unemployment. The explanation for this is that women are expected to leave the workforce temporarily after childbirth, and by doing so, they are actually conforming to gender-based societal norms. Compared with men, women are also more likely to go from school to a full-time family role, and then return to school or enter the workforce for the first time after starting a family. Therefore, some women get a later start in their careers than do men. There are also gender differences in full-time versus part-time work, with married women being more likely than men to opt for the flexibility afforded by part-time work. Unfortunately, part-time work provides individuals with less visibility and exposure in organizations, which has been offered as one reason that women's careers often do not progress as quickly as men's careers.

A more permanent career interruption is job loss, and gender differences exist here as well. Women are less likely to occupy jobs that are revenue generating, and this makes them somewhat more susceptible to job loss than are men. However, there are few gender differences in individuals' emotional reactions to job loss (e.g., depression, reduced self-esteem), even though women tend to fare less well than men upon reemployment in terms of both extrinsic (e.g., pay) and intrinsic (e.g., quality of work life, job satisfaction) job characteristics. Women do respond to job loss with different behaviors. They are less likely to use problem-focused coping strategies (e.g., job search, relocation) and more likely to use symptom-focused coping strategies (e.g., talking to friends, getting involved in group activities). The opposite holds for men.

GENDER AND OCCUPATIONAL HEALTH

Individuals' career choices and experiences also influence a wide range of occupational health outcomes, and some gender differences are notable here. There is some evidence that professional women report greater overall stress than men and that they have a harder time unwinding from work. There are also consistent gender differences with respect to one specific type of organizational stressor: sexual harassment. According to the Equal Employment Opportunity Commission (EEOC), sexual harassment consists of unwelcome sexual advances, requests for sexual favors,

and other verbal or physical conduct of a sexual nature. Women are the typical targets of sexual harassment, and those experiencing harassment are more likely to report less favorable work attitudes, greater disengagement from work, lower psychological well-being, and greater physical health symptoms.

Another specific stressor with career implications is work-family conflict. *Work-family conflict* is a specific form of interrole conflict in which the demands of work and family are mutually incompatible in some way. It affects individuals' careers because greater work-family conflict is associated with lower job satisfaction, less career satisfaction, stronger intentions to leave one's organization, and poorer psychological and physical health. Although men and women both experience work-family conflict, there is some evidence that women report higher levels of work-family conflict than do men, presumably due to women's greater responsibilities for their families. The factors that contribute to work-family conflict differ somewhat among the genders. For instance, there is some evidence that work involvement has a stronger negative effect on work-family conflict for women and that family involvement has a stronger negative effect on work-family conflict for men. Regarding gender differences in outcomes of work-family conflict, there is some evidence that work-family conflict has a more negative effect on overall quality of work life for women and that work-family conflict has a more negative effect on overall quality of family life for men.

Although work-family conflict assumes that individuals have difficulty juggling multiple roles, multiple role membership has potential benefits as well. Membership in life roles can serve to buffer stress, be a source of satisfaction, increase opportunities to experience success, and provide opportunities for enriching interpersonal relationships. This is particularly likely if the roles that one occupies are satisfying (i.e., high role quality). While both men and women can benefit from multiple roles, women tend to occupy more life roles than do men. Furthermore, when imagining how men and women might enhance their role membership, people tend to think about men expanding their participation in the family role and women expanding their participation in the work role.

GENDER AND WORK ATTITUDES

Gender differences in work attitudes are also important, since how satisfied, involved, committed,

and motivated at work one is can influence a wide range of work behaviors, which, in turn, can impact career outcomes. For example, individuals who are more satisfied with their jobs and report greater attachment or loyalty to their organizations (i.e., have higher organizational commitment) are less likely to quit their jobs or be absent from work. Likewise, job involvement (the extent to which one identifies with his or her job) and work motivation are associated with career-related behaviors such as working longer hours and demonstrating stronger commitment to one's career, both of which can lead to greater career success. Interestingly, few differences have been found between men and women in job satisfaction and job involvement, although men may report higher organizational commitment than do women.

Gender differences in motivation have a long and controversial history. Initial conceptualization of motivation focused on *achievement motivation*, which is the desire to master tasks, excel and surpass others, and accomplish things as well as possible. Early studies of achievement motivation indicated that achievement motivation in women was distinct from that in men and, more important, that women's responses did not conform to the way scholars thought about achievement motivation. Thus, women were largely excluded from early research on achievement motivation, and assumptions were made that women do not desire achievement the same way men do. Later research dispelled this idea by finding that women actually have a stronger desire than men to work hard and do a good job, even when they are not likely to be recognized for their efforts, whereas men prefer challenging, competitive tasks that allow for individual recognition of task accomplishment. Although women are just as motivated as men to work hard (and perhaps more so), there are differences in what men and women find rewarding at work. Men value advancement, pay, and status and tend to judge their career success using these standards. In contrast, women have a broader conceptualization of career success by also considering factors such as personal growth, job accomplishments, challenge, and interpersonal relationships. Women are also more likely to define life success in terms of both work and family achievements, whereas men tend to focus more on the work domain.

Another work attitude of interest to understanding individual careers is *turnover intentions*. This work attitude reflects the extent to which one is thinking

about quitting one's job and is a strong predictor of the actual decision to quit. There is mixed evidence as to whether gender differences exist in turnover intentions, although some research finds that women are more likely than men to leave their organizations. Many of these studies have been conducted on managerial and professional women, and explanations for differential turnover rates often rest on women's disillusionment with corporate life, perceived barriers to career advancement, and unwillingness to engage in the political behavior often required to advance within the organization. Contrary to popular belief, women do not frequently report leaving their employers for family-related reasons. Furthermore, when one distinguishes between voluntary turnover (i.e., leaving by choice) and involuntary turnover (i.e., being let go), it appears that women tend to report slightly lower voluntary-turnover rates than do men.

GENDER AND PERCEPTIONS

As mentioned previously, men and women have different socialization experiences. Based on gender, they are treated differently and held to different standards by teachers, guidance counselors, parents, and others in their social environments. This, in turn, influences both career decisions and career opportunities. Of particular relevance here is the finding that people often view men and women in stereotypical ways. Generally speaking, women are believed to be more nurturing and sensitive, whereas men are viewed as more assertive and directive. These perceptions can influence perceptions of person-job "fit" in the job selection and promotion process (e.g., women may be viewed as less appropriate choices for male-typed jobs, and vice versa). Moreover, while general attitudes toward women have become more favorable over the years, sexist attitudes persist. Some individuals hold stereotyped attitudes about women's "place" in society in general or, more specifically, hold negative attitudes toward women in management positions. As an example, women are typically viewed as being less similar than men to the prototype of a successful manager. Women are also viewed as less appropriate candidates for jobs requiring heavy travel or relocation. These perceptions can influence women's career opportunities for being selected for transfers and relocation assignments, placement in high-risk internal job assignments, and receiving promotions. Others' perceptions can also undermine the

self-confidence of women in pursuing nontraditional jobs and careers.

Women report greater barriers in how they are viewed and treated by others in organizations. Women are more likely to report being excluded from informal organizational networks, which can restrict career opportunities. They are more likely to feel as though they do not “fit in” with the organization culture, which may lead some women to self-select out of high-level jobs or leave their organizations and pursue work elsewhere. Greater perceived barriers to developing mentoring relationships are also reported by women, as well as less contact and support from managers and peers. Finally, women in nontraditional jobs and occupations often experience tokenism at work, and the salience of their gender can encourage sex-based attributions for their behavior and result in higher performance expectations from managers. In addition, women in various family arrangements may face unique barriers resulting from the perceptions of others. For example, managers may believe that women in dual-earner marriages (i.e., where both partners work outside the home) are more likely to subordinate their own careers to their husbands’ careers. This may lead managers not to consider women when making high-level promotion or relocation decisions. Likewise, working mothers may be viewed as less committed to their careers by virtue of their parental status.

GENDER AND CAREER OUTCOMES

A substantial body of literature exists on the role of gender in understanding career outcomes such as pay, promotions, and career satisfaction. As a group, women earn less money than men. This gender gap in earning persists even after considering a wide range of factors that might explain the disparity, such as sex segregation by industry (i.e., men tend to work in higher-paying industries than women); variation in educational experiences; differences in the type and quality of job experiences; unequal family power between the genders (i.e., women tend to contribute less to the family’s income than men, which typically means less decision-making influence within the family); differences in family structure (e.g., married women are more likely to be married to a working spouse than vice versa); and self-selection (e.g., women may be more likely to withdraw from relocation offers or promotions). This discrepancy in earnings

is often attributed to the presence of a “glass ceiling” for women, which prevents them from attaining high-level, high-paying positions within organizations. Gender differences in earnings exist, but there is conflicting evidence as to whether or not there are gender differences in promotion rates. Some research suggests that women managers are promoted more swiftly than men, whereas other studies find no difference or faster promotion rates for men.

Notwithstanding these discrepant findings, men and women appear to take different paths to achieving career success. Men tend to progress within their careers in a traditional, hierarchical manner, whereby they have few gaps in employment and move into positions of increasing authority and status. In contrast, women are more likely to follow a sequential career path, whereby they experience a series of promotions, followed by career interruptions or a reduction in workforce participation, followed by a resumption of their careers. Furthermore, although there are probably more similarities than differences in terms of what predicts career success for men and women, some distinctions exist. Engaging in more training and development, working longer hours, minimizing employment gaps, remaining employed at the same organization, having greater home and family commitments, and displaying independence are more highly related to career success for men than for women. In contrast, obtaining a higher level of education, displaying more masculine personality characteristics, and having fewer home and family commitments appear more important to career success for women.

Self-reported satisfaction with one’s career represents another career outcome of interest. Interestingly, despite differences in objective indicators of career success, such as pay and job stature, men and women do not differ significantly in their self-perceptions of career success. Some argue that this is because women hold lower expectations for success than do men or that women compare themselves to other women when judging career success, rather than making comparisons to their male counterparts.

GENDER, FAMILY STRUCTURE, AND CAREERS

Family structure influences individuals’ careers, and gender differences are observed here. Family structure characteristics include parental status, marital status (married, single); marital type (single-earner

marriage, dual-earner marriage); and combinations of these characteristics. Parents report greater work-family conflict than do nonparents, and parenting can take time and energy away from some work pursuits. Being married also entails additional role responsibilities and makes career decision making more complicated, since one person's career decision influences his or her partner as well. For example, one person's decision to accept a promotion requiring relocation may mean uprooting a stay-at-home spouse from his or her community or lead to job loss for a working spouse. Finally, individuals in dual-earner marriages report higher stress than those in single-earner marriages, as well as unique stressors such as deciding whose career is most important and juggling both household and work-related responsibilities.

The influence of parental status, marital status, and marital type on individuals' careers varies somewhat between men and women. For women, the timing of parenthood influences the career paths chosen, as well as the extent to which career interruptions are experienced. Parenthood has less effect on men's career experiences. Furthermore, although men are much more involved in parenthood today than ever before, women are still primarily responsible for dependent care. This can put women at a disadvantage when competing with men for higher-level jobs, since they may have less time to invest in work or believe that they will not be able to successfully balance work and family obligations. Furthermore, significant dependent-care responsibilities can make it difficult for some women to maintain their career momentum. In fact, career-oriented women tend to have fewer children and are less likely to want children. Moreover, women in nontraditional occupations are less likely to have children than women in traditionally female occupations. No such differences are found among men.

Marital status and marital type have different effects on men's and women's careers. Marriage is associated with greater career success for men, whereas a comparable "marriage bonus" does not exist for women. In fact, for women, remaining single is associated with greater educational attainment and greater pursuit of nontraditional occupations. Being single is not associated with educational attainment or occupational choice for men. The typical family arrangement among male and female executives is also striking; executive men are more likely to be married to a stay-at-home spouses and have children, whereas executive

women are more likely to be single and without children. In terms of marital type, women in dual-earner marriages are much more likely to be "trailing spouses," following their husbands in job-related geographic moves. This can have negative career effects, as trailing spouses tend to report that they move into new jobs that offer less salary, benefits, and advancement opportunities than their previous jobs. In addition, dual-earner parenting can place greater stress and strain on women than on men. For instance, dual-earner mothers report greater perceived time pressure than dual-earner fathers. Men and women in dual-earner marriages also handle work-family conflicts differently, with women being more likely than men to restructure their work to accommodate family demands. Given these differences in how family structure relates to career outcomes for men and women, it is not surprising that women engage in more future role planning than men with respect to how they might integrate and balance work and family roles.

Family structure is believed to have different career effects for men and women for several reasons. As noted previously, even in egalitarian marriages, women have greater responsibilities for dependent care and household chores than do men. These additional responsibilities can restrict women's career opportunities. Another explanation is that as a group, women place greater emphasis on family than on work. If this is the case, it may lead some women to self-select out of jobs and careers that they believe will not allow them to accommodate their family responsibilities. Finally, societal stereotypes likely play a role as well, such that individuals in more "traditional" marriages (e.g., working husband with a stay-at-home wife and children) are viewed more favorably by organizational decision makers than those in other family arrangements (e.g., female parent in a dual-earner marriage).

GENERAL APTITUDE TEST BATTERY (GATB)

The *General Aptitude Test Battery* (GATB) is a work-related multiple-ability assessment developed by the U.S. Employment Service (USES), a division of the Department of Labor. The following sections review the historical development of the GATB; the primary characteristics of the most recent measure, the Ability Profiler; and the current usage and availability of the Ability Profiler.

HISTORICAL DEVELOPMENT OF THE GATB

In the mid-1930s, the USES initiated a program of aptitude test research, resulting in approximately 100 ability tests designed to predict success across a wide variety of occupations representative of the U.S. labor force at the time. The USES then examined a set of these tests through a series of factor analyses, ultimately identifying 12 tests measuring nine aptitudes. GATB edition B-1002 comprised these 12 tests and was published in 1947 in two forms (A and B). Two

additional forms (C and D) were subsequently published in 1983. State employment service offices used the GATB for vocational counseling and applicant referral, and high schools, technical schools, universities, labor union apprenticeship programs, vocational rehabilitation agencies, and other authorized agencies used the battery for vocational and career counseling.

In the late 1980s, a review of the GATB by the U.S. National Research Council (NRC) of the National Academy of Sciences raised a number of concerns, and, subsequently, the battery went through several important changes in development. The concerns of the NRC included aesthetics, speed of completion, scoring, and susceptibility to coaching. The result of the revision process comprised GATB Forms E and F, now referred to as Ability Profiler Forms 1 and 2, respectively. These forms represent the current operational versions of the battery and are designed exclusively for vocational counseling, occupational exploration, and career planning.

CHARACTERISTICS OF THE ABILITY PROFILER

The Ability Profiler, comprising 11 separately timed tests (see Table 1), measures nine work-related abilities:

Verbal Ability: ability to understand the meaning of words and use them effectively in good communication when you listen, speak, or write

Arithmetic Reasoning: ability to use several math skills and logical thinking to solve problems in everyday situations

Computation: ability to use arithmetic operations of addition, subtraction, multiplication, and division to solve everyday problems involving numbers

Spatial Ability: ability to form pictures of objects in your mind

Form Perception: ability to quickly and accurately see details in objects, pictures, or drawings

Clerical Perception: ability to quickly and accurately see differences in detail in printed material

Motor Coordination: ability to quickly and accurately coordinate eyes with hands or fingers when making precise hand movements

Manual Dexterity: ability to quickly and accurately move hands easily and skillfully

Finger Dexterity: ability to move fingers skillfully and easily

Table 1. The Ability Profiler Tests

<i>Test</i>	<i>Ability Measured</i>	<i>Test Time^a</i>	<i>Format</i>
Arithmetic reasoning	Arithmetic reasoning	20 minutes	Paper and pencil
Vocabulary	Verbal	8 minutes	Paper and pencil
Three-dimensional space	Spatial	8 minutes	Paper and pencil
Computation	Computation	6 minutes	Paper and pencil
Name comparison	Clerical perception	6 minutes	Paper and pencil
Object matching	Form perception	5 minutes	Paper and pencil
Mark making	Motor coordination	60 seconds	Paper and pencil
Place	Manual dexterity	45 seconds	Apparatus
Turn	Manual dexterity	1.5 minutes	Apparatus
Assemble	Finger dexterity	1.5 minutes	Apparatus
Disassemble	Finger dexterity	1 minute	Apparatus

SOURCE: Adapted from U.S. Department of Labor (2002).

^aAn additional 5-10 minutes per test are required for administration.

There are three options for administering the Ability Profiler. First, all 11 tests can be administered in approximately 2.5 hours. This option is preferable for individuals exploring all occupations, including those requiring psychomotor abilities. Second, the 7 paper-and-pencil tests can be administered in approximately 1.5 to 2 hours. This option is preferable when individuals are not exploring occupations requiring manual or finger dexterity. Third, the 6 nonpsychomotor tests can be administered in approximately 1.5 to 2 hours. This option is preferable when individuals are not exploring occupations requiring psychomotor abilities. For all options, examinees must (a) be at least 16 years old, (b) read English at a sixth-grade level or higher, and (c) not have taken any form of the Ability Profiler or GATB within the prior six months.

Extensive research generally supports the reliability and validity of earlier GATB forms. For instance, numerous studies indicate the GATB instruments demonstrate acceptable test-retest reliability (most estimates are greater than .70), convergent validity, and at least modest correlations with ratings of job performance, although the evidence is often stronger for the cognitive aptitudes (e.g., Verbal Ability) than for the perceptual (e.g., Form Perception) or psychomotor (e.g., Finger Dexterity) aptitudes. Although there is less evidence to date for Ability Profiler Forms 1 and 2, reliability and construct validity analyses also support the use of these forms.

CURRENT USAGE AND AVAILABILITY OF THE ABILITY PROFILER

The Ability Profiler is currently in use as part of the Department of Labor's Occupational Information Network (O*NET) Career Exploration Tools. The O*NET is an extensive computerized occupational database of both job and worker characteristics. The O*NET Career Exploration Tools consist of a set of instruments designed to help individuals identify their work-related abilities, interests, and values, as well as to find the occupations that best correspond to individuals' attributes. The Ability Profiler instrument compares the individual's profile of abilities obtained from the Ability Profiler tests to similar ability requirement profiles of each O*NET occupation. Occupations with profiles closely matching the individual's profile (as reflected in the correlation between profiles) are suggested as promising areas for further career exploration.

The Ability Profiler and supporting documents (e.g., score reports, user's guide) can be purchased from the U.S. Government Printing Office or downloaded from the O*NET Resource Center Web site. Although certification is not required to administer the Ability Profiler, training should be given; the O*NET Resource Center Web site also provides training materials. Furthermore, users are allowed to modify or extend the Ability Profiler tool to develop customized products, but they must do so in

accordance with the terms of the O*NET Developer's Agreement.

GLASS CEILING

In recent decades, women and people of color have made considerable progress in moving into management jobs, but they tend to be concentrated in lower and middle levels in the management hierarchy. Particularly at large, private sector companies, the majority of key senior-management positions are still held by Caucasian men. The term *glass ceiling* is a metaphor that has been used to describe this situation. It refers to an invisible but impenetrable barrier that prevents qualified women and people of color from advancing to senior-management jobs.

The possible existence of a glass ceiling is important from the perspectives of both individuals and their organizations. For example, women and members of minority racial or ethnic groups may find that regardless of their qualifications and talent, artificial glass-ceiling barriers sometimes limit their career

advancement opportunities. Moreover, when organizations allow the glass ceiling to exist for women and people of color, these organizations are deprived of the diverse talents and perspectives that women and people of color could bring to critical leadership and decision-making positions. Furthermore, managers who realize that their career advancement is blocked by glass-ceiling barriers may become frustrated and leave their companies to seek better career opportunities elsewhere. This entry begins with a historical perspective on the glass ceiling, followed by the current status, and examples of theoretical explanations and research into whether or why a glass ceiling might exist.

HISTORICAL PERSPECTIVE

The glass ceiling was not widely discussed until the mid-1980s, when two *Wall Street Journal* reporters used the term in an article about women managers who couldn't seem to break through a "glass ceiling" that blocked them from advancing to senior-management jobs. In addition, these reporters pointed out that women managers tended to receive lower pay and have less authority than male managers. Thus, the term was originally introduced in connection with women's careers, but other authors pointed out that members of minority racial and ethnic groups faced similar barriers that prevented them from advancing to executive-level jobs.

Glass-ceiling issues received even more public attention when the U.S. Congress passed the Civil Rights Act of 1991 and required the president and members of Congress to appoint a Glass Ceiling Commission, chaired by the Secretary of Labor. The commission was created to investigate glass-ceiling barriers and make recommendations about how to eliminate these barriers and increase opportunities for women and people of color to advance into organizational management and decision-making positions.

The Federal Glass Ceiling Commission issued a report summarizing its findings in 1995 and confirmed that there did appear to be a glass ceiling blocking advancement of women and people of color in U.S. businesses. For example, 97 percent of the senior managers in Fortune 1000 industrial companies were White, and 95 percent were men, despite the fact that approximately 57 percent of the workforce was made up of females or members of minority racial or ethnic groups. The report identified three levels of glass-ceiling barriers: (1) societal barriers, such as stereotypes and

prejudice associated with gender, race, and ethnicity; (2) structural barriers in organizations, including failure to recruit women and people of color; organizational climates that could alienate these groups; and barriers that could limit their opportunities to advance; and (3) governmental barriers, including inadequate monitoring and law enforcement. Based on examples of companies that had made progress in addressing these barriers, the commission also pointed out characteristics of successful glass-ceiling initiatives, such as having top-management support, linking initiatives to the organization's strategic plan, addressing stereotypes, tracking progress, and holding key managers accountable.

CURRENT STATUS

In recent years, women and people of color have made some progress in attaining senior-management positions. For example, research by the Catalyst organization found that in 1995, only 8.7 percent of the corporate officers of Fortune 500 companies were women, but in 2002, women's representation had increased to 15.7 percent, and 1.6 percent of the corporate officers were women of color. However, women and people of color tend to be better represented at higher management levels in the public sector (i.e., government jobs) than in the private sector. Thus, recent research suggests that the glass ceiling has not yet gone away, but women and people of color may find better career advancement opportunities in some types of organizations than in others.

THEORIES AND RESEARCH

A number of different theories have been developed to explain whether or why the glass ceiling exists. Some explanations for the underrepresentation of women and people of color in senior management focus on characteristics of individuals, and other explanations focus on various types of organizational barriers to career advancement of women and members of minority racial and ethnic groups. Examples of each approach are described in the sections that follow.

Glass-ceiling Explanations Based on Individual Characteristics

Theories that focus on individual characteristics propose that women and people of color are underrepresented in senior management not because of their

gender or race but because they lack experience, skills, motivation, personal characteristics, or other qualifications that are needed to perform these jobs successfully. For example, a woman may be considered less qualified for a promotion than a man of similar age if she has fewer years of managerial experience; thus, in this case, the man may be promoted because of his greater experience rather than his gender. Examples of explanations based on individual characteristics include the human capital theory and self-selection.

The *human capital theory*, developed by economists such as Gary S. Becker, is a well-known theory that focuses on individual characteristics to explain differences in career outcomes, such as advancement and compensation. According to this theory, individuals with better qualifications, such as more education, job training, and relevant work experience, receive better jobs and organizational rewards because they have more to offer their organizations than do individuals who are less qualified. Although research has shown that differences in human capital can explain a portion of the gender or racial gap in career success, most studies also find that some portion of the gap cannot be explained by human capital variables. In addition, organizational research has found that comparable human capital qualifications do not always ensure that men and women managers will be equally successful in career advancement. While less research has compared minority and majority group managers, there is some evidence that human capital qualifications have a greater payoff in career advancement for Caucasian managers than for African American managers. Thus, human capital appears to be important in explaining career advancement but does not fully explain why there are relatively few numbers of women and people of color in senior management.

Another perspective is that group differences in corporate advancement can be explained by *self-selection*. According to this explanation, women and people of color may be less likely to hold senior-management positions because they have less interest or are less willing to do what is required to attain these types of positions. For example, gender differences in corporate advancement are sometimes attributed to women's involvement with family and household responsibilities that interfere with the long work hours, travel, or relocations required for succeeding in a demanding managerial career. However, this explanation does not hold for many women and people of

color who encounter glass-ceiling barriers to their advancement but either do not have family responsibilities or are willing to meet the requirements of demanding managerial jobs regardless of family and personal responsibilities.

A different explanation for self-selection is provided by Robert Lent, Steven Brown, and Gail Hackett's social cognitive theory, which suggests that self-selection is sometimes based on awareness of external barriers rather than a lack of interest on the part of the individual. According to this theory, women and people of color may be less confident than Caucasian men about their ability to succeed in managerial careers because they expect to encounter organizational barriers and lack of support that will limit their opportunities. Moreover, because of these external barriers, women and people of color may decide to lower their career expectations or pursue other types of careers in which they expect to encounter fewer barriers.

Glass-ceiling Explanations Based on Organizational Barriers

A number of explanations for the glass ceiling focus on various types of organizational barriers that make it more difficult for women and people of color than for their Caucasian male counterparts to advance to senior management. Examples of these barriers include gender and racial bias in organizational selection and promotion decisions, exclusion from interpersonal networks that can facilitate career advancement, and occupational segregation.

A great deal of research indicates that there are widely shared stereotypes or beliefs about the characteristics of various groups, including gender and racial groups, and that these stereotypical characteristics are often assumed to apply to individual members of a particular group. For example, based on traditional stereotypes, women might be assumed to be nurturing, and men might be assumed to be assertive. Moreover, jobs may become *gender typed*, which means that they are believed to be more appropriate for men or for women, based on either the gender of typical incumbents or the perception that successful performance requires stereotypic gender-related attributes. For example, management jobs, particularly at senior levels, are generally believed to be male gender typed because these jobs are usually held by men and are perceived to require stereotypical male attributes, such as assertiveness and achievement

orientation. According to Madeline E. Heilman's lack-of-fit model, men are more likely to be chosen for male-gender-typed jobs, such as senior-management jobs, because men's stereotypical attributes are perceived to be a better fit with requirements of these positions than are women's stereotypical attributes. Thus, there may be gender bias against women when organizational decision makers select people to fill these positions.

Although more research has been conducted about gender bias than about racial bias in managerial selection decisions, some research suggests that group stereotypes can make it more difficult for members of minority racial and ethnic groups to be chosen for senior-management positions. Research has found that stereotypical attributes associated with specific racial groups differ; for example, Asian Americans have been described as technically oriented but not good at supervising other people; Latinos have been described as unassertive; and African Americans have been described as incompetent. Although the specific stereotypes differ across groups, none of these attributes is consistent with requirements for success in senior-management positions, suggesting that there is also likely to be a perceived lack of fit for members of these racial groups with senior-job requirements, making it less likely that they would be selected for these types of jobs.

A make it more difficult for women and people of color to be promoted to senior management, but research has also shown that these groups report difficulty obtaining developmental assignments that would help them learn new skills needed for promotion to higher-level positions. In addition, perhaps because women and people of color are not always viewed as having the potential to advance, research has shown that they are less likely to receive assignments that give them visibility and contact with senior managers. Thus, to the extent that subtle selection bias and stereotypes make it more difficult for women and people of color to obtain critical developmental assignments, these individuals become less competitive for future advancement opportunities.

Research has also shown that *social capital*, which refers to the number and quality of an individual's relationships with other people, is related to organizational advancement. However, Rosabeth M. Kanter's groundbreaking research found that when there were very few women in an organizational unit, they were often excluded from informal interactions with their

male counterparts. Similarly, other research has shown that network relationships are more common among demographically similar individuals. Thus, to the extent that there are few women or people of color at a particular managerial level, it is more difficult for these individuals to form extensive networks. When these individuals are excluded from informal networks with Caucasian male managers, they miss out on critical information about career opportunities as well as support and sponsorship from other managers.

Research has also shown that having mentors, especially Caucasian male mentors, is associated with career advancement for managers but that women and people of color are less likely than Caucasian males to have Caucasian male mentors. Because there are relatively few women and people of color in senior management at many organizations, managers from these groups have few successful role models to emulate.

Another explanation for the glass ceiling is that within organizations there may be occupational segregation, or “glass walls,” with the most desirable jobs held by Caucasian men rather than by women and people of color. For example, women and people of color are more likely to hold staff support jobs in areas such as human resources or public relations rather than the more critical line positions that involve managing business functions, such as manufacturing or selling products or services. Occupational segregation has important career consequences because lack of line management experience is often cited as one of the key reasons that women and people of color fail to be promoted to top management.

Finally, some theorists note that because men have traditionally held the most powerful organizational jobs, organizations often have “male” cultures and value systems. Research has found, for example, that both women and people of color who want to advance in the corporate hierarchy may have to modify their behavior to fit the corporate culture. In addition, organizational cultures that embrace traditional male values may not recognize employees’ needs to balance work with family or other personal responsibilities or interests. Because women continue to devote more time to family responsibilities than do men, women may have difficulty advancing in an organization in which employees’ needs to balance work with family and personal responsibilities are not recognized and supported. Although many organizations offer family-friendly benefits, such as flexible work

arrangements or leaves of absence to care for family members, research has shown that without a supportive culture, employees may be reluctant to utilize these programs. Also, there is research evidence that employees who take advantage of benefits such as leaves of absence may be penalized with fewer subsequent promotions.

CONCLUSION

Although the situation has improved in recent years, women and people of color are still not well represented in the senior-management ranks of large, private sector companies, suggesting that the glass ceiling may persist. As the review of various explanations for the glass ceiling indicates, these barriers are often complex and difficult to tackle.

On the other hand, in recent years, some encouraging research has highlighted strategies that successful women and people of color have used to overcome these barriers and rise to the executive suite. For example, studies of these executives have found that key advancement strategies include finding opportunities to prove their competence and developing relationships with powerful mentors and sponsors. Other research has found that companies with strong senior-management commitment to workforce diversity can dismantle glass-ceiling barriers and that women and people of color are more likely to advance in organizations with systematic human resource processes to help prevent selection bias and in organizations that emphasize internal development and promotion of employees. Thus, although glass-ceiling barriers have not been eliminated, recent research suggests that some progress is being made.

GLOBALIZATION AND CAREERS

The term *career development* represents a large body of theory and research that seeks to explain the structure and the development of career behavior, personal identity in work and other life roles, and factors that influence career decision making. Even though such a perspective on the functions of career development is accurate, it oversimplifies the complexity and the magnitude of the psychological and sociological content relevant to how individuals "construct" their careers across the life span. In particular, this perspective blurs the importance of the various political, economic, social, family, and other contextual factors that create the environments in which people choose, prepare for, and negotiate their work roles. *Globalization* is a contextual factor that is rapidly emerging in its power to shape the organization of work, how it is done, who does it, and where it is done.

Globalization tends to be at the center of what many scholars and journalists perceive to be a major shift in the

nature of work and individual reactions to it. Indeed, globalization has spurred related language, including *internationalization, international competition, global economy, and free trade zones* (e.g., The European Union, the North American Free Trade Agreement), which are all relevant terms. They collectively signal that most of the nations of the world are in transition—politically, economically, and socially—and that the factors that underlie these transitions have placed education, jobs, employment and unemployment, careers, and interventions in career development high on the policy agendas of many nations, including the United States. These terms are growing rapidly in international importance because the citizens of nations in transition are typically subjected to increased stress; deficits in information about their options, underemployment, and productivity; unemployment; inadequate education; decreased productivity; anxiety; and uncertainty and sometimes dread and apprehension. Edwin Herr, Stanley Cramer, and Spencer Niles wrote in 2004 that although the specific factors that affect the career development of persons differ from nation to nation, they tend to share some commonalities, as unemployment rates remain very high in many nations; many persons across the world are denied basic rights to jobs, education, or independent decision making because of gender, racial, ageism, and other forms of discrimination; and changes in access and adjustment to work processes and expectations are occurring in many settings around the world.

Among many other observers, Alvin Toffler, in his trilogy of books, *Future Shock, The Third Wave, and PowerShift: Knowledge, Wealth, and Violence at the Edge of the 21st Century*, has consistently addressed the acceleration of change as a function of new economic structures created by the emergence of information-rich knowledge societies, replacing agricultural and industrial societies in the United States and in many other parts of the world. A parallel period of change drove the rise of vocational guidance and vocational counseling at the end of the nineteenth century and the early twentieth century, as the United States moved from the agricultural era to the rapid changes spawned by the Industrial Revolution. Rapid changes are now spurring the refinement of and the search for new paradigms of career guidance, career counseling, and career services as a function of the transition from the industrial and manufacturing-dominated twentieth century to the "new economy" under way in the information-rich knowledge- and service-based global economic structure of the twenty-first century.

DYNAMICS OF THE GLOBAL ECONOMY

Advanced Technology

The *global economy* is not just a new catchphrase; it is made possible because of a variety of other changes that have direct effects on careers. Perhaps the most significant is advanced technology. The popular press now talks about e-commerce, cyber society, the wired world, the global village, and other metaphors that essentially reinforce the axiom that a global economy could not be possible without computers, telecommunications, the Internet and the World Wide Web, fiber optics, digitization, satellites, and related technologies that advance national interdependence, global transactions, and communications. The outputs of advanced technologies flow around the world, unfettered by national political boundaries; electronic transfers can move more currency overnight to support business transactions of multinational corporations than many nations have as their total capital reserves; management of work, movement of inventories of products, and adjustments to customized production can be done 24 hours a day without regard to the time or space of the originating workplace; individuals in one worksite can use computers to monitor and manage the work being done at worksites thousands of miles away; through digitization and satellites, work that originates in the United States can be sent to Ireland, India, or other offshore locations to be downloaded, processed, uploaded, and returned to the originating site; and workers in one geographical site can plan, design, and troubleshoot the machines that are being computer directed at other sites around the world.

Such processes have many implications for careers. One is that computers, the Internet, telecommunications, and other advanced technological processes are functions of the interaction of science and technology. Given the intense competition for international markets and corporate economic rivalry, industry in the United States and in many other countries is committed to translating new scientific ideas as rapidly as possible into products or forms of technology that can be applied and exploited commercially. Through the use of advanced technologies, the historical time lags between scientific discoveries and their translation into new products, new tools, and new technologies have decreased in virtually all fields, from architecture to airplane design, construction, health care and medicine, financial management, and manufacturing.

Knowledge Workers

Although the effects of globalization stimulate the continuous interaction of science and technology, such interactions can occur only if there are *knowledge workers* available who are able to adapt to the rapid changes in work processes and problems and apply new knowledge. It has become increasingly clear across nations that the primary asset of nations is not raw materials or even wealth but the quality of the workforce as defined by its literacy, numeracy, computer and communication skills, flexibility, and teachability. Peter Drucker, the international scholar of work organization and management, in conjunction with other scholars, contended that knowledge has replaced experience as the principal requisite for employment in most of the emerging occupations in the world. It has become clear that as more workplaces are seen as "learning organizations," more jobs and organizations must be staffed by knowledge workers who know not only how to perform work tasks but also why. Currently, more than 60 percent of the United States workforce is made up of knowledge workers. Knowledge work is different from the patterns of repetitive actions that are present in traditional jobs; it is much more clearly described as a sequence of figurative dialogues between workers and the data they are using, whether monitoring and troubleshooting a computer-driven lathe or a robot, engaging in computer-aided design, diagnosing which computer module is not functioning in a automobile, or scanning the human body for evidence of disease.

Lifelong Learning

Embedded in the growth of knowledge workers is the growing importance of lifelong learning and the reality that the skills of schooling and learning and the skills of the workplace are increasingly complementary and overlapping. In a knowledge economy, basic academic skills serve as the foundation knowledge for technical and occupational skills. Educational abilities and achievements become major elements of individual career development. This reality puts those who lack motivation for learning, minimal training, and a high school diploma at the risk of being permanently dislocated or constantly on the verge of being unemployed. In analyses of emerging occupations, it has become increasingly clear that few jobs are being created that do not require reading, the ability to use

mathematics, and strong interpersonal skills. In this sense, mastery of basic academic skills has become a prerequisite for employability, for having personal flexibility in the workplace, and for lifelong learning.

In response to the implications that globalization accents knowledge and new ideas, the World Bank has argued that a global society requires workers who have mastered technical, interpersonal, and methodological skills. These skills encompass formal disciplines (e.g., foreign language, literacy, mathematics, and science); the ability to communicate, lead, and work with others; and the ability to participate in lifelong learning and to function within a context of risk and change.

The World Bank has further suggested that these forms of learning are teachable and that functioning in the knowledge economy requires three categories of competencies: acting autonomously, using tools interactively, and functioning in socially heterogeneous groups.

Other observers have suggested that the new status quo for workers is characterized by continuous learning and feeling “on the edge” or off-balance, as one is constantly expected to be prepared to adjust and adapt to the frequent transformations in the workplace, which are ongoing in the lives of workers immersed in a global knowledge economy.

Changing Language of Work

In this context, knowledge work is much more difficult than physical labor to classify and divide into small segments of action. As globalization spawns learning organizations and knowledge workers as major elements of the ability to compete internationally, scholars have argued that jobs as a way of organizing work are social artifacts that have outlived their usefulness. In this view, there will continue to be many types of work, but they will be organized differently than has been true during the past 100 years or so. Jobs as discrete packages of tasks or rigid position descriptions will likely be less frequent in the future than more flexible organizations of work.

These ideas have been transformed into current terms such as *boundaryless careers* and *multitasking*. Thus, jobs as clearly defined fixed sets of tasks, which have been central to the organization and language of work for approximately the past 100 years, are giving way to the effects of expectations by employers that workers should be able to engage in multitasking; get

the work done that needs to be done regardless of the artificial boundaries of a specified set of tasks; be personally flexible and adaptable to change; and be comfortable with the hybridization of work (e.g., bionics, or the wedding of biology and electronics; geophysics, or geology and physics) in which the problems are so complex as to require knowledge of more than one discipline.

Changes in the Organization of Work

The perspectives associated with the global impact of how work is performed, the importance of learning, the pervasiveness of advanced technology in the workplace, multitasking, and related phenomena have led to a variety of important changes in the nature of work organizations, career paths, and workers' responsibility to be their own career managers. It is important to acknowledge that individual development in most nations and in many organizations is no longer linear, predictable, long-term, or secure. The availability of lifelong employment in one firm, one corporation, one occupation, or one job is very unlikely for most people, even though a generation ago, many workers expected such a career pattern. They hoped to obtain employment in an organization, advance through its ranks, and retire. The phases of such a pattern—exploration, preparation, induction, consolidation, advancement, and retirement—were age related, understood, and anticipated. The goals of many workers were to successfully advance up an organizational chart as far as their talents and luck would take them. That view of career development is significantly less likely to occur in a rapidly changing global economy.

New Conceptions of Careers

In essence, the rapidity and intensity of change in the language and organization of work reflected in emerging career paths suggest new realities in the relationships between globalization and careers. For example, Michael Arthur, a British scholar, has suggested that a fundamental challenge for career theorists and practitioners is the need to affirm new career realities. He has argued that models of career development need to (a) be more dynamic in their accommodation of rapid change in the career paths available to individuals and (b) integrate career mobility rather than neglect it.

Underlying so many of the current conceptualizations of globalization and careers is the belief that new patterns of careers are taking place that are qualitatively different from those of the past. For example, researchers have argued that the changes in the way work is organized and structured have affected how notions of “new careers” need to be conceived in many nations, including the United States. They contend these new careers will be reflected in a much larger array of career patterns that will be less linear and more fragmented, with more frequent transitions than in the twentieth century.

Other scholars have suggested that people’s career paths will become a succession of ministages and short learning cycles, comprising sequential stages of exploration-trial-mastery-exit as they make transitions from one type of work to another. For example, the concept of *protean careers* accents the importance of individuals being able to constantly adapt to change, being personally flexible, and taking personal responsibility for their careers. Embedded in these perspectives is the view that although constancy and stability, or homeostasis, have frequently been cited in the psychological literature as desirable traits for individual growth and development, career planning and choice in the future are likely to be more spontaneous, more values oriented, and more influenced by environmental and organizational flux, unpredictability, and turbulence.

Another view of the effects of the global economy on the organization of work as it plays out in many nations is what Charles Handy has described as the “Shamrock organization.” This perspective speaks of a vast reconfiguration of the world of work. Heightened competition in the global marketplace is forcing companies to downsize their personnel to only those who represent the core tasks of the company: those whose skills are essential to the management, the provision of technical support, and the performance of the fundamental processes that produce the products or the services of the company.

The Shamrock organization discussed by Handy can be conceived of as three leaves, or rings, that begin with an inner and relatively small core, or circle of permanent workers. These workers with essential core skills are the ones who keep corporations functioning. They are paid well; have long-term identity with the company; receive health, educational, and retirement benefits; and receive training or support for lifelong learning.

The second ring of the workforce is occupied by temporary, part-time, or contingent workers whose

time and skills are purchased as needed or on a seasonal basis. Handy calls these workers a “portfolio class,” persons who document and sell their skills in episodes to firms that need their services for specific projects or periods of time, rather than remaining in continuing relationships with the same organization. Such persons may have to work several part-time jobs simultaneously to have sufficient income or purchase the health and other benefits that their temporary employers do not supply.

The third ring is made up of persons employed by an outsourcing company that specializes in particular services, for example, custodial and maintenance, customized goods production, marketing, food-service catering, advertising, accounting, law, data entry, security, outplacement counseling, or transportation. These specialist firms can be contracted to provide workers prepared to perform specific tasks. Thus, the original corporation does not have to employ and pay the overhead rates to get these tasks done. The outsourcing company does all of that and delivers the end product, such as catered food, security, training, or advertising.

Offshoring/Outsourcing

One of the newest perspectives on outsourcing is that such activity is not confined to transferring jobs within the United States. Rather, outsourcing and offshoring are being combined. Outsourcing of jobs has become a global issue. European nations, Japan, and the United States are now engaged in job transfer to other nations. It has been widely chronicled that companies in the United States have shed large numbers of information-technology staffers, with many of these jobs being transferred to technology-rich facilities in Bangalore, Delhi, and other locations in India, where millions of world-class engineers, business and medical graduates, and other educated and competent persons are now participating in the U.S. new economy. These persons are having a major economic impact by developing new software applications for finance, digital appliances, and industrial plants; consulting on information technology, managing information technology networks, and reengineering business processes; handling customer service complaints and processing insurance claims, loans, bookings, credit card bills, and airline reservations for U.S. employers; engaging in research and development for microprocessors and multimedia chips; doing research, U.S. tax returns, financial analysis, and

accounting for U.S. investment banks, brokerages, and major accounting firms; doing research and development for U.S. manufacturers; and many other tasks. While China has acquired many of the offshore manufacturing jobs from U.S. companies, India has emphasized knowledge work and services work that will soon employ two-thirds of its workers.

It is currently estimated that 1 or 2 million U.S. jobs have been transferred offshore. This number represents a relatively small percentage of the total American workforce of nearly 140 million persons over 16 years of age. However, projections are that another 3 to 5 million jobs will be transferred offshore between 2004 and 2009 and that this trend will be an important issue for decades to come. This may be a conservative estimate, since, in addition to the visibility of outsourcing of jobs to China and India is the fact that many Caribbean nations, Ireland, Malaysia, the Philippines, and the West African nations of Ghana and Senegal are creating technology-rich facilities and educated populations capable of serving as outsource recipients for U.S. jobs.

The net effect of a three-ring configuration of the workforce is to remove what had been permanent jobs in many corporations and reassign them to part-time status or to other firms in the United States or overseas that subcontract to do specific tasks. Such processes literally force many U.S. workers, who would in earlier decades have been employed in large organizations functioning in various support roles, to become essentially self-employed managers of their own careers. They must constantly adapt to change and develop new skills that corporations are willing to purchase on a temporary basis or that outsourcing firms can purchase to subcontract to other organizations.

Labor Surplus and Skill Shortages

Globalization effects have another, less discussed impact on careers. Across the world, there is a surplus of labor, consisting of many well-educated and well-trained persons for whom there are not adequate opportunities to work in their own nations. At the same time, the United States is experiencing both skill shortages and an unemployment rate of about 5 percent. Within the global labor surplus, there is almost an unlimited supply of industrious and educated individuals working or willing to work at a fraction of U.S. wages. These persons naturally gravitate to the economic opportunities available in the United States, intensifying immigration at a level, even with visa controls, similar to the one that

occurred 100 years ago at the height of the Industrial Revolution in the United States. These immigrants are more likely to come from Asia, Central America, or South America than from Europe; they are welcomed by employers because they bring skills that are in short supply in the U.S. population. Because of either lack of interest or information, workers in the United States have not chosen to explore many jobs in service, craft, or technical industries, which are often well paid and are essential to the production of goods and services. Government predictions are that these sectors will be the leaders in creating new jobs over the next 10 to 15 years.

Within this context, if qualified applicants are not available in the United States, the choice is to transfer jobs offshore or try to import immigrants with the skills needed. In recent years, U.S. corporations, health systems, and academic institutions have imported workers from other nations to work as tool-and-die makers, machinists, tractor-trailer drivers, nurses, physicians, mathematics and science teachers, scientists, and workers in other areas of skill shortages.

In both direct and indirect ways, globalization has affected the career paths available and the organization of work in the United States and in most other nations, has intensified international competition and encouraged employers to find ways to decrease their costs of production of goods and services, and has adopted advanced technology to increase productivity and decrease the number of workers necessary to perform the tasks essential to a particular workplace. In broad terms, the new work environments being created are shifting from preordained and linear, orderly structures, with clear guides for employee action and well-formed career paths, to perpetually changing career paths and possibilities in which uncertainty and flexibility are the order of the day and employees must make sense of their environments and plan their skill development and career paths accordingly.

CONCLUSION

A variety of implications for careers are embedded in the effects of globalization. They include the following:

Globalization has intensified the competition for jobs in many countries. Transferring jobs to other nations and immigration of well-trained persons affect which jobs are available and the competition for those jobs—and this, in turn, changes the career pathways available to

citizens in the country from which the jobs were removed and also in the country that receives the jobs.

As specific jobs move offshore, the occupational structures are changed in the receiving country and in the country from which the jobs were transferred. In many instances, educational requirements in both nations rise, accelerating the importance of knowledge and skill, as opposed to experience, as requisites for employability.

Nations engaged in the global economy are constantly seeking comparative economic advantages by transforming their work organizations and processes through the use of advanced technologies, mergers, and consolidation of organizations; by expecting workers to constantly improve their skills; and by placing workforces in other nations with markets for products and services. From a career standpoint, these trends suggest that workers at almost every level of skill and in every industry must be familiar with and able to work with computers, telecommunications, and other advanced technologies; be strong communicators; be able to work with others in teams; have effective interpersonal skills, be willing to constantly develop new skills to enhance their employability, and, in many cases, be available for international assignments. Even though the primary language of the global economy is English, bilingual or multilingual skills are prized abilities for workers in multinational and many governmental organizations.

Work organizations are taking less responsibility for the careers of their workers. While many firms provide information about position vacancies, anticipated changes in work processes, and important skills, the expectation is that workers will be their own career managers, analyzing trends that will affect them, participating in lifelong learning, and committing themselves to engaging in the processes that will keep them employable.

Career paths are likely to become more horizontal than vertical in the future. As greater responsibility is given to workers or worker teams to manage quality control, make decisions about work processes, and share electronically transmitted information relevant to tasks for which they are responsible, it is likely that positions in middle management or senior management will be reduced in number. As more management tasks are invested in workers, the ability to problem-solve, to work with others, and to take responsibility for performing work that goes beyond one's job description (multitask) will be important.

Career pathways will be more diversified and less institutionally based. A contingent workforce is rising around the world that includes temporary employees whose skills are purchased for limited periods of time and do not have long-term institutional identification. Such

employment may involve part-time or self-employment or involvement with specialized outsourcing firms that supply employees to workplaces for limited periods of time to complete particular projects or sets of tasks.

H

HALL OCCUPATIONAL ORIENTATION INVENTORY

The *Hall Occupational Orientation Inventory* (HALL), first published in 1968, was developed by Lacy G. Hall to provide a more complete assessment of work-related personality variables than do the extant standardized interest inventories. Hall based the development of this inventory on the humanistic personality need theory elaborated by Abraham Maslow and adapted by Anne Roe, and on occupational-interest research. Since 1968, HALL has been revised four times (fourth revision published 1989). HALL was developed to expand the domain of the traditional trait factor interest inventories by assessing other domains in addition to interests: personal values, psychological needs, job characteristics, abilities, and choice style. This 175-item instrument is a vocational counseling inventory designed to be self-administered, self-scored, and self-interpreted. There are several forms of HALL, designed for different populations and age groups: Intermediate, Young Adult/College/Adult, Adult Basic, and Form II. HALL can be used with the *Guide for Occupational Exploration*, published by the U.S. Department of Labor in 1979.

The 175 items of HALL are grouped into 35 scales of 5 items each. There are 9 Needs-Values scales (e.g., Creativity-Independence, Self-Actualization, Routine-Dependence); 6 Career Interest scales with 6 corresponding Ability scales (e.g., People-Social-Accommodating, Things-Physical, People-Business-Influencing); 8 Job Characteristics scales (e.g., Coworkers, Time, Risk); and 6 Choice Style scales (e.g., Subjective External Authority, Interdependent,

Procrastination). The response formats vary depending on the type of scale. The Needs-Values scales, Career Interest scales, and Job Characteristics scales are assessed on a five-point scale ranging from *most desirable* to *very undesirable*. The Choice Style scales use a three-point scale ranging from *not like me* to *very much like me*. Last, the Ability scales employ a four-point response continuum ranging from *weak* to *strong*.

HALL is designed to be self-administered, self-scored, self-profiled, and self-interpreted. The intent is to provide individuals with an organizational scheme for rating, prioritizing, and evaluating a variety of personal factors known to be related to successful career choice and satisfaction. The scoring system uses raw scores to evaluate the relative importance of the personal characteristics to the individual taking the inventory, rather than comparing the individual's scores with those of a normative sample of other people. The goal of this type of scoring system is to facilitate exploration rather than result in prediction.

Items on this instrument present only one variable at a time to the individual. No specific occupation is identified by any of the items, so a respondent is evaluating only a single need or interest dimension as he or she considers a response to each item. Similarly, all the items on each scale are logically related to the scale. No empirical, predictive occupational scales are used, because Hall believes that empirical scales do not facilitate exploration or interpretation. In addition, since the instrument is based on Maslow's humanistic dynamic developmental theory of personality, it is not expected to exhibit long-term temporal stability but only to provide a snapshot of evolving personality variables at a given moment in time. The argument is

that people no longer choose one occupation that will last a lifetime. Most workers change occupations several times during their careers, and the priorities and values of a 20-year-old college student or entry-level worker may not resemble the priorities and values of that same individual in 10 or 20 years' time. HALL was intentionally designed to aid individuals in searching for new directions as they change and develop as people.

HANDWRITING ANALYSIS IN HIRING

Handwriting analysis, or *graphology*, as it is otherwise called, is the study of an individual's handwriting sample done in order to make judgments about the individual's personality traits or his or her tendency to behave in certain ways. The major use of contemporary handwriting analysis is as a staffing tool by business organizations. Job applicants submit handwriting samples to trained graphologists, who examine characteristics of each applicant's handwriting and provide a summary of personality traits suggested by characteristics of the writing sample. The graphologist's conclusions may indicate the degree to which applicants possess certain personality traits and may be accompanied by a summary statement of the degree to which each individual is likely to be successful in the job for which he or she is applying. Handwriting analysis in personnel selection is very common in Western Europe, where perhaps as many as 75 percent to 80 percent of companies use it in hiring. It is less common in the United States, but some estimates have suggested that more than 2,500

American companies may use handwriting analysis for at least some portion of their workforces.

HISTORY AND BACKGROUND OF HANDWRITING ANALYSIS

Published work in handwriting analysis dates as far back as the seventeenth century. The modern science of graphology, however, originated in the late nineteenth and early twentieth centuries. Three separate schools of handwriting analysis are commonly identified by experts. Two of these schools are from late-nineteenth-century Europe, one from France and the other from Germany. A French priest, Michon, originally coined the term "graphology" to describe a science of "fixed signs" in which every handwriting feature, such as slants, loops, and spacing of letters, was associated on a one-to-one basis with a specific personality trait.

The classic school of graphology originated with the late-nineteenth-century work of Germans Wilhelm Preyer and Ludwig Klages. They and others transformed handwriting analysis into a "scientific" form, based on the premise that all motor activity, including handwriting, is performed without conscious thought or by habit and reflects specific stable drives, traits, or tendencies that capture the writer's personality. The German school does not embrace the "fixed sign" approach of the French graphologists, but proposes that handwriting must be interpreted within the context of individual "rhythms" and that specific handwriting features must be interpreted differently based on the rhythm of the writing sample as a whole and on the analyst's experience. The German school saw handwriting as an expressive movement similar to commonly used projective techniques in psychology, such as the Rorschach ink blot test.

The third school of handwriting analysis was founded by American M. N. Bunker in the late 1920s and is called *graphoanalysis*. The graphoanalysis school is widely thought to represent a compromise between the French and German schools. While it relies on the interpretation of unique writing features, the method is based on Gestalt psychology and involves establishing a consistent pattern within the specific writing characteristics to establish an overall pattern of personality. The work of all handwriting analysts is based on many of the same general principles involving the size of letters, words, or numbers, spacing between words and lines, slant of letters, margin size, and pressure on the writing instrument. In graphoanalysis, for

example, slant is an indicator of emotional responsiveness. However, different analysts, particularly those trained in different schools of graphology, weigh factors differently, and standards for evaluating handwriting vary.

RELIABILITY AND VALIDITY IN HANDWRITING ANALYSIS

The major focus in employee selection is on the ability of selection instruments to predict one or more aspect of job performance. To be able to predict job performance, all selection devices must be able to demonstrate that they are both reliable and valid measures. *Reliability* refers to the property of a test that allows it to produce consistent results. Where handwriting analysis is concerned, this means that if one's handwriting sample were evaluated at different points in time or by different evaluators, the results would all be roughly the same. The evidence on the reliability of handwriting analysis is mixed. There is some evidence that graphologists with similar training (such as those trained at the Graphoanalysis Society in Chicago) are somewhat consistent in their interpretations of samples. Other experts question the reliability of handwriting analysis, suggesting considerable variation in interpretations across both schools of handwriting analysis and interpretations of different analysts.

A selection test is useful only to the extent that it has demonstrated *validity*, defined as the ability to infer or predict some aspect of job performance based on scores on the test. For handwriting analysis, there are two separate but related validity issues. First, handwriting analysis must be shown to be able to validly predict personality *clusters*, or sets of personality traits. Second, these clusters of general personality traits must be associated with better fit for specific positions or better job performance. The validity of handwriting analysis is determined by both the extent to which graphology accurately measures the personality traits in question and how well those traits relate to some measure of job performance.

Research on handwriting analysis is not as extensive as research on other selection instruments, such as cognitive ability or personality testing, and it suffers from small sample sizes and some lack of rigor. What research does exist, however, suggests that handwriting analysis does not validly predict either personality traits or job performance. In most attempts to demonstrate its validity in predicting personality

traits by comparing graphology results to established measures of personality, analysts have not been able to replicate independent measures of personality produced with other personality measures. The ability to predict job performance has been even more disappointing. In virtually all cases, trained handwriting analysts do no better at predicting job performance than do untrained students, nor are their predictions any better than those expected by chance.

CONCLUSION

Research on graphology suggests that at best, it has only low-to-moderate reliability, and there is little evidence that graphology is accurate in predicting personality traits or that the narrow traits that many analysts infer from handwriting samples correlate with job performance. Despite the lack of evidence of a direct link between handwriting analysis and various measures of job performance, many companies continue to persist in its use. In fact, there is some evidence that the use of handwriting analysis in selection is actually increasing, perhaps because handwriting analysis has face validity to many people. It "makes sense" to them and seems as though it should work. One clearly positive aspect of graphology that is not true of many other devices is that it is not prone to faking, since handwriting samples can be solicited with veiled purpose. Certainly, graphology appears to be more art than science, and there may be some graphologists who through better training, advanced skills, or better intuition may be able to make more accurate predictions than other analysts. The research that does exist, however, provides no support for the hypothesis that handwriting analysis works. For the practicing manager, it appears that the scientific evidence suggests that handwriting analysis should have little, if any, role in the staffing process and that managers should rely on other measures of personality, such as contemporary measures of the Big Five personality instruments.

HISTORY OF CAREER STUDIES

This entry outlines the main schools within the broad area of career theory, which here have been defined as (a) a sociological perspective focusing on the structural influences over one's working life and the interplay between individuals and institutions, (b) an "individual differences" or vocational perspective concentrating on fitting round pegs into round career holes, and (c) a developmental or life cycle perspective examining the way people develop and change over the course of their lives. This is not to say that additional perspectives are not relevant to theorizing about careers, only that the main areas of theoretical interest within the careers area have been dominated by these perspectives. Since it is impossible to do justice to the diversity and number of specific career theories in this brief space, we concentrate on the most important influences in the field and on general themes and tensions that have persisted throughout career theory.

CAREER THEORY FROM A SOCIOLOGICAL PERSPECTIVE

Historical Influences

The sociological perspective on careers focuses on the social structures, cultural norms, and institutions that define, direct, and constrain people's actions at the societal level, as well as how those structural forces shape individuals' behavior as they navigate through institutions, professions, and occupations. Careers work on occupational and professional boundary definition, mobility, status assignment, and constraints on occupational choice has roots in early sociology. Emile Durkheim (1858-1917) and Max Weber (1864-1920) contributed to some of the most

seminal early theoretical work in careers, most notably that of Everett Hughes.

Durkheim's contribution to the careers literature focused on the nature of the relationship between the individual and societal structure, the importance of the division of labor to collective and individual identity, and the importance of occupational identity and association to the organization and integration of society. *The Division of Labor in Society* posited that individuals tend toward increasing functional specialization as society becomes increasingly industrialized, and these shifts change the foundation of social solidarity from individuals sharing similar functions within a community to individuals dependent on one another within a highly organized division of labor. This division of labor strongly determines individuals' occupational lives and identities.

Karl Marx and Adam Smith were also preoccupied with the division of labor in industrial society. However, Durkheim did not argue that its effect on workers necessarily implied class conflict, as did Marx, and he was more concerned with its effects on social cohesion than was Smith (though Smith was more ambivalent about the societal effects of capitalism than one would assume given contemporary memory). The main concern with division of labor was how it leads to excessive specialization, dangerous in particular when accompanied by social inequality. Division of labor supports social integration only when specialization is not accompanied by an unjust division of status. When people are required to narrow the scope of their everyday professional activities to atomistic proportions, individuals begin to suffer from *anomie*, or alienation from their social collective, which undermines the stability of the collective. Durkheim's work on the division of labor translates well from the societal to the organizational level, what he terms the "corporative" level, which he sees as an important secondary source of social cohesion, mediating between the societal level and the individual level. His work reminds organizational theorists to pay attention to how career boundaries and job scope within organizations play an important part in determining the cohesiveness of organizational groups and in developing organizational norms.

Occupational groups also play an important role in Durkheim's work, in particular for their capacity for moral influence, rivaling the influence of the family as a source of collective morality and group identity and as protection against the alienating aspects of postindustrial life. As professional life has overtaken other

sources of individual identity, Durkheim's work on occupational groups has been reflected in career theory on professional identity, occupational attachment, and professional ethics.

In addition to remaining the most elegant theorist on the value of (and dangers inherent within) bureaucratic organizing, Max Weber was also the first theorist to describe the characteristics and stages of the administrative or bureaucratic career, newly emerging within early industrialized commerce and the movement in the nineteenth century toward a public service. Along with Durkheim, Weber was also concerned with a central tension within society between the need for individual freedom and the need for social control. Yet while Durkheim prioritized the maintenance of social integration and social order, Weber was more concerned with the value of individual freedom and humanity, which could be silenced within the efficient but depersonalized "iron cage" of bureaucratic organization.

As is well-known, Weber defined a number of characteristics of the modern bureaucracy, including the following: (a) fixed and continuous offices (b) governed by rules and/or laws within (c) an organizational hierarchy, managed by (d) officials with fixed sets of duties and (e) predetermined qualifications for office, including (f) specific training for that office. Weber was profoundly ambivalent about bureaucracy and the rationalization of processes that it requires. It has been claimed that Talcott Parsons tempered this ambivalence in his early translations of Weber's work, which stressed the positive aspects of Weberian descriptions of bureaucracy over negative ones, whereas later translations of Weber's work by Hans Gerth and C. Wright Mills highlighted this ambivalence. Weber's ideas about bureaucratization in the modern state and corporation speak to the career theory on career paths, job scope, occupational and organizational socialization, and occupational and organizational identification. His ideas on the tension between (a) the gains of efficiency, stability, and fairness provided by bureaucracy and (b) the dangers to individual freedom and growth extended by the same process translate into theory on the relationship between an individual's need for growth and development and the organization's need for stability, reliability, and continuity.

Weber has also been credited with developing an early analysis of social hierarchy that separated out *class hierarchy*, the classification of individuals based

on economic advantage, from *status hierarchy*, the classification of individuals based on honor or occupation. Distinguishing status and class allows one to conceptualize occupational attachment from both economic and prestige perspectives and informs career theory on occupational identity formation and attachment, echoed in Everett Hughes's (see below) understanding of the creation of "professions." Group identity can serve both to separate one group from another (economically or via prestige) and to help a group cohere internally (through commonalities in economic advantage or prestige).

Everett Hughes occupies a unique space in the history of career theory, since he is often designated as one of the founders of the field and was writing about the sociology of occupations as early as 1928. Using the institution as the central level of analysis allowed Hughes to continue to focus (in a Durkheimian sense) on the structural forces that constrain and shape human behavior, while remaining attuned to how individuals continually create meaning and norms within those institutions. For Hughes, institutions serve both as a regulatory or moral function for individuals, providing a source of collective identity and therefore mitigating against anomie in postindustrial society, and as an efficient way to organize resources. Hughes took on the division of labor and its importance to social relationships and its danger of undermining social stability. Framing the division of labor as a social phenomenon with implications beyond simple economic results allowed Hughes to frame work as a crux between the individual and society and point out that no profession can be understood without placing it within the context of a social matrix or system.

Weber's influence on Hughes is also evident throughout his work. In "Institutional Office and the Person," first published in 1937, Hughes wrote about the characteristics of formally held offices in much the same way that Weber wrote about characteristics of bureaucracy, including how offices define and prescribe one's role and, in so doing, confer status on an individual. He echoes Weber's understanding of status assignments by pointing out how offices can be communicated through ritual, such as taking a vow (like the Hippocratic oath), which defines office holders against others. Hughes was also interested in how professions are defined and circumscribed, repeating concerns about how professions maintain problematic boundaries, protecting themselves from outside intervention at the occasional expense of transparency and accountability.

Hughes's students at the University of Chicago conducted some of the most important ethnographic studies of professions and occupations, including Becker and colleagues' *Boys in White*, a classic study of the indoctrination of medical students into the profession of medicine, as well as studies of the careers of the taxi hall dancer, the professional thief, and the tubercular patient. Strains of Hughes and the concern for the effect of bureaucratization on individuals can be seen directly in some of the dystopias described in sociological investigations of the "modern corporation," such as *White Collar*, by C. Wright Mills, or William Whyte's *Organization Man*.

In the second half of the twentieth century, sociological career theories tended to focus on the social-structural determinants of occupational choice and attainment or, more ethnographically, on individuals' experiences of career navigation through social structures.

A great deal of empirical work has studied the effects of class background and parental occupational attainment on the outcomes of individuals. Classic work in this area includes labor market theory, which speculates about the importance of both external and internal labor market features to individual work outcomes: Delbert C. Miller and William H. Form's industrial sociology; and Peter M. Blau and Otis Dudley Duncan's status attainment theory, which posited (and demonstrated empirically) that individual occupational status is heavily influenced by parental attainment. The second trend draws more heavily on the ethnographic work of the Chicago school sociologists, conducting inductive investigations of individuals' navigations through careers and the interactions between the micro- and macrolevels of analysis.

Edgar Schein is the most obvious representative of this second sociological trend. Using a firmly interactionist approach, Schein examined both how the organization serves the acculturation and socialization needs of the individual and how the individual serves the innovation needs of the organization. His work on *career anchors*—the individual self-concept with which individuals approach their working lives and that could be based on technical competence, managerial competence, security, creativity, or autonomy—drew attention to the nature of the subjective career and the notion that organizations would be better served if they could accommodate individuals' changing self-concepts. In terms of how individuals navigate through organizations, Schein conceptualized the organization

as a cone, containing multiple classes of boundaries representing different types of status passages: external/internal boundaries, vertical boundaries (promotion), and horizontal boundaries (movement toward the "inner circle" of organizations). Michael Driver's directional pattern model of careers, driven partially by the individual and partially by the organization, recalls Schein's understanding of unique individuals navigating unique paths through organizations.

The desire to capture what a *career* is, both for the individual and within an organizational context, continues to receive a great deal of theoretical attention. The general trends have been to expand earlier understandings or metaphors of career, generally more static, predetermined, and organizationally and objectively defined, to be more dynamic and broadly, individually, and subjectively defined. Douglas Hall's theory of the protean career and Michael Arthur's theory of the boundaryless career represent keys to this trend.

CAREER THEORY FROM A VOCATIONAL PERSPECTIVE

Historical Influences

The idea that an occupation exists that will best match or fit any individual was particularly attractive after industrialization undermined the traditional artisan- and guild-based organization of labor and after migration to cities (together with waves of immigration to the New World) made the placement of new arrivals into productive positions in society more urgent. This challenge was approached both by early psychologists, who believed that testing individuals' abilities or aptitudes could be used to effectively place individuals in a societally productive way, and by civic reformers, who developed theories more concerned with individuals determining career choices that would prove individually "fit." Though both strains were concerned with "fitting" people to jobs, psychologists tended to prioritize what was best for the organization, while civic reformers tended to focus on the needs of the individual. However, all of these theories generally imply a static understanding of human nature: Once a correct choice is discovered, whether by expert testing or journeys of self-awareness, the peg would have found an appropriately shaped hole.

Psychology as a scientific discipline was in its nascent stages in the nineteenth century. Psychologists

such as Francis Galton (1822-1911), James McKeen Cattell (1860-1944), and Charles Spearman (1863-1945) were optimistic about the ability to measure and quantify individual abilities and potential, avidly devising tests to determine the nature and extent of individual differences and using those differences to predict various outcomes. Historically, the advancement of these types of early intelligence tests became useful as enlistment in World War I ballooned, which gave the military a tight timeline for figuring out how to most effectively place hundreds of thousands of personnel. The U.S. Committee on Classification of Personnel in the Army conducted one of the largest applications of intelligence and aptitude testing ever testing 1.7 million men and critically influencing the deployment of those military personnel.

It was, however, the development of personality and interest tests—such as the Strong Vocational Interest Blank and the Kuder Preference Record—which provided a boon to career theorists looking to develop propositions about what kinds of individuals would choose and excel in different jobs. The theories behind interest testing were conceptually different from the theories behind intelligence or aptitude testing, for they assumed that volition would determine performance at least as much as inherited ability would. Though vocational testing has moved beyond static understanding of human ability and the idea that scores on tests are alone enough to understand in what occupations individuals will thrive, these early theories and tests continue to maintain some authority in the field.

Moral and educational concerns motivated the second stream of vocational theorists. Instead of being primarily concerned with how organizations could most effectively gain productively from their human resources, early vocational guidance theorists were propelled by an interest in understanding the “person side” of the peg-in-hole metaphor: In what type of employment would an individual find the greatest satisfaction?

The reformist and theorist Frank Parsons (1854-1908) played as seminal and catalytic a role as the one played by Hughes within the sociological tradition of career theory. A lawyer by training, Parsons became concerned in the later stages of his career about the effects of industrialization on workers, especially among those most vulnerable (the young, the poor, and new immigrants). At Civic Service House in Boston, Parsons developed an experience-based theory: If individuals had accurate and thorough

self-understanding and had accurate and adequate understandings of different professions and the connections between those two sets of beliefs, a solid vocational choice could result. His motivation was to encourage vocational discovery as a process of self-actualization. Though Parsons’s theory of vocational choice was not new (similar ideas about vocational choice had been circulating since the 1700s), it remains most credited to him to this day.

It is possible to see the influence of both the individual-differences tradition and the vocational-education tradition in some of the earliest works of the career theory canon. In the 1950s, Anne Roe’s personality theory of career choice made predictions about career choice based on a combination of factors, including childhood experiences, our personal needs and need strengths (taken from Abraham Maslow), and our genetic predispositions (i.e., abilities). Though incorporating ideas from more developmental theories, such as attending to the importance of one’s childhood environment in later career choice, her theory remained primarily vocational in perspective, interested in the prediction of adult vocational interest patterns and choice based on a combination of individual-level factors. In an effort that enlarged the “fit” notion to include both individual and environmental factors, Lloyd Lofquist and Rene Dawis developed the concept of work adjustment. *Work adjustment* represents the continuing effort of individuals to ensure that their own needs are met within the work environment in ways that are commensurate with the requirements of their jobs; this correspondence then predicts satisfaction, effectiveness, and turnover. The inherent tension in the vocational guidance tradition within career theory involves the twin desire to predict people’s “best fit” profession, while acknowledging that prediction is, at best, probabilistic and that person-environment fit involves many interacting variables, which can all potentially change.

John Holland’s theory of vocational choice is perhaps the most representative “career” theory that tentatively explores the tension between knowing that individuals continually develop and prioritizing the notion that the goal of vocational guidance is to “fit” individuals to jobs. The theory proposes that vocational choice and behavior are driven by individuals’ attempts to best fit their personal orientations to their occupational environments. Individuals have patterns of personal orientations (Holland defines six: Realistic, Investigative, Social, Conventional, Enterprising, and

Artistic) that drive vocational choice. Congruence between individuals' personal orientations and the demands of their occupational environments then drive satisfaction and performance outcomes. The theory has taken on added complexity since first proposed in the early 1960s, for example with regard to emphasizing contextual factors. Although it does try to take into account how people may change and require adaptation to different environments (a position helped through the use of longitudinal research into the stability of vocational choice), it remains a more complex and nuanced restatement of older "peg-in-hole" theories. Linda Gottfredson's later theory of circumspection and compromise echoed Holland's interest in fitting individual preferences with occupational requirements, though from a lens of childhood psychology. She posited that individuals' vocational choices are made on the basis of narrowing occupational options (circumspection eliminates unwanted options, while compromise replaces unrealistic desired alternatives with more realistic ones) through an ongoing process of mapping one's self-concepts to held images of occupation.

CAREER THEORY FROM A DEVELOPMENTAL PERSPECTIVE

In contrast to most vocational theory, the developmental perspective focuses on careers as a dynamic and maturing process that evolves over time. The key theorists usually identified with this perspective have traditionally built stage-based models of career.

Historical Influences

Sigmund Freud (1856-1939) and Carl Jung (1865-1961), as well as Abraham Maslow (1908-1970) and Erik Erikson (1902-1994), contributed different visions of dynamic individual change and growth over the life cycle.

Freud's legacy is perhaps both underrepresented and diffused in the career theory canon. Freud did claim that life's twofold foundation is "the compulsion to work, the power to love." In particular, the key role that work plays in a well-adjusted personality and the unhealthy role it can likewise play in a less well-adjusted personality are persistent themes throughout his writing. Strains of this can be seen in Clayton Alderfer's work, which points out how Freud's work on transference is relevant to understanding how needs from other realms

could be sublimated through work. Work can represent the most positive achievement in individual life, but it also may represent attempts to avoid negotiating the unconscious. Freud's continued priority of childhood influences over the potential for seminal experiences in adult life and the frustrating untestability of his theories left him with less to contribute to career theory than other developmental theorists.

In contrast, Jung presented himself as one of the first theorists of midlife. Jung's own "midlife crisis," in 1913 at the age of 38, triggered a new understanding of the period between age 35 and 50 as a phase of life during which important changes in the psyche take place. During this phase, individuals tend to shift from a primary focus on the external world to a more internal, reflective state, opening the possibility for profound growth—as well as potential for withdrawal from the second half of life if the tasks one is confronted with at midlife prove too intimidating.

Following Freud and Jung, both Maslow and Erikson presented hierarchical stage-based models that are highly attractive and transportable to theorizing about careers (though they remain frustratingly uncooperative in empirical testing). Maslow's theory of motivation rests on a five-step hierarchy of needs, beginning with physiological needs; progressing through safety needs, affiliation needs, and achievement and esteem needs; and finally culminating in the need for self-actualization. Individuals are motivated by whatever set of needs is most personally salient and unmet at the time. Once a set of needs has been met, the next-higher level of needs assumes greater salience. Self-actualization has remained a popular construct representing an important career "success" outcome. However, empirical analysis has had little success confirming his theories; instead, Maslow's work has been reinterpreted by career theorists as speaking to a series of sequential career stages, representing status passages rather than sets of need gratification.

Erikson's eight-stage developmental theory contains a number of progressive tasks that directly influence career theory. The stage of *industry versus inferiority* requires that the school-age child integrate an understanding of the importance of work and accomplishment, while mitigating against a sense of inadequacy as he or she grapples with learning new technologies. This stage gives way to the stage of *identity versus role confusion*, during which the main task is to ensure the development of a strong sense of self, a key piece

in developing a strong vocational identity: Erikson claimed that the inability to resolve an occupational identity is a primary cause of disturbance in youth. The *intimacy-versus-isolation* stage, which occurs in early adulthood, requires individuals to commit both to intimate relationships and to stable employment or career (toward midlife) and builds toward the final two stages of life (both after midlife). During the stage of *generativity versus stagnation*, individuals are to guide and teach the next generation, while the final stage, *ego integrity versus despair*, represents the culmination of a life's journey toward maturity, during which one has accepted the limitations of one's individual life but remains an enlightened leader and legacy builder.

Traditional life span developmental psychology examines human development throughout life, with the perspective that developmental processes are best understood in a context that incorporates individuals' entire life courses. Clayton Alderfer's Existence, Relatedness and Growth (ERG) theory represents a fusion of theories from a number of different disciplines, though the work is most seriously indebted to Maslow's theory of motivation. Alderfer posed his theory as a more parsimonious, less rigid, and more career-focused alternative to Maslow's. ERG theory posits that individual needs can be characterized by "existence," or the importance of finding equilibrium in the satisfaction of human needs; "relatedness," or the importance of human interactions in social environments; and "growth," or the need of any system to increase in order and differentiation over time.

George Vaillant's study of successful adult adaptation also represents a theoretical stepping-stone between Freud, Jung, and career theory. In a 35-year-long cohort study of "people who are well and do well," Vaillant took Freud's work on the ego mechanisms of defense and arranged them in an evolutionary process, to range from the least- to most-adaptive defense mechanisms. His study demonstrated that individuals who are most successful are able to change their needs and priorities as they navigate the life cycle and demonstrate growth over time. Vaillant believed his longitudinal study also supported the theories of Erikson, finding that subjects at early midlife are more interested in their own careers (conforming to Erikson's stages of industry and identity), while by their 50s, they are more interested in their colleagues and staff (conforming to Erikson's stages of intimacy and generativity). He also noted that individuals could get stuck,

living their adult lives as if they were teenagers, harkening back to Jung's concerns about unsuccessfully meeting the challenge of complete individuation that meets one at midlife.

Seeing his study *The Seasons of a Man's Life* as a parallel to *Adaptation to Life*, Daniel Levinson focused on the midlife decade, which had caught the imagination of Erikson and Jung, because at 40, individuals must make the transition from wondering what one will be to coping with what one has become. Levinson distinguished himself from the more purely intraindividual theorists by stressing the interaction between the individual and his or her environment. Levinson posited universal stages through which most individuals pass, each of which is connected to either structure-building or structure-changing periods. The midlife transition, the point at which individuals become disillusioned with their current realities, involves confronting and reintegrating the polarities that define life, and it represents the most important structure-changing phase of life. Erikson referred to this as the "stage of generativity"; Jung first proposed it as the turning point between the first and second half of life.

From the 1950s on, Donald Super distinguished between occupational and career theory—the former representing the static theories of the vocational psychologists and the latter representing the more dynamic theories covered in this section. Influenced by both life stage theorists and social role theorists, Super built a staged model of careers positing that career development occurs along a set of phases during which individuals continually implement and then revise self-concepts. Super's "life-span, life-space" approach to careers charges that individuals' developmental tasks and requirements change over time, as do their social roles, and that both influence career development recursively. Work and life satisfaction depend on the ability of individuals to implement their self-concepts in a fulfilling way, appropriate to their life stages and social roles at the time. Like Schein, Super believed the driving self-concept became more stable as individuals matured.

Though Super's developmental theory has withstood the test of time, a number of similar career theories echoed many of the same ideas, such as Eli Ginzberg and his colleagues' theory of occupational choice, based heavily on developmental psychology, and David Tiedeman and Robert O'Hara's theory of career development. Super's attention to social roles has also withstood the test of time, becoming all the

more important as theorists grapple with issues of dual careers, women's unique career issues, and the work/life and work/family interface.

There have been serious criticisms of these life course theorists that highlight the need for any theorist of adult development to attend to both intraindividual processes and processes of individual-society interaction. The main criticism of life stage models is their persistent though restrictive tendency for developmental models to make the assumption that developmental stages are sequential, unidirectional, teleological, irreversible, and universal.

CONCLUSION

We close by identifying three themes that have remained relevant to career theory over time. First, running through the entire literature on careers is the tension between *individual agency*, the notion that we are what we make of ourselves (present most fully in vocational theory), and *social determinism*, in which individual behavior is determined by structural constraints (present most fully in sociological theory). Second, the tension between career as a dynamic process and career as a choice or fit phenomenon has been continuously apparent throughout the history of career theory. Though current trends are toward dynamic models, the bulk of empirical work in career theory remains tied to static models, which are easier to design, operationalize, and model statistically. And third, level-of-analysis issues continue as an ongoing tension in career theory. Sociologists have historically emphasized the importance of careers in the stable reproduction of the social order; vocational theorists have emphasized person-job fit as a mutual goal of both individuals and organizations; and developmental theorists have privileged the goal of personal self-expression and/or growth. This tension also speaks to the central fascination with careers as objects of study. They intersect with society at every conceivable level of analysis, from people living their careers to the societies that are formed and reformed in the process.

HOLLAND'S THEORY OF VOCATIONAL CHOICE

The *theory of vocational choice* developed by John L. Holland is one of the most widely researched and applied theories of career development. Based on the premise that personality factors underlie career choices, his theory postulates that people project self- and world-of-work views onto occupational titles and make career decisions that satisfy their preferred personal orientations. The theory incorporates several constructs from personality psychology, vocational behavior, and social psychology, including self-perception theory and social stereotyping.

Applications of Holland's theory involve assessing individuals in terms of two or three prominent personality types and then matching the respective types with the environmental aspects of potential careers. The theory predicts that the higher the degree of congruence between individual and occupational characteristics, the better the potential for positive career-related outcomes, including satisfaction, persistence, and achievement.

THEORY OVERVIEW

The typology inherent in Holland's theory organizes the voluminous data about people in different jobs and the data about different work environments to suggest how people make vocational choices and explain how job satisfaction and vocational achievement occur. Seven assumptions underlie the typology:

1. Most people possess one of six modal personality types: Realistic (R), Investigative (I), Artistic (A), Social (S), Enterprising (E), or Conventional (C). Table 1 summarizes each of the six "RIASEC" types and gives examples of occupations associated with them.
2. Six modal occupational environments correspond to the six modal personality types: Realistic (R), Investigative (I), Artistic (A), Social (S), Enterprising (E), and Conventional (C). Each environment is dominated by a given type of personality and is typified by physical settings posing special circumstances.
3. People search for environments that allow them to exercise their skills and abilities, express their attitudes and values, and assume agreeable circumstances and roles.
4. A person's behavior is determined by an interaction between his or her personality and the characteristics of the environment. Based on an individual's personality pattern and the pattern of the environment, some outcomes of such a pairing can, in principle, be forecast using knowledge of personality types and environmental models. Such outcomes include choice of vocation, job changes, vocational achievement, personal competence, and educational and social behavior.
5. The degree of congruence (or agreement) between a person and an occupation (environment) can be estimated by a hexagonal model (see Figure 1). The shorter the distance between the personality type and the occupational type, the closer the relationship.
6. The degree of consistency within a person or an environment is also defined using the hexagonal model. Adjacent types on the hexagon are most consistent, or have compatible interests, personal dispositions, or job duties. Opposite types on the hexagon are most inconsistent, or combine personal characteristics or job functions that are usually unrelated.
7. The degree of differentiation of a person or an environment modifies predictions made from a person's typology, from an occupational code, or from the interaction of both. Some persons or environments are more closely defined than others; for instance, a person may closely resemble a single type and show little resemblance to other types, or an environment may be dominated largely by a single type. In contrast, a person who resembles many types or an environment characterized by about equal numbers of workers in each of the six types would be labeled *undifferentiated* or *poorly defined*.

Holland, PhD, Copyright 1985. Further reproduction is prohibited without permission from PAR, Inc.

Career development professionals who use Holland's theory of vocational choice typically assess individuals' interest profiles from three primary perspectives: coherence, consistency, and differentiation. Holland has maintained that these factors correlate with the clarity and focus of individuals' vocational personalities. An analysis of a profile in this way is customarily a prelude to a career development professional's subsequent application of the theory, which involves translating an individual's Holland profile into occupational alternatives for further consideration. Print, computer, and Internet-based sources are available to facilitate this latter process.

Coherence relates to the degree to which the Holland codes associated with an individual's vocational aspirations or occupational daydreams conform to the Holland occupational themes (i.e., Realistic, Investigative, Artistic, Social, Enterprising, Conventional). The *consistency* concept involves analyzing the proximity of the individual's two dominant Holland types with respect to the hexagonal scheme. Adjacent types on the hexagon (e.g., Social and Enterprising) reflect high interest consistency; opposite types (e.g., Artistic and Conventional) reflect low consistency. The concept of *differentiation* relates to the variance between an individual's highest and lowest types, typically computed by subtracting the extreme scale scores as assessed by a measure such as the Self-Directed Search. The larger the difference, the more highly differentiated the individual's occupational interests.

Table 1. Description of Holland Types

<i>Holland Type</i>	<i>Description</i>	<i>Examples of Occupations</i>
Realistic	Interest in activities requiring motor coordination, skill, physical strength, and masculinity. People oriented toward the Realistic type prefer acting out problems or being physically involved in performing work tasks; they typically avoid tasks involving interpersonal and verbal skills and seek concrete rather than abstract problem situations.	Automobile mechanic Aircraft controller Electrician Surveyor Farmer
Investigative	Main characteristics include thinking rather than acting, organizing and understanding rather than dominating or persuading, and asociality rather than sociability. Investigative types prefer to avoid close interpersonal contact, though the quality of their avoidance seems different from that of their Realistic colleagues.	Biologist Chemist Physicist Anthropologist Medical technologist Geologist
Artistic	Manifestations of strong self-expression and relations with people indirectly through artistic expression are central to Artistic types. They tend to dislike structure and prefer tasks emphasizing physical skills or interpersonal interactions. They tend to be introspective and a social much in the manner of the Investigatives, but differ in that their interests are more stereotypically feminine than masculine, and they often display relatively little self-control and express emotion more readily than most people.	Composer Musician Stage director Writer Actor/Actress Interior decorator
Social	Social types generally gravitate to activities that involve promoting the health, education, or well-being of others. Unlike Realistic and Investigative types, Social types tend to seek close relationships. They are apt to be socially skilled and often averse to isolative activities, as well as to activities that require extensive physical functioning or intellectual problem solving.	Teacher Social religious counselor Clinical psychologist Case worker Speech therapist
Enterprising	Although often verbally skilled, Enterprising types tend to use these skills for self-gain rather than to support others, as do Social types. They frequently are concerned about power and status, as are Conventional types, but differ in that they usually aspire to attain power and status, while the Conventional types honor others for it.	Salesperson Manager Business executive Television producer Sports promoter Buyer
Conventional	Typified by great concern for rules and regulations, great self-control, subordination of personal needs, and strong identification with power and status. Conventional types prefer structure and order and thus seek interpersonal and work situations where structure abounds.	Bookkeeper Court reporter Financial analyst Banker Cost estimator Tax expert

PRACTICAL APPLICATIONS

Career development professionals' primary uses of Holland's theory of vocational choice pertain to orienting clients to the world of work, providing a systematic means for career exploration, and, ultimately, facilitating career decision making and planning. Many clients find the theory's basic tenets pragmatic

and easy to grasp. In addition, many career-related resources incorporate Holland's theory. These factors, in addition to its longevity, substantial research base, and renown among career-development professionals, have contributed to the theory's popularity and utility.

A complex workplace, numerous known and unknown career decisions, personal and workplace uncertainties, and many uncontrollable factors pose

daunting concerns to many people who confront career decisions. By imposing order and structure, Holland's theory offers a means of helping both career counselors and clients make career decisions that promise fulfillment. Awareness of a proven, practical method for easing the process can be empowering. The theory's research and applied bases, along with its structure and inherent systematic processes, offer clients assurance as they acquire a better understanding of themselves and their options.

Holland's theory has also served as a basis for classifying and organizing occupations. The U.S. Department of Labor, for example, has integrated Holland codes into the Occupational Information Network (O*NET), a national database of occupational interest areas, education and training requirements, earnings, growth projections, and anticipated openings. *The Dictionary of Holland Occupational Codes* provided an earlier compendium of occupations listed by respective Holland codes.

A host of Holland-based products incorporate elements of Holland's theory of vocational choice. The Holland theory is, for instance, integrated into some of the most well-known career assessment measures currently published, including the Self-Directed Search, Strong Interest Inventory, Vocational Preference Inventory, and the Career Assessment Inventory. Clients can take career tests integrating the Holland theory through traditional paper-and-pencil formats and via personal computers and the Internet.

The wide variety and availability of assessment measures that incorporate Holland's theory have contributed to both ease of access and administration, which, in turn, have also indirectly contributed to the theory's popularity. A variety of card sorts, self-directed career-planning books, and multimedia resources based in whole or in part on Holland's theory are also available.

While most research and published material related to Holland's theory of vocational choice have addressed career decision-making issues confronting youth and individuals early in their career development, the theory has been implemented well beyond these groups. Business and public organizations, for instance, have used Holland's theory of vocational choice in human resource matters ranging from employee selection and staffing decisions to developing mentoring and succession-planning programs. The theory is also used in litigation involving disputes about earning capacity. A career counselor serving as an expert witness in a dissolution-of-marriage case,

for example, could apply Holland's theory as a partial basis for proposing a plan to help a spouse's reintegration into the workplace after a period of absence or underemployment. Holland's theory is also widely used among vocational-rehabilitation counselors who assist persons with disabilities in reexamining their objectives and career development after acquired disabling problems interfere with or otherwise alter how they can proceed.

Like all theories, Holland's theory of vocational choice has had its detractors. Recent challenges to the theory's applicability include assertions that research has failed to find a strong link between congruence and outcomes, such as satisfaction and performance. Other reviews of Holland's theory have cited limitations that include problems inherent in trait factor theories, including the possibility that people can change themselves and their environments. Of course, the occupational and individual traits the theory attempts to match are variable and subject to modification. If an individual is dissatisfied with her job as an insurance claims examiner, for example, she has the option of attempting to change features of the job without changing its title. Job incumbents lacking career fulfillment quite often initiate these efforts before they seek job or occupational changes. Evaluations of Holland's theory of vocational choice and comparisons with other theories have been proffered since the theory's inception (see "Further Readings and References" section at the end of this entry).

CONCLUSION

Holland's theory of vocational choice is a staple among contemporary career-development professionals' thinking about the world of work and methods of promoting clients' career aims. It is among the most widely researched and applied vocational choice theories. Its longevity and appeal likely relate to its parsimony, its validation through scores of research studies, and the availability of multiple Holland-based resources that facilitate the theory's implementation. Challenges to the theory's validity will undoubtedly recur, and its continued viability will rest on its ability to assure its primary consumers, career-development professionals, that it meets the standards to which clients' career guidance can be entrusted.

HOSTILE WORKING ENVIRONMENT

A *hostile working environment* is an evolving theory of discrimination that derives from various federal antidiscrimination statutes that prohibit discrimination in employment on the basis of race, religion, color, sex, national origin, disability, or age (for persons 40 years and older). This theory recognizes that it is discriminatory for an employer to subject an employee to working terms or conditions that are hostile or abusive to him or her because of one (or more) of these characteristics. As a developing area of law, courts continue to refine the legal principles that shape our understanding of hostile work environment claims. In response to the guidance offered by the

courts, employers are increasingly making efforts to educate their employees about the kinds of behaviors that may create a hostile or abusive work environment and the measures that can be taken to prevent and address such claims. Indeed, an employer who tolerates a hostile work environment can be held liable for compensatory and punitive damages, and there are other remedies available under the respective federal statutes for this form of discrimination.

Most notably, the concept of a hostile work environment as a form of discrimination garnered national attention in 1991 during the U.S. Senate confirmation hearings for Associate Justice of the U.S. Supreme Court Clarence Thomas. At those hearings, Anita Hill testified about sexually harassing conduct allegedly engaged in by nominee Thomas during the time they had worked together at two federal agencies. Although Justice Thomas was ultimately confirmed to the Court, the hearings spawned an almost immediate rise in the number of sex discrimination complaints filed against employers, based on claims of sexual harassment in its myriad forms, including claims of a hostile work environment.

From a legal perspective, hostile work environment claims based on sex have received significant attention by the federal judiciary in recent years, prompting a spate of decisions by the U.S. Supreme Court that address issues raised by this developing theory of discrimination. The standards established by the Court in these decisions apply to hostile work environment claims based not only on sex but also on other characteristics protected from discrimination by federal statutes, including race, religion, color, national origin, disability, or age (for persons 40 years and older). Because of the influence and prevalence of sex-based hostile work environment claims, the following discussion will focus on this category of claims for purposes of illustrating the concepts essential to understanding this form of workplace discrimination.

As most commonly invoked and understood, a hostile work environment based on sex discrimination is an unlawful form of discrimination, rooted in the broad prohibition against sex discrimination in employment Title VII of the Civil Rights Act of 1964. Specifically, Title VII makes it "an unlawful employment practice for an employer . . . to discriminate against any individual with respect to his [or her] *terms, conditions, or privileges* of employment, because of such individual's *sex*." The Equal Employment Opportunity Commission (EEOC), the federal administrative agency responsible for implementing and

enforcing Title VII, has long held that sexually harassing conduct violates an individual's right to working terms and conditions free from sex discrimination. Consistent with this position, the EEOC conceptualizes sexual harassment as a form of sex discrimination in one of two ways: quid pro quo sexual harassment or hostile work environment sexual harassment. *Quid pro quo* (literally meaning "this for that") *sexual harassment* exists when a subordinate employee suffers a tangible employment action for refusing to submit to a supervisory employee's sexual demands or proves that an employment decision itself changed the terms or conditions of employment. For example, quid pro quo harassment arises when an employee is fired or denied a promotion for rebuffing a supervisor's request for sexual favors. Most of the early sexual harassment cases were framed and analyzed by the courts as quid pro quo claims.

By contrast, *hostile work environment sexual harassment* arises when an employee's working conditions are altered discriminatorily because of that employee's sex without resulting in a tangible job detriment. For example, a hostile work environment exists when a workplace is permeated with discriminatory intimidation or ridicule or insult perpetuated by a supervisor or coworkers that makes it more difficult for an employee to do his or her job. In 1986, the U.S. Supreme Court, in *Meritor Savings Bank, FSB v. Vinson*, recognized that a hostile work environment based on sex perpetuates inequality in the workplace and violates Title VII. Since *Meritor*, an evolving body of law has emerged from Supreme Court decisions as well as decisions from lower federal courts. These decisions attempt to provide guidance to employers who are committed to creating discrimination-free workplaces and avoiding lawsuits based on claims of a hostile work environment.

Consistent with Congress's intent to eradicate the entire spectrum of sex discrimination in employment, Title VII's protection against a hostile work environment extends both to women and to men. Courts now recognize that a hostile work environment, initially the subject of dispute, can result from discriminatory conduct perpetrated by members of the same sex as well as by members of the opposite sex. In its 1998 decision in *Oncale v. Sundowner Offshore Services, Inc.*, the Supreme Court held that a male employee could state a claim for a hostile work environment created by male supervisors and coworkers in his workplace. Offering further guidance, the Court explained

that a woman could conceivably create a discriminatorily hostile or abusive work environment for another woman through conduct that makes it clear that the alleged harasser is motivated by hostility toward the presence of other women in the workplace. The Court emphasized the importance of the context and impact of the conduct on the employee who is experiencing the behavior, rather than the sexual identity of the alleged perpetrator.

Because each work environment is unique and human behavior is as varied as the employees in a particular workplace, courts have not attempted to provide an exhaustive list of behaviors that would automatically create a hostile environment. Instead, courts have crafted some guiding principles that can inform an employer's understanding of the circumstances that are likely to be recognized as creating a hostile work environment in violation of Title VII. These principles are intended to help distinguish between the sort of inappropriate or uncivil workplace conduct that from time to time occurs (and does not give an employee the right to sue for discrimination) and conduct that is "sufficiently severe or pervasive" so as to alter an employee's working conditions because of his or her sex. Emphasizing this distinction, the Supreme Court has made it clear that conduct that is "merely offensive" does not violate Title VII (or, by inference, any other antidiscrimination statute). On the other hand, an employee does not need to prove psychological harm resulting from exposure to the hostile or abusive workplace.

To ensure a degree of objectivity, the alleged discriminatory conduct must be viewed through the prism of a reasonable person. In other words, an employee who alleges a hostile work environment must prove that he or she perceives the environment to be hostile or abusive and that a reasonable person also would perceive the environment to be hostile or abusive. In *Harris v. Forklift Systems, Inc.* (1993), the Supreme Court noted that some relevant factors to consider include the frequency of the discriminatory conduct, the severity of the conduct, whether the conduct contains a physical component, and whether the conduct unreasonably interferes with an individual's ability to do his or her job. Overarching this inquiry is the need to take account of "all the circumstances," including the broader social context in which the behaviors are occurring.

An example given by the Supreme Court in *Oncale v. Sundowner Offshore Services, Inc.*, highlights the critical role that context plays in evaluating

hostile-work-environment claims. Rather than emphasize the conduct itself, the Court focuses on the context in which the conduct occurs. It suggests, for example, that a reasonable person would understand that a distinction exists between the coach smacking a football player on the buttocks as he runs onto the football field before a game and the coach smacking his assistant on the buttocks back at the office. The inference is that the former action would be perceived as one of competence and confidence building (and would not be experienced as sex discrimination), whereas the latter action, in an office setting, would be perceived as demeaning and competence and confidence undermining (and would be experienced as sex discrimination). The contextual distinction in which the same conduct occurs makes all the difference.

As a practical matter, hostile-work-environment claims typically are based on a collection of behaviors and incidents that alter the workplace because of the employee's sex. Although the Supreme Court has indicated that one incident, in general, will not be sufficiently "severe or pervasive" to create a hostile work environment, it is possible to state a successful claim in which an employee alleges one incident that involves physical conduct or conduct that makes it virtually impossible for the employee to demonstrate competence and carry out the job requirements effectively in the future. In its narrowest construct, courts generally recognize the following kinds of overt sexual actions when "severe or pervasive" as sufficient to create a hostile workplace: sexist jokes or epithets, sexually explicit photographs or images, sexual gestures, and other conduct of a sexual nature. In addition, a growing number of courts are recognizing that nonsexual conduct that undermines an employee's competence or makes it more difficult for an employee to perform the job or to advance in the company because of the employee's sex also may create a discriminatorily hostile work environment. The courts are acknowledging that Title VII's goal of workplace equality can be undermined by nonsexual as well as sexually overt actions that reinforce gender stereotypes or have the effect of differentiating the workforce along gender lines.

Employers who tolerate hostile workplaces created by supervisory employees can be held vicariously liable for the actions of the supervisors. An employee who wins a hostile-work-environment claim may be awarded equitable relief as well as compensatory and punitive damages under Title VII (subject to a

maximum cap of \$300,000, depending on the size of the company). To motivate each employer to guard against a hostile work environment, the U.S. Supreme Court has recognized an affirmative defense to allow an employer to avoid vicarious liability when it shows that (a) the employer has taken reasonable care to prevent and promptly correct any sexually harassing conduct and (b) the employee unreasonably failed to take advantage of any preventive or corrective opportunities provided by the employer or to avoid harm otherwise. In response, employers are increasingly making efforts to educate their employees about the kinds of behaviors that may create a hostile or abusive work environment and the mechanisms internal to the company for addressing such claims. Case law provides some insight into the practical and proactive steps an employer might take to meet its duty and avail itself of the defense. Because an employer can also be held liable under a negligence standard for hostile work environments created by coworkers, these same preventive measures likely will serve an employer well if it is sued under these circumstances.

As an initial matter, an employer should publish and communicate to its employees a specific policy against sexual harassment (including claims based on a hostile work environment). Many companies provide training or other opportunities for employees to become more familiar with the concept of sexual harassment, the company's policy against sexual harassment, and the company's process for reporting and handling complaints or concerns about sexual harassment. In addition, to ensure that the policy is effective, an employer should implement a process for receiving and promptly investigating claims of sexual harassment. It is critically important that the process be designed in a way that encourages employees to report their complaints. Toward that end, the process must be accessible to employees and designed to lead to a resolution. Employers often create structures that authorize several alternative personnel to receive internal complaints alleging sexual harassment. This approach serves two purposes. It minimizes the likelihood that an employee will choose not to report the claim because he or she is uncomfortable sharing potentially sensitive and intimate behaviors with a particular member of management. It also prevents a situation in which the only person designated to receive complaints is the very individual alleged to be the perpetrator of the discriminatory conduct, such as the employee's supervisor.

During the course of the investigation, the company needs to protect the rights and interests of all parties, including the alleged harasser. If the investigation is not conducted with the appropriate level of confidentiality, the company could face a defamation lawsuit by the alleged harasser. Finally, based on the results of the investigation, an employer must remedy the situation promptly and effectively. At a minimum, the employer must stop the harassing conduct and minimize the risk of the behavior recurring. Here again, no specific guidelines exist except to recognize that any discipline imposed should not punish the alleged victim and should ensure that the discriminatory conduct has ceased and will not be repeated.

In recent years, employers have increasingly begun to adopt a zero-tolerance approach toward incidents of sexual harassment. Although no uniform definition exists, the concept of a zero-tolerance policy seems to imply a certain degree of rigidity with respect to the tolerance for incidents of sexual harassment and the consequences to individuals involved in the harassing conduct that has created the hostile work environment. Further empirical research, however, needs to be conducted to determine the overall effectiveness of zero-tolerance policies in light of the goals of Title VII.

Like any new legal theory, the standards applicable to claims of discrimination based on a hostile work environment will continue to evolve as courts develop more experience with these kinds of cases. Similarly, employers likely will continue to develop policies and practices designed to eradicate behaviors and climates that can create working environments that employees might experience as hostile or abusive on the basis of race, religion, color, sex, national origin, disability, or age (for persons 40 years and older). In the end, the overall goal of these developments must be to ensure that all employees enjoy the statutory right to pursue employment opportunities in workplaces free from discrimination.

HUMAN CAPITAL

Human capital consists of the knowledge, skills, general intelligence, educational attainments, and personality characteristics of an individual and covers all strengths and assets of a person. The concept is rooted in two different fields, economics and psychology, thus resulting in two somewhat different perspectives.

HUMAN CAPITAL IN ECONOMICS

Economists as well as industrial and organizational psychologists see human capital as the sum of all abilities that enable an individual to undertake a certain job, thereby ensuring the success of a company. In this vein, human capital consists of work-related skills and information representing specific knowledge. Such information is referred to as "know what" and "know why." "Know what" entails knowledge about "facts" and is thus close to what is conventionally called information. "Know why" refers to knowledge about principles and theories in relation to the organization and functioning of the natural world, society, and the human mind. Whereas the first type of knowledge can be communicated relatively easily, the second requires more insight and at times practical experience, which is more difficult to establish in individuals. Both types of knowledge relate directly to certain capabilities.

Even if human capital is successfully implemented in an individual, it does not automatically result in economic growth or other positive outcomes in and of itself. Rather, it must be incorporated into the production of goods and services. As a first step, educated and skilled individuals must be formed via educational and training systems. Then, in a second step, ways must be found to place these individuals in positions that match their abilities and skills, organize their work in ways to ensure the utilization of their competencies, and motivate them to use their knowledge and their skills in the work setting. When this set of prerequisites and conditions does not exist, investment in human capital will not pay off for the state, the company, or the individual. The effectiveness of any investment in human capital relates both to the conditions of the labor market and to the organization inside a specific firm.

Although fostering the success of a company through the systematic increase of each individual's level of human capital and by ensuring its utilization through the appropriate placement of employees and the provision of excellent working conditions may seem like a new idea, as early as the last decade of the nineteenth century, leading economists had already recognized mechanisms that relate human capital to productivity and the well-being of an enterprise. The German physicist Ernst Abbe (1840-1905), owner and managing director of the Zeiss company (maker of optical instruments in Jena, Germany), saw the success of a business as being fueled mainly by two sources: the capabilities of the workers and the scientific basis of the firm's technology. Abbe coined the term "human capital" to describe the set of experience, knowledge, and skills contributed by every employee that enables an enterprise to be competitive in the long term and to accumulate resources. His aim was to maximize human capital and firm-specific resources in the workers to ensure lasting prosperity of the company. In accordance with many of today's management theories, Abbe saw human capital as being of strategic value to a firm and thus undertook efforts to increase human capital in his workers and tie them to the firm for longer periods of time. The means of reaching this goal were manifold. He offered housing benefits, profit-sharing, health insurance, pensions, holiday pay, and recreational programs for the workers, all very unusual concepts in the 1890s.

Abbe's guiding philosophy in the management of the company was not rooted in philanthropy. Rather,

he strived to guarantee the prosperity and long-term survival of the business, and he succeeded in doing so. Human capital as defined by Abbe and many others was, indeed, shown to be relevant to work performance. The more skills a worker has, the better the results of his or her work. Thus, a company has a primary interest in building up human capital in its employees and a secondary interest in persuading its workers to stay with the respective firm once it has invested in their knowledge and skills. Indeed, companies constantly face the threat of losing the most skilled of their workers to competitors once those workers have accumulated substantial knowledge and built up their own networks of contacts within the industry. More than a century after Abbe's views were implemented in his company, employee ownership and stock option programs are being discussed as useful strategies with which to tie key employees to the firm. In times of increasing specialization and worldwide competition, the importance of human capital for venture success is growing. Thus, companies invest in their employees' skills and abilities and do more to create attractive working conditions, especially for young, talented, high-performing individuals.

HUMAN CAPITAL IN PSYCHOLOGY

Through *industrial and organizational (I/O) psychology*, the term human capital found its way into psychological research. In I/O psychology, human capital was seen in much the same way as in economics, with the exception that I/O psychology considers factors beyond simply work-related skills and knowledge. With this perspective, human capital was used more broadly, assessing psychological variables such as an individual's general intelligence, personality traits, and so-called soft skills, such as problem-solving abilities or leadership skills. Typical outcomes studied in this field were work performance, firm formation rates, and entrepreneurial success. Depending on the outcome measure, however, different assets and traits were identified as being related to positive results. Work performance, for instance, was shown to be predicted by different personality traits, depending on the job in question. Even in jobs that stem from related areas, the profiles of successful employees may show significant differences. Sales managers' work was shown to have the best outcomes if the individuals were extraverted (i.e., outgoing, social), conscientious (i.e., prudent, planful, diligent), and

agreeable (i.e., friendly, indulgent) personality types. Entrepreneurs, however, were shown to be more successful if they were not only extraverted and conscientious but also open to new experiences and, interestingly, if they were *not* agreeable. In comparing personalities of successful social workers with those of creative engineers, differences are likely to be even more obvious.

Researchers in developmental psychology picked up on the term human capital more or less in a similar vein. Individuals who are intelligent, physically attractive, knowledgeable, and have a number of favorable personality traits, such as a strong achievement orientation (i.e., are high in human capital), are likely to attain higher educational and career levels, show less problematic behaviors, reach higher ages in good health, and report better well-being. Longevity, for instance, was shown to relate to higher levels of conscientiousness in the childhood personality. Accidents and injury deaths were shown to be less likely among conscientious individuals. They were also found to show healthier behavior throughout their lives and have more stable careers and relationships. Very much in line with these findings, adolescents with more human capital were found to be less prone to showing risky behavior. In this sense, higher human capital may increase the ability to foresee possible outcomes of one's behaviors. If an individual has invested substantial time and energy to obtain a certain educational goal, he or she may think twice when it comes to behavior that might endanger earlier success. In this sense, human capital has been found to be a protective factor, especially in the face of adversity. Children who grow up in unfavorable environments may be less vulnerable to any maladaptive effects if they can face difficulties with sufficient resources, that is, human capital.

In cultural psychology and acculturation research, human capital has been used to describe the skills and experiences that are protective of the individual, especially in an immigrant situation. An individual who has acquired knowledge about another country's cultural values and the associated behaviors and attitudes of that culture can adjust to the new host country more easily. Such skills, which have been called *cultural knowledge*, can support access to information and social contact and can contribute to less anxiety and better coping. In addition to cultural knowledge, many other variables have been found to contribute to good adaptation of immigrants, although not necessarily

under the heading of human capital. Optimistic, sociable, highly educated individuals have been shown to blend into a new culture more easily than their less advantaged counterparts.

DIRECT AND INDIRECT EFFECTS OF HUMAN CAPITAL

The role of human capital is seen as twofold. There are direct effects, in that the more human capital an individual can draw on, the better the outcomes in all areas listed. There are also indirect effects. Human capital enables utilization of social capital, allowing the pursuit of interests and the subsequent development of self-efficacy. Thus, sociable, friendly, and easygoing people who are intelligent, creative, and open to new experiences are successful in establishing significant social relationships, pursuing interests, and maintaining high levels of self-efficacy—factors that contribute to healthy development, successful educational attainment, and excellent career outcomes. Consequently, human capital, although not explicit in most cases, has played a role in areas of career development and career counseling. The fit between the requirements of a position and characteristics of the person are known to direct outcomes in both work satisfaction and performance. The higher the congruence between individuals' traits and their work environments, the more satisfied respondents are with their work, the better their work output, and the higher the stability in jobs over time.

INTERVENTIONS FOR FOSTERING THE UTILIZATION OF HUMAN CAPITAL

Three general principles in interventions address human capital. One is to strengthen the human capital of an individual by fostering work-related skills or knowledge. Such programs are run as part of promotion initiatives in companies or on a private basis, and most of them are not evaluated scientifically. They are tailored specifically to fit the needs either of a certain firm or branch or of individuals wanting to qualify in specific areas. Target groups are employed and unemployed adults. The second principle also addresses the acquisition of individual assets but is directed to more general characteristics of a person, such as self-efficacy, problem-solving skills, and other broader abilities. Programs in this category are often institution based, and many are evaluated by psychologists or

related groups. They usually aim to increase the employability of individuals or lower their current and future problem behaviors. Programs of this category usually target adolescents or young adults. The third principle in programs on human capital can be seen in the promotion of individual self-exploration. Exploring one's traits, abilities, interests, and skills (i.e., one's human capital) may help one gain insight into careers that would match a personal profile of assets. There are no specific target groups for programs aiming at exploration, though most research on such programs is conducted with adolescent groups.

At first sight, research on the acquisition of human capital appears to have been done almost exclusively in the second category of programs. However, a significant amount of work has centered on the positive effects of a thorough exploration of traits and skills, and yet another body of literature deals with the relationships of certain traits and skills and career outcomes. Both the research on exploration and the work on career-related assets usually do not specify the keyword of human capital, even though they are clearly related to the concept.

CRITICISM OF THE CONCEPT

In Germany, *human capital* was designated as the "worst word of the year for 2004." The jury making this judgment consisted of artists, journalists, and linguists. Their primary reason for the decision was "the increasing economization of all aspects of human life" and the fact that the term "degrades not only employees but the human being as such to an economic variable." Although this criticism may seem somewhat unjust and was thus rejected by major economic leaders and consultant companies, researchers had earlier put forward similar arguments. The concept of human capital was criticized because of its strong notion of individual responsibility. In line with neo-classical economic models, a lack of human capital has often been seen as a personal failure to achieve goals—and thus as an issue of choice and rationality rather than the result of unfavorable social backgrounds or lack of learning opportunities. According to such models, individuals make voluntary decisions to invest in human capital. Following this line, one would have to assume, for instance, that individual disparities are simply a result of choice. However, given socioeconomic and institutional barriers as well as problems of individual discrimination, it is obvious that there is more to the acquisition of human capital

than just individual initiative. Individuals have very different opportunities to learn, according to their social and personal backgrounds and characteristics (i.e., gender, family background, disability, age, socioeconomic status of the family of origin, and so forth). The results of individual learning, as mirrored in academic achievement following initial and post-compulsory education, as well as the extent to which a person can make use of other individual resources and assets are clearly related to the educational and economic opportunities afforded that individual.

HUMAN RESOURCE INFORMATION SYSTEMS (HRIS)

A *human resource information system* (HRIS) is a means of acquiring, storing, manipulating, analyzing, retrieving, and distributing pertinent information regarding an organization's human resources. It may

be as simple as a box of index cards or a file cabinet full of manila folders or as complex as an interactive, Web-based computer application with role-based portals (an integrated and personalized interface to information, applications, and collaborative services). Regardless of whether one thumbs through a box of index cards or uses a computer to search data stored on a server, the purpose of an HRIS is to make information about the human resources in an organization available to organizational decision makers.

With the introduction of information technology, computers, and the Internet, today's HRIS really is a sociotechnical system. A *sociotechnical system* is a combination of technology and people with inputs, transformations, and outputs. An HRIS sociotechnical system based on computers and information technology consists of *hardware* (mainframes, workstations, peripherals, and connecting networks); *software* (operating systems, utilities, application programs, and specialized codes); *physical surroundings* (building structures and working environments); *people* (individuals, groups, roles); *procedures* (management models, reporting relationships, documentation requirements, data flow, rules, and norms); *laws and regulations* (equal employment opportunity, privacy, etc.); and *data and data structures* (how data are collected and archived and to whom they are made available). Consequently, to be effective, an HRIS must blend the technical expertise of information technology professionals with the people-management expertise of human resource professionals. A technologically sophisticated HRIS will not yield desired benefits if it is used incorrectly or if it is ignored when it could make a difference. Likewise, sophisticated employees and managers will not be able to make their maximum contributions to organizational performance if the HRIS does not have the capabilities to provide them with the information they need in a timely fashion.

Three major types of information are contained in an HRIS: organizational information, job information, and employee information. *Organizational information* may include policies, procedures, and processes. *Job information* may include position title, number of current vacancies, qualifications needed, place in career ladder, salary range, replacement candidates, and turnover rate. *Employee information* may include biographical data, equal employment opportunity classification, education, date of hire, position held with company, salary history, performance ratings, training, prior work experience, developmental needs,

career interests/objectives, specialized skills, honors and awards, benefits, licenses and certifications, payroll information, attendance data, tax deduction information, pension contributions, and turnover. One issue of concern regarding employee information is how long to keep it. State laws and practices vary, but record retention periods can range from 1 year for hiring records not related to hired employees to 30 years for some medical records.

Information about human resources is collected when individuals apply for jobs (e.g., completing an application form) and then added to or modified throughout an employee's tenure with an organization (e.g., updating an employee's education qualifications in a personnel file). In the past, changes in employee information were made manually on paper entirely by administrative staff in the human resource (HR) department. Today, much information can be collected and input—by those outside of the HR department—online through Web sites, workstations, interactive voice response (telephonic), or freestanding kiosks. In addition, many organizations make it possible for employees to “own” their information and maintain it themselves online. Thus, when something changes in their lives, such as the birth of a child, employees can update their own HR information directly.

Information about jobs, work processes, and other organizational issues is collected from managers and subject-matter experts for input into the HRIS. Organizational information is also modified and updated to reflect changes, for example, in job descriptions or business strategies.

Within the present business environment, even the smallest organizations are likely to keep human resource records in some type of computer file. Commonly available software programs, such as Microsoft's Access and Excel, can be used to create a rudimentary HRIS. Larger organizations are more likely to use specialized applications, such as ABRA, that provide greater data integration and HR functionality. Larger organizations also are more likely to use enterprise resource planning (ERP) systems, such as SAP, which integrate HR information with financial, operational, and strategic information.

An HRIS relies on *relational database* technology for storing and retrieving information. Rather than duplicating information (e.g., name, age, address, job title, and pay rate) in each of several separate files (e.g., payroll file, benefits file, employee records file), a relational database shows information only once in

an appropriate table (e.g., a table of demographics, a table of benefits, a table of employee skills). The relational database software can then link the tables together and locate and combine information from many tables for analysis or report generation. Consequently, both inputting and processing times can be reduced greatly.

Increasingly, HR departments are relying on networking applications that enable centralized data storage with decentralized access to information. A client-server system has a server that provides the centralized storage of information, while the client allows end users access to the portions of the data they need. Client software makes it possible to tailor data access depending on different organizational roles (e.g., managers have access to different information than do employees).

The Internet has increased the flexibility of developing client-server systems. Organizations can maintain their own servers or “lease” servers from other providers for centralized data storage. Then, through browser-capable device access, such as personal computers, personal data assistants, cellular telephones, and computer kiosks, clients can obtain needed information from the server.

Analysis of information in an HRIS can range from the tailored and self-generated processes needed by the small-business owner using office software applications to the workforce analytics and real-time “management dashboards” that provide users of sophisticated HRIS software with an array of automatically generated assessments. These analyses can be used to create reports for internal and external stakeholders, who may then use them for making decisions or determining compliance.

An HRIS is composed of several subsystems: a transaction-processing system, a workflow system, a reporting system, a decision support system, and an executive support system. The *transaction-processing system* contains records of employee activities, such as tracking time and attendance or enrollment in various benefits. This record-keeping repository feeds into other subsystems, such as the workflow subsystem and the reporting subsystem. The *workflow subsystem* facilitates the routing and transfer of forms or other work process information from person to person or department to department. Work processes, such as recruiting, selecting, and orienting new employees, are captured in this subsystem. The *reporting subsystem* generates two types of reports: (1) predetermined,

regularly generated reports, such as payroll and equal employment/affirmative action, and (2) ad hoc inquiries, such as the number of employees with specific skills, the number of employees who chose a particular benefit option, and so on. The *decision support subsystem* uses transaction data but makes it possible to go beyond simple report generation. These subsystems typically incorporate rules, formulae, or specialized displays designed to help end users make specific decisions, such as how to allocate merit increases. The *executive support subsystem* provides support for firm-level or strategic decision making. This subsystem draws on multiple sources of data for decisions, such as choosing a site for a new plant. The number of subsystems in any particular HRIS will vary depending on the size of the organization, the hardware and software used, and the needs of the end users.

Organizations that want computerized human resource information systems have several alternatives available to them. They can create their own HRISs in-house, or they can buy the software from a vendor. The HRIS software may be a stand-alone system with only HR functionality, or it may be part of an integrated ERP system. The HRIS can be installed on in-house computer systems or reside on servers owned by the software vendor. Today, many systems that once were available and affordable only to large organizations are also available and affordable to smaller organizations.

Early uses of the HRIS focused on supporting transaction processing; however, today, these systems increasingly are being used for process improvement and strategic purposes. Process-based uses focus on solving a specific problem, usually with a tangible cost impact inside the organization. For example, costs are reduced and accuracy is improved when employees are allowed to enter and monitor their own administrative data using self-service HR applications. A strategic focus goes beyond transactions and processes and seeks to connect HR activities with improvements in revenue generation. For example, one large retailer used data from its HRIS to demonstrate that a 5-unit increase in employee attitude led to a 1.3-unit increase in customer impression, which, in turn, led to a 0.5 percent increase in revenue growth.

A human resource information system can be used for assessing past performance or for future planning. Through the calculation of workforce analytics or key performance indicators, progress toward achieving goals can be examined from multiple levels: individual,

group, department, and organization. In addition, variables can be examined to determine cause-and-effect relationships. For example, turnover data aggregated at the department level may indicate a human resource problem that can be investigated further by looking at variables that may be related, such as pay satisfaction. In addition, the internal data can be benchmarked against external standards for still further analysis. Through modeling alternative business strategies, organizations with an HRIS can, for example, predict relevant costs of hiring new employees, retrain existing team members, or obtain new skills through a company acquisition. This human capital management perspective focuses on acquiring, retaining, and leveraging an organization's employee asset base.

An HRIS can be used in all functional areas of HR. Equal employment opportunity and affirmative action monitoring and reporting are enhanced with an HRIS that is able to track the dynamic employee flows (hires, promotions, demotions, transfers, voluntary and involuntary exits, etc.) in an organization. The recruiting function can use an HRIS for applicant tracking and correspondence, internal job posting and job-bidding processes, and the identification of internal candidates when no job posting is used. Collecting and assessing information about job applicants can be linked directly to the HRIS, and the HRIS, in turn, can be used to match applicants with available jobs. Performance appraisal results (e.g., 360-degree appraisals) can be input directly into the HRIS, enabling rapid feedback and decision making. In addition, performance-rating distributions can be monitored within and between departments to maintain consistency of standards. Compensation and benefits can be managed more effectively with an HRIS. The HRIS can be used to maintain compliance with the Fair Labor Standards Act, track executive compensation, conduct job evaluation studies, build wage structures, link internal data to market wage surveys, and determine bonus and incentive pay (e.g., from gain-sharing plans). Health and safety uses of an HRIS include tracking occupational diseases and injuries, providing reports for the Occupational Safety and Health Administration, monitoring employee safety training completion, and preparing reports for workers' compensation claims. Labor relations uses of an HRIS include tracking disciplinary actions and grievances, identifying trends in union activity and membership across locations and job types, and assessing alternative contract proposals.

An HRIS is particularly useful for human resource development and career planning for the benefit of both the employees and the organization. The quantity, utility, and accessibility of training and development information made available through an HRIS can allow employees to pinpoint and accurately assess their own interests, strengths, and weaknesses and tailor development plans to enhance their own human capital and value to the organization. Moreover, much training and development coursework can be delivered effectively and cost-efficiently when integrated with an HRIS. From an organization's perspective, an HRIS enables it to determine essential competencies needed to implement a chosen strategy, identify the distribution of those competencies currently available, and then assess competency gaps. Furthermore, once the competency gaps have been identified, an HRIS can enable decision makers to assess alternative means for closing the gaps, such as hiring employees from outside, retraining current employees, or acquiring another organization with the needed competencies.

An HRIS can increase both the efficiency and effectiveness of the HR function. Efficiency is enhanced because a greater number of HR transactions can be processed with fewer fixed resources, and many processes can be simplified. Effectiveness is enhanced through increased timeliness due to processing power and increased accuracy, precision, and completeness of data used for decision making. As a consequence, HR functions in organizations can shift their emphasis from administrative to more strategic concerns.

The HRIS is changing the roles of HR professionals. With fewer needs for administrative personnel in the HR function, those HR professionals remaining can be deployed more productively as consultants aiding managers and employees in solving problems and improving organizational processes. Helping managers and employees interpret and use the information available in an HRIS plays a more dominant role in the HR professional's activities. At the executive level, the role of the HR professional is that of strategic partner, weighing in on organizational decisions such as mergers and acquisitions, changes in business strategy, and so on. With a sound HRIS and the ability to identify and analyze relevant information, HR professionals can play a vital role in ensuring that the "people side" of the equation is seriously considered in major organizational decisions.

The HRIS is also changing the roles of employees and managers. For example, a Web-based HRIS with

role-based portal access places more HR services under direct control of end users. Managers can view their departmental HR data, conduct “what if” scenario analyses, consult decision “wizards” that guide them through decision-making processes, and implement actions that previously would have taken place over longer periods of time (as paper forms passed through many hands) and involved training and back-and-forth consultation with representatives from the HR department to ensure compliance with organizational rules and policies. Likewise, employees can view their own HR data, make changes in their personal information, conduct “what if” scenario analyses on, for example, different retirement options, assess their own career plans, enroll in training online, and do all of this without ever physically going to the HR department.

The potential for HR information systems to improve and facilitate career planning and development as well as other HR functions is only now beginning to be realized. Future advances will likely make it possible for both employees and organizations to jointly achieve their separate goals. However, as human resource information systems become more widely accessible and more advanced technologically, organizations will confront many challenges.

HUMAN RESOURCE PLANNING

Human resource (HR) planning is a combination of forecasting staffing needs and strategic planning. It involves planning, developing, implementing, administering, and performing ongoing evaluation and assessment of recruiting, hiring, orientation, and organizational exit to ensure that the workforce will meet the organization’s goals and objectives. The typical role of an HR professional performing the staffing function is selecting appropriate employees to meet the needs of the organization, training them for future needs, developing their careers, and retaining them as staff so the organization will not spend time and money replacing them. In essence, HR planning results in strategies for staffing to ensure that both short- and long-term organizational objectives are met.

Strategic HR management refers to an organization’s use of employees to obtain a competitive advantage over competitors in the marketplace. Through formally contributing to companywide strategic planning efforts or by being knowledgeable about concerns facing the organization, an HR professional can be strategic about HR planning. When an HR professional hires a productive employee, that action in itself is contributing to the organization’s bottom line. High productivity leads to higher competitive advantage and profitability. Other HR activities that add value to an organization’s competitive advantage are compensation, benefits, performance management systems, and job design. Yet many in HR perform these tasks without ever tying them to the organization’s competitive advantage.

The Society for Human Resource Management (SHRM) believes that there are three major roles in HR—strategic, operational, and administrative—and that strategic HR activities include change management, organizational culture and structure management, and performance management system development. Strategic HR includes HR planning, and part of that is forecasting. *Forecasting* involves identifying expected future staffing conditions based on information about the past and the present. Forecasting staffing needs is a

four-step process: demand analysis, supply analysis, reconciliation of the budget, and strategic analysis.

Demand analysis consists of obtaining or creating a forecast for the organization's demand for future employees. This can be accomplished simply by requesting future staff estimates from managers within the organization. For this type of forecasting to be effective, an organization must consider all the various conditions and issues that might arise. When forecasting their future staffing needs, managers should consider any new or different skill sets required, structure changes in the organization, contract labor (temporary workers) needed, and identify any positions that can be eliminated, combined, or changed. The organization's size and budget should also be considered when conducting a demand analysis. Another method for forecasting is to conduct a statistical analysis of the potential need for the organization's products and/or services (normally, a greater demand for the product or service means more need for staff). This type of analysis should be conducted in conjunction with formal strategic planning.

Supply analysis includes a review of the current workforce, the future demographic makeup of the labor force, current and future productivity needs, and the organizational structure. An organization should also consider issues such as internal promotions, diversity of the workforce, transfers, retirements, layoffs, training and retraining, voluntary and involuntary separations, health care costs, and many other factors. It is also important to review corporate trends such as sales and productivity over time to forecast future staffing needs.

Reconciliation of the budget is vital in this process as well. The forecast should be presented in dollars and should include how much the staffing forecast will cost the organization.

Last is *strategic analysis*. Not only should HR professionals review current supply and demand when forecasting staffing needs, but they should also consider replacement planning and succession planning.

SUCCESSION PLANNING AS PART OF HR PLANNING

The horrific events of September 11, 2001, actually caused organizations to place more emphasis on succession planning. A *succession plan* allows an organization to fill open leadership positions with internal candidates who have been developed and prepared for those roles. Succession planning is a systematic way

of planning for the replacement of key leaders in an organization. However, limiting a succession plan to the replacement of only the "chief officers" would not constitute sound business. Ideally, a succession plan should cover several layers of leadership, down to at least the supervisory levels. The organization should determine which positions should be included in the succession plan. Potential leaders must then be identified and prepared, through career development activities, to take on those roles. It is not enough to select people in the organization who seem "right" for the job. Not only should the experience and duties be considered, but also the personality, leadership skills, and readiness for taking on key leadership roles.

Several "hopefuls" should be identified for each position to be filled. This allows the potential leaders to be groomed, trained, and mentored for the possibility of filling the positions the organization has identified as key. When the time comes for these positions to be filled, there will be several people from which to choose, all of whom have had time to develop and prepare for the new role.

To prepare these potential leaders, the gap must be determined between their current performance levels and skills and what preparation they need to be ready for the new role when it is available. This is called a *gap analysis*. This information can help determine what training, experience, and mentoring are needed. Once the potential leaders have been identified, a career-development plan for each person should be designed that will close or narrow the gap.

ROLE OF TRAINING IN HR PLANNING

Training activities are important in the HR planning process. All employees should have a career-development plan—even those in entry-level positions. No one wants to feel that promotion is not possible. All employees should receive training with respect to their current jobs, potential future jobs, customer service, roles in the organization, and the organization's role in the market. All employees must understand how they fit into the "big picture" as well as how the organization fits into the marketplace.

FORECASTING METHODS

An HR forecast is a guess or estimate and can be based on simple assumptions of what the future may hold or on complex computer statistical models. On the

simple end, a forecast may be based on asking all supervisors or managers how many employees they expect to hire in the next year or so. This is called a *managerial estimate*. Another method is the *Delphi technique*, in which each member of a group of experts, without ever having met in person, individually provides forecasts until all members of the group agree on one model forecast. A similar method is known as the *nominal group technique*, but in this situation, the group of experts meets face-to-face to recommend the best forecast. There are several statistical or mathematical methods of forecasting. Statistical forecasting is completed through either regression analysis or simulation. Simulations are “what if” scenarios allowing the organization to speculate on the future. On the complex end, a forecast may be based on statistical regression analysis. Regression analysis is used to project future needs on a comparison of employment level and one or more variables related to employment, such as gross sales.

An HR forecast should cover three time periods: short-term, intermediate, and long-term. A short-term forecast would cover a period of less than or up to one year. An intermediate forecast would cover one to five years, and a long-term forecast would cover beyond five years. Forecasting, however, is not strategic planning. Forecasting is a way to predict, by reviewing current and past business trends (such as sales), what the future trends will be. Strategic planning is much more—it is a plan to prepare an organization for the future. Part of strategic planning, however, is HR planning.

STRATEGIC PLANNING

Strategic planning is an essential activity for any successful organization, and one in which HR should be involved, since employees are an essential part of any business. If the HR professional expects to develop a meaningful staffing plan, then this involvement is a must. Sometimes, the HR professional is also the organization’s strategic planning leader, bringing all of the planning together into a substantial whole.

An organization does not have to go through the entire strategic-planning process to conduct human resource planning, but it is a good idea. As part of the strategic planning process, an environmental scan is conducted to monitor four environments: macro, industry, competitive, and internal/organizational. Issues to consider when conducting an environmental scan are demographics, technology, economics, political factors such as government regulations, and competition in the marketplace.

During the environmental scan, an organization should look specifically at the following:

- Government regulations related to HR; local, state, and federal tax legislation; pension regulations; tax benefits for training programs; and tax credit programs for employee benefits
- Economic issues related to HR, such as labor economics (unemployment rate, local skill shortages, employability)
- Local and regional competition and other geographic concerns related to HR, such as migration into or out of the area, new local companies that could recruit the organization’s employees, and competitors’ pay rates and benefits
- Demographic and social conditions related to HR, such as the local availability of diverse candidates; the number of temporary, seasonal, or part-time candidates; the flexibility of the local workforce (ability to perform shift work, etc.); basic and special skills; corporate social responsibility; ethics; unions; turnover trends; immigration and migration; and shifts in occupational trends
- Technological factors related to HR, such as the ability to telecommute, technological skills of potential and current employees, and use of new technology and machines in the workplace

When conducting the internal assessment of an organization’s workforce, the HR professional should perform a job audit to determine the jobs that currently exist, how many employees are needed to do those jobs, how essential those jobs are, and the positions needed by the organization to perform future work.

This information should be stored in the HR information system (HRIS), which is a database of employee names, jobs, competencies, skills, reporting structure, pay, benefits, training, and any other information that would aid in determining future staffing needs. Other information should also be housed in the HRIS: employee data, such as age, gender, length of service, equal employment opportunity information, promotions and positions held, awards, potential retirement dates, and so on. All of this information used together can be of great importance when trying to determine staffing gaps in the organization or future organization. It can also be used for succession planning and career development.

EVALUATING HR PLANNING

An organization’s HR plan will be successful if and when the personnel decisions made align with the

business needs. Once an organization has executed a human resource plan, the evaluation stage begins. Questions to ask during the evaluation phase are as follows: What worked about the plan? What did not? What can be changed so that the plan is more effective? Did the plan allow the organization's leaders to better understand why HR planning is vital to the business? Did the plan help lower the organization's costs? Did the plan assist the organization in identifying talent, skill gaps, and career-development opportunities? These types of questions and others relevant to the organization should be answered during the evaluation phase, and changes to the plan should be made accordingly.

CONCLUSION

Human resource planning is essential to any organization, regardless of size. An HR plan is an important way for a company to prepare for the future and is one of the most important elements HR professionals should have in their toolkits. An HR plan should aid the organization in filling its needs for talent in an effective and efficient way and should be directly linked to the business strategy.

HUMAN RESOURCE SUPPORT SYSTEMS

As the term implies, *human resource support systems* are the various activities, programs, and initiatives used by organizations to assist in the development of human resources. In general, these systems, which are typically operated by an organization's human resource department, include training and development, performance appraisal and feedback, career management, formal mentoring, and various types of employee services and assistance programs. The primary goal of these activities is to assist in the growth of the employee as a means of improving individual and organizational performance. Secondly, these activities are intended to enhance employee work attitudes and increase employee commitment to the organization.

TRAINING AND DEVELOPMENT

Usually viewed as the most important of the human resource support systems, *training and development* includes various categories of formal and informal mechanisms to create a better-performing workforce. Training programs are intended to allow employees to learn new skills or adapt to new work processes. Remedial training is designed to help employees correct deficiencies in performance. Training can be provided by an organization's internal training staff, the employee's departmental management, or an external training organization.

Compared with training, development programs are more future oriented, representing an organization's long-term investment in its employees. In essence, these programs attempt to help employees "develop" the abilities that the organization will require in the future. Depending on the company, these programs could include job rotations, seminars and university-based educational programs, mentoring, behavior modeling, three-hundred-sixty-degree feedback, and individual coaching.

PERFORMANCE APPRAISAL AND FEEDBACK

Another major category of human resource support systems is the appraisal or evaluation of each

employee's performance and the related task of discussing or "feeding back" the contents of the appraisal to the employee. The *performance appraisal and feedback* process serves a number of purposes within organizations. From an administrative standpoint, appraisal allows for the ranking of employees based on job performance, which then drives compensation and promotion decisions. From a developmental perspective, performance appraisal and feedback provides information to the employer and the employees regarding activities necessary to improve individual and organizational performance. These activities might include attendance at a particular training session, movement to a new job or operating department, or honing of a certain skill.

CAREER MANAGEMENT

Modern organizations recognize that they have a responsibility to assist their employees in managing their careers. The basis for the provision of this career management assistance is the concept of person-environment (P-E) fit, or the idea that employees are more satisfied with their jobs, are more committed to the organization, and perform better when their job requirements and working conditions are consistent with their personalities and talents. Thus, it is incumbent on organizations to help employees manage their careers so as to optimize the potential for achieving P-E fit and ensure a ready supply of human resources to fill critical positions.

Organizations have a number of programs that can be utilized to help employees manage their careers at various stages of development. Typical career management programs can include realistic recruitment, orientation, job postings, assessment and counseling centers, mentoring, performance feedback and coaching, job rotations, and other developmental initiatives.

MENTORING PROGRAMS

Research on individual career development has consistently recognized the positive benefits that *mentoring programs* can produce in terms of employee socialization and development. Mentoring involves an interpersonal relationship at work between an experienced organizational associate (the mentor) and a less experienced colleague (the protégé). The more experienced mentor provides the protégé with ongoing advice, support, and sponsorship within the organization. Research has shown that mentoring is related to

a number of positive outcomes, including higher degrees of organizational commitment, job satisfaction, and compensation on the part of the protégé. Employees who become mentors also experience positive outcomes, including a higher degree of engagement in the organization and greater feelings of self-worth. Given the positive outcomes, many large organizations have implemented formal mentoring programs, whereby a newer employee is paired with a senior colleague to create a formal mentor-protégé relationship.

EMPLOYEE PERSONAL SERVICES AND ASSISTANCE PROGRAMS

Most large organizations provide various services to help their employees balance time between work and nonwork commitments, allow for personal development, and cope with personal issues. Personal services offered to employees can include financial and banking options, such as access to a credit union or an on-site ATM; legal assistance; an on-site or near-site child care facility; social or recreational activities, such as an on-site health club; and many other amenities, such as an on-site laundry or meal service. Beyond these employee programs, organizations often provide assistance services to help employees cope with personal problems, such as substance abuse or addictions, stress, or depression. In most cases, this type of service involves the use of a phone line that the troubled employee can call to receive counseling or a referral to a professional for treatment in a confidential fashion.

I

IDENTITY

A person's *identity* develops as a consequence of the interplay between biological, psychological, sociological, and historical influences. At its core, it emerges out of the individual's efforts to maintain a sense of personal uniqueness and continuity in the face of changing developmental tasks and life circumstances—and at the same time feel a sense of solidarity with a group. Another way to conceptualize identity is to describe the attributes of individuals who have achieved a firm sense of personal identity. They would in all likelihood be described as people who know who they are, and others would be likely to view them in a manner that is generally consistent with how they view themselves.

An important feature of identity is that a person's overall sense of identity is a composite of identity in a number of domains. Although there is some disagreement about the number and definition of these domains, there is general agreement that the vocational, sexual, and ideological (e.g., religious and political) domains are among the core components of a person's identity. More recent research has produced evidence to suggest that ethnic identity, which is derived from a person's membership in an ethnic group, may also be an important identity domain that impacts the perceptions and behaviors of individuals in their social and occupational contexts. Ethnic identity, however, appears to be more salient to individuals who are members of minority groups in their societies than to individuals who represent the majority group or individuals who live in a culture with little ethnic diversity.

The vocational domain of identity has been described as the most critical component of the young person's quest for identity, in part because it appears to temporally "lead" identity development in other domains. Indeed, everyday experience confirms that at least in Western societies, adults are more likely to identify themselves by saying, "I am a contractor" or "I am a psychologist" than by saying, "I am heterosexual" or "I am Caucasian" or "I am Catholic." In short, occupation is often the primary determinant of a person's social status and economic well-being, and it is most influential in how one spends one's leisure time and with whom. Chances are high that one's spouse will be selected from among the people with whom one works. Thus, who we become and who we are in our own perceptions and in the views of others are often determined to a greater extent by our vocational identities than by anything else.

Developing a self-chosen identity is viewed as a not only necessary but also very desirable accomplishment that signifies the successful transition to adulthood in Western industrialized societies. Western ideals of independence and autonomy are reflected in the identity pursuits of Western adolescents, but they are clearly not universal. In Japanese culture, for example, autonomy is deemphasized, and cooperative behavior and social subordination are emphasized as the means of fostering a sense of belonging and harmony within the group. Clearly, this has implications for the development of vocational identity, as illustrated by the contrasting images of the "self-made man" in American society versus the "company man" in Japanese society.

THE DEVELOPMENT OF VOCATIONAL IDENTITY

Current thinking about vocational identity has been shaped primarily by Erik H. Erikson's theory of psychosexual development. All of Erikson's eight stages of life span development have implications for career development, as demonstrated by his many references to the central importance he assigned to the individual's ability to create a successful work role within the opportunities and limitations imposed by the interpersonal and sociocultural context. Nevertheless, career researchers have focused their attention on the stage of identity formation and on its immediate precursor, which is the stage during which children develop a *sense of industry*. Children who successfully establish a sense of industry have the beginnings of the capacity to feel useful; they begin to feel confident in their abilities to make things (and to make them well); and they gain confidence in their abilities to learn what it takes to be a well-functioning and productive member of society. It should thus not be surprising that developing a firm sense of industry in childhood is a necessary condition for developing a self-chosen identity during adolescence and young adulthood, particularly for developing a firm vocational identity.

Although thinking about the career development implications of children's behaviors and experiences may require an expansion of much of the current theorizing about career development, there is a growing body of research that supports the idea that children learn about the world of work quite early in life and that they formulate ideas about what they want to be when they grow up and, perhaps even more important, about what they don't want to be (and do). There is also growing evidence that children who experience success and recognition as a consequence of their efforts and achievements have a good chance to succeed in acquiring a sense of industry, which not only is a precondition for the development of identity but has also been shown to benefit their school performance and protect them from various forms of deviancy.

The successful acquisition of a sense of industry thus serves as a springboard for a process that is absolutely essential for the development of a vocational identity, namely, exploration of the world of work and occupations. This may start out as relatively random and fortuitous and then progress to include more systematic and sophisticated exploratory activities. Gradually, adolescents are able to focus their

explorations not only on the pertinent dimensions of likely occupations but also on their perceptions of how their own interests, abilities, and values correspond to both the demands and the rewards that various occupations have to offer.

Individuals are assumed to start out, as they emerge from childhood, lacking a well-defined identity. This is referred to as *identity diffusion*. For many young adolescents, this is followed by *identity foreclosure*, which occurs as they adopt the beliefs, goals, and values of significant others. Because young adolescents do not have the necessary experience (i.e., they have not engaged in sufficient exploration) to have a self-chosen identity, foreclosure identity is considered to be a premature commitment to an identity, and often adolescents eventually relinquish their foreclosed identity in favor of a period of moratorium or active (re)exploration. If successful, they can then emerge with a self-chosen identity, which is referred to as *identity achievement*. Although this developmental course is normative, it is not invariant. Some individuals do not foreclose, some may go back to diffusion following a moratorium period, and some never achieve a self-chosen identity.

Although it is generally accepted that adolescence and early adulthood are the periods of life in which identity development represents a primary developmental task, it is also clear that especially in the vocational domain, identity development does not stop there. Changing economic conditions and advances in technology have eliminated whole occupational categories (e.g., telephone operator) and, concurrently, have forced countless individuals to abandon their vocational identities, explore alternative occupations, and develop new vocational identities. Even within broad occupational categories, advancement or promotion may also lead to changes in vocational identity. As more individuals pursue midlife career changes or serial careers, their views of who they are and what they do (i.e., their vocational identities) invariably change as well. Thus, it is clear that the task of vocational identity formation should never be considered finished once and for all. Individuals have the capacity to reinvent themselves and their careers from early adolescence through old age.

Adolescence has been identified as the period when most of the "work" of identity formation takes place, but questions have been raised regarding the significance of achieving a firm sense of vocational identity (i.e., making a firm commitment following a period of

exploration) during adolescence. One line of reasoning is that because many adolescents spend most of their time in school and school-related activities, they may be relatively ignorant of the world of work and thus may be unable to make an informed commitment, even if they have engaged in a period of exploration. Countering that view is research that has demonstrated that part-time work involving moderate hours, which is experienced by the majority of adolescents in the United States, has a positive impact on adolescents' realism about work and vocational choice, thus facilitating the achievement of a vocational identity. Moreover, some researchers have demonstrated that a significant number of adults developed rather firm ideas when they were quite young about the type of work they wanted to do and their current occupations are consistent with these early ideas.

RESEARCH ON VOCATIONAL IDENTITY

James E. Marcia's identity status framework has stimulated a great deal of research on identity. Marcia introduced the concept of *identity statuses* to operationalize the four possible outcomes (diffusion, foreclosure, moratorium, achievement) of what Erikson called the "quest for identity": Marcia reasoned that since the four identity statuses represent a complete and exhaustive conceptualization of identity development outcomes, any adolescent should be categorizable into one of the four statuses. To accomplish this, Marcia developed a semistructured interview procedure. Other researchers subsequently developed self-report questionnaires to facilitate the classification of research participants into the identity statuses. In each case, the principal objective was to assess a global construct of identity, although the assessment of various identity domains, including vocational identity, can also be accomplished.

In using the identity status paradigm, a basic underlying assumption has been that the *identity achievement status* is the most advanced of the statuses, resulting from a period of exploration of alternatives and a subsequent well-defined commitment. The *moratorium status* precedes identity achievement primarily because the individual's focus is on exploration of alternatives, and commitments tend to be tentative and vaguely formed. In the *foreclosure status*, the individual is assumed to have done very little exploration but remains firmly committed to childhood-based values. The *identity diffusion status* is the

least developmentally advanced status, consisting of a lack of commitment and usually only haphazard exploration. Although this categorization of the identity statuses from most to least developmentally advanced has been generally accepted, some researchers have offered evidence to suggest that for a significant number of adolescents, the progression is not a smooth one. In other words, it is likely that some adolescents make several changes into and out of the moratorium status.

Throughout the process of exploration, contextual factors (most notably peers, school, media, and family) play important roles in channeling the vocational explorations of children and adolescents. One line of research on the development of vocational identity development has focused on gaining a better understanding of how contextual influences operate to (often inadvertently) limit the exploration (and consideration) of male-dominated occupations by female adolescents, as well as the exploration of female-dominated occupations by male adolescents. A number of reasons have been offered to account for this apparent sex bias, but most researchers agree that more research is needed on the impact of the media on the vocational exploration of children and adolescents and on the relationship between vocational identity development and the early formation of vocational aspirations, goals, and commitments.

Another line of research has examined the relationship between advancement in identity status, on the one hand, and a variety of positive psychological and psychosocial outcomes, on the other. Findings have been quite consistent: Adolescents who have attained the more advanced vocational identity statuses (moratorium and achievement) score higher on these positive indicators than do adolescents who place in the less advanced identity statuses (diffusion and foreclosure). Adolescents in the least advanced group (especially those in diffusion status) have been found to be more likely to be involved with drugs and alcohol, to have lower scores on measures ranging from autonomy to independence, and to be less likely to accept personal responsibility for their own lives. Adolescents in the most advanced group (especially those in achievement status) been found to have more positive feelings about school and about their teachers, to have better grades and higher educational aspirations, to have higher levels of self-esteem, and to be more involved and active within their various contexts (e.g., school and community).

Using the identity status framework with a focus on vocational identity, researchers have examined how adolescents feel about work. Interestingly, nearly all adolescents classified as *identity achieved* have been found to be enthusiastic about work (and their future work roles) and committed to being productive members of the workforce. In contrast, two-thirds of the adolescents classified as *identity diffused* have been found to be comfortable with avoiding work or have extremely negative views about the worker role in general and about their future as workers in particular. Researchers have also found that adolescents had clearer vocational goals and scored higher on measures of career maturity as they advanced from identity diffusion toward identity achievement. Consistent with these findings is research that documented predictable differences in career indecision, on the one hand, and membership in one of the identity status groups, on the other. Invariably, adolescents classified as identity achieved no longer experienced any significant career indecision. They apparently knew what career they wanted to pursue, and they felt relatively comfortable with their decisions. Adolescents in all of the other identity statuses, including foreclosure, still experienced significant indecision.

The identity status framework has been productive in the study of vocational identity, but it is not the only framework for studying identity. Michael D. Berzonsky has introduced the notion that individuals within the various identity statuses also differ in how they think, solve problems, and make decisions. Accordingly, he proposed that these differences amount to differing identity-processing styles, which he referred to as “informational,” “normative,” and “diffuse/avoidant.” Individuals tend to use one of these identity-processing styles to deal with identity questions and situations in which they are called on to make decisions. Although there has not been a lot of research using identity-processing style in examining vocational identity, it is likely that the joint consideration of identity status and identity-processing style can yield the best insight into the role played by identity in the vocational development of individuals and their behaviors at work and in other important contexts.

How individuals construct their vocational identities has important implications not only for them but also for their families and for the communities and organizations within which they function. After all, people who “have their act together,” who know who they are and what they want, and whose perceptions

of themselves match the perceptions of those who know them also tend to be the people who set goals and then do what it takes to achieve them. They tend to be the most productive and self-confident members of a society that relies on them and rewards them. Clearly, more research is needed to identify what it takes to achieve a firm sense of vocational identity and to understand the conditions that facilitate this desirable outcome.

IMPRESSION MANAGEMENT

Impression management (IM) is the process by which people attempt to influence the images that others have of them. That is, IM describes the many strategies that individuals use in an attempt to be seen in a certain way

or to create a particular impression in others' minds. Related concepts include self-presentation, influence tactics, organizational politics, and the careerist orientation to work. In studying IM, researchers typically label those who seek to influence others' impressions of them as *actors* and label those whose impressions are being influenced as *targets*.

Most researchers argue that IM is a common phenomenon and a fundamental part of human interaction. IM behaviors often reflect a basic human motive to be viewed favorably (and to avoid being viewed unfavorably) by others. However, in some instances, IM is not used in an effort to be perceived positively per se, but to influence others to view one in a specific way or to influence others to respond in a certain way (e.g., through the use of intimidation). There is some disagreement among IM researchers regarding the authenticity of the impressions that people convey. In what has been labeled the *restrictive view of IM*, a few researchers have narrowly defined the construct as an attempt at interpersonal manipulation through the creation of a false or untrue image of oneself. By and large, though, most scholars subscribe to what has been labeled the *expansive view of IM*. According to this viewpoint, while the impressions that individuals seek to create can be false, most often they are not. The expansive view of IM suggests that individuals typically use IM to portray their characteristics in the most positive light (e.g., during an interview) or in attempt to have others view them as they view themselves (e.g., in accordance with their self-concepts). Thus, an actor who uses IM to be viewed as an attractive job candidate may, indeed, be smart and conscientious, or an actor who wishes to be seen as likable may, in fact, be a nice person.

Not all IM behaviors are consciously executed. That is, some IM behavior occurs subconsciously or is performed so habitually that individuals are not fully aware of their actions. IM theorists have argued, though that when IM is the result of a conscious process, the motive to manage impressions is a function of three factors: the goal relevance of the impression, the value of the desired outcomes, and the perceived discrepancy between an individual's desired and current image. *Goal relevance* means that the motivation to manage impressions is especially high when the impression one makes is critical for attaining social outcomes (e.g., approval, friendship, assistance) and/or material outcomes (e.g., better jobs, higher salaries). For example, an individual's motivation to

manage impressions tends to increase when his or her behavior is public (rather than private) and when he or she is dependent on a target (e.g., the target is the person's supervisor). The value of desired outcomes suggests that the more people want certain outcomes, the more likely they are to manage impressions in an effort to obtain them. Thus, it is not surprising that job applicants and those seeking promotions typically engage in IM behavior. Finally, the discrepancy between the desired and current image means that individuals are particularly motivated to engage in IM when they believe that others see them in ways that are inconsistent with how they would like to be seen. So, individuals who realize that they are viewed negatively are often eager to use IM behaviors to change the minds of those who view them unfavorably.

Broadly speaking, IM tactics are described as being either assertive or defensive. *Assertive tactics* of IM are initiated by people to create or reinforce a certain impression to a target. In contrast, *defensive strategies* of IM are more reactive and are typically employed when individuals are faced with situations in which they are likely to be viewed negatively.

ASSERTIVE IMPRESSION MANAGEMENT

Although a number of assertive IM behaviors have been identified, the five tactics that have most often been discussed are (1) *ingratiation*, whereby individuals seek to be viewed as likable by doing favors for others, agreeing with others, or flattering others; (2) *exemplification*, whereby people seek to be viewed as dedicated by acting like a good role model and going beyond the call of duty; (3) *intimidation*, whereby individuals seek to appear dangerous by making threats or signaling their power to punish or create pain and discomfort; (4) *self-promotion*, whereby individuals hope to be seen as competent by playing up their abilities and accomplishments; and (5) *supplication*, whereby people seek to be viewed as needy or in need of assistance by "playing dumb" or advertising their shortcomings and weaknesses.

Although IM tactics are used in the effort to create desired images, attempts at IM also carry the risk of being perceived negatively. Indeed, for every desired image sought by individuals using IM, there is a corresponding undesired image that is risked. For instance, individuals use self-promotion in order to be perceived as competent; however, they risk being perceived as conceited instead. Thus, while IM is often

used in an attempt to advance one's career interests, it sometimes backfires such that individuals end up creating unfavorable impressions instead. Along these lines, research suggests that some individuals are more adept at using impression management than others. In particular, not only do high self-monitors use IM more frequently than low self-monitors, but high self-monitors who use IM are also more likely to achieve the desired image (and avoid the undesired image) than are low self-monitors who use IM.

From among the five IM strategies identified above, most studies have focused on the tactic of ingratiation. Researchers have identified three distinct forms of ingratiation. *Opinion conformity* occurs when actors express agreement with the opinions and views of a target. *Favor-doing* describes instances in which an actor does something for the benefit of the target. Last, *other-enhancement* (or flattery) occurs when actors make positive statements about a target. Generally speaking, investigations of ingratiation reveal that such tactics are positively related to performance evaluation ratings, judgments of liking, and indicators of career success. Of the three ingratiation strategies, though, other-enhancement seems to be the most effective tactic.

The *ingratiator's dilemma* describes the idea that the more dependent individuals are on the target's approval, the more transparent their motives for engaging in such behavior become, and, as a result, the more unlikely it is that their attempts at ingratiation will succeed. Consistent with this notion, studies in this area suggest that ingratiation behaviors tend to backfire when targets question the motives of actors who engage in ingratiatory behavior. In general, however, women appear to be less inclined than men to question the motives of those who ingratiate.

Self-promotion is another IM tactic that has received a significant amount of research attention. According to the *self-promoter's paradox*, individuals who are exceptional workers rarely need to promote their competence, as they are likely to be viewed favorably by others. As a result, engaging in self-promotion is sometimes taken as evidence that individuals are not really as competent as they are making themselves out to be. Thus, the individuals who need to self-promote the most are the ones least likely to benefit from its use. Self-promotion, then, often entails significant risks to an actor, as targets may either discount the claims of those who self-promote or simply view such individuals as conceited and arrogant rather than as competent and accomplished.

Indeed, in contrast to the research on ingratiation, studies of self-promotion indicate that such behavior is often ineffective. For example, whereas some studies indicate that self-promotion may be helpful to individuals who are interviewing for jobs, other studies have typically found that self-promotion is negatively related to performance evaluation ratings, judgments of liking, and indicators of career success. Research also suggests that self-promotion may be especially harmful to women. Specifically, women who use self-promotion are often seen as more competent but, at the same time, are seen as less likable and less hireable than men who employ this behavior.

Relatively speaking, the IM strategies of exemplification, intimidation, and supplication have received less research attention. With regard to exemplification tactics, the research findings are somewhat mixed. In some studies, those who attempt to project an image of dedication or commitment seem to be evaluated more favorably than those who do not make such efforts; however, in other investigations, the use of exemplification seems to have very little impact on how one is viewed by others. With regard to intimidation, studies suggest that those who seek to be seen as tough or intimidating also tend to come across as bossy, pushy blusterers. Similar to the research on self-promotion, there is some evidence that the use of intimidation may have positive consequences for men (e.g., in terms of performance appraisal ratings) but have negative consequences for women. Studies suggest that supplication is sometimes used by individuals who want assistance with a task or who want to avoid doing an unpleasant assignment. In addition, research suggests that people who use supplication are frequently successful in projecting an image of neediness but often also tend to come across as lazy and less competent. In general, intimidation and supplication tend to be used less often within organizations than the other forms of impression management. Moreover, intimidation and supplication appear to be fairly risky IM strategies. That is, although an individual who uses intimidation or supplication may be able to coerce others into engaging in certain behaviors, doing so almost always comes at some cost to the individual's reputation and interpersonal relationships.

DEFENSIVE IMPRESSION MANAGEMENT

In contrast to assertive IM, defensive IM is utilized in an attempt to protect individuals' reputations from further harm or to restore individuals' reputations in

circumstances in which they are likely to be perceived negatively. Thus, defensive IM tends to be more reactive than assertive IM. Although a number of defensive IM behaviors have been identified, three tactics that have been addressed most often are (1) *self-handicapping*, whereby people make excuses in advance of performing a task so that if they do poorly, they will already have a justification for their weak performance (and will look even better if they actually do well at the task); (2) *excuses and justifications*, whereby individuals seek protect their images by dissociating themselves from certain events, by denying their involvement or responsibility, or by explaining the circumstances that caused them to behave in a certain way; and (3) *apologies*, whereby individuals express that their past actions were wrong and indicate that they will behave more appropriately in the future. The key issue is not the use of defensive IM per se, but whether the IM tactic has the desired effect on the target. In general, three characteristics influence how successful a defensive IM tactic is likely to be: the perceived adequacy of the explanation, how normative the particular explanation is (i.e., the extent to which the explanation provided is generally accepted within a particular context), and the perceived sincerity of the actor in providing the explanation.

OTHER APPLICATIONS OF IM THEORY

Whereas most research on IM has focused on the ways in which individuals utilize certain tactics and the outcomes associated with the use of those tactics, more recent research has focused on how individuals' IM concerns may affect their behavior more indirectly. In particular, scholars have explored the ways in which IM motives and concerns may make employees more likely to manipulate information, less likely to ask for assistance, less willing to ask for feedback regarding their performance, and less inclined to support controversial causes in their organizations. Leadership scholars have argued that charismatic leaders use IM in order to be seen as trustworthy, credible, morally worthy, esteemed, and powerful. Studies of organizational citizenship behavior have sought to better understand how IM motives might explain employees' willingness to go the extra mile for organizations by helping out their colleagues, taking on extra assignments, working weekends, and so on. For example, this research suggests that individuals may be especially willing to go beyond the call of duty when they believe it will enhance their

images at work. In the area of organizational justice, some researchers have argued that projecting an image of fairness (i.e., looking fair) is often just as important as actually treating employees fairly (i.e., being fair). Some scholars have also explored the ways in which people can create the image that they have "paid their dues" or have earned what they have. Finally, at a more macro level, researchers have also examined the ways in which organizations use a variety of IM tactics to create an organizational image or identity in the eyes of employees, customers, shareholders, regulatory agencies, and other stakeholders.

MEASURING IM BEHAVIOR

IM tactics have typically been assessed using observation (under experimental or real conditions) or surveys distributed to employees and/or their supervisors. For example, some scholars have evaluated the use and effectiveness of the IM tactics individuals use when interviewing for real jobs. Other scholars have put subjects into certain (manipulated) situations and then observed their use of IM. The principal strength of this type of measure is that it does not rely on self-reported IM behavior, which reduces concerns regarding social desirability bias. A number of other studies, though, use surveys to obtain a large number of responses about a variety of IM behaviors. The most popular measure was developed by Wayne and Ferris and focuses on the extent to which employees use supervisor-focused, job-focused, and self-focused tactics of IM. These types of IM are very similar to the strategies of ingratiation, self-promotion, and exemplification, respectively. Researchers who have focused specifically on ingratiation in organizational contexts have often relied on Kumar and Beyerlein's Measure of Ingratiation Behaviors in Organizational Settings (MIBOS), although some scholars have raised questions about the dimensionality and validity of this measure. More recently, Bolino and Turnley have developed an impression management measure designed to tap ingratiation, self-promotion, exemplification, intimidation, and supplication in work contexts.

INDIVIDUAL CAREER MANAGEMENT

Individual career management is the process by which a person can make reasoned, appropriate decisions about his or her work life as well as the relationship between the work and nonwork domains. This process of career management takes place over the course of a person’s lifetime and is based on the idea that individuals constantly seek jobs and work environments that match their personalities, talents, and lifestyle preferences. People are more fulfilled and more productive when their work and life experiences are compatible with their own desires and aspirations. Research supports the notion that people are more satisfied with their career choices and jobs when

their work experiences are consistent with personal qualities such as needs, values, and preferences. Similarly, performance in a career is enhanced when the job requires the application of skills and abilities that the individual possesses.

The emerging concept of the *boundaryless career*, whereby employees are faced with an ever-changing work landscape, mandates that individuals take individualistic, proactive approaches to managing their careers. Indeed, changes in technologies, corporate reorganizations and contractions, and internal leadership can all affect an individual’s career within a particular organization. Employees who are not sensitive to the implications of such changes in the environment in the management of their careers might be ignorant of their career options or might make inappropriate career decisions.

Past research on individual career management sees it as a series of distinct steps or phases through which a person passes as he or she arrives at and implements appropriate career decisions. In general, these ongoing steps include the gathering of information to develop or increase awareness of oneself and the work environment, establishing career goals and strategies, and obtaining feedback to help appraise progress against established goals.

CAREER EXPLORATION: DEVELOPING INDIVIDUAL AND ENVIRONMENTAL AWARENESS

The first step in the individual career-management process requires the person to engage in career exploration. *Career exploration* is the collection and analysis of information regarding career-related issues. Most people need to gather information so they can become more aware of their own values, interests, and talents as well as the opportunities and obstacles in their environments. It is assumed that the more extensive their career exploration, the more likely people are to become aware of different aspects of themselves and the world of work. If conducted properly, career exploration should enable the person to become more fully aware of himself or herself and the work environment.

Two types of career exploration can be differentiated on the basis of the type of information that is sought. One type, *self-exploration*, provides a greater awareness of one’s personal qualities, including interests, the degree of job challenge one desires, strengths and

weaknesses, talents, and limitations. Self-exploration can also provide a better understanding of the balance of work, family, and leisure activities that best suit a preferred lifestyle. The other type, *environmental exploration*, involves learning more about the work environment, including seeking information on alternative occupations, organizations, and industries. Environmental exploration can also provide useful information on a family's needs and aspirations, a spouse's career values, and the relationship between one's work life and family life.

Research suggests that career exploration has a beneficial effect on career management. The most immediate consequence of career exploration is an enhanced awareness of self and environment. Indeed, the more career exploration individuals engage in, the more aware they are about their work values and the more knowledge they report about their chosen careers. *Awareness* can be defined as a relatively complete and accurate perception of one's own qualities and the characteristics of one's relevant environment. An awareness of self and environment enables a person to set appropriate career goals and to develop appropriate career strategies.

ESTABLISHING CAREER GOALS AND STRATEGIES

A greater awareness of oneself and the work environment can help individuals choose a career goal or goals toward which to strive. Goals are likely to be more appropriate and more realistic when they are based on an accurate picture of self and environment. A *career goal* is a desired career-related outcome that a person intends to attain. The advantage of establishing a career goal is that a person can direct his or her efforts in a relatively focused manner.

The establishment of a realistic goal or set of goals can facilitate the development and implementation of a career strategy. A *career strategy* is a sequence of activities designed to help an individual attain a career goal. Past research identifies several general categories of career strategies that can be used to enhance an individual's chances of career goal fulfillment. These broad strategies include attaining competence in the current job, putting in extended work hours, developing new skills, developing new opportunities at work, attaining a mentor, building one's image and reputation, and engaging in organizational politics. The usefulness of a particular career strategy is

dependent on a number of factors, including the nature of the job, the type of the industry, and the culture and norms of the particular organization. Indeed, a career strategy that may be successful in one case may not work in another.

CAREER APPRAISAL

Whether or not one is making progress toward a goal, the implementation of a career strategy can provide useful feedback to the person. This feedback, in conjunction with feedback from other work and non-work sources, can enable a person to appraise his or her career. *Career appraisal* is the process by which people acquire and use career-related feedback to determine whether their goals and strategies are appropriate. The information derived from career appraisal becomes a vehicle for career exploration that continues the process of individual career management.

The career-appraisal process may lead to a reexamination of career goals. More precisely, the feedback one obtains from work or nonwork sources can reinforce or lead to the modification of a goal. Career appraisal can also affect strategic behavior, since feedback might indicate that one type of career strategy is effective and should be maintained while another strategy is ineffective in achieving a career goal and should therefore not be pursued in the future. Regardless of its particular source, the information derived from career appraisal completes the individual career-management cycle by becoming another source of exploratory information that can enhance one's awareness of self and environment.

ORGANIZATIONAL SUPPORT FOR INDIVIDUAL CAREER MANAGEMENT

Contemporary organizations provide a number of programs and human resource practices intended to help their employees manage their careers. Organizations provide this assistance based on the belief that employees will have more positive work attitudes and will perform at higher levels when their jobs and work environments match individual characteristics and desires. In addition, by helping employees manage their careers, organizations are attempting to ensure a committed workforce that will stay loyal to the company and be ready and able to move, either laterally or hierarchically, into new and more challenging assignments.

Organizations can offer their employees a number of specific programs to assist in the career-management process, including the provision of a job-posting program; formal and informal mentoring; job rotation and lateral transfers; formal education, training, and development initiatives; career-assessment centers and workshops; performance appraisal and feedback systems; and employee and executive coaching. Each activity and program is intended, in whole or in part, to support employee development and improve individual career management and decision making.

CONCLUSION

Individual career management is a process by which individuals develop, implement, and monitor career goals and strategies. It is an ongoing process in which an individual gathers relevant information about himself or herself and the world of work; develops an accurate picture of his or her talents, interests, values, and lifestyle preferences as well as alternative occupations, jobs, and organizations; develops realistic career goals based on this information; develops and implements strategies designed to achieve these goals; and obtains feedback regarding the effectiveness of the strategy. Organizations can help their employees in the career-management process by providing various activities and programs that support employee development and individual awareness.

INDUSTRIAL REVOLUTION

The *Industrial Revolution* refers to a societal shift that occurred when agricultural economies changed to economies driven by industry. The Industrial Revolution began in Britain in the eighteenth century and by the turn of the twentieth century had swept many regions of Europe and the United States. The significant and rapid changes brought about by industrialization altered every aspect of American life, including where people lived, their leisure pursuits, and the nature of work. The changes brought by the Industrial Revolution provided the social, political, and economic foundations for the emergence of vocational guidance, vocational psychology, and career development.

Three aspects of the Industrial Revolution had a significant impact on career development: (1) rapid industrialization, which led to a reorganization of the workforce; (2) rapid urbanization due to migration to urban industrial centers; and (3) the birth of reform movements that developed as a response to deteriorating living and working conditions.

RAPID INDUSTRIALIZATION

Between 1880 and 1920, city centers grew dramatically. Propelling this dynamic growth were railroads, which connected cities across the expanding landscape of America. Oil and steel manufacturing provided economic strength, which sustained technological progress. In a 1999 article, Howard Zinn pointedly observed that during the Industrial Revolution, steam power and electricity took the place of human muscle and more permanent and sturdier materials were used in construction and in the products that were manufactured. He also noted that oil was used to lubricate machines and to light homes, streets, and factories and that people and goods had newfound mobility through the railroad. Products that were previously made by simple machines or by hand were being manufactured in great quantity by technologically advanced equipment. As a result, home-based or workshop-based production declined, and large factories were constructed to accommodate the new manufacturing base. Improved methods for producing goods required new ways of organizing the workforce, including the specialization and division of labor.

The rapid pace of industrialization transformed the nature of work, which began to rely on precise and

efficient use of skills. The consequential restructuring of the workforce was intimately related to the emergence of vocational psychology. Fredrick W. Taylor facilitated this process with his idea of *scientific management*. Taylor analyzed jobs and converted skilled crafts into a series of simplified tasks that unskilled workers could be easily trained to perform with machinery. Next, production was systematically planned, and job tasks were directed through various stages of the manufacturing process. As a result, large industries and assembly lines produced significant quantities of refined goods at improving rates. To handle increased production, more specialists were hired to operate a growing number of distinct machines. In addition, skilled technicians, engineers, and machinists were needed to design and construct new equipment and maintain and repair existing equipment. Many people performed the mechanical work and labor, and others were needed to supervise and direct it. The results were greater divisions of labor, including management, administration, research, sales, accounting, and several others. As divisions in labor grew, equally important changes in the organization of social class divisions emerged.

The disparity between the rich and the poor continued to increase. The wealthy owned the major institutions of the industrial age, including factories, railroads, and banks. In the course of the Industrial Revolution, many members of the traditional middle class became factory owners, supervisors, managers, and clerks. Simultaneously, a new professional middle class emerged, consisting of doctors, lawyers, scientists, teachers, and engineers. Finally, there was the working class, which was divided into skilled and unskilled labor. Often, members of the working class migrated in large numbers to urban industrial cities in search of a better life.

RAPID URBANIZATION AND IMMIGRATION

The overwhelming economic growth brought by the Industrial Revolution was highly dependent on an abundant supply of labor. Because people were tempted to urban areas by new employment opportunities and prosperity, the Industrial Revolution brought intense growth to cities. In 1860, there were 9 American cities with a population of more than 100,000; by 1900, this number had grown to 38 cities. Although technological progress increased agriculture productivity throughout the nineteenth century, many small farms in rural areas

struggled to keep pace with large commercial farms. Several farmers went bankrupt; others sold out to larger farms and went to look for work in the burgeoning industrial cities. An analysis of the first federal census demonstrates that from 1790 to the end of the nineteenth century, the percentage of employment dependent on agriculture consistently decreased. For example, in 1790, 75 percent of the workforce consisted of farm laborers, and this rate dropped to about 40 percent near the turn of the twentieth century. Another cause of urbanization during the Industrial Revolution was immigration. Between 1870 and 1920, almost 25 million immigrants came to America, mainly settling in cities in the Midwest and Northeast.

For those relocating to the new urban centers, life could, indeed, be hard. Industrialization created wealth, but mostly for factory owners, not for the working class. Immigrants and displaced farm laborers found themselves in crowded housing with inadequate ventilation and poor sanitation. Many neighborhoods quickly deteriorated into industrial slums. Although there were employment opportunities, members of the working class had few rights. Factory owners could exert considerable control over workers because labor was readily available, replaceable, and cheap. If workers' wages were too low, their hours too long, or their working conditions too dangerous, they had no legal recourse. In addition, many factory machines could be operated by women and children, making the pool of workers larger and wages lower.

REFORM AND VOCATIONAL GUIDANCE CONVERGE

Federal policy regarding the rights of workers did not keep up with the rapid pace of industrialization and urbanization. Workers found their greatest ally in a rising social consciousness that gave animation to a reform movement that, among other things, allowed for the emergence of *vocational guidance*.

The Young Men's Christian Association (YMCA) was founded in 1844 as an evangelical reaction to society's urban problems. Throughout the Industrial Revolution, the YMCA provided social and educational resources aimed at character building and employment. The YMCA operated libraries, reading rooms, and employment bureaus. They offered education and training through vocational and trade schools, and correspondence courses.

Public education was another venue in which reform was beginning to take shape. The public education movement was responsible for enacting new compulsory education laws that kept children in school and tried to end child labor exploitation. Many scholars credit Jesse B. Davis, a school administrator in Detroit between 1898 and 1907, with having introduced systematic vocational guidance into the school system. Having seen the vocational and social problems faced by his students, Davis created a specific guidance curriculum that would reach large numbers of students where they were, in the classroom. Other social scientists, such as Helen Thompson Woolly, studied school dropouts and developed programs of in-school vocational guidance to improve graduation rates. Clearly, educational and social reforms were providing a solid foundation from which vocational programs would develop.

In the 1890s and early 1900s, political progressives instigated many social reform efforts. The results were greater government regulation of industry and an attempt to limit governmental corruption. In 1881, Jane Addams, a philanthropic social reformer, opened Hull-House, a settlement home on Chicago's Near West Side. The settlement home was a new social phenomenon. In cities across America, social progressives were taking up residence in working-class neighborhoods. They provided working families a place to learn English, complete high school, and discover their civic interests, rights, and duties. One of these settlement homes, The Civic Service House in Boston, Massachusetts, was the setting for the birth of vocational guidance.

ADVANCEMENT OF VOCATIONAL GUIDANCE

Parsons and the Vocation Bureau

In 1908, Boston attorney and political progressive Frank Parsons opened the vocational bureau as a part of The Civic Service House. Parsons saw a tremendous waste of human potential and industrial inefficiency in the random selection of workers for jobs. To remedy this, he advocated a system of vocational choice based on scientific methods. He set forth an individualized program of vocational counseling using a tripartite model of self-knowledge, occupational knowledge, and matching self to job using "true reason." This model came to be known as *trait-and-factor guidance* and earned Parsons the moniker of "father of vocational guidance" (as well as father of career development, vocational psychology, career guidance, etc.). Parsons's work significantly advanced

job-description literature and promoted the psychological measurement of individual differences in aptitudes, abilities, and interests.

The Measurement Movement

In Parsons's time, the study of individual differences was of interest to psychology. Early applied psychologists developed mental tests to assess individual traits and became skilled at constructing the objective measures of abilities, interests, and aptitudes that provided vocational guidance with a measure of scientific respectability.

At the beginning of the twentieth century, French psychologist Alfred Binet and his colleague Theodore Simon published an intelligence test to identify developmentally delayed children who needed supplementary aid in school. The test measured a variety of functions, including judgment, comprehension, and reasoning. It marked the beginning of intelligence testing as we know it today. The ability to use paper-and-pencil tests to sort and classify children based on intellectual ability soon found its way into group measures of intelligence. The testing movement in America gained popular appeal after the U.S. Army used group-administered tests of intelligence and aptitude to screen recruits for service during World War I. After the war, interest in testing and classification led to significant advances in the principles and practices of personnel selection, vocational guidance, and career development.

CONCLUSION

Modern career development can trace its beginnings to the Industrial Revolution of early-twentieth-century America. Industrialization created changes in the nature of work, impacted population demographics, and created new calls for social justice. The shift brought with it a need for efficiency and differentiation of function of both workers and machines. The applied psychology of individual differences provided the scientific support for the establishment of assessment tools that became the cornerstone of vocational guidance. Theories of career development continue to evolve, yet they remain committed to the tradition of matching people to the world of work that began with the Industrial Revolution.

INEQUALITY

It is no secret that jobs vary widely with respect to the pay, benefits, security of employment, and intrinsic rewards they offer. What is less well-known is that many of these disparities have been growing in recent decades, reversing a trend toward equalization that dates back to the Great Depression. This entry describes *inequality* in wage income and other characteristics of labor-market careers, with particular attention to trends in the United States during the last three decades of the twentieth century. Some of the micro- and macrolevel processes by which persons may be allocated to qualitatively different jobs are briefly considered.

WAGE INEQUALITY IN THE UNITED STATES

Historical data show two peaks in income inequality during the twentieth century, the first occurring

just prior to World War I and the second occurring prior to the Great Depression. These peaks were followed by what economic historians have dubbed the "Great Compression" during the New Deal and World War II eras, when President Franklin Roosevelt introduced social and economic policy measures aimed at reducing income gaps. In the quarter century following World War II, the American economy enjoyed rising wages, low unemployment rates, and sustained economic growth. Wages of the median earner doubled between 1950 and 1970, and those further down in the income distribution made even greater progress. Since the early 1970s, these trends have undergone a dramatic reversal, as median wages have stagnated and income disparities have grown. Earnings polarization has increased within all large demographic groups—even among employed White men working full time.

One way of measuring the degree of inequality in wage income is to divide the population into equally sized groups and compare the percentage of total wage income earned by different groups. Analyses of this sort show that top-tier earners control a large and growing share of the economic pie. In 2000, for instance, the top 10 percent of wage earners alone accounted for 36 percent of wage income earned in the United States. This share increased from 26 percent in 1970. Analyses by economists Thomas Piketty and Emmanuel Saez have revealed that most of the gains made by this top decile have accrued to the top 1 percent of earners, whose share of national wage income increased from 5 percent in 1970 to 13 percent in 2000. The above figures take into account only the portion of individual income derived from wages and salaries. The distribution of income derived from capital and financial investments is much more strongly skewed.

The growing concentration of income at the top of the economic ladder has coincided with corresponding declines in the shares of wage income earned by the average worker. Real wages of median workers stagnated through most of the 1970s and 1980s and then fell sharply in the 1990s. The federal minimum wage, which is not indexed to inflation, is no higher today in constant dollars than it was in the 1950s, according to recent data from the U.S. Census Bureau. Stagnation of median wages and a decreasingly progressive tax structure have meant that increasing numbers of American families require two incomes to sustain a middle-class lifestyle.

Trends in income inequality are also commonly assessed with reference to changes in the ratio of a

company's top salary brackets to amounts paid to workers at the bottom. Plato once maintained that no one should earn more than five times the pay of his lowest worker. In 1965, CEOs in major American companies earned 24 times more than the average worker. In 2003, this ratio was 185 to 1 (having fallen from 300 to 1 in 2000). A recent analysis by *Fortune Magazine* found CEO pay in the nation's top 100 corporations at the turn of the twenty-first century to be more than 1,000 times that of the average worker (\$37.5 million in 1999, compared with \$1.3 million in 1970). Although income inequality has grown in other wealthy industrialized countries, the trend has been especially pronounced in the United States.

WHY THE GROWING WAGE DISPARITIES?

Numerous explanations have been offered for increasing wage polarization and inequality. Some focus on demographic shifts (i.e., changes in the supply of available workers), and others emphasize changes in the socioeconomic and ideological contexts of employment.

Some of the most important changes in the demographic profile of the labor force since World War II include growing rates of female labor-force participation, increased immigration, and the entry of a large cohort of baby boomers into the labor force. By expanding the labor supply, these demographic shifts have likely contributed to downward pressure on wages for many types of work. They may have also contributed to a growing polarization of the labor force in terms of skills and other human-capital assets.

Among the most commonly invoked structural explanations for growing income inequality are deindustrialization and expansion of the service industry, trends that both increase the demand for a highly skilled workforce and reduce the market value of a high school education (because well-paid manufacturing jobs are replaced with poorly paid retail trade and service jobs). Other relevant factors include declining unionization, labor-saving technological changes, effects on market wages of a stagnant minimum wage, the rise of flexible employment relations (i.e., decline in lifetime employment and decreasing reliance on firm-internal labor markets), and economic globalization (i.e., growing imports from low-wage countries and job outsourcing). In addition, the dramatic growth in executive compensation has been attributed to changing corporate and social norms regarding the acceptability of high levels of inequality, including an

increasing emphasis on the growth-enhancing powers of individual and corporate "greed" since the 1980s.

OTHER WAGE GAPS: GENDER AND RACE/ETHNICITY

Although women's wages have increased relative to men's since the 1970s in the United States, women working full time, year-round in 2003 still earned only about 76 cents to every dollar earned by the comparable group of men. The gender gap in earnings varies by age and is much larger among older workers. According to data from the 2000 U.S. census, the average 25-year-old woman earned 90 percent of what her male counterpart earned, while the corresponding figure for 55-year-olds was only 65 percent.

The overall pay disparities between men and women are largely attributable to the lower wages associated with female-typed work. Despite strong female inroads into prestigious professional and managerial occupations over the past three or four decades, women remain heavily concentrated in a relatively small number of poorly paid "occupational ghettos," most notably in clerical, personal service, and retail sales work. Most analysts agree that the persistent segregation of men and women into different occupations, industries, economic sectors, subspecialties, and firm types accounts for the lion's share of the gender pay gap in the contemporary United States. There is less agreement, however, regarding the causal mechanisms underlying this relationship. For example: Do female-dominated jobs pay poorly because they involve stereotypically "female" work? Are jobs female-dominated because of their historically poor pay? Does the pay gap reflect differences in the skill, training, or labor force experience required for male- and female-typed jobs?

Wages also vary strongly by race, ethnicity, and immigration status. In 2003, the median income of non-Hispanic White households (many that included more than a single wage earner) was about \$48,000. The median for Black households was 62 percent of that for White households; for Hispanic and Native American households, it was about 69 percent; for Asian households, it was 117 percent. According to data published by the U.S. Census Bureau, households with U.S.-born heads had a real median income in 2003 of about \$44,000, compared with \$37,000 for households in which the householder was born outside the United States and its territories. As with the gender gap, these disparities are partly attributable

to the concentration of minorities and immigrants in low-wage occupations and industries (as opposed to differential pay rates for the same job). Direct discrimination (i.e., different pay for the same job) undoubtedly occurs as well, but the prevalence of this problem is difficult to assess for a variety of reasons.

The *comparable-worth movement* represents an effort to overcome the wage effects of occupational segregation by requiring that wages be commensurate with jobs' skill requirements. As noted above, however, researchers disagree regarding the extent to which the low pay associated with female, minority, and immigrant work reflects these groups' lower average levels of human capital (e.g., education, skills, job experience), as opposed to a lesser average payoff to such human-capital assets.

OTHER DIMENSIONS OF LABOR MARKET INEQUALITY

The current state of knowledge concerning some other highly consequential forms of labor-market inequality is summarized below.

Health Insurance and Other Benefits

Unlike most other wealthy democracies, the United States has no comprehensive system of national health care. As a result, Americans rely heavily on employer-provided health insurance. Such plans have been declining in both quality and availability in recent years, with 5 million fewer workers covered in 2004 than in 2001. Those who do enjoy coverage are bearing a growing share of the total cost.

Declining coverage can be attributed in part to skyrocketing premiums, which have increased nearly 60 percent since 2001. In 2004, the \$10,000 average annual premium for family coverage approached the gross annual earnings of a worker employed full time at the federal minimum wage. Given the soaring overall costs, it is not surprising that workers have seen their annual contributions rise rapidly (by 10 percent in 2003), along with their deductibles and copayments.

Overall, more than 45 million Americans, including 8.4 million children, have no medical insurance today. The vast majority of uninsured children live in families with at least one employed adult. Those hardest hit by declining employer-provided health insurance include temporary and part-time employees, workers with little education, and those employed in blue-collar and low-wage service jobs. U.S. Census

Bureau data show that the uninsured are disproportionately racial minorities: Among Whites, 11.1 percent are uninsured, compared with 19.5 percent of Blacks, 18.7 percent of Asians, 32.7 percent of Hispanics, and 27.5 percent of Native Americans. Noninsurance and underinsurance represent significant social and economic problems, since individuals without health coverage often do not seek or receive the type of preventative and prenatal care that can save lives and prevent costly emergency interventions.

Job Security

Since the recession of the early 1980s, American firms have been downsizing their workforces and relying more on nonstandard work arrangements, such as employment of temporary and contract workers. The number of employees involuntarily working part time (i.e., working part time because they could not find full-time work) grew during the 1980s and stabilized during the 1990s. According to estimates by Neil Fligstein and Taek-Jin Shin, temporary part-time workers made up about 2.5 percent of the labor force in 2000, and involuntarily part-time workers made up about 4.5 percent of the workforce. Other relevant changes include the growing practice of outsourcing jobs to countries with lower labor costs and the declining use of firm-internal promotion (i.e., "internal labor markets") to tie workers to firms and provide lifetime employment opportunities.

Growing insecurity at work can be assessed by considering trends in average job tenure (i.e., the length of time that individuals stay with the same employer). Due to scholarly disagreements about how best to measure tenure and the meaning of observed trends, there is no consensus on whether tenure rates have decreased for all types of workers. There is agreement, however, that average job tenure has declined more for younger, less educated, blue-collar, and service workers. Attitudinal surveys indicate that fear of job loss increased in the United States during the last decades of the twentieth century, especially among blue-collar workers in the 1980s and among managers and professionals in the 1990s.

Working Conditions

Jobs vary a great deal in their working conditions, including workplace autonomy, intellectual rewards, physical and emotional demands, work hours, scheduling flexibility, and exposure to danger. Many of

these job characteristics vary with income. Available evidence suggests a growing bifurcation of the workforce since the 1980s and 1990s, with differences in the working conditions faced by high- and low-wage workers increasing over time.

Job Satisfaction

Attitudinal data from the U.S. General Social Survey show that low-income workers report lower levels of job satisfaction than do high-income workers and that inequality in job satisfaction increased during the last two decades of the twentieth century. The percentage of workers at the bottom quintile of the income distribution reporting that they were “very satisfied” with their work decreased from 46 to 39 between 1978 and 1998, whereas the percentage among those in the top quintile increased from 57 to 62.

Unemployment and Underemployment

Unemployment rates are strongly linked to the overall health of the economy. They increase during economic downturns and decrease during periods of economic growth and prosperity. At the time of this writing, the official unemployment rate is approximately 5.4 percent. In addition, a significant fraction of people belonging to the employed labor force work in part-time jobs because they cannot find full-time work.

The United States enjoys lower levels of unemployment than do other rich industrialized countries. Although this is generally attributed to the relatively low wages and benefits paid to American blue-collar and service workers, sociologist Bruce Western and colleagues have suggested that high incarceration rates of American males (especially African Americans) may account for some of the difference between U.S. and European unemployment rates.

Unemployment rates have historically varied by race/ethnicity and sex. Since 1970, the African American rate has been approximately double the White rate. The unemployment rate for Hispanics is higher than that of Whites but lower than that of African Americans. Differences by gender are less pronounced. Between 1970 and 1990, women were slightly more likely to be officially unemployed than were men, but the gender gap all but disappeared after 1990. The latest figures for 2004 show a slightly higher unemployment rate among men than women. Convergence of the male and female unemployment rates is likely due to the expansion of female-labeled

service and clerical jobs and the contraction of male-dominated manufacturing occupations in many metropolitan labor markets.

Official unemployment statistics do not take into account so-called discouraged workers (i.e., individuals who would like to work but have given up looking for jobs). There are few reliable estimates on the size of this population.

Who Gets a Good Job?

Much sociological and economic research has been devoted to studying how individuals are sorted across qualitatively different labor market positions. This work can be divided into two categories: micro- and macrolevel studies.

Microlevel accounts of labor market inequality focus on characteristics of the workers themselves. The most comprehensive accounts are human capital theory (from economics) and functional theory (from sociology). By these arguments, high-quality workers (i.e., those with high levels of education, experience, or other productivity-relevant traits) are allocated to the best-paid and most functionally important jobs, because this is the most economically and socially efficient arrangement in competitive market economies.

Human capital theory has often been applied to explain inequalities between men and women in the labor market. The core premise underlying this line of analysis, advanced, most notably, by economist Gary Becker, is that women have a competitive advantage in domestic work and therefore expect to be discontinuously employed. They rationally choose female-dominated occupations because wage penalties for labor force withdrawal are lower in these occupations.

Sociologists have long disputed the power of such microlevel accounts to explain observed patterns of labor market inequality. They question, in particular, neoclassical economists' assumptions of perfect information, individual rationality, and nondiscrimination, pointing instead to the cultural and structural processes that influence the allocation of persons to jobs (see especially work by Paula England questioning the economic rationality of gender-typed employment for women).

Macrolevel accounts of inequality focus on understanding the social and cultural contexts in which individuals and groups are sorted across qualitatively different labor-market positions. Researchers in this tradition point to institutional, organizational, and ideological constraints that prevent members of

historically underprivileged groups (especially women, persons of color, and individuals growing up in lower-class families or impoverished neighborhoods) from developing the human-capital assets, network ties, and personal dispositions that are rewarded, sometimes arbitrarily, in the labor market.

By treating wages as characteristics of jobs rather than persons, “new structuralists” have, moreover, directed attention to the processes by which certain occupations and jobs come to pay “above-market” wages (i.e., wages higher than would obtain in a perfectly competitive labor market). These processes include the imposition of licensing and credentialing requirements by professional groups and reliance on informal recruitment networks or firm-internal labor markets to fill job openings. Such “closure” practices tend to inflate wages by restricting the supply of individuals who can effectively compete for particular positions.

Taken-for-granted cultural norms concerning the appropriate gender or ethnic identity of particular job incumbents (as well as norms concerning the appropriate jobs for individuals with particular gender or ethnic identities) have also been identified as powerful macrolevel mechanisms in the generation and maintenance of occupational segregation and labor market inequality.

INFORMATIONAL INTERVIEW

To find the best employees, companies and organizations conduct time-intensive and costly recruiting activities resulting in numerous interviews with multiple candidates to fill just one vacancy. The interview process, from the employer’s perspective, is to find the best-qualified candidate who has the right match for the job and the company. The job seeker, on the other hand, sees the interview strictly as an invitation that has to be extended by the employer before he or she can step inside the company. What if an individual does not wait to be invited for an interview, but instead, requests an interview? Is this allowed? Yes it is, in the form of what is called an *informational interview*.

An informational interview is a meeting with a person that one arranges to gain information on a career, a company, its employment opportunities, and any other company items relevant to his or her career exploration. Because the individual is not a job applicant, the informational interview does not require the person to sell himself or herself to an employer. Therefore, an informational interview allows one to circumvent the formal interview process and have valuable face-to-face time with a person who can provide career advice and who could potentially extend a job offer.

Although most job seekers may use an informational interview as a way to audition for an actual job interview by gaining experience and confidence talking about themselves with business professionals, a key objective of the informational interview is to become more informed as to whether or not a company is truly a good fit. Fit can come in the form of location, company size, company culture, opportunities for career advancement, or style of management. Informational interviews can provide insight on these company aspects and help one to decide whether or not to pursue employment opportunities with the company.

ARRANGING INFORMATIONAL INTERVIEWS

How are informational interviews obtained? First, individuals should identify a target list of 5 to 10 companies, which, based on research (size, location, type

of business, etc.) seem most interesting. The next step is for individuals to identify persons they want to meet with through informational interviews at any of those target companies.

One can identify people by reading annual reports of target companies or visiting the companies' Web sites to find a person's name whose title is closest to the type of career one is interested in discussing. For example, a person who is thinking of a marketing career may want to find the director of marketing, a marketing manager, or a market researcher. Also, individuals should keep in mind the network of people they already know. Friends, fellow students, present or former coworkers, supervisors, or neighbors can be good sources for contacts.

After obtaining the name of a person he or she would like to interview, an individual must decide whether to request the interview by writing a letter or a making a phone call. In either case, an individual should simply introduce himself or herself, indicate the source for the person's name, and ask whether the person would be available for a brief meeting to discuss his or her occupation. Because individuals seeking informational interviews are not asking for jobs, they should convey a genuine interest in simply learning more about a particular person's career and the company. Last, individuals should never send résumés when requesting an informational interview via email or regular correspondence, because that signals an intention to change the meeting into a job interview.

PREPARING FOR THE INFORMATIONAL INTERVIEW

The key to a successful meeting is to have a list of questions prepared in advance to ask the interviewee. Be sure to read about the career area related to the interviewee and develop questions that are specific to the interviewee's background, experience, and challenges in his or her career. Some sample questions to ask are as follows:

Tell me what made you decide to enter this career.

What do you find most rewarding about your work?

What is the toughest part of your job?

Where do you see yourself in a few years, such as long-term goals you wish to achieve related to this career or starting a new one?

The types of questions to ask about the company are just as critical. Therefore, it will be necessary to complete some research on the company's history, its senior management team, its products, and the type of industry it is associated with. Here are some sample questions:

What trends do you see for this industry that will positively or negatively affect your company?

How would you describe the company culture?

Which other companies would you consider your company's primary competitors, and why?

Aside from profit increases, how does your company measure success?

CONDUCTING INFORMATIONAL INTERVIEWS

Once an informational interview has been scheduled, there are some basic guidelines to follow for conducting the interview. First, interviewers should arrive 10 minutes early and keep the interview within the time frame agreed upon. It is important to not exceed the requested time, as a sign of courtesy and professionalism.

Second, individuals should dress in formal business attire as if the meeting were an actual job interview. The first impression one makes with a prospective employer is very important no matter what the circumstances may be.

Third, individuals should take the initiative with the questions they ask throughout the interview so that they obtain the information they need but also engage the interviewee in a discussion that allows both parties to have a conversational tone. Finally, be sure to observe the working environment and notice any aspects of the workers in terms of the way they dress or how they communicate. Individuals should also take notice of the offices and other facilities of the company that might enhance or detract from their working experience.

Follow-up Etiquette

On completion of each informational interview, individuals should ask themselves whether they feel more or less enthusiastic about the company. If they like what they learned about the company and believe it could provide a good fit, they should follow up with the interviewee by sending a thank-you card stating

their appreciation for his or her time and declaring their interest in being considered for employment opportunities at the company. An individual might visit the company's Web site once a month and as he or she comes across a job that is appealing should apply for it as instructed but also send a résumé and a copy of the job description to the interviewee requesting a referral to the hiring manager of the position.

An individual who is not interested in working for the company but enjoyed speaking with the interviewee should still send a thank-you note and express appreciation for having learned more about the company and the person's career background.

CONCLUSION

Informational interviews can be an invaluable tool in a job search campaign. Instead of waiting to apply for jobs that are listed on company Web sites or job boards, individuals can be more proactive and introduce themselves to potential employers through informational interviews. After conducting several informational interviews, individuals will have become more familiar with the hiring process, strengthened their interview skills, and developed positive job-hunting techniques that make them more competitive and effective job seekers.

INTEGRITY TESTING

Integrity testing refers to the task of assessing an individual's integrity, usually within a preemployment

assessment situation, for the purposes of determining whether that person might be considered suitable for employment in a specific job role. Until recently, *integrity* was viewed as synonymous with the term *honesty*, and thus integrity testing originally referred to the assessment of an individual's honesty, an attribute defining someone as being sincere and genuine and not prone to stealing, lying, or cheating. This assessment could be undertaken by a self-report questionnaire, as in the famous London House psychometric tests, or perhaps by structured interview or even by measurement of autonomic nervous system functions, such as respiration rate, heart rate, skin conductance, pupil dilation, and muscle tension. These latter measures were usually undertaken by a trained assessor using a polygraph.

The use of self-report integrity testing specifically as an assessment of an individual's honesty is mostly associated with retail, transient storage, and warehouse work situations. For example, this form of integrity testing has been used for occupations such as retail and supplies warehouse staff, airline baggage handlers, and checkout operators in supermarkets. These are the kinds of jobs in which the opportunities for theft and cheating are readily available to staff. Likewise, security workers, law enforcement officials, and workers who may be handling sensitive corporate, government, or military information would be likely to undergo a structured interview or some form of biologically based preemployment integrity screening. These latter kinds of tests are more expensive in time and expertise to administer but have the advantage of not relying solely on the "honesty" of individuals to self-report their responses to probe questions. Furthermore, such tests may be applied throughout employment as part of a periodic security clearance check.

More recently, two other terms have come into use to describe workplace integrity in employees: *employee reliability* and *counterproductive behavior*. The two terms reflect the broadening of the meaning of honesty and integrity from the relatively narrow conceptualization of theft, lying, and cheating that first defined the integrity tests of the early 1980s to a range of employee behaviors, attitudes, and dispositions considered not conducive to efficient and effective work practices or counterproductive to organizational "health." In this widening of the definition, the use of personality tests as integrity tests has become more prevalent in preemployment testing.

Attributes such as conscientiousness, self-control, and agreeableness are now considered the primary characteristics associated with well-adjusted, productive employees. Individuals who display less of these characteristics are seen as potentially counterproductive or unreliable employees. Recent research evidence, compiled and averaged over hundreds of studies, has confirmed that integrity and counterproductive personality attributes are highly valid predictors of successful job performance and training success, alongside general mental ability.

INTELLIGENCE, SCHOOLING, AND OCCUPATIONAL SUCCESS

Research relating educational attainment to earnings has consistently found dramatic benefits for employees with increased schooling. Over their lifetimes, high school graduates will earn \$212,000 more than nongraduates, and each additional year of school attainment beyond high school is associated with increasing income. For example, college graduates will, over their lifetimes, earn \$812,000 more than high school dropouts, and graduate students with professional degrees will earn nearly \$1,600,000 more than college graduates.

The correlation between school attainment and earnings is likely due to a combination of an indirect effect and a direct effect. First, schooling has an

indirect effect because schooling affects intelligence, which, in turn, affects economic outcomes. That is, individuals who attain more schooling are more intelligent, and intelligent workers are rewarded for the skills they display in training and in doing their jobs. Second, schooling has a *direct effect* because of minimum entry-level educational standards required for acquiring certain higher-paying jobs. For example, many civil service jobs require minimum educational credentials, and higher earnings are associated with jobs requiring more schooling.

The reasons for the indirect effects of schooling on intelligence are less clear. It could be that staying in school is related to later earnings because individuals who were more intelligent before they entered school stay in school longer. Thus, when employers hire based on high educational attainment, they may be selecting individuals who were simply smarter to begin with.

Alternatively, it could be that the very act of attending school makes one smarter regardless of one's initial level of intelligence and this acquired intelligence produces workers that are more effective. Even the least intelligent student is bound to pick up some of the instruction, and this instruction is helpful when it comes to taking intelligence tests as well as performing jobs. Consider that IQ tests ask about information and events that may have been covered in school, such as "Who wrote *Hamlet*?" or "What country are the Great Pyramids in?" While one can come across such information outside of school, most individuals acquire such knowledge through explicit schooling and school-related activities (e.g., participating in plays).

To support the notion that schooling increases intelligence, one has only to compare two types of individuals who were comparable in intelligence in eighth grade. One type continued to attend school until graduation from high school, while the other type dropped out of school sometime between 9th and 12th grade. When these two groups are retested at age 18, they no longer have comparable intelligence. The dropouts lose, on average, nearly two IQ points for every year short of high school completion. Because the two groups had equivalent intelligence before the latter group began dropping out, we cannot attribute the IQ differences at age 18 to anything other than differences in schooling. Thus, when employers choose individuals based on their educational attainment, they are likely to be choosing employees who have acquired higher levels of intellectual ability.

Over two decades ago, researchers demonstrated that so-called general intelligence was far more predictive of occupational success than were specific ability factors such as arithmetical reasoning, vocabulary, spatial skills, and memory. These findings clearly explain why employers want to hire individuals with increased educational attainment. Given that these individuals would likely have higher general intelligence because of increased schooling, they are likely to be more productive and successful employees. Furthermore, these findings suggest to some that training individuals with low general intelligence in specific skills is not likely to be as effective as hiring someone with higher general intelligence.

It is important to note that at each level of schooling completed—finishing high school, finishing junior college, finishing a four-year college, and so on—there are pronounced differences in intellectual ability among students at the same level of schooling. Figure 1 shows the probability of an individual holding a white-collar job as a function of level of schooling completed as well as intellectual level—in this case, a reading comprehension score on the International Adult Literacy Scale. As can be seen, there is enormous disparity in intellectual level within any given level of educational attainment, with the highest-scoring individuals being far higher than the lowest-scoring ones. No school-induced increase in IQ or general intelligence can fully explain the substantial differences in intelligence that exist among students at the same level of education; there will always be individual differences in intelligence. Even though dropping out of school can be shown to cause IQ to drop, it is nevertheless true that among those who stay in school, there are large differences in IQ.

The available evidence thus suggests that schooling and intelligence make independent contributions to job success and lifetime earnings. Consider that even among those with comparable levels of schooling, the higher a person's level of intellectual ability, the higher that person's weekly earnings will be. As shown in other studies, there is a linear trend for a rise in earnings to be associated with increasing intellectual ability. Workers with the lowest levels of intellectual

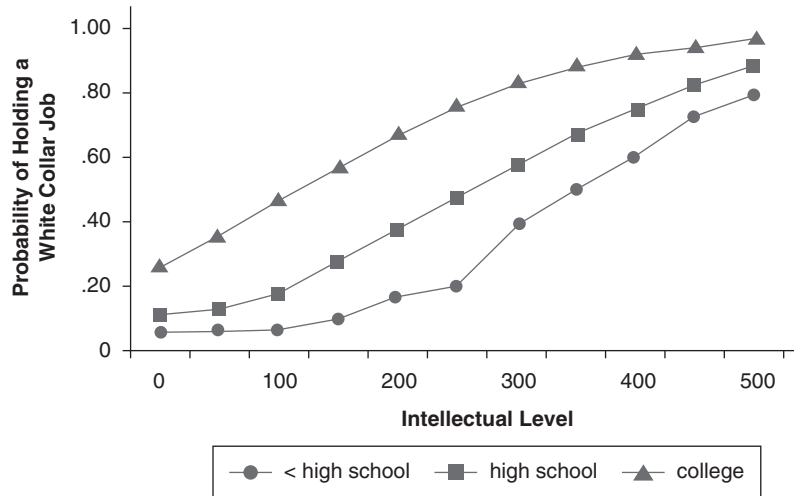

Figure 1. Probability of Holding a White-collar Job Among 26- to 35-year-olds as a Function of Educational Attainment and Literacy

SOURCE: Adapted from data collected at Statistics Canada Web site, <http://www.statcan.ca/>.

ability earn only two-thirds of what workers at the highest level earn. Because differences in schooling are statistically controlled in such studies, the source of the rise in earnings must be due to other factors, such as variations in intellectual ability. Thus, intelligence conveys significant advantages in lifetime income.

Data provided by the U.S. Department of Labor show a significant statistical relationship between measures of general intelligence and job-related aptitudes such as manual dexterity, spatial ability, and so on. In addition, a composite of nine different aptitudes, including a measure of general intelligence, significantly predicts performance in over 400 different jobs. Although the prediction of job performance is far from perfect, it is strong enough to suggest employers can save some money by hiring persons with more intelligence. Furthermore, the IQ measure by itself also significantly predicts job performance.

Another study found that the ability of a measure of general intelligence to predict job performance (that is, its predictive validity) was stronger as the job demands became more complex. In this study, IQ (and related measures) predicted occupational success almost as well as IQ has been shown to predict school grades. Although selection based solely on general intelligence is certainly not perfectly accurate, including a measure of general intelligence in a selection

battery holds great promise because it can be combined with other measures (e.g., grades, letters of reference) to still further increase the predictive validity of the selection battery.

The value of using a measure of general intelligence as part of the hiring process depends on several factors: how many qualified applicants are in the pool, how intellectually demanding the job is, and how substantial the differences are between good and poor performance on the job. Earl Hunt commented in his 1995 book *Will We Be Smart Enough?* that it doesn't pay to use tests to select someone for a job that almost anyone can do, such as cutting your lawn. However, a testing program can be useful when relatively few people can perform the job effectively, when not many people are needed to do the job, and when the costs of making a hiring mistake are substantial. In other words, testing for general intelligence can be useful to an employer, but only under certain conditions.

Because intelligence may be one of the best predictors of occupational success and because there is substantial variability in intelligence within groups of individuals with the same educational attainment, employers may also opt to use standard IQ tests in addition to level of schooling in choosing employees. To outsiders, the use of intelligence to select workers or trainees is fraught with problems. Regardless of any statistical relationship between measures of intelligence and job performance, there will inevitably be applicants who are mispredicted. This is also true of using Scholastic Aptitude Test (SAT) scores to predict who will succeed in college or Medical College Admission Tests (MCATs) to determine who will be successful in medical school; the future performance of some applicants will be underpredicted (i.e., they will achieve better grades than would be expected on the basis of their SAT scores), whereas the performance of others will be overpredicted (they will never live up to their high scores). No prediction based on intelligence is ever perfect or even close to it.

Given the fact that intelligence tests are imperfect predictors of employee performance, one may wonder why they should ever be used for selecting employees. Despite the fact that intelligence tests may be only moderately predictive of employee performance, mathematical models show that even a modest predictive value can lead to large economic benefits for employers. Increasing the probability that new hires may be more qualified for the job decreases the likelihood of attrition, lowers the amount of money that

employers need to spend on training programs, and increases productivity. Thus, from the standpoint of employers, utilizing intelligence tests for the screening of applicants makes good economic sense under the conditions described above. Indeed, "utility analyses" that estimate the financial benefits of using tests in hiring decisions suggest that utilizing IQ tests to select employees translates into economic savings in the range of millions to billions of dollars.

In sum, both level of educational attainment and level of general intelligence (IQ) are related to employee earnings. The increases in employee earnings associated with increased educational attainment are likely the result of both the increased ability of employees with higher levels of education and the fact that higher-paying jobs have higher minimum-education requirements. Because intelligence predicts job performance and better performance is likely to be rewarded with increased salary, individuals with higher intelligence (and more schooling) are likely to earn more than those with lower intelligence (and less schooling). In addition, because performance on standard IQ tests also predicts employee performance, employers may opt to use IQ tests to select job applicants. Although these tests may not be perfect predictors of job performance, utilizing them can lead to significant economic benefits for employers, particularly in highly skilled fields where the applicant-to-openings ratio is large and the costs of poor hires are extreme.

INTERESTS

The term *interests* refers to what an individual likes and dislikes, as associated with specific tasks, activities, or objects. Interests are a function of factors such as values, family background and experiences, social class, culture, and environment. For 80 years, interests have been one of the most useful and most enduring constructs in career development. E. K. Strong Jr. and Frederic Kuder were the early trailblazers in interest measurement. More recently, the theory and classification scheme of John Holland has dominated the field. Strong is famous for his resolute empiricism and for creating occupational scales with the method of contrasted groups. Kuder was both a pioneer in psychometrics and a leader in measuring interests with homogeneous content scales. Holland systematized Strong and Kuder's contributions into a simple, user-friendly, and popular theory and classification. Today, millions of interest inventories are completed each year by young people beginning careers and by older adults considering career changes. The five prominent inventories featured in this entry are well researched, with demonstrated psychometric robustness and distinctive utility for career assessment.

Early interest measurement, notably the leading edge forged by Strong, was largely empiricism devoid of theory. Only more recently, led especially by the theoretical work of Holland, has interest measurement been anchored in theories that explicate interests as constructs with meaning within a theoretical network. Nonetheless, the full understanding of interests within a nomological and causal network is still elementary. We have propositions within social cognitive career theory that suggest interests develop from self-efficacy, but such causal links are still debatable and subject to continuing research.

TWO TYPES OF SCALES

Strong is best known for creating the occupational scale with the method of contrasted groups. Such scales require intense empiricism to collect data about diverse and contemporary occupations. The Strong Interest Inventory has been routinely revised by collecting samples of men and women in diverse occupations. In the latest revision, David Donnay and his colleagues followed the procedures Strong created for constructing occupational scales. Separate occupational

scales were created for women and men, based on the somewhat different interests of women and men in general, and sometimes within specific occupations. Thus, Donnay and his colleagues created a new occupational scale for female rehabilitation counselors and a new scale for male rehabilitation counselors. The steps can be described using female rehabilitation counselors as an example. The rationale for an occupational scale is to differentiate people in that occupation from a general sample of workers representing a broad cross section of the workforce. High scores on a scale indicate that the person shares the likes and dislikes that differentiate people employed in that occupation from people in general. Thus, in this contrasted-group method, the responses of 254 female rehabilitation counselors were compared with other women on each of the 291 items in the newly revised Strong inventory. Items on which they differed in either the *like* or the *dislike* direction by 19 percent or more became the 38 items in the female rehabilitation counselor occupational scale. Some things that female rehabilitation counselor like more than other women are not surprising, such as psychology, career counseling, and motivating other people. Female rehabilitation counselors are differentiated more by their likes than their dislikes; however, they tend to dislike making computer databases and diagnosing computer problems more than do women in general.

It could be said that interest measurement has been hindered by its own success. Strong's creation of the empirical occupational scale was hailed as such a success in academic circles that conceptual progress in interest measurement was perhaps delayed. The occupational scale, actuarially defined by the items empirically distinguishing the people in that occupation, was an apt metaphor for the "dustbowl empiricism" of the 1930s and 1940s. But this kind of contrasted-groups scale has conceptual limitations. An occupational scale is not readily interpretable other than by the actuarial locution "You have the interests of X." A high score on, for example, the physicist scale, does not directly tell the interpreter that it means the person loves science, math, and mechanics but abhors selling, entrepreneurship, and marketing. Interpretation of such a scale becomes inscrutable. This problem led to the development of homogeneous content scales.

The Kuder Preference Record, developed in the 1930s, was the first popular interest inventory to use homogeneous content scales. In contrast to Strong's occupational scales, Kuder designed a content scale to

be directly interpretable because its items reflected similar content. Such items tend to correlate with each other, and thus such a scale has internal consistency. Today, content scales are present in nearly all major interest inventories. Many use content scales to measure the six broad Holland RIASEC (Realistic, Investigative, Artistic, Social, Enterprising, and Conventional) domains. Others, such as the Campbell and Strong inventories, also have specific content scales, called Basic Interest Scales (BISs). For example, the newest Strong revision has 30 BISs, measuring such specific dimensions as interest in protective services or entrepreneurship.

MAJOR CURRENT INTEREST INVENTORIES

The five most widely used interest inventories are the Campbell Interest and Skill Survey (CISS), the Kuder Career Search with Person Match (KCS), the Self-Directed Search (SDS), the Strong Interest Inventory (SII), and the Unisex Edition of the ACT (UNIACT) Interest Inventory. The SDS and UNIACT inventories are the least complex of these inventories; they primarily measure the six Holland RIASEC dimensions. Because of their large number and kinds of scales, the most complex inventories are the Strong and the Campbell inventories. The Kuder inventory uses fewer scales, but it is also currently the most innovative of the inventories because of the way it is being used for an online career-assessment system. The utility of these inventories has been extensively supported by research. Interest scales effectively differentiate and predict important career behaviors such as career choice and persistence, college major, and educational aspirations.

The Campbell Interest and Skill Survey (CISS) is one of the more recent interest inventories. It has quickly become popular because it has many of the assets of the Strong inventory but also because Campbell added innovative measures of self-rated skills that parallel the interest measures. The CISS is the latest of these inventories. Campbell brought many key advances to the Strong inventory during the 1960s and 1970s. In his CISS, he replicated many of the valued attributes of the Strong inventory. Using a Holland-like organizational structure, the CISS contains broad scales similar to the Holland dimensions, basic interest scales, and occupational scales. Campbell chose to rename the Holland RIASEC dimensions in more common language; for example, the Enterprising

dimension became "Influencing." He also added a seventh general scale called "Adventuring." The notable innovation of the CISS is the addition of self-rated skills that match the interest scales. Skills and interests in the same domain are plotted together so that their matches or mismatches are evident. This leads to a qualitative shift in how an interest inventory might be used, especially when interest for an activity is high and the parallel skill is low (or conversely). Such mismatches lead to a counseling dialogue about how the person might seek experiences to gain interest or skill. Campbell's addition of skill ratings stimulated the Strong and Kuder publishers to add similar skill self-ratings as companions to their interest measures.

The Kuder Career Search with Person Match (KCS) was originally developed by Frederic Kuder. Kuder is recognized as one of the most important early figures in interest measurement. The Kuder legacy is now carried on by Donald Zytowski, who has infused Kuder's work into a leading comprehensive online career assessment and exploration system. This system is called the Kuder Career Planning System, under the auspices of the National Career Assessment CAP System, Inc. (<http://www.NCASI.com>). Its interest inventory is now called the Kuder Career Search with Person Match, and it has many of the features of what was previously called the Kuder Occupational Interest Survey. Kuder's approach heavily focuses on interests as rank ordered. Interest items are presented in triads, and the respondent selects the most-liked and the least-liked activity in the triad. The KCS inventory is scored for six dimensions that are similar to Holland's RIASEC but with different names. These scores are then ranked to give a three-point code, very similar to the Holland system, which then permits the Kuder system to link to rich sets of educational and occupational databases, such as the Occupational Information Network (O*NET). The individual's interest results are scored by "person matching" to an archive of personal occupational vignettes of people with similar interests. The online interactive system also includes assessments in self-rated skills (Kuder Skills Assessment) and in values.

Following John Holland's goal for simplicity and utility, the Self-Directed Search (SDS) is one of the simplest interest inventories, yet it is widely used. In a self-scored format, it assesses the six RIASEC dimensions of Holland's theory. It contains four different kinds of items in separate sections of the inventory: Activities, Competencies, Occupations, and Self-Estimates. The

Competencies and Self-Estimates items are more like indicators of self-efficacy. Adding these kinds of items to the more interest-like items of activities and occupations yields RIASEC Summary Scores, tapping a mix of interests and self-rated competence. Thus, these scores are different from those for inventories such as the Strong and the Campbell, which assess those domains separately. From the ranking of the six summary scores, a three-point code (or type) is derived to denote the person's highest RIASEC scores. Such codes are widely used to identify occupations and college majors with similar Holland codes. There are many published studies on the SDS showing its reliability, validity, and utility for stimulating career explorations.

The Strong Interest Inventory (SII) is typically revised each decade to keep it current with career trends and to update its occupational scales, the hallmark of the SII since the 1920s. The SII is the most data-driven interest inventory, given its occupational scales, its large national norm groups, and the number of articles about it appearing in the literature. Over the years since the 1960s, SII revisions have successively incorporated several sets of content scales: first, the Basic Interest Scales, then the Holland General Occupational Theme Scales, and more recently, the Personal Style Scales. In the newly revised version, the SII contains 244 occupational scales, representing the same 122 job titles for women and men, marking the first time since its inception that the inventory includes the entire set of occupational scales for both genders. The SII can also be used with the companion Skills Confidence Inventory, which measures confidence in each of the six Holland RIASEC dimensions.

The UNIACT Interest Inventory (UNIACT) is available to American high schools, colleges, and many others as a component of ACT's educational and career development programs, such as the ACT assessment and PLAN. Used by nearly 5 million people each year, the UNIACT inventory is the world's most frequently used interest inventory. First published in 1977, this inventory contains 90 items, 15 per each of six scales, corresponding to the six RIASEC interest types. Items emphasize work-relevant activities that are familiar to people, through either participation or observation. Occupational titles and job duties are not used. The full name of UNIACT, the Unisex Edition of the ACT Interest Inventory, reflects special efforts to identify interest items that assess basic interests while minimizing gender differences. Individuals' scale scores are used

to plot their location on the World-of-Work Map, an extension of Holland's hexagon. The UNIACT inventory is a core component of DISCOVER, ACT's Internet-based computerized comprehensive career guidance and planning system.

QUALITY AND UTILITY OF INTEREST MEASURES

Individual differences in vocational interests are huge in most general groups of people. The consequences are manifold. For test developers, it means most people can readily express their passions and aversions by responding to simple, straightforward inventories. Interest scales built from such inventories have potent psychometric properties. They have high reliability of several kinds, notably internal consistency and temporal stability. Such interest scales also exhibit some of the best validity indicators in psychology. There is a large and venerable literature on the validity of vocational interests for differentiating occupational and educational groups and for predicting career outcomes. Many of the suggested readings at the end of this entry address such issues.

Especially in the hands of a skilled career counselor, interest inventories can be useful in several ways. The best use will help clients better understand themselves and their vocational options and stimulate directions for action. Best practices in vocational assessment blend subjective information from counseling with objective information, such as interest inventories, to reveal the client's career story.

Broad scales, such as Holland's RIASEC scales, and specific scales, such as basic content scales, have different roles to play in counseling and in self-understanding. The broad scales are readily understood and readily organize broad career options. They are the best place to start the process of formulating a career story and charting directions for exploration. The specific scales then supplement this broad information when clients start refining their career stories and more precise paths for exploration. A broad Enterprising scale points to a broad venue of influencing, yet more precise scales such as Merchandising and Public Speaking relate distinctively to the options of retail sales versus politics. The specific scales are especially useful in identifying client strengths because there are a larger number of them, and therefore they are more likely to show some high scores indicating areas of interest.

By young adulthood, the passions and aversions of most people are clear and affect the choices they make. The likes and dislikes of people in different educational and occupational venues are often sharply different. For example, in the norm group for the 1994 version of the Strong inventory, 148 of 200 women airline attendants liked “looking at things in a clothing store” versus just 66 of 200 women physicists. For these same women, 131 of the flight attendants disliked calculus as a school subject versus none of the physicists.

The fact that individual differences in interests are very wide and deep also has positive consequences for a complex society. Whatever activities are needed to make a society function, there is a likely a group of people eager to tackle that task. Fortunately, there are some people who variously love computer programming, cleaning teeth, harvesting a field of wheat, diagnosing diseases, comforting the distraught, or making sales calls to reluctant customers.

Vocational interests have been the cornerstone of career assessment and counseling for 80 years. Interests deeply tap enduring and important individual differences and play a key role in defining a person’s identity. What a person variously likes or dislikes—math, public speaking, using a torque wrench, reading about DNA, trading stocks, or bungee jumping—does much to define that person. This distinctive individuality is powerfully related to life activities such as learning, working, playing, and relating to other people.

INTERNAL LABOR MARKETS

Organizations have always been faced with the dilemma of using external or *internal labor markets*. Hiring and promotion practices vary depending on whether firms use internal or external labor markets. External-labor-market firms concentrate on recruiting from the outside, while internal-labor-market firms concentrate on promotions from within.

Organizations that depend on an internal labor market make hiring decisions with a long-term outlook and hire individuals with the idea that these individuals will stay with the company for a long time. These organizations are very concerned with promoting from within, obtaining commitments from their employees, and rewarding seniority.

Early organizational theorists believed that internal labor markets would be advantageous to organizations because they would allow employers to develop a motivated and specialized workforce. Management efficiency arguments also support the use of internal labor markets. Managers can create greater efficiency by reducing their dependence on the external labor market. This independence reduces their need for information about future external labor markets. Managers and workers may both benefit from internal labor markets. Management will have reduced transaction costs and greater loyalty, whereas workers will have greater security and stability.

Internal labor market models demonstrate distinct job ladders that employees follow. There may be multiple internal labor markets within one firm. Job ladders allow entry only at the bottom, and movement up

the ladder is believed to be associated with an increase in skill. A person's future career path is primarily determined by the job ladder on which he or she enters the firm. An employee's entering job determines future advancement probabilities. The internal labor market job ladder model hypothesizes that once an individual is on a career ladder, his or her career options are limited by the ladder.

Within internal labor markets, potential employees encounter barriers to entry into the firm's workforce and are restricted to a number of low-level positions from which they must work their way up. People within the organization enjoy job security and anticipate future advancement, reducing the probability of turnover and increasing their commitment to the organization. In an internal-labor-market organization, an employee's job assignment, tenure, and hierarchical level are the direct outcomes of managerial decisions, in contrast to an external-labor-market organization, where outside labor forces affect who fills the top positions in the firm. Managerial decisions in internal-labor-market firms constitute the enacted promotion policies of an organization. Firms using external labor markets are not as dependent on their recruiting and promotion practices as are internal-labor-market firms.

Internal labor markets are believed to reduce turnover and keep the transaction costs associated with turnover to a minimum, while at the same time helping the firm obtain greater employee loyalty. Firms that invest in their employees to develop company-specific knowledge tend to have internal labor markets and work to develop and retain their workforces.

Organizations may use different labor markets depending on the degree of professionalization or specialization a firm requires. If a worker's skills are highly portable, that employee is easily replaced, leading to use of an external labor market. If a firm requires a high degree of specialization, employees with these skills are not easily replaced. Therefore, the organization must attempt to retain the employee and may use an internal labor market.

The subject of external versus internal labor markets is often looked at cross-culturally. The United States is portrayed as having a short-term perspective and using external labor markets, while Japan is portrayed as having a long-term perspective and using internal labor markets. Japanese firms' high productivity is often attributed to their strong culture. Nonetheless, many firms in the United States do maintain a long-term perspective in their hiring and

promotion decisions and utilize internal labor markets.

To select and retain the best employees, managers must be aware of the determinants of career attainment in their firms. Such an understanding is especially important in internal labor markets, because outsiders are not allowed access to high-level positions in the firm. Therefore, market forces do not ensure that the best employees attain top slots. These top slots will be filled by those already employed by the firm. Therefore, it is imperative in internal labor markets that the determinants of career attainment in the firm are consistent with their intended promotion policies; a misalignment between policy and practice may lead to firms' not promoting and retaining the most-talented individuals.

It is also important to consider that firms limited to an internal labor market may not be getting the best talent available. Internal labor markets rely on their existing employees and do not look to the external market to replace their employees with the most-talented individuals available in the market.

Employees in internal labor markets also need to be aware of the career attainment determinants in their organizations. Recent literature has highlighted the effects of unethical behavior in internal labor markets. Employees or managers who are perceived as performing unethical practices, such as earnings management, are often passed over for promotions in internal labor markets. This appears to occur whether or not the company approves of the unethical behavior.

Attempts by firms to partially utilize internal labor markets are usually unsuccessful. Research has shown that when an internal-labor-market firm does hire employees from the external market, these external hires have a quicker promotion rate than existing employees. Current employees may notice the hires from the external labor market being promoted faster than they are and make plans to exit the firm.

While the benefits and costs of internal and external labor markets will continue to be examined for years to come, it is essential that both employees and employers be aware of these benefits and costs. Organizations and individuals must make informed decisions based on their own needs and their perceptions of how these needs can be met.

INTERNATIONAL CAREERS

Most employees used to have chiefly domestic careers in which, in the main, they did not carry out international, across-country work. The exceptions were the small number of employees, or "expatriates," deployed by their organizations on assignments abroad. By contrast, many employees now carry out international work in their jobs, and their careers are more international in scope than they were previously. Examples include those who self-initiate relocating abroad for long-term work to develop careers abroad and those who carry out jobs at home that include substantial international work, including "global" managers who work from the home country overseeing work abroad.

WHY HAS THERE BEEN AN INCREASE IN INTERNATIONAL CAREERS?

Due to the globalization of industry, organizations now operate in an international environment that is highly competitive. To be competitive, organizations need to develop products and services for markets abroad in order to survive and prosper, or else they may fail or be taken over, perhaps by companies from abroad. The multinational enterprise (MNE) is the norm, and employees need to see their careers as international in scope. Organizations often have operations abroad to produce their own products and services, and there are also truly global companies that function as integrated or networked operations with global markets.

WHAT IS AN INTERNATIONAL CAREER?

What has this contemporary international work environment meant for individuals' careers? A *career* is a pattern or sequence of jobs over a lengthy period of an employee's life. An *international career* is one in which the employee performs a series of international jobs, or jobs including international work, over a long period of time. Because of the globalization of industry, an individual may have an international career chiefly with one organization or be mobile across organizations (a "boundaryless" international career), have a career that arises through organizational deployment or is self-initiated, or have a career that is domestically based or based abroad or both.

WHAT ARE THE DIFFERENT TYPES OF INTERNATIONAL CAREERS?

Employees are involved in international careers in a number of different ways. First, employees can be deployed abroad by their organization to transfer the company culture and develop the organization, to transfer skills and fill positions abroad, to transfer knowledge, and to develop a cadre of international managers for the organization. The assignments may be short-term (a few months to up to a year), medium-term (e.g., one to three years), or long-term (over three years). The employee may carry out one assignment and return home or move from one international assignment to the next over the long term. Expatriates/assignees are usually parent-country nationals who reside abroad and are often the senior managers of the organizations' operations abroad.

Second, organizations use host-country nationals (HCNs), citizens of the host country, in their operations abroad. Few HCNs run MNE operations abroad, though organizations at high international levels (e.g., global or transnational organizations) are more likely to use HCNs as senior managers than are organizations at low international levels.

Third, companies may use inpatriates who are host-country nationals and are moved to the parent company permanently or semipermanently for management and career development; to transfer the parent-company culture, expertise, and capability back to operations abroad on their return to senior-management roles abroad; or to bring international or global expertise, technologies, and perspectives into the parent company. Organizations seek to develop HCNs to manage their operations abroad by inpatriating managers and

professionals to the parent country to develop their managerial skills and learn the parent-company and country culture.

Fourth, third-country nationals are from countries other than the parent-company country or the host country who are deployed to run operations abroad or to provide expertise and capability. They may form part of an expatriate pool of managers and professionals available worldwide or may work only for the company.

Fifth, domestic international jobs are jobs in the parent company that include international, across-country work. Much international work is performed from an international company's domestic base. The manager or professional resides at home performing across-country work, often from headquarters. Domestic international work is performed at lower levels (e.g., professionals working in consulting firms, university lecturers using online materials to teach students abroad) through to the highest levels of the top-management team (TMT) and the chief executive officer (CEO). The across-country work is performed by travel (e.g., frequent flying), technology (phone, fax, e-mail, videoconferencing), visits (e.g., business trips of a week up to a month), and short residential stints abroad (e.g., for a month up to three months). The use of technology may be very high, resulting in virtual assignments in which the manager runs the operations abroad remotely by advanced technologies. Travel can be extensive as domestic international managers may be frequent fliers who are rarely at home. They may commute weekly or monthly to work abroad in their firm's operations, reside abroad for regular intervals (e.g., during the week or the month), and come home at the end of the interval (on weekends, at the end of the month for a period) to reside with their families at home. Often the commute replaces expatriation to dangerous locations or occurs when the country is close to the home country or when the employee's family will not relocate.

Sixth, there is a special group of domestic international jobs called *global* or *transnational managers*. Global managers work in MNEs, where they manage the work of an organization across the globe, often from headquarters. These individuals may be (a) global business managers developing work abroad and implementing the organization's strategy across the globe in an integrated way, (b) worldwide functional managers operating in specialist areas to provide integration and consistency across the firm (e.g., in human resources, law, finance, accounting, information technology), or

(c) country managers who run operations abroad in single countries from headquarters. The three types of managers are managed by the TMT.

Finally, there are skilled individuals who self-initiate relocating abroad for work, either having found jobs abroad before leaving or becoming employed once abroad. Many are young, recently graduated professionals. They are considered part of a country's diaspora or population abroad, may leave to reside abroad long-term (e.g., over a year), and often intend to return home. They are not migrants relocating to other countries permanently based on economic hardship in their home countries, or refugees or asylum seekers or other groups escaping persecution or political problems. Individuals who self-initiate international careers are often a country's skilled workers (e.g., professionals, tradespersons). They seek international work to test themselves against the best in the world, to advance their careers and succeed at an international level, to develop international expertise, and to experience adventure, excitement, and other cultures. Their home countries are often concerned at this "brain drain" and develop considerable initiatives to return their skilled nationals home (called "brain circulation").

The seven types of international work are often related and can result in an employee developing an international career over the long term that combines these different types. For example, some employees, originally abroad for one assignment, pursue a series of company-deployed assignments abroad or self-initiate a series of jobs abroad, in one country, a region, or across regions. Some host-country nationals or parent-country nationals relocate to other countries to work as third-country nationals and become part of the expatriate labor pool used by MNEs worldwide. Managers and professionals who have gained high-level skills in international, across-country work early in their careers return home to move into domestic international jobs because of their international expertise and perspectives. International experience leads to career advancement in MNEs that require global and transnational expertise and perspectives for their operations at higher management levels and that find the expertise to be in short supply.

WHAT LEADS INDIVIDUALS TO DEVELOP INTERNATIONAL CAREERS?

Taking the globalization of business and trade as the starting point that provides the opportunities, the

factors that lead individuals to develop international careers are from both the individual, in terms of his or her predispositions, attitudes, cognitions, human capital, and demographic and life stage issues, and from the environment, in terms of the organization, the family, and the country of destination.

The influence of individual and environmental characteristics varies according to the type of international work. Some individuals self-initiate jobs abroad or international work in their domestic jobs and gain international careers through their own initiative. Others develop international careers at home or abroad because their organizations deploy them on assignments. Organizational factors have a major influence on an employee's developing a domestic international career, because an individual's acceptance of that type of position is easier to obtain than for an expatriate position where relocation is involved. By contrast, individual influences may be great when employees develop international careers by working abroad, because even when expatriation is at the employer's behest, individuals and their families must agree to relocate.

Individual Influences

Characteristics of individuals in terms of their predispositions, international attitudes, cognitions, human capital, and demographic and life stage factors affect their seeking or accepting careers abroad.

Predisposition plays a major role. Some individuals are willing movers with respect to relocating geographically for work. Employees who have positive attitudes to moving in general and are willing to relocate domestically for jobs are also more willing to relocate abroad for work. Employees who have a high willingness to relocate abroad for work long-term seek and actively search for work abroad and accept opportunities offered to them. The earlier willingness to relocate abroad for work explains later willingness and actual relocation abroad.

Employees' international attitudes (i.e., their international orientation) can be relevant. Employees with high international orientations have positive attitudes toward other countries and cultures and seek cross-cultural experiences and development, and thus seek or accept jobs and careers abroad.

Cognitions, in terms of high self-efficacy and high outcome expectancies of international work, are proposed by social cognitive career theory (SCCT) to inform individuals' decision making with respect to

taking up international careers. SCCT proposes that the personal agency for living and working abroad, and thus the exercise of control, helps develop interest in an international career. Self-efficacy ("Can I do it?") and outcome expectancies ("If I do it, what will happen?") jointly give rise to interest in international careers. SCCT uses self-efficacy theory to explain its influence on the development of the individual's career interests. People form enduring interests in activities in which they view themselves as self-efficacious and in which they anticipate positive outcomes, and the interests lead to career choice goals and actions, such as searching for a job abroad. Some individuals have high self-efficacy or confidence that they can work and live in countries with cultures different from their own or have a low preference for country ease, being more willing to work with, or in, culturally dissimilar or difficult countries than individuals with low self-efficacy or high preference for country ease.

If individuals do not believe there are positive outcomes from international work, they are not likely to take it up. SCCT uses expectancy theory to explain the influence of outcome expectancies on the development of an individual's career interests. When individuals have high expectancies that they can gain positive outcomes from relocating abroad for work or carrying out international work in their domestic jobs, they are more willing to develop international careers abroad or at home, respectively. Individuals expect to gain cross-cultural experiences, personal and professional development, and particularly pay and career advancement and opportunities by taking up international work abroad or at home.

Human capital also helps individuals develop international careers. Based on human capital theory and the links of human capital investments to career development, human capital investments through gaining international experience and expertise pay off in gaining international careers (e.g., future international assignments or domestic international jobs). There are various ways of investing in human capital for international work, through (a) prior assignments abroad, trips abroad, or having lived abroad; (b) fluency in a foreign language(s); and (c) having a degree, including an international major. Individuals who have invested in such human capital are more likely to seek international work at home or abroad or be selected because of their ability and competencies for international work.

Demographic and life stage factors are also linked to taking up international careers. Younger employees

are more willing than older employees to take up work abroad and to seek and accept opportunities, partly because they expect more positive outcomes and have fewer family barriers to relocating abroad for their careers.

By contrast, gender may not affect the development of international careers. On the whole, women are not less willing than men to relocate abroad for long-term work. Nonetheless, women are slightly less willing than men to relocate abroad long-term to culturally dissimilar countries. Moreover, some women may be reluctant to take up international careers because they have male partners with careers who exert the major power in family relocation decisions and are unwilling to relocate abroad for their partners' work.

Organizational Influences

Environment affects the development of interests in international work, including the work and family environments. SCCT emphasizes that individuals' environments provide opportunities, support, and barriers that affect the development of their career interests. Characteristics of their employing organizations (international level, international focus, management preferences) affect individuals' developing an interest in international work abroad or at home, perhaps providing opportunities for employees to carry out international work and the human resource (HR) support to do so.

With respect to organizations' international levels, MNEs need their parent company managers and professionals to accept deployment abroad to run the organization's operations, manage start-ups, develop new business and partners abroad, and provide and transfer capability and specialized technical expertise. When organizations are starting up operations abroad, they are more likely to deploy parent-company expatriates to run the operations than to use HCNs. They train host country managers to take over operations once the operations are well established. Organizations at high international levels also provide opportunities to carry out international work in domestic jobs more than do organizations at low international levels.

Organizations that are increasing their international focus, seeking to expand globally to meet their business objectives, may encourage an interest in their employees in international work abroad or at home through providing opportunities, HR support, norms, and role models. Organizations seeking to increase their international focus provide the opportunity for

their employees to carry out international work in their domestic jobs in order to grow the international business and for employees to relocate abroad once the organization has operations abroad.

During international relocation, HR support (e.g., training, relocation assistance, family assistance) can be more important to spouses/partners—who are concerned about securing a new job—than to employees themselves. HR support is also needed for employees to carry out domestic international jobs because of substantial barriers and difficulties (e.g., constant travel, time away from home, lack of integration with host-country nationals in the foreign operation, communication and cross-cultural difficulties, stress).

Management preferences affect how organizations staff international work. Managements with ethnocentric preferences use parent-country nationals (e.g., expatriates, domestic international managers) to run operations abroad and make little use of HCN managers except at lower levels. When management has geocentric preferences, carrying out international work is not based on nationality. Thus, parent-, host-, or third-country nationals can develop international careers by being selected for positions throughout the organization. Host- and third-country nationals can work in the parent country and so develop truly international careers.

Family Influences

The family is a major influence on relocating abroad and may provide another type of barrier. The family may also affect whether an individual takes up international work in a domestic job because of the disruption to family life caused by constant travel and the out-of-hours works necessitated by different time zones.

With respect to careers abroad, a partner/spouse, children (especially teenage children), a partner with a career, and a partner less willing to relocate abroad for the other person's job reduce an individual's willingness to take up work abroad. Family structural theory emphasizes that the family is a system in a state of equilibrium. Considering taking or actually relocating on an international assignment causes pressures and forces within the family (e.g., the effects on children) and external to the family (e.g., the availability of employment for the spouse) that disrupts its equilibrium and thus affects the decision to relocate abroad.

The family system provides a barrier to relocating abroad in many instances, for those younger or older and with or without an immediate family involved in

the relocation. However, employees are most likely to be influenced by family factors when they have children and when they have partners, especially when the partner has a career and is unwilling to relocate. There is greater anticipated disruption and actual disruption to the equilibrium of the family system from the employee's relocating, usually reducing an individual's interest in a career abroad.

The spouse has a particularly important effect. The lack of adjustment of the spouse is the largest contributor to the lack of adjustment of the employee when on assignment abroad. Moreover, when the spouse has a career, the employee is less interested in and is less likely to go abroad for work than when his or her partner does not have a career. Family power theory explains that the partner who makes the greatest financial contribution to the family's resources has the greatest power over family relocation decisions. Hence, partners with careers have greater influence over family relocation decisions through their financial contributions than do partners without careers, resulting in less likelihood of the development of international careers by their spouses.

The family system is also a barrier to carrying out domestic international work, though less so than for expatriation abroad, due to time away from the family and the stress incurred. Domestic international jobs disrupt family and nonwork life, reducing the employee's interest and participation in a domestic international career.

Country of the International Work

Finally, the destination country has an impact on relocating abroad for work. Employees are less willing to relocate abroad for work to developing or culturally dissimilar countries than to developed or culturally similar countries. From uncertainty reduction theory, we know there is greater disruption to established routines and thus greater uncertainty from considering or actually relocating to developing or culturally dissimilar countries, resulting in less interest in such locations.

WHAT ARE THE CONSEQUENCES OF INTERNATIONAL WORK?

The consequences of international work vary according to the type of international work, for example, whether the individual is a company-deployed

expatriate, a host-country national or an inpatriate, or a domestic international worker. There are positive and negative consequences for individuals.

Positive Consequences

Because managers and professionals skilled in international work are in short supply, international experience can lead to an employee's developing an international career. International experience leads to career advancement in MNEs, as they require global and transnational expertise and perspectives for their operations.

With respect to positive effects on career advancement, because there is a shortage of managers skilled in international work, having international experience results in managers' gaining career opportunities and advancement, especially if they are willing to move between companies and adopt boundaryless careers. Expatriates gain advancement by relocating abroad to take up new international roles for their organizations. Once there, expatriates can be "poached" by competitors abroad, resulting in career opportunities and advancement. "Expatriate pools" exist abroad, and other organizations take advantage of them.

Expatriates on return home may rise in rank to become domestic international executives because they have international experience, expertise, and perspective. Having prior international assignments predicts holding a senior domestic international manager position, though not necessarily in the same company. Moreover, individuals who self-initiate relocation abroad to work are often sought by governments and employers to return home to senior roles because of their international experience and advanced expertise.

There are also opportunities for career advancement for HCN managers. Some organizations avoid expatriating their employees because of the substantial costs (e.g., allowances, relocation expenses, repatriation home) and problems (e.g., personal and family adjustment) involved. Instead, they run their operations abroad using HCN managers, third-country nationals, parent-country nationals already abroad in an expatriate pool, and domestic international managers from home. There are therefore opportunities for career advancement by HCN managers. HCNs may be inpatriated to headquarters for management development to take on more senior roles on their return abroad or to bring in needed global or international perspective or expertise, or

they may be expatriated as third-country nationals to manage the organization's operations in another country.

There are positive consequences of undertaking domestic international work because it can lead to advancement to senior levels in the company. Domestic international work enables the learning of international skills and expertise, which executives and CEOs of companies require in the global environment.

Negative Consequences

There are also negative effects from participation in international work, especially for mid- and long-term company-deployed expatriates, on pay and advancement, on premature return, and on labor turnover. On the negative side, companies localize the pay and conditions of expatriates to avoid the costs and problems of expatriation. Companies may deploy expatriates with no opportunity of return to the home host country. Because of the lack of support and unmet expectations, expatriates may prematurely return from their assignments or leave their employers while abroad.

There may also be negative effects of expatriation on career advancement within the organization. Expatriates are usually "out of sight, out of mind" and may be passed over for promotion. The largest career problem for company-deployed expatriates is repatriation. There is usually no job to come back to, or there is one at a lower level than the job abroad. The result is dissatisfaction and a lack of organizational commitment by expatriates and their families and the feeling that their international experience is not valued, resulting in intentions to leave the organization or actually leaving. However, the turnover may be to a higher-level job in another company because of the shortage of skilled international managers and executives.

Self-initiated expatriates abroad also find it difficult to gain positions on their return home that take advantage of their international expertise and perspectives. Hence, repatriates may again expatriate abroad after a short time to gain career opportunities.

Being a woman appears to be a disadvantage for career advancement through international work. A very low proportion of company-assigned international assignees are women. The reason may be that senior managers and executives are attracted to people similar to themselves. Because there are more men in these top-level decision-making positions, they may therefore select men more often than women for

international assignments and domestic international jobs.

Such similarity attraction effects may also mean that parent-country executives are more likely to select parent-country nationals than HCNs to run their operations abroad. Host-country managers are unlikely to be selected outside of their countries or regions for more senior roles in an organization. Companies favor parent-company nationals or those from culturally similar countries for advancement to the most senior levels of the organization.

There are also negative consequences of participation in domestic international work. Employees in domestic international jobs often incur substantial stress through frequent travel; being away from the family, friends, and social life; working out-of-hours to match time zones abroad; not being integrated with host-country nationals abroad; and needing cross-cultural and communication skills, often for several cultures at once. Hence, those working in international domestic jobs may seek purely domestic jobs to avoid the stress incurred from the working conditions described.

CONCLUSION

Individuals are now more likely than ever to have international careers rather than purely domestic careers. International careers may occur domestically or abroad, may be bounded within one organization or boundaryless through mobility across organizations, or may be voluntarily developed by individuals who take advantage of opportunities that arise through the deployment by organizations of their own employees.

International careers may be developed in a number of ways: (a) through a series of assignments abroad, (b) through switching between assignments abroad and international work at home, (c) through carrying out a series of domestic international jobs, (d) through being part of an expatriate pool of workers from which MNEs recruit, and (e) through self-initiating relocation abroad for work and return home to capitalize on the experience and expertise gained abroad.

Challenges arise in international careers chiefly from the lack of jobs on return home; the adjustment and stress inherent in international work, including for the family; the labor turnover of internationally skilled employees; and the brain drain when skilled nationals relocate abroad for long-term work and do

not return home. By contrast, there are also substantial advantages for career advancement from international work and for exciting, adventurous lives.

it is under continuous development. This relatively new approach, which has emerged along with the rise of the Internet as an alternative communication tool, is still characterized by limited investigations. Thus, its use, though becoming gradually pervasive, is generally based on users' experience rather than on validity research. Specific methods employed for Internet career assessment are influenced in part by the purpose of the evaluation, the variety of Internet communication channels and modalities, and the technological tools available. Continuous technical development, as well as initiatory research in the area, implies that current procedures relate to limited possibilities but that future procedures will be quite revolutionary.

The most developed, frequently used Internet application exploited for career assessment is online testing, mostly psychological in nature. *Online testing* refers to a general procedure by which an individual take tests of various types using a personal computer connected to a Web site that presents a test, provides instructions for filling it out, and usually scores and provides interpretation for it. Although online tests generally reflect the variety of test types and formats available offline, quite a few variations of this general procedure have been used, with differences in questioning sophistication, responding formats, scoring methods, and ways and depth of interpreting the test results. In addition, because publishing on the Internet is easy, generally rewarding, and essentially costless, online tests differ greatly from one another in terms of their levels of professionalism. This means that numerous tests published online and offering assessment to the public in various domains have been created by nonprofessionals for various reasons and do not fulfill accepted standards of test construction. This creates a major problem, as most Internet users cannot distinguish between "good" and "bad" tests and thus might be misguided in their serious attempts to gain help by means of Internet resources and make wise career-related decisions.

Parallel to offline (paper-and-pencil) testing, online tests differ in their focus of measurement, whether intelligence, specific aptitudes, attitudes, personality, or the like. Also parallel to offline testing, there are various formats for online tests: multiple choice, rating scales, and open-ended questions. However, because of the advantage of computerized scoring, online tests employ the first two formats; open-ended tests, which need human involvement, are rare. Usually, too, an online test is designed in such a way

INTERNET CAREER ASSESSMENT

Career assessment through the Internet is an emerging though complex endeavor based on multiple methods;

that the user can respond easily through mouse clicks and the scoring procedure is automatically conducted. Online tests take advantage not only of computerized scoring (and preplanned interpretation) but also of the convenient capability of integrating multimedia-enhanced components (e.g., use of color and animation, audio, and video), automatic time watching, and more. A special advantage of online tests is the ability to tailor tests to test takers according to preestablished individual characteristics. Likewise, adaptive testing (in which an individual's success on an earlier test item determines the difficulty of the subsequent item) can easily be integrated into the system.

Research in a variety of assessment areas has typically found much support for the validity and reliability of measurement through online tests; they are, in fact, very similar to their offline counterparts. This has encouraged the use of such tests for a number of career-assessment purposes, including school guidance, career counseling, and employee selection. Online testing in each of these activities can provide specific and partial information for the test taker and/or assessor to be integrated in a broader assessment process. For instance, a client involved in career decision making may go through face-to-face counseling sessions while, in between these sessions, also taking online tests suggested by a counselor. Such integration of different channels of communication and interaction is cost-effective and convenient for many, as tests may be taken individually by clients at optimal timing without exploiting other resources. Other advantages include (a) centrally executed, easy, and quick modification of tests for editing of items and instructions and updating scoring procedures; (b) convenience in time and place of testing; (c) rapid and accurate scoring and interpretation according to preassigned theoretically and empirically grounded algorithms; and (d) the possibility of quick, detailed feedback.

Disadvantages and problems should not be overlooked, however. These include (a) publishing of countless unsupervised, nonprofessional tests that, in many cases, look like professional tests; (b) direct and immediate conversion of an offline test to an online version without the necessary adjustments, which might damage valid measurement; (c) use of test norms based on offline test-taker populations, which is known to be erroneous (online raw scores, in many tests, are elevated relative to the offline scores of the same test); (d) lack of a close human being to support the client's acceptance of disappointing results;

(e) use of online assessment that supports social injustice in providing testing opportunities to wealthier people (related to the "digital divide"); and (f) difficulties in identifying and verifying test takers and surveilling their conduct.

Another vehicle that the Internet makes possible for use in career assessment is online interviewing. Similar to telephone interviews, online communication—synchronously via Instant Messaging (e.g., ICQ, Windows Messenger), chat (e.g., LivePerson), and webcam and asynchronously via e-mail—enables interviewing from a distance. Although this procedure has several obvious advantages (e.g., cost, convenience, storage of written dialogues, augmented interviewee openness caused by the online disinhibition effect), it also has disadvantages (uneasiness for some interviewees owing to the lack of eye contact, loss of important physical and nonverbal communication cues, and difficulties in identifying the interviewee). This approach might therefore be used for initial screening or for career counseling by specifically trained interviewers.

An emerging online assessment approach that has recently been proposed adopts ethnographic and anthropological methods in observing people's behavior in Internet-enhanced environments (e.g., forums, chat rooms) while interacting in group situations or individually in any number of possible virtual stimulations. Although validity research is still lacking, this approach is promising in light of recent technological developments (e.g., enriched multimedia, sophisticated 3-D virtual reality, integrated video-audio tools) and growing research. This way, observation and appraisal of individual behavior in cyberspace could either complement face-to-face evaluations in an integrated assessment center or serve as preliminary screening of job applicants.

Online career assessment is still in an embryonic stage. Much research and development ought to be put into this area to make it routinely available for use in assessments for career counseling or employee selection.

INTERNET RECRUITMENT

Since the early 1990s, there has been a dramatic change in the process of employee recruitment due to the emergence of the Internet as a significant means of exchanging employment information. The Internet is used today around the world by organizations of all sizes and in every industry. Job seekers can leverage the Internet using a variety of online avenues to pursue almost any kind of job, from entry level to senior executive, from trade work to professional services. The emergence of the Internet has spawned a new industry intent on helping organizations find and select candidates for available jobs using various Web-enabled methodologies. At the same time, substantial research efforts have tried to better understand how job seekers use the Internet to search for jobs and the value of such endeavors in actually finding employment. At the intersection of business practice and research lies significant debate around defining the value of the Internet for attracting and ultimately selecting the right kinds of candidates.

The Internet has emerged as a significant mechanism for employee recruitment because it offers unparalleled promise for facilitating applicant flow to employment opportunities and subsequent decisions regarding the fit between a job candidate, an employer, and an available job. *Internet recruitment* has enhanced the abilities of organizations to advertise employment opportunities to a global audience. Within the World Wide Web, there are a number of sources for finding available jobs. Job seekers can

search online job boards that contain millions of job advertisements, utilize Web sites of professional organizations or niche job boards that may contain more targeted opportunities based on professional interest, or visit the employment Web pages of almost any organization, where information about a company, its people, and its job opportunities can be reviewed and applications can be submitted. The ease with which job opportunities can be found on the Internet has expanded the conceptual definition of a job seeker to include both active and passive candidates. Active job seekers are those who are currently unemployed or employed in positions from which they wish to depart. This concept of the job seeker is consistent with traditional notions of job applicants. Passive job seekers are those who are currently employed, not engaged in active job search, and might not even be thinking about changing their current employment. However, the Internet has provided passive job seekers with a more time-efficient mechanism for exploring job opportunities and has empower organizations with new tools for finding and communicating with this kind of individual.

Because the Internet presents so many options for employment search, research on Internet recruitment has focused on two primary areas. The first area has evaluated the impact of the Internet on the job seeker's search and the subsequent quality of an organization's selection decisions. This perspective most closely maps to the interest of employers trying to determine how best to invest their employment-marketing budgets. The second area focuses on analyzing how job seekers experience and use the Internet to find jobs. This perspective blends the interests of job seekers and employers in the hopes of creating a better online employment search experience.

EVALUATING THE IMPACT OF THE INTERNET

The demand for demonstrating the value of the Internet as a recruitment source has increased with the size of organizational investments in online recruitment. From an employer's perspective, there are several major sources of online candidates, including Mega Job Boards, Niche Job Boards, Company Web Sites, and Virtual Networking Communities. A challenge for companies is determining the right investment strategy so that sources can be leveraged for maximum return with regard to the quality of applicants, performance of

new hires, retention of new hires, and efficiency of the candidate selection process.

Mega Job Boards offer job seekers thousands of job opportunities, provide employers with access to millions of résumés, and represent the primary exchange for employment information on the Internet. The nature of the postings on these sources reflects a focus on basic job information and the minimum requirements for jobs. The cost to an employer of posting to such Web sites is relatively modest compared with more traditional recruitment sources (e.g., newspaper classifieds), and applicants are drawn to these sites because of the number of job opportunities available for review as well as job-seeker support services available, such as résumé coaching. The popularity of these Web sites may also be their main drawback for employers interested in more targeted groups of job seekers. Niche Job Boards are typically structured in much the same way as their larger counterparts but offer opportunities and career information targeted at specific types of professional groups such as information technology workers, marketing professionals, medical workers, or engineers. The focus of niche sites toward the professional concerns of specific kinds of job seekers make them popular destinations of both active and passive job-seeking professionals and generates brand loyalty not typically affiliated with the use of Mega Job Boards.

The popularity of the Internet for employment search purposes has been clearly demonstrated by the integration of employment advertising into company employment Web sites. Almost every company in the Fortune 500 has pages on its Web site specifically designed for employment purposes. Within these Web pages, job seekers have access not only to the postings of available job opportunities but also to specific information about an organization, its people, and information regarding the benefits of employment with the organization and insights about how their careers may develop within the organization's structure and through use of its developmental resources. A fourth category of online recruitment sources is interactive communities that increasingly allow job seekers direct access to employees of firms with whom they seek employment. Such communities allow both employers and job seekers to more effectively leverage social networks in the hiring process and not only learn about employment opportunities but also gain firsthand testimonials about the employment experience available at potential employers.

The variety of ways the Internet can be used in the employment process makes it a dynamic area of study and professional debate. As organizations attempt to find the right kinds of applicants in more efficient ways, comparisons are made not only between the Internet and more traditional sources of employee recruitment, such as newspaper advertisements and job fairs, but also between the different sources that can be utilized for finding candidates. The advantages of job boards for attracting a wide variety of applicants can be somewhat mitigated by the number of nonqualified applicants who apply for positions. On the other hand, employment Web pages on company Web sites typically provide job seekers with more information about an organization and its employment opportunities as well as application mechanisms for filtering candidates tailored to the specific needs of an employer. However, these Web pages can require intensive resource investment to develop and are only as effective as the ability of the organization to drive applicant traffic to the page.

JOB-SEEKER EXPERIENCE

The Internet has made the job-search experience more similar to a consumer experience. On the Internet, hundreds of thousands of job listings from thousands of employers are available for individuals to review. Therefore, attracting and engaging the attention of the right kind of applicant audience has become an increasing concern for corporate recruiters. This shift in paradigm toward treatment of job seekers as consumers of employment-related information has turned research attention toward gaining a better understanding of how job seekers experience and use the Internet to find employment. It is not just the generation of an applicant pool that interests companies and researchers but also how to initially attract job seekers who match the employer's requirements and "fit" with the corporate culture and working environment.

On the Internet, job seekers are more heavily interested in ancillary characteristics of employment advertising than in traditional recruitment sources (e.g., newspaper classifieds). Certainly, the messages contained in an online job advertisement or organizational employment Web site will have a significant impact on job-pursuit behaviors. However, a number of additional characteristics of the employment-advertising mechanisms, such as the aesthetics of a

Web site, ease of use in obtaining information and using application tools, perceived credibility of the information source, and trust in the application mechanism, have a significant impact on job-seeker attraction toward a job and the likelihood of pursuing an employment opportunity.

The Internet provides companies with flexibility in how they can present employment-advertising messages on their corporate Web sites. Some organizations choose to present information on these pages in a rather static fashion, providing basic information about the organization with a limited number of supporting Web pages. Other organizations provide detailed information about corporate history, the kinds of people who make up its workforce, developmental opportunities available to employees, and benefits that employees receive as part of an employment package. Best-practice organizations go even further, offering unique insights into an organization's culture through virtual tours of company headquarters, profiles of employees in popular occupations, information that provides a realistic preview of what someone might expect when taking the job (e.g., an employee's typical work day), and inventories that job seekers can take to assess whether their personalities match the profile of a successful employee within an organization.

The Internet allows organizations to unleash the creative powers of its marketing department on the job-seeking public. However, the effectiveness of online employment advertising is contingent on the receipt of information by the job-seeking public and subsequent actions in which they engage (e.g., application, recommendation of the company to job-seeking friend). As means of employment advertising become more advanced and tools become more interactive, the sophistication of users required to effectively receive employment-marketing messages and successfully apply for jobs increases. To this end, employers and researchers have attempted to consider how different types of users experience and use the Internet as a tool for job search. The characteristics that most impact online job-search experience include age, race, gender, past computer experience, and current employment status. Older job seekers tend to be more concerned about the security of their personal information when using online job search tools. The demographic makeup of individuals featured on a Web site may have an impact on the way minority members or females perceive the company's perspective on diversity. Passive job seekers may be more

sensitive to the ease with which they can find information on an employment Web site or within a job-search engine, as their time for job search may be limited while at work or while searching for jobs after hours.

Employers at the cutting edge of online recruiting consider the possible experiences of different kinds of job seekers when designing employment Web sites or job advertisements to be used on job-search engines, so that the information communicated and means of application can be optimally facilitated. Based on the type and number of employees an organization is trying to attract, an employer may design a Web site to have more of a recruiting, selection, or mixed orientation. Employers who design employment Web pages primarily for attracting applicants are likely to provide more marketing-oriented information that casts the organization in a positive light, so that a maximum number of potential employees might be attracted to the job opportunities. Employers who are more concerned about finding the right kinds of applicants as efficiently as possible design their Web sites with a greater selection orientation. To this end, job seekers might be able to view information about an organization, but the focus of information would be to encourage use of an online screening tool that will either formally filter applicants or promote self-selection into or out of an applicant pool. Job-search engines are typically more selection oriented, as they allow job seekers to view information about available job opportunities and provide a mechanism for efficient application but allow little opportunity for job seekers to learn about any one employer. Many larger organizations have the luxury of blending these orientations together so that a job seeker can learn about an employer and then submit an application using some sort of automated mechanism.

FUTURE ISSUES

The Internet will continue to change the way job seekers find and apply for jobs. Traditionally, networking with friends and professional connections has been the most effective way for a job seeker to obtain high-probability employment leads. Virtual networking promises to affect the way job seekers find and gain access to high-probability employment opportunities. Such networking takes place on Web sites specifically designed to facilitate such connections and also through some of the larger job boards,

whose members number in the hundreds of thousands. Acquisition of information through such channels may supplant the value of certain information provided by employers through their Web sites, such as employee testimonials. Future research in the area of Internet recruitment will certainly examine the impact of virtual networking on job-seeker perceptions and subsequent applicant pools. In addition, future research will likely focus on testing models of job-seeker perceptions to better understand how Web sites can be designed to optimize the job-seeker experience and maximize corporate return on investment. Although the Internet has enabled organizations to realize tremendous gains in efficiency with regard to the recruitment process, it has also changed the standards by which recruiting and hiring are measured. Research and practice must continue to converge on the areas of Internet recruiting that lead to smarter and faster hiring of employees. Nevertheless, Internet recruiting has forever changed the way employers and job seekers find each other, and it will continue to be a powerful force in shaping the workforce of twenty-first-century organizations.

INTERNSHIPS

An *internship* is a short-term work experience that provides the opportunity to explore an area of career interest, an occupation, or an industry. Typically, internships last for a semester, but they can last up to a year. Internships are designed to reinforce academic theory with real-life experience. The internship activity is supervised and is concurrent with coursework, and school credit is frequently awarded. Internships can be found outside of the intern's home country and can yield global work experience, sometimes with a total-immersion language-training opportunity. Intern work may include special projects, a sampling of activities in many disciplines required by the sponsoring organization (employer), or, in some cases, intense activity within a particular discipline or department. Internships are commonly, but not necessarily, paid positions. Both for-profit and not-for-profit corporations as well as government agencies provide internship opportunities. An internship is sometimes called a *practicum*.

Although the goals are similar, it is important to distinguish internships from *cooperative education*, or *co-ops*. Cooperative education features the toggling of full-time academic work with full-time paid work experience in blocks of time, commonly six months. The co-op position is closely related to the student's major and is considered a formal part of the education process. Co-op positions are typically used in applied fields of study, such as engineering or the sciences. With a co-op job, there is more emphasis on the compensation as a major feature of the relationship. Frequently, co-op positions provide essential tuition money. Also, there is a clearer connection between a successful co-op experience and full-time employment at graduation.

An internship is a supervised work experience with many objectives and great opportunity if managed correctly. As such, each intern has a supervisor at the academic institution who builds a strong rapport with both the intern and the sponsoring organization. The internship supervisor can be a professor or a staff

member specializing in industry relations. Commonly, the internship supervisor is responsible for finding, selecting, and maintaining a relationship with employers. The internship supervisor will match the intern to the employer that meets his or her needs in terms of career interest and schedule. Employers interview prospective interns to ensure a good interpersonal and career match.
