About the Editor

Byron Kaldis, BA Honours (University of Kent), DPhil (University of Oxford), is Professor of Philosophy and Director of Studies in the School of Humanities at the Hellenic Open University. He has previously held positions at universities in the United Kingdom, United States, and Greece and has recently been a visiting scholar in the departments of philosophy at the University of California, Berkeley and the University of Helsinki. He will be again a visiting scholar at Harvard University and Rutgers University.

He has taught and published in the areas of the philosophy of social sciences, metaphysics and epistemology, history of philosophy and political thought, and the ethics of technoscience. He currently works on the relationship between philosophical issues in cognition and social ontology.

He is the editor of a forthcoming edited volume: *Mind and Society: Cognitive Science Meets the Social Sciences*, to appear in the Synthese Library of Studies in Epistemology, Logic, Methodology, and Philosophy of Science, and co-editor of another forthcoming edited volume titled: *Wealth, Commerce and Philosophy* published by The University of Chicago Press.

Byron Kaldis will be editor of a new academic book series in the philosophy of the social sciences and serves as member of the advisory board on the philosophy of sociality book series at Springer. In 2011, he launched together with colleagues the European Network for the Philosophy of the Social Sciences (ENPOSS).

Introduction

Philosophy *and/of* the Social Sciences

This Encyclopedia is the first of its kind in bringing together philosophy and the social sciences. As its title suggests, it is not only about the philosophy *of* the social sciences; it is also about the relationship between philosophy *and* the social sciences.

The subject of this encyclopedia is purposefully multi- and interdisciplinary. Knowledge boundaries are both delineated and crossed over in this reference work. The goal is to convey a clear sense of how philosophy looks at the social sciences and to mark out a detailed picture of how exactly the two are interrelated, interwoven at certain times but also differentiated and contrasted at others. The encyclopedia brings forward the ways in which philosophical understanding throws light on the social sciences and, in particular, on their central concepts or key themes; it also explores the ways in which each of the different social-scientific subdisciplines handles such concepts and themes by exhibiting diverse responses to the philosophical analysis of its methods.

Though the theme of this relationship has had its own history and received some academic treatment in the past, there are fresh developments on the current scene. Novel domains are rapidly developing in the area of social ontology and collective intentionality, with discussion of such concepts as shared action, plural subjects, and group mind. New areas of investigation are also emerging at the interface between philosophy and certain modern areas of social-scientific research spawning out of artificial intelligence and cognitive studies and their subfields, which demand a totally new and rather more complex perspective than erstwhile. There are also burgeoning efforts to link logic or its subfields, such as deontic logic, with attempts at regimenting the way human (social or collective) action can be understood.

In addition, it is becoming increasingly apparent that the traditional branches of philosophy (such as philosophy of mind or philosophical psychology) and the social sciences are being linked to each other via recent developments in the area of cognition—for example, research in evolutionary psychology and genetics, primatology, and evolutionary political science, along with neuroscientific studies invading traditional social-scientific fields, has made old-fashioned, rigid divisions between the humanities and social science(s) outmoded. Furthermore, new fields in epistemology, probability theory, and confirmation (e.g., Bayesianism or formal epistemology) represent another area of osmosis between philosophy and the social sciences that has made earlier philosophy of social science rather obsolete.

At the same time, advances in social-scientific research, such as rational choice theory, statistical or stochastic models of decision making, and mathematical modeling of action or game-theoretic approaches, coupled with evolutionary biology or with computer simulation modeling, have in their turn had an impact upon philosophy itself. In this sense, a theme emerging from this work is that there is, at certain loci, a synergistic effect brought about by a process of two-way interaction between philosophy and the social sciences, over and above the one-way study of the social world by means of philosophy.

In this sense, the entries in these volumes cover also fields that are both controversial and on the cutting-edge, thereby foregrounding the central goal

of this project, namely to show the interrelationship between philosophy and the social sciences, especially as it is found in entirely novel niches.

Here is just one case illustrating this tendency of a profoundly changing philosophy of the social sciences: "Homophily" and "social interactions" based on economic models is an example of divergent ways of studying social actors' contact and interaction from within different social disciplines, ranging from sociology to economics, or from novel disciplinary matrices ranging from the analytical study of social mechanisms to complex-networks theory and on to the merging of economic models with physics. It is clear that all such cases raise substantive philosophical issues, thus radically altering the character of the philosophy of the social sciences.

In addition to its novel and multi- and interdisciplinary theme, the encyclopedia's structure is designed so as to best serve as a useful study guide supporting research and instruction at both undergraduate and graduate levels in colleges and universities world wide. It is uniquely placed to serve as both a quick and up-to-date guide for those outside the field(s) and a useful information channel for novel developments and interrelationships for readers who are knowledgeable about one, but not the other, of the two areas here related. This is the added value of this reference work.

To achieve this double benefit for two groups of readers, special attention has been given to two features that are particularly and constantly highlighted. Firstly, the feature of cross-referencing is particularly vital for an encyclopedia with a subject matter that combines two major academic areas, a principal one for the humanities linked with the social sciences. Secondly, because of this distinctive feature and the resultant deeply interdisciplinary nature of the whole project, a Reader's Guide is included to classify entries according to unified themes or subject areas. The inclusion of the cross-references and the Reader's Guide ensures that the encyclopedia is not simply a mirror of achieved knowledge or a catalogue of fossilized dictionary meaning but an active participant contributing to the growth of philosophical knowledge of the social world. Consequently, though the term *reference work* is used in this introduction following established convention, it is important to underline that this encyclopedia is not a mere "reference device" containing dictionary definitions as opposed to encyclopedia entries (to borrow a distinct but related, important idea about a speaker's internal meaning from Gilbert Harman), that is, mere definitions of the meaning of terms as opposed to encyclopedia entries containing facts known to be true descriptions of an outside reality.

An additional feature is the inclusion of entries covering central topics or core historical episodes in both (i.e., central areas of philosophy and of the social sciences), thus assisting readers with no, or limited, knowledge of one of the subject areas to gain a foothold in it by becoming familiar with some of its center points (e.g., entries on Epistemology or on the Philosophy of Language or on Truth, on the side of philosophy, and on Explanation Versus Understanding, on the side of the social sciences). The same is done with classic concepts in the philosophy of science (from which the philosophy of the social sciences has borrowed a lot)—e.g., there are entries on Observation and Theory-Ladenness, on Kuhn, etc. Yet other entries, such as Objectivity or Positivism, etc., straddle all three domains: philosophy, philosophy of science, and philosophy of the social sciences. Finally, a number of entries deal exclusively with the particular "philosophy of" relationships between philosophy and each of the social sciences, as in the philosophy of sociology or the philosophy of history and so forth. Thus, the unique mark of this encyclopedia as serving a neglected educational need is the interrelationship between philosophy and the social sciences and the novel niches thus produced, especially found in fresh ideas and unprecedented hybrid disciplinary areas.

In this way, the encyclopedia serves also a further dual purpose: that of forging a path for the renewal of the philosophy of the social sciences, on the one hand, while on the other helping to establish or promote novel modes of dealing with some of the classic problems where previous attempts have become outmoded or have led to an impasse.

Novel Features

The philosophical searchlight has always been turned on scientific knowledge, but whereas the philosophy of physical and biological sciences is a

well-covered field in terms of textbooks, especially in recent years, the philosophical exploration of the social sciences has remained relatively patchy or partitioned into subfields of social sciences (e.g., philosophy of economics as opposed to philosophy of history, etc.) without a unified and detailed treatment like the one this encyclopedia provides. It is therefore quite important that it includes entries that underline both the novelty of current directions together with the historical tracing of the evolving relationship between its two domains.

Common Concepts

One of the most important aspects of the whole project is the comparative and contrastive exposition of certain core concepts that traditionally receive different or partially compatible or even asymmetrical treatments in philosophy as opposed to social sciences, on the one hand, as well as amongst the various social scientific subdisciplines, on the other. So the reader will encounter an extended number of headwords (from causation to relativism) in double or even triple entries, one dealing with that concept and its role in philosophy juxtaposed to the other covering that concept as it has been understood in the social sciences. In this manner, the reader has a direct view of similarities and differences but also of crucial interrelationships. One is reminded of how one of the classic concepts of social and political philosophy, Jean-Jacques Rousseau's "general will," originated from a purely theological notion (of God's "general will") employed by Antoine Arnauld, Nicolas Malebranche, and others before him.

The encyclopedia therefore follows a novel approach whereby a topic of central and perennial importance is covered jointly by more than one entry and from different angles. This is both useful and pedagogically instructive for students.

Audience

Combining two vast and complex disciplinary areas for the first time, the encyclopedia will be of real benefit to a large and diverse audience. Readers of this encyclopedia will include both undergraduate and graduate students of the humanities and of the social sciences, as well as university professors, researchers, and scholars of both fields. It will also be of benefit to readers unfamiliar with either of the encyclopedia's two domains.

The special aim of this project, as mentioned, is to underline interdisciplinary connections between the humanities and the scientific study of the social world, by drawing analogies, illuminating conceptual kinships, and demarcating interesting contrasts between philosophy and the social sciences, thus for the first time providing readers coming from different disciplinary backgrounds a vista from which to survey novel aspects of the relationships between the humanities and the social sciences.

Thus, the entries in this encyclopedia give readers an opportunity to explore interconnections, clarify commonalities as well as differences or comparative contrasts, discover new fields or ideas of intellectual interest, explore adjacent conceptual zones that may be found to further expand their own disciplinary domains, and also understand better their own academic areas of expertise and the historical provenance of each. The entries are written and arranged with this special aim in view as well as with the goal of introducing students and scholars of a certain scientific discipline to notions, theories, and developments in another with which they are not familiar. The contributors took extra care in writing entries that can successfully accommodate both of these aims.

As was noted above, the overall goal of such a project was to bring together in a fruitful way philosophers and social scientists, even as coauthors of this vast project, and open up, to each, pathways of communication by introducing them to the main elements constituting each other's area. In addition, thanks to the wide coverage of topics and the special selection of entries and their interconnecting lines of cross-reference accomplished in this encyclopedia, undergraduate and graduate university students as well as instructors will have the opportunity to find a wide range of information collected in a single book, rather than seeking it in many different reference works scattered in different places. Students will also be guided by reading the entries on how to enhance their understanding of specific topics, while advanced scholars will be offered the opportunity to trace further interconnections.

Organization of the Encyclopedia and How to Use It

The encyclopedia runs into well over 700,000 words and contains 402 alphabetically arranged entries that range from relatively short ones of c. 1,000 words to mid-sized ones of c. 2,000 words to longer ones of over 3,000 words, and sometimes up to 5,000 words. The latter are meant to be short essays introducing a key concept or major development that requires a substantive analysis extending beyond a brief introduction. Other topics are covered aggregately by more than one entry; in these cases, we have chosen a cluster of shorter entries, each contributing an aspect of the larger topic, while also making sure to provide in addition a longer entry that offers a commanding view of the whole terrain in question. This has been the case mostly with the central and currently burgeoning area of social ontology and collective intentionality, as well as with some of the all-time classics, as it were, of the philosophy of the social sciences, such as the holism/individualism debate or the controversy over the reduction of the social sciences to the natural sciences. In these cases, the topic is discussed directly in entries bearing that title but also in other entries that deal obliquely with the same topic or with that issue (e.g., holism) where and when it had made a central appearance in a particular social science (e.g., psychology or economics). Another example of this approach is the topic of explanation versus understanding or reasons versus causes in action explanation that dovetails with the other two just mentioned, holism/individualism, and reductionism, or with naturalism, dealt in a number of entries.

In all such cases, special care was taken to contrast the issues relevant to the philosophy of the social sciences with the same concerns that had appeared prior to that in the philosophy of the natural sciences or had matured in the latter before they were bequeathed to the social sciences, as is the case with recent attempts of applying Bayesian epistemology, formal-epistemological models, game-theoretic approaches, or computer simulations to the philosophical study of how social explanation does or ought to work. At the same time, we devoted a considerable number of entries to topics in philosophy (e.g., Mind–Body Relation, or Truth) or to the history of philosophy (e.g., Empiricism, Idealism, etc.) and to the philosophy of the social sciences that can be used as background knowledge for readers and also as pointers for further interconnections.

Cross-References

This encyclopedia emphasizes the interconnectedness of learning and of knowledge in general; therefore, special care was taken to identify cross-references and further readings with an eye to such interconnectedness. This resembles a quasi-coherentist principle of encyclopedic knowledge, leading the reader from one headword to another (not to be confused with the distinction Harman attacked, as mentioned previously), or what can be called the "Hobbesian principle": coming across the demonstration of the Pythagorean theorem by chance, when glancing over a page in a copy of Euclid's Elements open before him, Thomas Hobbes was so astonished by the theorem that he determined to convince himself of its truth by tracing the interconnecting steps leading from one proposition or partial proof to another.

We strongly recommend that readers seek out the suggested cross-references listed in the "See also" section at the end of each entry. These cross-references have for the first time a double goal: to point to associated topics, further links, and related issues of kindred nature, or also to a concept or topic from the "other side" as it were—that is, either from philosophy or from the social sciences (e.g., Death, Space, Complexity, Time), on the one hand, or even to a totally contrasting notion, on the other hand (i.e., on certain occasions we include under "See also" an entry that contains a contrasting topic so that the reader is led to consult that as well). The latter device is of importance for it serves the overall purpose of this work, namely to pinpoint not only interconnections but also differences between philosophy and the social sciences.

The Reader's Guide

To guide the reader to clusters of interwoven items and kindred areas, all the entries have been listed thematically in the Reader's Guide, which

follows the List of Entries in the front matter. Each entry has been listed in at least one of the following seventeen subject categories:

- Philosophy, General
- Philosophy of Social Science
- Philosophy of Science
- Social Ontology and Collective Intentionality
- Philosophy and Anthropology
- Philosophy and Economics
- Philosophy and History
- Philosophy and Politics
- Philosophy and Psychology
- Philosophy and Sociology
- Philosophy of Action
- Cognitive Sciences, Neurosciences, and Social Explanation
- Biology and Social Science
- Evolution and Social Science
- Feminism and Social Science
- Logic and Social Science
- Sociology of Science

This listing is itself a significant contribution to the dynamically developing philosophy of the social sciences, since the taxonomies presented here (e.g., Biology and Social Science or Evolution and Social Science or Logic and Social Science) can themselves be contestable disciplinary divisions that play a significant role. As we said, quite a few of the entries are classified under more than one of the above themes, given that the essential feature of this reference work is the interconnections between concepts and issues appearing both in philosophy and in the social sciences.

Further Readings

Finally, each entry ends with a helpful list of Further Readings that are designed to include representative work by thinkers mentioned, or items referred to, in the body of the entry. These listings will enable readers to locate the principal texts in question and to find additional sources through which they can pursue further their study of the specific topic.

Acknowledgments

I would like to thank all the authors for their high-quality contributions; the members of the Editorial Board—Ann Cudd, Margaret Gilbert, Ian Jarvie, Tony Lawson, Philip Pettit, John Searle, Raimo Tuomela, and Stephen Turner—for embracing the idea right from its inception, as well as for their support; and all the people at SAGE who made it possible for this project to materialize: in particular, the development editors, Diana Axelsen and Sanford Robinson, for the substantive and knowledgeable help they provided throughout but also for their encouragement and patience; the SAGE reference tracking system coordinators, Anna Villasenor and Laura Notton, for their flawless work and graceful assistance at all times; the production editor, David Felts, and the copyeditors and proofreaders who went over the whole manuscript with meticulous care and professional expertise; the senior marketing manager, Carmel Schrire, for her efforts in promoting the final product; and, of course, Jim Brace-Thompson, the senior acquisitions editor, who believed in this project from the outset. Special thanks go to my friend and colleague Leslie Marsh for his valuable input at the start.

Byron Kaldis

A Priori and A Posteriori

According to a distinction codified by Immanuel Kant and broadly agreed upon in contemporary epistemology, epistemically justified beliefs are divided into two kinds. Those that are *a posteriori* justified are justified by experience, most importantly by empirical observation using the five external senses. For example, your belief that there is now English text in front of you is a posteriori justified since it is based on your current visual experience. *A priori* justified beliefs are nonexperientially justified; they are justified by powers such as intuition and rational insight. Your belief that $7 + 5 = 12$, for example, is a priori justified if it is based on your mental grasp of this sum or a mental calculation. Understanding this important distinction helps one identify the respective roles that empirical evidence and armchair thinking play in justifying beliefs, including beliefs in the social sciences. This entry further clarifies this distinction and then reviews the main kinds of a posteriori and a priori justified beliefs. Along the way, some examples of a priori and a posteriori justified beliefs in the social sciences will be highlighted.

A posteriori justification and a priori justification are species of epistemic justification. A belief is epistemically justified if it is well aimed at the truth. Beliefs may target practical or moral goals; epistemic justification, though, is solely concerned with whether a belief is well aimed at the truth. Being well aimed at the truth is significantly different from being true. For example, a wild guess that happens to be correct is not well aimed at the truth, so it is true but not justified. Conversely, an 18th-century scientist's belief in Newtonian mechanics was justified despite being false. Since the general nature of epistemic justification allows for justified false beliefs, some such beliefs are a priori justified. Someone, for example, who performs a mental calculation that leads her to believe that $67 \times 67 = 4{,}549$ might have an a priori justified belief (since it was arrived at using a method available from the armchair), even though that belief is false.

It is important to see how the a priori/a posteriori distinction differs from the innate/acquired distinction. Kant highlighted this key difference. While a person might need to undergo some specific experiences in order to furnish his mind with the concepts he needs to form some belief, the justification for that belief might nonetheless be a priori. For example, suppose (as is plausible) that humans are not innately endowed with concepts of numbers or concepts of arithmetic operations; instead, they acquire these concepts from their environment. In this case, a person's belief that $67 \times 67 = 4549$ depends on experience to enable him to have thoughts about multiplication, equality, 67, and 4549. However, if his evidence for this belief consists in a mental calculation that he performs, that belief is a priori justified.

Let's turn next to classification. Justified beliefs based on observation using our five external senses are obviously a posteriori justified. Though these beliefs are clearly central to the social sciences, they probably do not exhaust the justified beliefs of social scientists. Other justified beliefs originate from sources that have been traditionally classified as a posteriori: testimony, introspection, memory, and

the internal senses that report our bodily states. Of these, testimony probably plays the most important role in the social sciences—for example, in social anthropology, criminology, and economics.

Most figures in the history of epistemology and contemporary epistemology endorse some a priori justified beliefs. They often argue from cases, pointing to justified beliefs in the areas of mathematics, logic, and ethics; justified beliefs in analytic and definitional truths (e.g., all bachelors are male); and justified beliefs that arise from reflecting on thought experiments. Justified beliefs of each of these types show up in the social sciences. Some social sciences, like economics, make heavy use of mathematics. Deductive and inductive rules of inference from logic are used throughout the social sciences whenever a conclusion is inferred from evidence. Whether ethical claims have a legitimate place in social-scientific inquiry is a vexed issue; but if they do, this is another place for a priori justified beliefs. Beliefs in analytic and definitional truths are at work when social scientists employ their specialized terminologies. And if there are social-scientific thought experiments that yield justified beliefs (e.g., in economics), then this too might be a place for a priori justified beliefs.

Radical empiricists like John Stuart Mill argue that there are no a priori justified beliefs. They claim instead that only a posteriori sources can justify beliefs. They have two options for responding to any alleged a priori justified belief: Either argue that it is not justified at all or argue that it is a posteriori justified. Those who oppose these empiricists and claim that there are a priori justified beliefs often offer two kinds of arguments. One invokes the nonempirical practices of mathematicians, logicians, and ethicists, pointing out, for example, that university mathematics departments do not have labs. The other appeal is to beliefs that some claim are necessarily (as opposed to contingently) true. Proponents of a priori justified beliefs, like Kant, maintain that the justification for these beliefs cannot be construed as a posteriori, since empirical observation only tells us how things happen to be, not how they must be. These beliefs are therefore justified a priori.

Abduction and Inference to the Best Explanation

Abduction, or—as it is more commonly called nowadays—inference to the best explanation, is one of three major types of inference, the other two being deduction and induction. The distinction between deduction, on the one hand, and induction and abduction, on the other, corresponds to the distinction between necessary and nonnecessary inferences. In deductive inferences, what is inferred is necessarily true if the premises from which it is inferred are true. This is not so for the other two types of inference. Broadly speaking, in inductive inferences a conclusion is reached on the basis of statistical information. This type of inference is at work when a doctor concludes that a patient has a certain ailment given the patient's symptoms and given that almost all people who have those symptoms have the ailment. What singles abduction out among the nonnecessary inferences is that in abductive inferences a conclusion is reached on the basis of explanatory considerations, as when we conclude that a friend has missed the train since that best explains why she is late.

The term *abduction* was coined by the American pragmatist philosopher Charles Sanders Peirce in the context of his work on the logic of science. For him, the term did not quite mean what we mean by it nowadays. The main difference between his conception and the modern one is that for Peirce, abduction had its proper place in the so-called context of discovery, the stage of inquiry in which we try to generate hypotheses, which may later be assessed. In particular, he saw abduction as a guided process of forming hypotheses, where explanatory considerations serve as the main guide. Deduction

and induction, then, come into play in the so-called context of justification, in which we are concerned with the assessment of those hypotheses: Deduction helps derive testable consequences from them, and induction finally helps us reach a verdict on them.

By contrast, in the modern conception of abduction, this type of inference belongs in the context of justification as well. The idea is that we may be warranted to accept a hypothesis on the basis of its explanatory power, as the standard textbook formulation of abduction brings out:

> ABD Given evidence E and candidate explanations $H_1, \ldots, H_n$ of E, accept the H_i that best explains E.

For example, given the evidence that our friend is late, and given a number of possible explanations for why she is late, we conclude that she missed the train, because that best explains her being late.

Not only is abduction common in everyday life, philosophers of science have argued that it is a cornerstone of scientific methodology. Often, scientists are confronted by the fact that a number of rival hypotheses that they are considering are all consistent with the available data. The idea is that where the data alone are insufficient to warrant a choice between such hypotheses, an appeal to explanatory power may break the deadlock. Of two or more hypotheses that are consistent with the data, one may still stand out as best explaining those data, given that consistency with the data is necessary but not sufficient for explaining those data.

While it is generally agreed that, as a psychological matter of fact, abduction finds frequent employment in both our everyday and our scientific reasoning, the status of abduction is controversial. A major worry is that the best explanation will always only be the best of the candidate explanations that we have been able to conceive. Given that we generally will not be able to think of all possible explanations for the evidence at hand, and do not have the guarantee that we will at least be able to think of the correct explanation, the explanation we pick as being the best may well be the best of a bad lot (as was famously argued by Bas van Fraassen).

It has been argued in response that this worry arises only due to the rather simplistic way in which ABD and kindred textbook presentations explicate the idea of abduction. Specifically, the worry arises due to the fact that ABD gives license to an absolute conclusion—that a given hypothesis is true—on the basis of a comparative premise, namely, that that particular hypothesis is the best explanation of the evidence relative to the other hypotheses available. To undo this asymmetry, we can either have the rule require an absolute premise—for instance, that the hypothesis whose truth is inferred not only be the best of the available potential explanations but also be good enough—or have it sanction, given a comparative premise, only a comparative conclusion: For instance, the best explanation is closer to the truth than any of the other available candidate explanations.

Even if sufficiently sophisticated versions of the rule of abduction escape objections like the one mentioned, there is still the question of whether application of the rule is rational. More exactly, the question has been raised whether following the rule has any tendency to increase the number of truths among our beliefs. There are several ways to argue that the rule does have this tendency. The best-known argument for the claim that abduction is truth conducive is an empirical argument developed by Richard Boyd.

The argument starts by underlining the theory dependency of scientific methodology, which comprises methods for designing experiments, assessing data, choosing between rival hypotheses, and so on. For instance, in considering possible confounding factors from which an experimental setup has to be shielded, scientists draw heavily on already accepted theories. The argument next calls attention to the apparent reliability of this methodology, which, after all, has yielded, and continues to yield, impressively accurate theories. In particular, by relying on this methodology, scientists have for some time now been able to find ever more instrumentally adequate theories. Boyd then argues that the reliability of scientific methodology is best explained by assuming that the theories on which it relies are at least approximately true. From this and from the fact that most of these theories were arrived at chiefly by abductive reasoning, he concludes that abduction must be a reliable rule of inference.

Action, Philosophical Theory of

The philosophical theory of action relates to issues as diverse as those of agency, autonomy, criminal liability, Decision Theory, human nature, practical reasoning, free will, mental acts, individual and collective responsibility, intention, motivation and explanation, rationality, speech acts, addiction, compulsion, and weakness of will. So while it is a distinct area of enquiry in its own right, many philosophical views on action have been expressed from within various fields, including philosophy of mind, ethics, metaphysics, legal and political philosophy, philosophy of history, philosophy of language, philosophy of science, behavioral science, and cognitive ethology. It is thus central to the philosophy of the social sciences.

Ontology, Individuation, and Agency

Action theory has also been central to modern philosophy of mind, ever since René Descartes's contemporaries first criticized the account of *mental causation* suggested by his substance dualism by asking when, where, and how the nonphysical mind caused bodily movement (i.e., the immaterial substance *mind* caused the material substance *body* to act, and vice versa, a thesis called psychophysical interaction). Descartes famously located the crucial psychophysical event in the pineal gland, but he may have done better to maintain that when A causes B it is ontologically promiscuous to postulate some third event of A's causing B, itself in need of a further cause, ad infinitum.

While some philosophers use the terms *action* and *behavior* interchangeably, others reserve the former for behavior that is intentional and/or voluntary (at least under some description). Actions are frequently identified by theorists as events and/or processes; however, there is much dispute over *which* events actions are to be identified with. Donald Davidson, for example, maintains that actions are identical to certain movements of our bodies. Yet, as Jennifer Hornsby has cautioned, we must not conflate the *act of moving* one's body with (mere) bodily movement (the term may be used in both a transitive and an intransitive sense). Hornsby further distinguishes between the thing one did and (the event of) one's doing it.

How one individuates action depends on one's understanding of what it is for an action to be *basic,* in particular whether the difference between basic and nonbasic action is a matter of *kind, degree,* or *description.* Arthur C. Danto introduced the term *basic action* with the aim of picking out the subset actions that have not been caused to happen (at least not by the agent doing anything else first). He gives the example of his moving his arm without doing anything to cause it to move. Yet on this account, *almost all* actions would count as basic. As Annette Baier has noted, the search for basic action is a hunt for the most manageable and/or minimal cases of action. Without an account of what it is for an action to be basic, we can have no firm conception of what agency consists in.

Alvin Goldman has criticized Danto for confusing *causation* with *causal generation,* to be further distinguished from conventional generation, simple generation, and augmentation generation. The problem of specifying what we mean by "basic" remains even after we have settled for a specific causal, teleological, or meditative relation. Baier accordingly divides actions into at least eight kinds of "basicness": causally basic, instrumentally basic, conventionally basic, ontologically basic, logically basic, genetically basic, ease basic, and isolation basic. To this we might add epistemically basic, and no doubt further categories may be imagined.

Whatever notion of basicness we stipulate, it is tempting to think of qualifying actions as token members of a *class.* So understood, basicness is an *absolute* property (such as that of being saturated) and not a relative one (as is tallness). Such a conception nonetheless allows for varying *degrees* of

approximation: My act of operating the pump may appear less basic than that of moving my arm but more so than that of replenishing the water supply (itself less basic than that of poisoning the inhabitants). But how distinct are these four acts?

Irving Thalberg has labeled as *reductive unifiers* those who side with Elizabeth Anscombe in claiming that we here have one action with several different descriptions. This is because they maintain that being basic is a matter of *description,* not kind. The most influential of these claimants, Davidson, maintains that *all* actions are events that are basic under-some-description (one among many descriptions under which they will also be intentional). By contrast, *pluralists* or *multipliers,* such as Goldman and Judith Jarvis Thomson, claim that each of the above descriptions picks out a different action, only one of which can be the most basic. Thalberg's own position, *nonreductive unification,* rejects the choice between identity and independence in favor of a part–whole relation, according to which the event of my replenishing the water supply, for instance, *includes*—but is not identical to—the event of my operating the pump. But whether the two events are numerically distinct is a moot point, and we may prefer to follow Hornsby's talk of *identifiers* and *differentiators.* Moreover, we should be wary of equating the individuation of events with that of things we *do,* for there may be one event of my doing several distinct things. Still, we can at least sometimes offer multiple descriptions of one and the same action: Oedipus does not kill Laius *and* his father, though it is true that he *strikes* Laius and that he kills his father.

Suppose that Bob Marley shot the sheriff at time *t*1 but the sheriff only died at a later time, *t*3, before which—at time *t*2—Marley records his famous song. Did Marley kill the sheriff before or after recording his song? (He certainly didn't do it during the recording.) It would be as implausible to claim (with Goldman and Thomson) that Marley did not kill the sheriff until *t*3—after he had left the scene of the crime and was back in the recording studio—as it would be to follow Davidson and Hornsby in maintaining that he killed the sheriff at *t*1, before the sheriff died.

Jonathan Bennett has objected that the implausibility of the latter claim is not metaphysical but linguistic. We do not *call* a woman a mother before she has any children, yet we may, after the birth or adoption of her first child, legitimately speak of what the child's *mother* did before she had any children. Similarly (or so the argument goes), while we cannot at *t*1 (when the sheriff was still alive) truthfully say that Marley has killed the sheriff, at *t*3 (when the sheriff is dead) it becomes perfectly acceptable to talk of the *killing* having occurred at *t*1. Yet if it proves anything, the analogy seems to prove the opposite, for we do not imply that the woman was a mother *before* the advent of the child, and we likewise cannot plausibly state at *t*3 that Marley had killed the sheriff at *t*1, even though it is correct to say that the person who shot him then was indeed (to be) the sheriff's *killer.* A variant of this view claims that events acquire properties over time, much as physical objects, like people, acquire properties over time: Just as a deceased man may, at the time of my birth, acquire the property of being my great grandfather, so Marley's act of shooting acquires the property of being a killing once the sheriff dies. But while we know what it is for the event of Alekos Sandis's birth to acquire later the property of being the event of his great grandfather's birth (through what Peter Geach has called a "Cambridge change," that is, by virtue merely of my subsequent birth, without any change effected on him), it is less clear how a shooting can become a killing without *itself* changing. This is because killings are *causings* of death, whereas shootings are at most a *cause.*

We may call both causings and causes "events"; it would be absurd to think of the causing of an event as something that could itself be brought about (though it may be that *in* raising my arm I make it the case that the event of my raising my arm occurs). Causings may always be spatio-temporally in varying degrees of fine-graininess. To always insist on the same precision of location with regard to them leads to the absurdity of insisting that all actions must have a smaller spatial location than, say, that of an average-sized dining table. If Marley shot the sheriff in March 1973 (before recording his song about it in April 1973) and the sheriff (unlike the deputy) does not die until November 1973 (after the hit record was released), then Marley killed the sheriff in (no particular month of) 1973. The impossibility of locating any given event more precisely than in a certain minute, hour, day, week, month, season, year, decade, or century does not imply continuous duration throughout that period (think of cricket matches).

Volition and the Will

Most rationalists and empiricists believed in the existence of conative *mental acts* of "the will" ("conative"—from *conatio,* a tendency or desire to

attempt to do something—is standardly contrasted to "cognitive" and is used to refer to the volitional part or desiring aspect—i.e., "wanting to"—of a mental act or process). Volitionism comes in numerous forms, stemming from different understandings of the relation between volition and "bodily movement."

One popular form may be labeled "volition *as* action." According to this Cartesian view, all actions are mental "acts of will" that cause our bodies to move. Thus, for example, H. A. Prichard maintains that acting is a successful form of willing: When I move my hand, the movement of my hand, although an effect of my action, is not itself an action or even part of one. A recent variant of this position defended in Hornsby's early work is the view that all actions are *tryings*. One way of reaching this conclusion is by means of the argument from failure: Since it is always possible to fail to do what we set out to, the most *basic* thing we ever do is attempt or *try* to act. Everything else we do is a *consequence* of such basic acts. Such views can have important consequences in ethics. Prichard concluded that while we are morally obligated to *try (*our best) to execute our obligations, we cannot be obligated to succeed.

A second form of volitionism claims not that actions are volitions but that an action is a (mere) bodily movement *caused* by a volition. On this view (espoused by empiricists such as John Locke and David Hume), actions are *voluntary movements,* defined further as movements caused by a volition: We will to do something, and the act (viz., the bodily movement) follows (note the aforementioned ambiguity of the term *bodily movement*).

A third form of volitionism claims that action is *sometimes* a volition and *sometimes* a bodily movement caused by a volition. Proponents of this view (including Thomas Hobbes, Thomas Reid, and Jeremy Bentham) hold that we must therefore distinguish between two *kinds* of action, *internal* and *external,* the former being "acts of mind," such as that of intending, and the latter corporal "acts of the body," such as that of moving one's fist. A fourth identifies action not with one thing but a series of two: a mental event followed by its physical effect. A related account identifies action with the process or event of a volition's *causing* a bodily movement.

Volitionism suffered a serious blow at the hands of Ludwig Wittgenstein, who, questioning what sort of thing a "willing" was meant to be (is it something we can do intentionally? voluntarily?), argued that whether or not an action counts as either voluntary or intentional does not depend upon the causality of some "inner" event of volition or intention but on the wider context in which the action was performed (e.g., was it coerced or performed under duress?). These suggestions were subsequently elaborated upon and developed in various directions by his students. The suggestion that action is the *expression* (as opposed to effect) of one's beliefs and desires brought Wittgensteinians in an unexpected allegiance with Hegelians and Collingwoodians (i.e., British idealists like R. G. Collingwood), which continues to this day (e.g., in the Pittsburgh school).

In opposition to this behavioristic zeitgeist, Peter Geach has argued that while we often distinguish between *thinking* and *acting,* many cases of thinking, calculating, and judging are episodic cognitive mental acts, which we often perform intentionally, and for reasons, and which have duration and phenomenology. In a similar vein, J. L. Austin reminds us that utterances can also be understood as *speech acts* of describing. Some *illocutionary* speech acts are *performative utterances*—that is, performances of the very actions they describe, for we do numerous things "with words," for example, make promises, get married, name ships, deny accusations, and give orders. We also perform *perlocutionary* speech acts of convincing, scaring, emphasizing, persuading, annoying, and so on.

Reasons, Motivation, and Explanation

Intentional action frequently overlaps with action performed for reasons, though both a priori and experimental philosophy have recently challenged the assumption that (a) intentional actions are always performed for reasons and (b) actions performed for reasons are always intentional.

In arguing that the primary reason for an intentional action is its cause, Davidson attacked the received Wittgensteinian view, replacing it with an influential version of the Humean theory of motivation (though whether David Hume himself held this view is another matter). Humeanism became the orthodoxy in analytic philosophy for the second half of the 20th century. In recent years, however, it has recently faced a new wave of resistance from defenders of agent causation of one form or another, as well as from those who maintain that it is a mistake to view the reasons for which we act as psychological states.

These and other debates are frequently couched in terms of "motivating reasons." This has misled philosophers to write as if questions about what *motivates* us to act are identical to questions about the *reasons* for which we act. But although we can be motivated by greed, greed need not be a consideration we act upon, and as detective fiction reveals, one may have a motive to do something without being in the least inclined to act upon it.

Additional questions, such as whether facts can be said to cause anything and how we should understand the distinction between causal relations and causal explanations, between triggering and structuring causes, and between explaining something and (merely) rendering it intelligible, bring action theory closer to the philosophy of science. It is worth noting here that similar debates about the explanation of action took place in the 1960s and 1970s within the philosophy of history and social science more generally.

Responsibility and Freedom

Action theory gives rise to ethical questions concerning agency, free will, and responsibility, including the controversial *doctrine of double effect* and the *acts/omissions* distinction, both of which continue to divide consequentialists from their critics. Similar questions regarding the grounds of liability arise in criminal law.

It is a common belief that all natural phenomena are causally determined. This thought threatens our common-sense conception of ourselves as free and responsible agents. Its neuroscientific incarnation has received strong resistance from a truly diverse group of critics.

Philosophers respond to the threat of determinism in various ways, the most popular of which are "soft" compatibilist determinism, "hard" incompatibilist determinism, incompatibilist libertarianism, and agnosticism. Some theorists also find confused consolation in the thought that the randomness of indeterminism somehow leaves space for free agency. The fact that nobody adopts compatibilist nondeterminism is arguably a telling sign of the motivations behind some of the aforementioned positions.

If by "free will" we mean "free to act as one chooses or desires," there is no question that many people often act freely. But an equally legitimate and considerably more demanding understanding of free will requires its bearer to be a *source* of choice and action in a sense that would not allow for agent causation to be reducible to event causation. The possibility of such freedom is challenged by *causa sui* arguments that aim to show that such a phenomenon is epiphenomenal since it requires us to be self-causes, and not even divine beings can be such things. Such Nietzschean pronouncements may be tempered with the Sartrean thought that since not even God could act in a vacuum, the factors that make up our "facticity" are in fact *enablers* of free action.

A third notion of free will is that of having the power to do otherwise at any given moment. Harry Frankfurt has argued that such a power is not required for moral responsibility, since the latter is a function of the *reasons* we act upon. Attempts to render psychological determinism compatible with responsibility, so conceived, include appeals to whole-heartedness and second-order desires, self-reflection and satisfied plans/intentions, the semblance of responsiveness to reason, the capacity for critical evaluation, self-awareness and the desire to act in accordance with reasons, and guidance control. These models all share a commitment to an identification principle that states that we are only responsible for those beliefs and feelings that we consciously identify with, regardless of their origin, but they are divided on the issue of whether this identification is a matter of desire or normative judgment. On this issue depends the understanding of further phenomena, such as those of weakness of will and of acting against one's better judgment. The overall lesson to draw here is that agency and free will come in shades and degrees that we do not all share equally.

Actor-Network Theory

Actor-network theory (ANT) is the name given to collective Franco-British efforts at renewing social theory tout court, including its epistemology and its metaphysics. Initiated in the early 1980s by Bruno Latour and Michel Callon at the École des Mines in Paris, ANT was later extended into the United Kingdom via the efforts of John Law (and others). The theory was born through close encounters with the techno-sciences, as part of an interdisciplinary field of science and technology studies. This accounts in part for its most distinctive tenet, namely, the central role afforded material objects in the constitution of social life. ANT has since become a full social theory, promising to undo all of the latter's Great Divides: agency/structure, micro/macro, subject/object, culture/nature. As social theory, ANT seeks to reassemble the social.

In terms of theory formation, ANT is more a family resemblance of shared philosophical and methodological sensibilities than a tightly knit conceptual framework. Since its inception, the collective of ANTs has been sensitive to naming. Some, like John Law, prefer to speak of a *material semiotics* and others, like Annemarie Mol, of *ontological politics*. On his part, ANT preeminent Bruno Latour once quipped humorously that there are only four problems with ANT: the word *actor,* the word *network,* the word *theory*—and the hyphen! While agreeing that "actant–rhizome ontology" would be a more precise label, however, Latour remains ready to defend his creation, given appropriate conceptual care.

To start from one end, the actor of ANT bears little resemblance to those flesh-and-blood humans of which social theory is full. Rather, the ANT actor is always an *actant,* a semiotic entity to which action capacities are ascribed or delegated during the course of collective affairs. While I may (or indeed may not) be an actor, so may the French state, a stone, IBM, Popeye, whales, or any other *figuration,* at once semiotic and material, that interferes with the distributed action of situations and events. Moreover, all this depends on the *relations* established among entities. According to ANT, any actant attains its identity from the relations it enters into and within which it is set; this is true, as well, for human intentionality and subjectivity.

This brings us to the network. With ANT, network is neither a social network of friendship, family, or professional ties nor a technological network like the Internet or London Underground. Instead, "network" designates *any* association or assemblage of heterogeneous human and nonhuman elements. For Louis Pasteur to become the scientific icon that he is today, he needed first to enroll the microscope,

the anthrax bacillus, the vaccine, and the pest-ridden late-19th-century French agriculture into his laboratory network. In the process, the Pasteur network grew in length and size; he started macrostructuring the whole of France. Like the *rhizomes* of the French philosopher Gilles Deleuze, ANT networks are dynamic and changing, and they crisscross scales from local to global.

On to the hyphen. As Latour himself acknowledges, the hyphenated actor-network is easily mistaken as yet another take on the agency/structure debate, running deep in social theory from Émile Durkheim to Pierre Bourdieu. Just as actants are not agents, however, networks are not structures. Actor and network designate two sides of the same coin: When Pasteur acts as the *spokesperson* of his laboratory, he is himself a *black-boxed* network, the sum total of his many relations. ANT bypasses the agency/structure and micro/macro distinctions all at once. A macrostructuring actor like Pasteur is a micro-actor sitting on top of numerous more or less stable techno-scientific black boxes (microscopes, vaccines, bacilli). In ANT, power means the power of association.

Why is this not straightforwardly a theory? For ANT, the goal of social theory is not to *explain* the social by invoking structures, fields, or systems; instead, the goal is to *describe* how the social is gradually composed and reassembled. Society explains nothing; it must itself be explained. Such is the revenge, Latour asserts, of Gabriel Tarde over Émile Durkheim a hundred years on. To see how the social is reassembled, one must *follow the actors,* not impose on them a preset metatheory. Like the ethnomethodology of Harold Garfinkel, ANT seeks to learn from the ethnomethods of social actors. Rather than a theory, it is a method for deploying and mapping the world-building capacities of actors. With ANT, actors contain their own variable ontology, even their own metaphysics; this is why Latour describes his aim and style as *empirical philosophy.*

On this note, Latour plays a philosophical double game. While his ANT invites actors to define the social ontology for him, he clearly has no hesitation in engaging in serious philosophizing himself. Most famously, Latour (1993) takes his studies in the anthropology and sociology of science as evidence that we, the West, have never been modern. Modernity, to Latour, consists in the ontological dictum of keeping nature separate from culture, facts from values, science from politics. The many *hybrids* generated in techno-scientific laboratories, however, have never respected such boundaries; in a world of ecological crises—of ozone holes, nuclear radiation, and climate change—such nature–culture infiltrations are increasingly obvious. In the end, ANT is the social theory needed to trace the many hybrids of our *non-modern* (not post-modern) world.

In terms of its ability to form a heterogeneous academic network, ANT represents a social science success story. Concepts from ANT have been taken up widely across a range of disciplines, and its methods have been brought to bear on an expanding range of topics. Well beyond the world of science and technology, there are now actor-network–inspired takes on everything from art making to lawmaking, from organization studies to religious studies.

In this process of translation, ANT encounters a range of obstacles, as social theorists and philosophers object to its post-humanism, its relativism, or its lack of critical distance. Latour, however, rejects these terms of debate: ANT is *nonhumanist,* not post-humanist; it is *relationalist,* not relativist; and it seeks *critical proximity,* not critical distance. Ultimately, ANT thus demands nothing less than a new social-philosophical vocabulary, as it embarks on the adventure of non-modernity.

Affective Intelligence in the Social Sciences

Affective intelligence refers to a set of skills and abilities that allows individuals to recognize, manage, respond to, and communicate *emotions* effectively. There has been growing popular recognition of the pivotal role of affect in social life, matched by extensive interest in affectivity in the social sciences, including economics, sociology, political science, and education. Psychological research aimed at measuring and defining this construct is a relatively recent development.

This entry introduces the novel field of affective intelligence, explains the notion, points to its historical precursors, and shows the importance of affect and emotions in affective intelligence, social cognition, and social-scientific inquiry in general.

Within Western philosophy, philosophers such as Aristotle, Socrates, Plato, St. Augustine, the Stoics, René Descartes, Blaise Pascal, Baruch Spinoza, Adam Smith, and Immanuel Kant have all sought to understand the role of affect in general and emotions in particular in thinking and behavior. Plato, for example, thought that affect constitutes a more primitive, animal aspect of human nature that is incompatible with reason and that the latter should direct or subjugate the former. The idea that affect subverts rational thinking was perpetuated in the speculative ideas of Sigmund Freud and others. Some writers, such as Arthur Koestler, even thought that humans' inability to know and control their emotions suggests a fatal "flaw" in the way their brains developed, an evolutionary mistake that may threaten the very survival of our species. Surprisingly, most of what we know about the role of affect in social cognition and behavior has only been discovered recently. Although feeling and thinking were often assumed to be separate faculties by early philosophers and psychologists, recent research suggests a fundamental interdependence between affect, cognition, and behavior.

In the past few decades, neuroscientists and psychologists produced incontrovertible evidence that affect is not only not dangerous but does in fact provide essential and adaptive information necessary for dealing with the manifold challenges of social life. For most of the history of the social sciences, *intelligence* and *affect* were considered as completely unrelated areas. The development of empirical tests of intelligence brought rapid progress in that field, but research on affect remained neglected during the dominance of behaviorist and cognitivist paradigms in psychology. Charles Darwin's view of emotions as biologically determined and serving an adaptive purpose was not really taken seriously until the 1970s by evolutionary sociologists and psychologists. By the 1980s, many researchers on human cognition came to embrace the notion that affect is a necessary and integral part of all thinking, and there was a rapid explosion in research exploring the interaction between affect and cognition. Cognitive scientists showed growing interest in incorporating affective reactions into their artificial intelligence models, and there was also renewed interest in studying the evolutionary, adaptive functions of emotions.

In a sense, the concept of affective intelligence emerged before there was a proper empirical approach to define and measure the construct. It was not until the 1990s that psychologists such as Peter Salovey and Jack Mayer proposed a theory and *measurement* of affective intelligence, integrating work from neuroscience, psychology, philosophy, and clinical psychology. Popular writers such as Daniel Goleman soon claimed that affective intelligence is one of the most important predictors of personal and professional success in life, although its nature and characteristics remained fuzzy and poorly defined. Despite impressive research efforts to measure and define affective intelligence, there remains a fundamental disconnection between the notion of affective intelligence as used in the popular media and the available scientific evidence supporting this concept. There have been a variety of conflicting definitions and empirical approaches, and there is still no reliable consensus on what the term means and how it should be measured.

For example, one might define and measure affective intelligence as a number of distinct

affective competencies assessable in an inventory, although it remains unclear if these competencies are related and necessarily occur together in the same person. Others define affective intelligence as encompassing all *noncognitive* abilities or skills that influence one's ability to succeed in coping with environmental demands and pressures. This approach resulted in the measurement of a variety of often unrelated personal characteristics, such as empathy, flexibility, happiness, impulse control, self-regard, and the like.

Alternatively, affective intelligence has been defined by Mayer and Salovey as a general, underlying ability to recognize the meanings of emotion and their relationships and to reason and problem solve on the basis of them. Affective intelligence is probably involved in the capacity to perceive emotions, assimilate emotion-related feelings, understand the information of those emotions, and manage them. Mayer and Salovey's test of affective intelligence measures four kinds of abilities: the ability to (1) perceive emotion, (2) use emotion to inform thinking, (3) understand emotional meanings, and (4) manage emotions in oneself and others.

It is still unclear if affective intelligence refers to a single, coherent, and definable individual characteristic or whether it is a term that encompasses a variety of already known individual abilities that simply have not been considered in conjunction before. There is some evidence that some affective intelligence scales do measure characteristics that are different from those measured by either existing intelligence scales or personality measures, or are not well captured by them. However, some of the other scales and definitions of affective intelligence appear highly correlated with existing personality characteristics and thus turn out to be redundant.

Another critical question concerns the usefulness of affective intelligence in predicting important future outcomes, as does, for example, intelligence. Daniel Goleman even suggested that affective intelligence may be more important than the intelligence quotient (IQ) in predicting everyday success. Unfortunately, the evidence has failed to support such claims. Some empirically minded psychologists came to despair of the concept and concluded that little remains of emotional intelligence that is unique and psychometrically sound.

Despite the fact that affective intelligence is undoubtedly a complex, multifaceted, and hard-to-measure construct, and is not particularly effective in predicting future outcomes, it nevertheless remains an important concept in the social sciences in general and psychology in particular. Understanding how affect functions in informing us about the demands we face in everyday situations remains a critically important question in economics, education, psychology, and philosophy. George Marcus and others have suggested that affective intelligence is also a key concept in understanding *political judgments* and behavior, such as voting and party identification. Furthermore, studying affective intelligence can be a useful avenue for improving self-knowledge and our understanding of others; it should help people recognize and act upon emotional signals; and it can contribute to improved awareness of the importance of emotions in organizational, clinical, educational, and interpersonal situations.

Agency

Agency is the property of being an agent. An agent is an entity that acts. This makes acting or action the primary notion in terms of which agency is defined.

Actions and Agents

There are more and less inclusive uses of the word *action* in ordinary English. In a very inclusive use, there are the actions of acids, waves, and winds. For example, acids dissolve things, waves push and drag things, and winds blow things around. Events of these kinds count as actions in a broad sense. Philosophers tend to have little interest in events that are actions only in this very broad sense. They are primarily interested in the sphere of intentional actions. In this connection, they are also interested in unintentional actions: Part of what is required for understanding what intentional actions are is understanding how they differ from unintentional actions.

Agents may be divided into kinds along two different dimensions. On the one hand, there are human agents, canine agents, feline agents, and so on. Here, the division is biological. (If chemical agents are included, the principle of division is broader.) On the other hand, there may be agents that are capable of exercising free will and agents that are not, agents that are capable of constructing and executing plans for the distant future and agents that are not, agents that are capable of acting intentionally and agents that are not, and so forth. Here, the division is based on agential capacities. An interesting question that has not received much philosophical attention is how agency of the second kind is related to agency of the first kind. For example, how far does the capacity for intentional action extend in the animal kingdom?

Intentional Action and Intentions

How the question just raised about intentional action in the animal kingdom is to be answered depends on what intentional action is. It is plausible that only agents that have intentions are capable of acting intentionally. So how far do intentions extend in the animal kingdom? That depends, of course, on what intentions are.

Intentions have been a topic of considerable discussion not only in philosophy but also in neuroscience, various branches of psychology, and legal theory. It is fair to say that no single definition of the term is widely used. According to one view of intentions, their contents are plans and one of their functions is to contribute to the execution of these plans. The plans are representations of what is intended.

Intentions may be divided into different kinds. One main division is between proximal and distal intentions—intentions about what to do now and intentions about what to do later. Many human beings have distal intentions that aim years into the future. A student's intention to graduate four years from now is a case in point. How far into the future intentions of nonhuman animals can aim is a topic for investigation.

Intending to do something should be distinguished from merely wanting to do it. Ann wants to have dinner with Bob today at 6 p.m., as she always does after their Tuesday seminar; but she also wants to hear a lecture that begins at 6 p.m. She is undecided about what to do. She can settle matters by forming a relevant intention—for example, an intention to attend the lecture. That is what she does.

In Ann's case, competing desires generate uncertainty about what she should do, which she resolves by forming an intention to attend the lecture. At what point in their development do human children start resolving uncertainty generated by competing desires by forming intentions? Which kinds of animal do this? These are topics for investigation.

Human Agency

Understanding human agency is a partly conceptual and partly empirical enterprise. Important questions include, but are not limited to, the following. How are intentional human actions produced? Does anyone have free will? Are we ever morally responsible for what we do? Given persisting disagreement about the meaning of some of the crucial terms, it may be thought that we are in no position to conduct scientific investigations of some of these topics. But this is unduly pessimistic.

Take free will as an example. According to some ways of understanding it, an agent whose conscious intentions are never among the causes of corresponding actions lacks free will. When this is assumed about free will, scientific investigations of connections—or the absence thereof—between conscious intentions and the corresponding actions are relevant to free will. And there are such investigations. In his book *The Illusion of Conscious Will,* Daniel Wegner argues, on the basis of various data, that conscious intentions are never among the causes of corresponding actions. On the other side of the issue, studies of implementation intentions provide evidence that conscious intentions (or their neural correlates) sometimes are among the causes of

corresponding behavior. In the case of subjects who share a certain distal goal—for example, conducting a breast self-examination the following month or exercising vigorously for 20 consecutive minutes the next week—those who are instructed to decide now on a place and time to pursue that goal later have a much higher success rate than those who are not given this instruction. In the aggregate, the conscious implementation decisions or intentions seem to make a significant behavioral difference.

The production of intentional human actions is another good example of something that can be investigated scientifically, even though there is significant disagreement about the meaning of a key term—*intentional action,* in this case. There is an ancient philosophical theory, advanced in Plato's *Protagoras* and elsewhere, according to which it is not possible for human beings to willingly (or freely) act contrary to what they know is best. According to this theory, when people seem to be doing this, either they are acting unwillingly (think of a compulsive hand washer who washes his hands even though he is convinced that he should not be doing that again so soon) or they have come to believe that what they are doing is best. Hard evidence about how intentional human actions are produced may be expected to shed light on whether this theory should be accepted or rejected.

There is evidence that the motivational strength or action-causing power of our desires is influenced not only by our beliefs about what is good but also by factors such as the perceived proximity of prospects for desire satisfaction, the salience of the desired objects in perception or in imagination, and the way we attend to the desired objects. The evidence indicates that what we are most strongly motivated to do at a time may be out of line with what we judge it best to do then, even when we are free from compulsion. In such a case, if we act as we are most strongly motivated to act, we falsify the ancient theory.

Perhaps in some cases in which we are tempted to act contrary to what we deem best on the whole, we can go either way. A full-blown theory about how human actions are produced will tell us something about how actions are produced in these situations. Normal agents apparently can influence the strength of their desires in a wide variety of ways. For example, they can refuse to focus their attention on the attractive aspects of a tempting course of action and concentrate instead on what is to be accomplished by acting as they judge best. They can attempt to augment their motivation for performing the action judged best by promising themselves rewards for doing so. They can picture a desired item as something unattractive—for example, a wedge of chocolate pie as a wedge of chewing tobacco—or as something that simply is not arousing. Desires typically do not have immutable strengths, and the plasticity of motivational strength is presupposed by standard conceptions of self-control. Intentional self-intervention—action aimed at changing one's own motivational condition—is a topic for further philosophical and scientific investigation.

Self-Deception

Ordinary human agents seem to have a capacity for self-deception. Predictably, philosophers disagree about what "self-deception" means. But the competing accounts of its meaning have been set out with some precision, and we can look for hard evidence on whether or how self-deception happens, given the various accounts. One view about what self-deception means is inspired by Sigmund Freud: At the view's core is the idea that a person who is self-deceived regarding some proposition *p* subconsciously believes that *p* is false while consciously believing that *p* is true. We can look for hard evidence on whether this ever happens. According to an alternative view (one of several alternatives), self-deception is, very roughly, motivationally or emotionally biased false belief. Obviously, on this view, scientific work on the influence of motivation and emotion on belief is relevant to understanding how and why self-deception happens.

A related disagreement about what self-deception is (or means) features intentional action. In garden-variety cases of self-deception, do people *intentionally* deceive themselves? Proponents of agency views of self-deception answer yes; their opponents—anti-agency theorists—answer no. One can imagine relatively clear cases of intentionally deceiving oneself into believing that *p* is true. A student who made a fool of himself in class today but would like to believe that he performed well writes the following in his diary: "I was awesome in math class today!" He knows both that he has a bad memory and that his policy is to read his entries for a semester after that semester ends. A month later, he reads his diary entry for the day at issue and believes what he wrote,

having forgotten why he wrote it. But such cases seem remote from garden-variety self-deception.

Disputes About Meaning and Experimental Philosophy of Action

When philosophers disagree about the meanings of terms, they sometimes claim that their opponents have strayed unacceptably far from ordinary usage. Experimental philosophy of action is a relatively new development that aims to test such claims; to shed light on ordinary usage of terms such as *action, intentional action,* and *free will*; and to gather evidence about what influences people's judgments about things such as whether an agent did something intentionally or had free will when he did it. The method features presenting nonspecialists with vignettes and asking questions about the agents in them—for example, whether a character in a vignette intentionally hit a target or deserved to be blamed for some harm she caused. Much of experimental philosophy of action is done by interdisciplinary teams of researchers—especially philosophers and psychologists.

Group Agency

Agency is an enormous topic, even when it is limited to individual agents, as has thus far been the case here. But we talk as though agency extends to groups—for example, teams and corporations. In this sphere too, acting or action is the basic notion. Is a team an agent? If so, that is because a team is an entity that acts. How actions of groups, if there are any such actions, are related to actions of individuals is an intriguing question that lies beyond the scope of this entry.

Agent-Based Modeling and Simulation in the Social Sciences

This entry reviews agent-based modeling (ABM) with respect to three aspects: (1) its main features and relationship to other simulation techniques, (2) the distinctiveness of the ABM methodology in terms of its approach to the problems of agency and explanation, and (3) open questions for practitioners in the field. The entry ends with a list of useful resources available on the web.

The Field of ABM

ABM is a methodology for the study of social phenomena by exploring, through the use of computational models, the relations connecting microbehavior with macro patterns. This methodology is increasing in popularity for three reasons. The first is the increasing technical advances in computing capability since the last decades of the 20th century. The second is the flexibility of programming languages compared with mathematical and logical formalisms. The third is the growing interest in features such as complexity, emergence, self-organization, nonlinearity, and path dependence in the social sciences.

ABM is framed in a wider approach to social phenomena: computational social simulation. Computational simulation allows one to avoid both the vagueness and ambiguity of verbal description and the stringent assumptions of purely mathematical description. It works through the design of a model intended to mimic or replicate the desired

social phenomenon in a particular way. The model can then be subjected to experimentation by the manipulation of prespecified parameters.

Computational models to study social phenomena can be divided into three types: macro-simulation, micro-simulation, and agent-based simulation. In the first, models are used to explore system dynamics, a name often used to describe this type of simulation. Such models use sets of difference or differential equations to estimate the behavior of system variables over time. The *macro* prefix is used because this estimation is performed from a top-down perspective: The target system is simulated as a whole. Individuals are not taken into account in the model but only population-level attributes. These attributes are thought of as causally connected, and causal relations are represented in the model's equations. During the simulation, the equations calculate the values for each variable at every time step, according to the previous value of the variables with causal influence.

In micro-simulation, the estimation also depends on sets of equations, but the opposite approach, bottom-up, is employed. This means that estimation is based not on the values of system variables but on the attributes of the basic units (individuals, households, organizations, etc.). Micro-simulation works by applying transition rules that change these individual attributes as time passes. The individual results are then aggregated into a hypothetical sample that represents the overall population once the simulation is over.

Although different in their approach, micro- and macro-simulations are both simulation techniques in which models are fed with empirical data and in which the main concern is prediction. ABM is grounded in a different principle. As with micro-simulation, ABM uses a bottom-up approach. However, in ABM, the basic units have the possibility to interact. This important feature has channeled the discussion about ABM into two specific topics: (1) the characterization and role of the basic units—that is, the agents in the models—and (2) the way in which the tension between explanation and prediction in social science is approached with ABM.

Agency and Explanation

The notion of "agent" in ABM is less elaborated than is typical in philosophy. In the latter, agency is usually associated with intricate issues such as free will, determinism, and so on. In ABM, "agent" simply refers to a self-contained program—in other words, an independent portion of computer code with the ability to choose an action according to its perception of the surrounding environment. This "intelligent" behavior is possible because agents can perform symbolic manipulation according to some coded set of instructions. There are three ways to build agents that can do this: (1) direct programming, using the features of object-oriented programming languages to code agents and the environment; (2) production systems, in which agents are created as structures composed by a set of rules, a working memory, and a rule interpreter; or (3) neural networks, mimicking the operation of a nervous system, to simulate agents as the nodes of neural networks or as neural networks themselves.

Although there are some differences in the way they work, all three methods allow for the construction of an agent that can perceive the environment, record information about it, and generate behaviors (e.g., communication, movement, and action on the environment). This feature makes it possible to use ABM to analyze situations where there is no central coordination in populations of heterogeneous agents. In these models, social properties or patterns are studied as emerging from the interactions of individuals with each other and with the environment.

ABM tends to emphasize explanation above prediction. Positivistic philosophy gave a decisive role to prediction, which was commonly equated with explanation. Post-positivistic stances criticized this view and called for more comprehension-based explanations. ABM is a suitable methodology for comprehension for it allows for focusing on the "how," by representing entities directly in interactions and by simulating one process with another. There is an ontological correspondence between agents in the model and agents in real life. The same is true with the environment when it is spatially explicit—that is, with a direct representation of the objects surrounding the agents.

ABM is also oriented to the "why"—that is, etiological explanation—explaining how a phenomenon is brought about, that is, referring to its cause(s). The most common approach to explanation in ABM is the *generative* approach. According to this, to explain a phenomenon one has to "grow" it. This means recreating the initial conditions at the micro level and running the simulation in order to check if, through interaction, the desired macro property or pattern is obtained. This approach has found theoretical

support in the mechanist perspective in the social sciences, which is also focused on the analysis of entities and interactions through time. There are some issues still to be clarified in terms of compatibility, but this theoretical framework could make explanation through simulation more robust in the future.

Critical Questions

In addition to the adoption of the mechanist perspective, there are other issues that remain as open questions. ABM is usually considered as combining some of the features of qualitative and quantitative methodologies. Some argue that simulation could also be used as a tool for developing formal theory. Formal theory is usually seen as a way to avoid ambiguity and vagueness both in concepts and in causal links. In the social sciences, however, formalization is quite uncommon, except in some areas of economics. ABM could be used for formalization for four reasons. Compared with mathematical equations or systems, (1) programming languages are syntactically and semantically richer and (2) allow for the construction of independently separated segments of code that can be easily altered or removed, in order to change the behavior of the model. This flexibility also allows for (3) the design of heterogeneous agents that (4) can act in parallel in the environment, with no specific sequential order. This theoretically driven conception of ABM, despite its possible advantages, is rarely explored, not only because of the dominance of the methodologically driven view but also because of the lack of theoretical foundations for the current approach. As the value of simulation becomes better appreciated and more social scientists get involved with modeling, further advances could be achieved in this regard.

Although ABM was thought of initially as a tool for theoretical exploration with few predictive ambitions, some researchers in the field have argued in favor of more complex models, based heavily on real data to calibrate the simulation. This shift has an epistemological basis, for some believe that traditional models are too simple to yield useful information, but it is also being advocated for practical reasons, because ABM is now being used in areas where more complex models might be desirable, such as public policy. The debate has been labeled as KISS (Keep It Simple, Stupid) versus KIDS (Keep It Descriptive, Stupid). In the former camp, models with few parameters and agents with low cognitive capabilities still dominate. It is believed that the more complex the model, the harder it is to identify the mechanisms linking microbehaviors and macro patterns. In the latter camp, more realistic interaction rules and agent behavior are considered desirable. Some researchers, however, develop strategies that move between these two poles and link theory and empirical data in two different ways. In some cases, simple theoretical models are generated and then tested against empirical data; in others, empirically calibrated models are built, and then theoretical insights are derived from them.

This debate is linked to a third open discussion on ABM: verification and validation. The flexibility in the way computer models are built has led to an accumulation of models that, although dealing with the same topic, have parameter specifications that make them incommensurable. This is even more problematic in the cases where model results are significantly path sensitive. When the model is calibrated with real data and the model is intended to replicate observable social phenomena, verification and validation become easier, for the output can be compared with the empirical data. Empirical cross-validation, however, does not work in every case. ABM does not assume the linearity of the problem analyzed, which can be another source of incommensurability if results are compared with those produced by the more traditional analytical methods that rely on the general linear model.

There has been an increasing concern with internal and external methods of validation, including not only scientific but also social criteria for verification and validation. Model verification and validation is now seen more as a process in which interaction and feedback from different stakeholders can provide valuable insights in terms of consistency and accuracy, not simply as a close scientific matter that researchers can solve by themselves with a prescribed set of evaluations and procedures. Still, this remains an open topic for discussion inside the simulation community and has been a thorny issue in terms of the acknowledgment of ABM as a proper scientific tool for inquiry.

Resources

Several free online resources are available about social simulation. One option is to download and try

demonstration models using a simulation toolkit. The three most popular are Netlogo (http://ccl.northwestern.edu/netlogo), Repast (http://repast.sourceforge.net), and Mason (http://cs.gmu.edu/~eclab/projects/mason). They each include resources such as libraries, sample models, and documentation. Other websites, such as OpenABM (http://www.openabm.org), Agent-Based Computational Economics (http://www.econ.iastate.edu/tesfatsi/ace.htm), and Agents-Based Models: Methodology and Philosophy (http://www.agent-based-models.com/blog), contain useful information about software and about researchers and institutions working with ABM. There are two useful e-mailing lists that regularly feature information about events, publications, and jobs: SIMSOC (http://www.jiscmail.ac.uk/lists/simsoc.html) and Complexity Digest (http://www.comdig.org).

Agnotology, Ignorance, and Uncertainty

Agnotology is the study of ignorance (from the Greek word *agnoia* (ἄγνοια), meaning "ignorance"; *a* = "non" and *gnosis* = "knowledge"). The term is a neologism coined by Robert Proctor.

Ignorance, uncertainty, and related terms refer variously to the absence of knowledge, doubt, and false belief. This topic has a long history in Western philosophy, famously rooted in the Socratic tradition. It has a considerably shorter and, until recently, sporadic treatment in the human sciences. The focus of this entry is on relatively recent developments within and exchanges between both domains.

A key starting point regarding ignorance is that anyone attributing it cannot avoid making claims to know something about who is ignorant of what: A is ignorant from B's viewpoint if A fails to agree with or show awareness of ideas that B defines as actually or potentially valid. A and B can be identical, so that A self-attributes ignorance. Numerous scholars thereby have noted the distinction between conscious ignorance (known unknowns, learned ignorance) and meta-ignorance (unknown unknowns, ignorance squared).

The topic has been beset with terminological difficulties due to the scarcity and negative cast of terms for referring to unknowns. Several scholars have constructed typologies of unknowns, in attempts to make explicit their most important properties. Smithson's book, *Ignorance and Uncertainty: Emerging Paradigms,* pointed out the distinction between being ignorant of something and ignoring something, the latter being akin to treating something as irrelevant or taboo. Karin Knorr-Cetina coined the term *negative knowledge* to describe knowledge about the limits of the knowable. Various authors have tried to distinguish reducible from irreducible unknowns.

Two fundamental concerns have been at the forefront of philosophical and social-scientific approaches to unknowns. The first of these are judgment, learning, and decision making in the absence of complete information. Prescriptive frameworks advise how this ought to be done, and descriptive frameworks describe how humans (or other species) do so. A dominant prescriptive framework since the second half of the 20th century is subjective expected utility theory (SEU), whose central tenet is that decisional outcomes are to be evaluated by their expected utility; that is, the product of their probability and their utility (e.g., monetary value, although utility may be based on subjective appraisals). According to SEU, a rational decision maker chooses the option that maximizes her/his expected utility. Several descriptive theories in psychology and behavioral economics (e.g., Prospect Theory

and Rank-Dependent Expected Utility Theory) have amended SEU to render it more descriptively accurate while retaining some of its "rational" properties.

The second concern is the nature and genesis of unknowns. While many scholars have treated unknowns as arising from limits to human experience and cognitive capacity, increasing attention has been paid recently to the thesis that unknowns are socially constructed, many of them intentionally so. Smithson's 1989 book was among the earliest to take up the thesis that unknowns are socially constructed. Related work includes Robert Proctor's 1995 *Cancer Wars* and Ulrich Beck's 1992 *Risk Society.* Early in the 21st century, this thesis has become more mainstream. Indeed, a 2008 edited volume, bearing *agnotology* in its title, focuses on how culture, politics, and social dynamics shape what people do not know.

Philosophers and social scientists alike have debated whether there are different kinds of unknowns. This issue is important because if there is only one kind then only one prescriptive decisional framework is necessary and it also may be the case that humans have evolved one dominant way of making decisions with unknowns. On the other hand, different kinds of unknowns may require distinct methods for dealing with them.

In philosophy and mathematics, the dominant formal framework for dealing with unknowns has been one or other theory of probability. However, Max Black's groundbreaking 1937 paper proposed that vagueness and ambiguity are distinguishable from each other, from probability, and also from what he called "generality." The 1960s and 1970s saw a proliferation of mathematical and philosophical frameworks purporting to encompass nonprobabilistic unknowns, such as fuzzy set theory, rough sets, fuzzy logic, belief functions, and imprecise probabilities. Debates have continued to this day over whether any of these alternatives are necessary, whether all unknowns can be reduced to some form of probability, and whether there are rational accounts of how to deal with nonprobabilistic unknowns. The chief contenders currently include generalized probability frameworks (including imprecise probabilities, credal sets, and belief functions), robust Bayesian techniques, and hybrid fuzzy logic techniques.

In the social sciences during the early 1920s, John Maynard Keynes distinguished between evidentiary "strength" and "weight," while Frank H. Knight similarly separated "risk" (where probabilities are known precisely) from "uncertainty" (where probabilities are not known). Ellsberg's classic 1961 experiments demonstrated that people's choices can be influenced by how imprecisely probabilities are known (i.e., "ambiguity"), and his results have been replicated and extended by numerous studies. Smithson's 1989 book proposed a taxonomy of unknowns, and his 1999 experiments showed that choices also are influenced by uncertainty arising from conflict (i.e., disagreeing evidence from equally credible sources); those results also have been replicated.

More recent empirical research on how humans process unknowns has utilized brain imaging methods. Several studies have suggested that Knightian uncertainty (ambiguity) and risk differentially activate the ventral systems that evaluate potential rewards (the so-called reward center) and the prefrontal and parietal regions, with the latter two becoming more active under ambiguity. Other kinds of unknowns are yet to be widely studied in this fashion, but research on them is emerging. Nevertheless, the evidence thus far suggests that the human brain treats unknowns as if there are different kinds.

Finally, there are continuing debates on whether different kinds of unknowns should be incorporated in prescriptive decision-making frameworks and, if so, how a rational agent should deal with them. There are several decisional frameworks incorporating ambiguity or imprecision, some of which date back to the mid 20th century, and recently at least one incorporating conflict as well. The most common recommendation for decision making under ambiguity amounts to a type of worst-case analysis. For instance, given a lower and upper estimate of the probability of Event E, the usual advice is to use the lower probability for evaluating bets on E occurring but to use the upper probability for bets against E. However, the general issue of what constitutes rational behavior under nonprobabilistic uncertainties such as ambiguity, fuzziness, or conflict remains unresolved.

Alienation: From Philosophy to Sociology

Although occasionally disparaged as a vague term, the concept of alienation has been dealt with widely in philosophy and is still important in fields as disparate as law, medicine, religion, economics, sociology, political science, psychology, as well as literature. Historically, from *alienus,* meaning "other," Roman law used "alienation" to signal that the seller has relinquished all claims to some given property. Contemporary legal scholars examine alienation as a phenomenon of administrative law, a blot on relations between administrators and the public. From medieval to early-modern times, insanity was identified as alienation from reason, with psychiatrists—"alienists"—having the power to prescribe appropriate cures or sequestration of the irrational. Theologians have dealt with alienation as a self-defeating separation from the divine. In positivist economics, alienation is important as a measure of social distance between identifiable groups of agents. Political research examines alienation in relation to the political behaviors. In literature, individuals' alienation is explored as the affective formation of personality. In sociology and in social psychology, alienation has been used to describe the operations of social structures under capitalism, as well as modes of social engagement among peers, in families, in organizational life, and in politics. All these approaches in the social sciences and the humanities stem from views of alienation as a philosophical issue.

Philosophy

Alienation may be traced as a concept to the Hebrew and Christian Bible, and in Roman thought to Plotinus's doctrine of emanation; it is significant for understanding the split between idealism and materialism, between G. W. F. Hegel and Karl Marx, and for tracing developments in social and political philosophy.

G. W. F. Hegel

In Hegel's writings, as Spirit moved through history, two terms, *Entäusserung* ("externalization") and *Entfremdung* ("estrangement") referred to alienation. Alienation as *Entäusserung* has a neutral or even a positive connotation, as it is intrinsic to the externalization of thought. Interpreted as the self-objectification of Spirit, *Entäusserung* was the basis for the dialectical contradictions whose negations, new syntheses, and subsequent negations (of negations) moved Spirit through history toward its telos—often a "journey of despair." But when understood by philosophers who seek precision and clarity of the world, absolute knowledge provided a joyous or spiritual consciousness. With absolute knowledge, alienation is overcome, since knowledge now knows itself. As Plato and Aristotle said, a life devoted to knowledge for its own sake is the "happiest" life.

Hegel's analysis of "the alienated spirit" heralded several developments. As a critic of religion, Ludwig Feuerbach (1854/1989) saw "alienation produced when the self . . . makes its own essential nature another objectified being [God]" (that stood without and acted as an alien force. For Hegel's phenomenology, the transformation of nature through the labor of the slave provided the initial moment of self-awareness as differentiation from nature and, in turn, recognition of the master. Hegel's description of the master's appropriation of the labor of the slave, and the slave's subjection of self to the master, set the stage for Marx's critique of capitalism as the bourgeois appropriation of proletarian labor. *Entfremdung,* an outcome of increasing machine mediation between humans and nature, came to have a pejorative sense.

Karl Marx

Although Hegelian idealism was the dominant philosophy of the era, Marx's interest in materialism in early Greek philosophy, as well as in the contemplative materialism of Feuerbach, led to his rejection of idealism. Still, he remained indebted to the idealists' grasp of the active side of history. Embracing the Hegelian dialectic, with its critique of domination as embodied in the Master–Slave struggle for recognition, and the central role of alienation as objectification and estrangement, Marx developed a materialist epistemology and ontology informed by a view of human beings as destined to work and refashion nature. Observing the adverse effects of capitalist modernity, Marx inverted Hegel's idealism in favor of a materialist basis for the subject as well as ideas and moved alienation from its ontological status into a sociological moment as the basis for a critique of capital. In his theorization, the material conditions, the capitalist mode of production based on the sale of wage labor as a commodity and its resale as exchange value, constituted the person as a thing, thwarting the move from immanence to transcendence and the possibility of human fulfillment.

Marx's 1844 *Manuscripts* showed that the worker no longer controlled the labor process; she owned neither her materials nor her tools, or the products that she produced for the market. While Hegel's Slave could acquire self-consciousness through transforming nature, even though the process and the products were appropriated by the Master, under the capitalist system, this was impossible. Arguing that Master and Slave were to be understood as classes—those who owned capital, the bourgeoisie, and those who sold their labor power, respectively—Marx shows that workers were rendered powerless by the very economic system they made possible. With the externalization of the products of their own labor, the capitalist system then stood outside the workers, refluxed back upon them as an alien force, turning them into powerless objects. With their labor reduced to costs of production, wealth was produced for the capitalist and immiseration for the objectified workers. Consequently, they were estranged from their work and its products, their selfhood and its potential, isolated from each other and bereft of their very humanity (species-being, *Gattungswesen*) as elaborators of nature.

In sum, human growth, freedom, creativity, and community were frustrated by "commodity fetishism" integral to capitalism. The social relationship of capitalist and worker was reified, congealed within commodities, and sold for their exchange value. Products/commodities were then endowed with surplus value, while the concrete social relationship between those who own capital and those whose work produces the appropriated surplus value is intentionally hidden.

György Lukács

For Lukács (1885–1971), the eminent Hungarian Marxist philosopher, reification (from the Latin, *res,* "thing") was a special form of alienation for understanding bourgeois society. While the *1844 Manuscripts* had not yet been found when he wrote *History and Class Consciousness,* his close reading of Marx on "commodity fetishism" revealed the relation of alienation to commodification and how, in turn, reification shaped both the structure of capitalist society and its subjective moments. Describing commodity structure as "a relation between people," he insisted that it

> takes on the character of a thing and thus acquires a "phantom objectivity," an autonomy that seems so strictly rational and all-embracing as to conceal every trace of its fundamental nature: the relation between people. . . . The reification produced by commodity relations assumes decisive importance both for the objective evolution of society and for the stance

> adopted by men towards it . . . the commodity become[s] crucial for the subjugation of men's consciousness to the forms in which this reification finds expression and for their attempts to comprehend the process or to rebel against its disastrous effects and liberate [themselves] from servitude to the "second nature" so created. (pp. 83–86)

Reification, in which social relations become objectified, is embedded within bourgeois ideology and consciousness, thwarting the ability of the working class to articulate its own standpoint—notwithstanding how they produced the very wealth that was the foundation of capitalist society and the basis of their reification. Nor could they become aware of themselves as the unified subject–object of history.

Frankfurt School

In the work of the Frankfurt School, alienation, qua the reduction of workers to reified objects with attenuated social bonds, meant that people experienced themselves as socially fragmented, powerless objects whose externalized work activities and their social consequences have become the dominant forces in their lives. They were bereft of experiencing themselves as creative agents shaping their own destinies, they experienced the world as "a complicated social machine to administer the technical machine [Man has] built. The more powerful and gigantic the forces are which he unleashes, the more powerless he feels himself as a human being" (Fromm, 1955, p. 124). To resolve these contradictions of capitalism, such people were disposed to seek comfort in fascism/totalitarianism (this is what Theodor Adorno called the authoritarian personality).

Instrumental reason, the dominant ideology of capitalism, aided and abetted by a mass-mediated popular culture of deception and distraction, has served as a technique to produce and sustain alienation through the domination of consciousness. Moreover, the post–World War II expansion of capitalism colonized desire and consciousness in a society where more and more people based their very identities and lifestyles on consumption. For theorists like Herbert Marcuse, alienation was no longer based on the production of commodities but was seen in "one-dimensional thought," consumerism, and "repressive desublimation."

Sociology

Empirical Social Research

While philosophers engaged in various forms of critique, sociologists, informed by Max Weber's theories of demystification and entrapment by reason and by Émile Durkheim's discussions of anomie, undertook empirical investigations of alienation. Robert Merton's classical analysis of anomie as the degree of concordance of means and ends encouraged a number of empirical studies. Following on M. Seeman's literature review in which he found that alienation had been treated in sociological theory as meaninglessness, powerlessness, normlessness, social isolation, and self-estrangement, several researchers operationalized these dimensions of alienation in scales of various degrees of sophistication. Robert Blauner conceptualized alienation by examining four kinds of work settings—textiles, automobile assembly, lithography, and chemical process—to explore alienation qua creativity and agency in the work process, and workers' cohesion and solidarity. He found that alienation was inversely correlated with workers' skillfulness and cohesion. Recent studies have researched alienation among immigrants, among adolescents, and in families, as well as in education. Critics of this empiricist trend argue that such research reduces capitalism to a social psychology of individual differences and its positivistic empiricism is itself an expression of alienation.

Postmodernism and the Return of the Alienated Actor

In the late 1970s and 1980s, critics such as the French philosopher Jean-François Lyotard and the French sociologist, philosopher, and cultural critic Jean Baudrillard argued that having reached the postmodern age, the grand narratives of modernity, such as those of Marx or Weber, were no longer relevant. The massive expansion of consumerism and domination by the mass media, along with the demise of socialist regimes, signaled the downfall of the political and the advent of a world of decentered subjects exposed to endless simulations. Concern with alienation waned as foci shifted to cultural studies and the humanities, privileging local knowledge. For the American Marxist literary and social theorist Fredric Jameson, the ascent of postmodernism with its endless media spectacles is the cultural

expression of a ruthless globalized capitalism. While hyperconsumption provided both profits for global capital and its legitimating ideology, it colonized consciousness, transformed desire, and resulted in the proliferation of "shopping mall selfhood."

In early capitalism, Marx saw alienation as a condition for the production of commodities; in late capitalism, commodified selfhood is objectified, powerless, estranged from its own potential. The only genuine bases of community are shared consumer tastes, membership in mass audiences, and affiliation with fandoms—all of which are expressions of alienation.

Meanwhile, with wages stagnant, extravagant consumer tastes were financed largely through credit. By the late 1980s and 1990s, the implications of globalization were becoming more evident as manufacturing jobs were increasingly either automated or moved to the developing countries. Indeed, consumer debt, intertwined with consumption-based lifestyles, became another source of alienation. Although this was evident to a number of economists, sociologists, and political scientists, it would take the great meltdown of 2007 for debt-based consumerism to be seen as the catalyst for widespread alienation. Some genres of popular culture embraced transgressive themes and grotesque aesthetics—"carnivalization"—in which various moral transgressions can be seen as resistance via a critique of capitalist alienation and dehumanization of rationality. A significant sign of the trend is the spread of nihilism in such forms of popular music as punk and heavy metal and their offshoots. Such subcultures would seek to resist, if not overcome, alienation through the embrace of an alternative cultural agenda, but ultimately, given the role of the culture industries, the seeming resistance sustains the reproduction of capital.

Globalization/Economic Stagnation/Crisis

With the implosion of the European and American economies, as millions of people lost their jobs and often their homes, alienation became palpable in anger and *ressentiment* (to use Nietzsche's term). Capitalism could no longer promise upward mobility, affluence, and consumerism to cloak its underlying effects. A typical reaction was White right-wing mobilization in the United States, with the Tea Party as a voice of discontent not unlike the European fascist mobilizations of the 1920s and 1930s. These movements generally tend to express anger against existing elites as well as xenophobia toward those seen as "outsiders."

But some mobilizations are progressive, among them the World Social Forum, in which activists, embracing a variety of causes, gather from all over the world to forge networks and coalitions that would make a world of equality and humanity possible. In the spring of 2011, after many years of oppressive political leadership, economic stagnation, and shortages of basic commodities, vast numbers of people in the Middle East mobilized to rise up against oppressive governments, in attempts to overcome powerlessness and alienation.

Conclusion

When Hegel criticized Immanuel Kant's notion of Reason as static and ahistorical, he introduced the concept of alienation to explain the movement of spirit (*Geist*) through history. Moreover, the center of his phenomenology was the master's appropriation of the labor and recognition of the bondsman. But when Marx appropriated the concept of alienation, he offered a critique of capitalist domination in societies based on wage labor congealed within commodities produced for exchange. He claimed that the contradictions of capitalism would lead to a society based not on necessity but on freedom, community, and the full realization of species-being. Little did Marx anticipate that his insights would not only foster revolutions but also generate a great deal of sociological theory and research. His insights on alienation continue to help us understand the consequences of global capitalism in its consumerist moment, with its popular culture and its many reactionary and progressive mobilizations.

Allais Paradox

The Allais paradox, discovered by Maurice Allais, provides an example in Decision Theory of preferences that violate the most widely accepted normative theory of decision making, expected utility theory. This entry briefly explains expected utility theory, along with the paradox, and describes responses to the paradox.

The Paradox

Consider a decision maker choosing between lotteries, that is, probability distributions over outcomes. According to expected utility theory, as long as the decision maker is rational, her preferences can be represented by a utility function of outcomes with the property that of any two lotteries she prefers the lottery with the higher expected utility value. The idea that decision makers maximize expected utility—the "expected utility hypothesis"—was put forth in part to account for the fact that many decision makers are risk averse in the sense that they would rather have, for example, a sure-thing amount of money than a lottery with the same average monetary value. While such behavior is not consistent with maximizing expected *monetary* value, it is consistent with maximizing expected utility, relative to a concave utility function of money.

The link between a decision maker's preferences and her utility is cemented by "representation theorems": These theorems show that being (representable as) an expected utility maximizer is equivalent to having preferences that satisfy particular axioms. One of the earliest and most influential axiomatizations is that of John von Neumann and Oskar Morgenstern. The axioms of von Neumann and Morgenstern's theorem—and those employed in representation theorems in general—seem to many to be requirements of rational preferences.

The Allais paradox is a counterexample to the expected utility hypothesis. Allais asks us to consider the following choice scenarios. First, we are asked whether we prefer Situation A or Situation B.

Situation A: \$100 million for certain.

Situation B: a 10% chance of \$500 million, an 89% chance of \$100 million, a 1% chance of nothing.

We are then asked whether we prefer Situation C or Situation D.

Situation C: an 11% chance of \$100 million, an 89% chance of nothing.

Situation D: a 10% chance of \$500 million, a 90% chance of nothing.

Allais hypothesized that most people strictly prefer A to B and also strictly prefer C to D, on the grounds that in the first choice scenario the advantages of certain gain from A outweigh the perhaps higher but uncertain gain from B but that in the choice between C and D the much higher gain outweighs the slightly higher probability of a much lower gain. This pattern of preferences has been confirmed experimentally.

As mentioned, this pattern of preferences violates the expected utility hypothesis: There is no possible assignment of utility values to \$0, \$100 million, and \$500 million such that A has a higher expected utility than B and D has a higher expected utility than C. (One can strictly prefer A to B and C to D, or one can strictly prefer B to A and D to C, but no other combination of strict preference satisfies the expected utility hypothesis.) The particular axiom that these preferences violate is von Neumann and Morgenstern's independence axiom.

Responses

Broadly speaking, there are two ways to take a Decision Theory: as an analysis of the canons of instrumental rationality ("normative" Decision Theory) or as a description of actual people's preferences ("descriptive" Decision Theory). For normative decision theorists, the standard choices in Allais's example are "paradoxical" in that they seem rational to many people and yet they violate the dictates of the expected utility theory, which seems to correctly spell out the requirements of rationality. For descriptive decision theorists, the Allais choices aren't so much paradoxical as they are a counterexample to the idea that expected utility theory is the correct descriptive theory.

Descriptive theorists have responded to the paradox by formulating alternative theories that are compatible with the Allais choices.

For normative decision theorists, there are three ways to respond to the paradox. The first is to claim that contrary to initial appearances, the Allais choices are simply irrational: Although many people unreflectively have the standard Allais preferences, once an individual sees that her preferences violate the independence axiom, she ought to reevaluate her preferences and bring them in line with expected utility theory.

A second response to the paradox is to claim that contrary to initial appearances, the Allais choices do satisfy the expected utility hypothesis and the apparent conflict is due to the fact that the choices have been underdescribed in the initial setup. Since decision makers prefer A to B on the grounds that A yields \$100 million *for certain* or on the grounds that an individual who takes B and ends up with nothing will feel *regret,* this response claims that the actual outcomes in the problem are not simply monetary amounts but also include the decision maker's feelings about getting those outcomes in each situation. Since it is possible to assign utility values to, for example, the outcomes \$0, \$100, \$500, and \$0 *with regret* such that the Allais choices maximize expected utility, they do not violate expected utility after all.

Finally, normative decision theorists might respond to the paradox by denying the expected utility hypothesis and arguing that expected utility theory is inadequate as a theory of rationality. This response claims that the Allais choices genuinely

violate the theory and that they are nonetheless rational. Theorists advocating this response may draw on the aforementioned descriptive theories and argue that the preferences of the decision makers they describe are in fact rational.

Analytical Marxism

Analytical Marxism includes philosophers and social scientists who use the methods of analytical philosophy, modern economic theory, and sociology to clarify or reconstruct ideas central to Marxist social theory while discarding other, less well-grounded aspects of it. This entry examines the background and assesses the success of this school within Western Marxism. It also shows important epistemological lessons social science can draw from the methodological debates on Marxist social explanation that took place within this school.

Early Cold War critiques of Marxism claimed that Marx's philosophy of history and society was both conceptually and theoretically confused. Analytical Marxism responded by promising to reconstruct Marx's theories so that they were clear, rigorous, and scientifically supported, or discard them if this failed. Analytical Marxism also was a response to interpretations of Marx's social theory propagated by Marxist political movements and those influenced by the German idealist tradition within Western continental philosophy. In this respect, analytical Marxism is primarily a phenomenon of the philosophy of Marx in the English-speaking world, self-consciously exhibiting the "common sense" of English philosophy.

Analytical Marxism progressively discarded or reconstructed some key concepts and theoretical premises of Marxism, thereby raising the question of whether Marx's social theory could bear rigorous scrutiny. It more or less sympathetically attempted to reconstruct Marx's theory of classes, theory of historical materialism, theory of exploitation, and theory of capitalism. There were some dismissive overall surveys of Marx's social theory, such as Jon Elster's *Making Sense of Marx* (1985).

Analytical Marxists largely reject two aspects of Marx's theory that he considered among his most significant contributions. One was his use of a critique of classical political economy to reveal the conflict between classes at the foundation of capitalist society. The other was his claim that this conflict would result in a revolutionary transformation of capitalism into socialism. With regard to the first, many analytical Marxists dismiss Marx's analysis of class and exploitation because it relies on an outdated labor theory of value and a distinction between labor and labor power. Rejection of the labor theory of value led most to dismiss Marx's measure of the rate of exploitation as surplus value divided by the value of labor power, though this measure was sometimes equated with Marxian exploitation itself. Reliance on neoclassical economic theory also led to rejection of Marx's picture of capitalist exploitation as the basis of capitalist industry, which Marx claimed was concealed by superficial fairness in the way free laborers and capitalists agree on the terms and conditions of employment.

Analytical Marxists are divided among themselves between those who think that socialism is possible and those who think socialism can only be a merely utopian ideal of working-class politics, which realistically should only aspire to reforms within the ambit of welfare capitalism. Elster claims that Marxist political movements face a dilemma. In less developed capitalist societies, revolutionary mass action is possible, but what Marx claims to

be necessary conditions for socialism are missing. In developed capitalist societies, objective social conditions for socialism might be present, but the working class does not want change strongly enough to form revolutionary working-class political movements.

Some analytical Marxists use mathematical models of rational, self-interested choice by individuals to question whether revolutionary struggles can be sustained if participants are not subject to coercive discipline, like that imposed by what the Russian revolutionary Vladimir Ilyich Lenin called a "vanguard" party. Their analysis also raises the more general question of whether free collective action is possible and whether socialism can be seen as a free association of workers, as Marx saw it. The alternative takes socialism as essentially a planned economy, which has been shown in practice to be very inefficient and corrupt, and so hardly worthy of support.

One characterization of analytical Marxism is that it rejects any sharp separation of Marxist methodology of science from methods used in the social sciences more generally. In itself, this should be acceptable to other interpreters of Marx. A problem arises when some leading analytical Marxists reject some of Marx's ideas with as little care as some other Marxists show when they slavishly accept them. In these cases, little attempt is made to clarify what Marx actually thought or, where necessary, reconstruct his ideas. Dialectics and dialectical method are dismissed as "bullshit" rather than clarified to see whether they have substance or are worth reconstructing.

Although John Roemer provides a striking and original account of class and exploitation, he constructs more or less parallel ideas to those of Marx rather than providing a careful interpretation of Marx's social theory. Roemer shows that you can profit from lending money to workers. He also shows that owners of better-quality land can exploit owners of poorer land. Roemer thus thinks Marx is misguided in claiming that capitalist control over the duration, intensity, and productivity of the labor of their employees is crucial to capitalist exploitation. However, Roemer is too intent on leaving Marx behind to notice that Marx may accept his claims about exploitation through moneylending and control of more productive land. Marx has a general notion of exploitation, where some live off the forced labor of others, and a specific version of this within a capitalist economy. Marx thus may allow forms of exploitation other than a specifically capitalist form. Marx never simply equates exploitation with a transfer of surplus value or surplus labor, as Roemer claims.

Analytical Marxism faded away after the fall of the Soviet Union, although Gerald Cohen continued until his death in 2009 to argue strongly for the justice of socialism, while tackling John Rawls's theory of justice.

Analytical Sociology and Social Mechanisms

Analytical sociology is a reform movement within sociology and social theory. Its identity is not based on a common object of study, a shared historical

tradition in sociological theory, or an empirical research method. Rather, it is founded on the idea that the social sciences should do more than describe and classify social processes. According to analytical sociologists, the primary epistemic aim of the social sciences should be the *causal* explanation of social phenomena. Sociological theory should aim to develop clear and precise accounts of the *social mechanisms* by which the intentional activities of social agents bring about social phenomena.

The historical roots of analytical sociology can be traced back to the works of late-19th-century and early-20th-century pioneering social theorists such as Alexis de Tocqueville and, later, Max Weber and to prominent mid-20th-century sociologists such as the early Talcott Parsons and Robert K. Merton. Among contemporary social scientists, Jon Elster, Raymond Boudon, Thomas Schelling, and James Coleman have profoundly influenced the analytical approach. Although they are rather different types of scholars, they complement each other in important ways, and they all share a commitment to precise, abstract, and action-based explanations.

The current generation of analytical sociologists is building upon the foundations laid by these authors, aiming to develop an analytical middle-range approach to sociological theory that avoids the somewhat empiricist and eclectic tendencies of Merton's original middle-range approach. Examples of recent work in this tradition can be found in anthologies edited by Hedström and Swedberg (1998), by Hedström and Bearman (2009), and in a monograph by Hedström (2005).

Social Mechanisms

The core idea of analytical sociology is that sociological theory explains by specifying the *causal mechanisms* by which social phenomena are brought about. The specifically social causal mechanisms are called *social mechanisms*.

Analytical sociologists are dissatisfied with the traditional covering-law account of explanation, which has a large number of philosophical problems and embarrassing counterexamples. It has also provided justification for the use of "black box" explanations in the social sciences, as it does not require that the mechanism linking *explanans* and *explanandum* be specified for an acceptable explanation to be at hand. This omission has given leeway for sloppy scholarship. In contrast to this fundamentally empiricist account of explanation, analytical sociologists require that explanations should articulate causal mechanisms rather than simply subsume phenomena under empirical generalizations.

Apart from providing explanatory understanding as to why the dependency holds, the information about the causal mechanisms also provides justification for causal claims. Distinguishing between real causal claims and spurious statistical associations is a major challenge in the social sciences. The real causal dependences are transmitted via causal processes, and the search for causal mechanisms directs attention to these processes.

The idea of causal mechanisms is related to broader ideas about the growth and organization of scientific knowledge. In mechanism-based accounts, scientific knowledge is embedded in mechanism schemes and not in empirical generalizations, as in more traditional empiricist accounts. According to this view, scientific knowledge expands by adding items to, or improving upon, items already present in the toolbox of possible causal mechanisms. Understanding accumulates as the knowledge of mechanisms gets more detailed and the number of known mechanisms increases.

The mechanism idea is important in a highly specialized and fragmented discipline like sociology. Although empirical data, research methods, and substantial theories differ from one subfield of sociology to another, the general ideas about possible causal mechanisms are something these fields could share and thereby benefit from each other's work. In this vision, sociological theory provides a set of explanatory tools that can be employed and adapted to particular situations and explanatory tasks. The mechanisms are (semi)general in the sense that most of them are not limited to any particular application. For example, the same type of mechanism can be used for (partially) explaining residential segregation and success in cultural markets.

This mechanism-based vision of knowledge has much in common with Robert K. Merton's idea of sociological theories of the middle range. A theory of middle range is a clear, precise, and simple type of theory, which can be used for partially explaining a range of different phenomena but which makes no pretense of being able to explain all social phenomena and is not founded upon any form of extreme reductionism in terms of its *explanans*. Middle-range theories isolate a few explanatory factors that explain important but delimited aspects of the outcomes to be explained.

Social *Explananda* and Individual Action

The main focus of analytical sociology is on social (as distinct from psychological) *explananda* that are not definable by reference to any single member of the collectivity. Important examples of such properties include the following:

- Typical actions, beliefs, or desires among the members of a collectivity
- Distributions and aggregate patterns, such as spatial distributions and inequalities
- Topologies of networks that describe relationships between the members of a collectivity
- Informal rules or social norms that constrain the actions of the members of a collectivity

A key insight of analytical sociology is that explanations that directly relate macrovariables to each other are unsatisfactory. They do not specify the causal mechanisms by which the changes in one macro variable bring about changes in another. Deeper explanatory understanding requires opening up the black box and finding the causal mechanisms that have generated the macro-level pattern. Rather than analyzing relationships between phenomena exclusively on the macro level, one should identify the *situational mechanisms* by which social structures constrain individuals' action and cultural environments shape their desires and beliefs, describe the *action formation mechanisms* according to which individuals choose how to act, and specify the *transformational mechanisms* by which individuals, through their actions and interactions, generate various intended and unintended social outcomes. Only by understanding the whole chain of situational, action formation, and transformational mechanisms have we made sense of the observed macro-level relationship.

This argument does not imply commitment to the doctrine of methodological individualism. Most formulations of methodological individualism are much stronger than is required by the mechanism-based perspective. Some form of *structural individualism* is sufficient for the purposes of mechanism-based explanations of social phenomena. Structural individualism is a doctrine according to which all social facts, their structure and change, are in principle explicable in terms of individuals and their properties, actions, and relations to one another. Structural individualism differs from most formulations of methodological individualism by emphasizing the explanatory importance of relations and relational structures. It does not require that all explanatory facts are facts about individual agents in the strict sense: Facts about topologies of social networks; about distributions of beliefs, resources, or opportunities; and about institutional or informal rules and norms can have a significant role in mechanism-based explanations.

Historically, analytical sociology has some of its roots in the tradition of rational choice sociology. However, current analytical sociology does not have any special commitment to the assumptions of rational choice theory. For this reason, it is a mistake to take analytical sociology as rebranded rational choice sociology. Rather than relying on some preconceived ideas about human motivation or cognitive processing, the mechanism-based perspective suggests that our account of human agency should be based on the findings and theories of psychological and cognitive sciences. The explanatory agenda of mechanism-based social science has some methodological implications, however. As understanding of complex phenomena is only possible in a piecemeal way, we must abstract away from many details of human mental life. Only those aspects of cognition that are relevant for the explanatory task at hand should be included in the explanation; the explanatory task thus determines how rich the psychological assumptions must be.

So, although the mechanism-based approach emphasizes the importance of action in the explanation of social phenomena, it does not subscribe to an axiomatic vision according to which a specific action theory should be used for all purposes. As different theories of action emphasize different aspects of human action, the choice between them should be made on methodological grounds. In some modeling contexts, rational choice theory is a natural choice, while in contexts where the emphasis is on the habitual dimensions of human actions, the analytical sociologist might choose to employ some psychological dual-process theory. For many social-scientific purposes, a relatively simple desire–belief–opportunity model will be sufficient. This simple theory provides a building block for accounts of social mechanisms of interaction through which the actions of some actors may come to influence the beliefs, desires, opportunities, and actions of others.

Agent-Based Modeling

A recent development in analytical sociology has been the use of agent-based computer simulations. Much of the development of mechanism-based knowledge consists of developing "how-possibly" explanation schemes. These schemes are not intended to explain any particular empirical facts directly but to provide a general understanding of how things could work. Given the limitations of experimental methods and the complexity of social phenomena, computer simulations are important for this kind of endeavor.

The promise of agent-based simulation is based on the fact that the dynamics observed at the social level typically are complex and hard to understand, but often it is possible to describe the basic cogs and wheels of these social processes with rather simple models. Macro-level outcomes and relationships tell us very little about why we observe the macro-level outcomes and relationships we do observe. Only by explicitly considering the micro-level actions and relations and how they unfold over time can macro-level outcomes be explained. This basic insight is at the heart of analytical sociology: To understand collective dynamics, we must study the collectivity as a whole, but we must not study it as a collective entity.

One important feature of agent-based simulations is that they do not impose any a priori constraints on the mechanisms assumed to be operating. Unlike rational choice theory, agent-based modeling is not based on any specific theory of action or interaction. It is a methodology for deriving the social outcomes that groups of interacting actors are likely to generate, whatever the action logics or interaction structures may be. Agent-based simulations should not only be regarded as a tool for theoretical exploration, however. Empirically calibrated agent-based models make it possible to integrate theoretical ideas with the results of empirical research.

Conclusion

Mechanism talk is becoming increasingly popular in the social sciences. Many sociologists use the word *mechanism* in a loose sense without any commitment to the type of mechanism-based explanatory strategy focused upon here. Underlying the mechanism-based approach is a commitment to *realism:* The explanations should reflect the causal processes responsible for the phenomenon to be explained. This requires stringency in theoretical practice and imagination in the design of empirical research. It also implies that social scientists should pay attention to what mechanisms are made of rather than treating them as black boxes.

Analytic/Synthetic Distinction

The analytic/synthetic distinction was motivated historically by a number of issues. Immanuel Kant explicitly drew the distinction as it has been best known since. Synthetic statements are often understood as factual statements known by experience. In contrast, some statements seem knowable by reason

alone, without appeal to sense experience. Such statements are called a priori. Some statements seem necessary, not merely contingently true. If the necessity of a statement cannot be known by appeal to experience, then the fact that *p* is necessary seems to be knowable, if at all, a priori. Various statements seem to be uninformative or trivial in a peculiar way. Some examples are obvious truths of logic, such as "If p, then p," or well-known truths concerning abbreviational definitions, such as "Vixens are female foxes." David Hume distinguished "relations of ideas" from "matters of fact" in a way motivated by this third distinction, although it is not altogether clear why "relations of ideas" should be knowable **a priori**, or trivial/uninformative, or necessary. It is clear that epistemic distinctiveness (experiential transcendence) played a major role historically in motivating the distinction.

The Logical Empiricist View

The analytic/synthetic distinction was a central pillar of the form of empiricism that came to dominate the first half of the 20th century, logical empiricism. According to logical empiricists, any statement whose truth is knowable, but not knowable on the basis of sense experience, is analytic. Any statement neither analytic nor synthetic is "metaphysical" in a pejorative sense. Logical truths, truths of mathematics, and various seeming necessary truths, such as color exclusion claims (that nothing can be two different colors at the same time), were particularly difficult cases for the logical empiricists, who wanted to assimilate all nontrivial or informative statements to the "synthetic." Their picture of scientific knowledge required that there be no "substantive" a priori knowable truths that are not analytic.

Alfred J. Ayer's famous book, *Language, Truth, and Logic,* presented a description of our epistemic circumstances as understood by logical empiricists. Ayer assimilated the necessary, the a priori, and the "trivial" or "uninformative" to the same category of statements, the analytic ones. Since a modal feature such as necessity seems to transcend what is determinable empirically, as Hume and other empiricists had argued, and we take some statements of science to be necessary, knowledge of such statements and/or their modal status were thought to require appeal to analyticity, and similarly for other apparent necessities such as color exclusion. Both mathematics and logic seem to be knowable, if at all, without appeal to sense experience, at least in the sense that our justification for believing such truths does not seem to appeal to sense experience. Ayer argued that no empirical data would be taken to undermine our confidence in, say, $2 + 3 = 5$, and that no empirical data could be taken to confirm these statements either. Rather than arguing that our arithmetical beliefs are unjustified, logical empiricists preferred to assimilate these statements to the class of analytic statements.

Rudolf Carnap emerged as the most prominent of the logical empiricists, and he developed various accounts of the workings of language and of scientific methodology that crucially involved the notion of an analytic statement. It is Carnap's developed views, as well as the logical empiricist views expressed by Ayer, that generated some of Quine's most powerful objections to the distinction.

Quine's "Two Dogmas of Empiricism"

Willard Van Orman Quine wrote a number of papers attacking the analytic/synthetic distinction, the best known of which is "Two Dogmas of Empiricism (TD)." In that paper, he raised a number of objections to analyticity. One objection is a form of circularity objection. Quine noted that various attempts to clarify the notion of analyticity appealed to other notions such as necessity, semantic rule, or synonymy. According to Quine, all of these notions, to the extent that they seem interdefinable with "analytic," are equally problematic. This class of interdefinable notions includes meaning and synonymy, both of which he rejects as obscure or worse.

A second part of Quine's TD argues that no statement within science is "immune to revision" on the basis of experience. According to Quine, even truths of logic seem alterable on the basis of empirical facts (e.g., "quantum logic," which rejects the distributive law of classical logic in response to experimental data pertaining to the quantum realm). Mathematical statements are empirically revisable as well (as observed, they claim, in the transition from Euclidean to non-Euclidean geometries). This argument is given in order to undermine another potential account of analytic statements, that they are those statements that are taken to be "confirmed" relative to any experience.

Around two decades later, Gilbert Harman summarized the state of the arguments concerning analyticity, extending and improving Quine's original

arguments to better address some of the objections raised against it by Paul Grice, Peter Strawson, Carnap, and others. Harman argued that "analytic" was akin to "witch," in the sense that we now think that there are no witches because appeal to witchhood does no helpful explanatory work and that we should similarly reject analyticity because it does no helpful explanatory work either.

Some Responses to TD

Some early responses to TD raised difficulties for Quine's position. For example, Quine claims in TD that stipulative definition for the purposes of abbreviation yields unproblematic analytic statements. Grice and Strawson argue that Quine cannot consistently accept such stipulations as analytic. If there are some clear cases of analytic statements, then the notion must not be incoherent or unintelligible, contrary to the central conclusion of Quine's TD.

Many commentators have argued that Quine's circularity arguments are unconvincing. Other fundamental notions, such as one of Quine's favorites, truth, seem indefinable. This should not cast doubt on a notion's coherence or as to whether the concept has instances. Furthermore, as Glock points out, Quine's argument would appear to stack the odds unfairly against the possibility of explication. Quine treats any concept used to elucidate analyticity to be equally suspicious, to suffer "guilt by association." It is difficult to see how any elucidation of any concept could ever be given under the constraint that any proposed clarification is taken to cast doubt on the concepts employed in the attempted elucidation.

One of the central points that Grice and Strawson make is that philosophers seem capable of classifying an indefinite and open-ended number of statements as either analytic or not, with considerable agreement. This shows, they think, that there must be some intelligible notion that is implicitly shared by philosophers, even if they cannot yet give an explicit and clear elucidation of the notion.

In response to this second objection, Harman argues that the fact that people agree by and large on their classifications does not show that there are, in fact, instances of a concept. For example, it may have been the case that in Massachusetts in the 1600s people would have substantially agreed on how to classify women as witches or nonwitches. That fact does not show that there were actually witches.

Another sort of objection that has been made is that if Quine is correct in his arguments against meaning and synonymy, there is no distinction between change in meaning and change in theory. But intuitively, there seem clear cases in which a word has changed its meaning, as opposed to merely changing our views concerning the term. A Quinean response to this objection grants that there seem to be such different cases but attributes the difference to our inclination to use two different sorts of "translation schemes" in the two cases. Sometimes we translate the same word differently across time into our own language, whereas other times we translate the word, as used across time or community, into the same word of our current language. The notion of a good translation scheme is not, according to Quineans, to be understood as requiring preservation of meanings, since there are no meanings and there is no such thing as synonymy. Instead, good translation schemes are the ones that have some pragmatic virtues, including preserving of belief (treated behavioristically as "dispositions to assent to sentences") as well as preserving "obviousness."

As to Harman's concern that analyticity does not explain anything, a possible response is to grant a sense in which that is correct but deny that this sense of explanatory failure undermines the coherence of the distinction or show that there are no instances of "analytic." If being analytic within some linguistic practice is elucidated as "a statement understood as an empirically indefeasible stipulation," then analyticity is in some respects similar to chess bishops, stop signs, and many other classificatory concepts that are plausibly taken to be "intention dependent" in a broad sense or sometimes as "social constructions." That some mini sculpture is a chess bishop (as used on some occasion) is arguably an intention-dependent fact. Noting that the item is a chess bishop can help a bystander understand why the players are moving it only diagonally. In another sense, Harman is correct, though, in that describing something as a chess bishop does not explain anything not explained by appeal to the relevant intentions constituting the item's being (taken to be) a chess bishop. If we ask why it tends only to move diagonally on a board, this fact is explained, if at all, by appeal to the beliefs and intentions of the game players, including their belief that the piece is a chess bishop, along with associated dispositions of use and related intentional states. If being analytic is in this respect like being a chess

bishop or a stop sign, then it is importantly disanalogous to witch-hood, which is commonly understood to involve special magical powers, for example, rather than constituted by broadly social factors.

Metaphysical Versus Epistemic Accounts

More recently, Timothy Williamson and some others have distinguished between *epistemic* conceptions of analyticity and *metaphysical* conceptions. According to Williamson, both conceptions fail as accounts of a notion of analyticity that would be philosophically interesting or important. Williamson understands epistemic conceptions to be conceptions that take analytic truths to be those that any competent speaker of the language must accept. Williamson then argues that any statement can be rejected by a speaker who is linguistically competent. For example, someone might have strange conspiratorial views according to which "bachelors are unmarried men" was initially spread as part of a mind control project and is really false, that bachelors are actually twice married women. It might be unclear whether such a person is competent in English. If we tell him, "No, bachelors really are unmarried men," he might respond, "Of course, I know that's what all of you drones have been brainwashed to believe. It's false, though." It is difficult to explain why such a person should count as incompetent in English, as opposed to merely having bizarre views. According to Williamson, this sort of consideration can be generalized to any other statement.

As to "metaphysical" conceptions, Williamson takes these to involve a special type of truth property had by analytic statements. He argues that there is no good reason to think that there is more than one type of truth.

Analyticity on the Contemporary Scene

Quine was thought by many to have once and for all undermined the distinction between analytic and synthetic statements. Developments since Kripke (in the 1970s) had made some philosophers more optimistic that analyticity could be resuscitated, while for other philosophers they have seemed to sound the death knell for reasons other than those provided by Quine. Gillian Russell argues in her book *Truth in Virtue of Meaning* that there are indeed analytic statements. Her paradigm example of such a statement is "I am here now." Such statements have the distinctive characteristic, Russell argues, that any token utterance of that sentence in a context will be evaluated as true in that context, in virtue of reference-determining facts about the words contained within, along with the sentence's structure. According to Russell, this is a semantic profile for sentences that does not have anything like the epistemic significance that logical empiricists took it to have. In that respect, her view takes Quine to be right about the epistemic bankruptcy of analyticity but wrong about the semantic bankruptcy. Gillian Russell also investigates a question suppressed in most philosophical discussions (including the present one), namely, whether analyticity is in the first instance a feature of sentences, propositions, statements, utterances, or thoughts. Others influenced by possible-worlds semantics and metaphysics have come to think that there is no room for analyticity for reasons other than those given by Quine. *Semantic externalists* think that semantic relations (including truth) are "external" to minds in ways that can make them epistemically inaccessible, in a sense incompatible with a more "internalist" picture within which analyticity was introduced. Analyticity thus remains under attack along two very different fronts: the radically empiricist Quinean front and the metaphysical possible-worlds front.

Philosophers continue to draw a distinction between *conceptual truths,* stipulations, and definitions, on the one hand, and *substantive* claims, on the other. Relatedly, metaphysicians often take it that there are metaphysically "thick" ontological claims versus merely "thin" ones that seem to be akin to analytic statements of existence. Mathematics and its relation to empirical science remains ill understood, and some optimists retain the hope that appeal to analyticity in some form may illuminate that domain better than contemporary Neo-Quinean empiricist accounts. Debates in *meta-ontology,* such as those concerning the genuine existence of mereological sums, may also be well served by a new look at the analytic/synthetic distinction. The ringing of the death knell of the distinction by its many opponents may yet prove premature.

Androcentrism and the Philosophy of Science

The term *androcentrism* derives from the Greek *andros* genitive of *aner* (*ἀνήρ*), for "man" or "male." This word and its variant *androcentric* are used to describe perspectives, research, theories, and methods that emphasize the behavior, activities, or experiences of males, and minimize or exclude those of females, although the research or theory might be understood to be gender neutral. Since the mid-1970s, feminist scientists and philosophers of science have argued that androcentrism is common in the methods, research questions, and hypotheses advanced in the biological, biobehavioral, and social sciences and that its presence is consequential. This entry focuses on androcentrism in the social sciences. It begins with arguments for its role advanced by feminist scientists and philosophers of science. The next sections summarize, respectively, what feminist philosophers of science argue to be some general implications of androcentrism for the philosophy of science and quite different views of the implications held by more traditional philosophers.

Androcentrism, as opposed to sexism (the view that one sex is superior), is a subtle phenomenon, one that scientists might not recognize as informing their questions, emphases, or theories. Feminist scientists and philosophers point to several dichotomies—in this case, classifications understood to divide opposed sets of behaviors, characteristics, or spheres along the lines of gender—as influencing 19th- and 20th-century social science. The dichotomies date back to the works of Plato and Aristotle.

"Gendered" Dichotomies

Examples include reason/emotion, production/reproduction, culture/nature, public/private, objectivity/subjectivity, and universality/particularity. In each, feminists argue, men are typically associated with the first category, women are associated with the second, and the characteristic, entity, or activity associated with men is taken to be worthy of study and superior to that to which it is opposed.

Some examples are in order. In psychology, Jean Piaget and Lawrence Kohlberg each developed an influential theory proposing that moral and cognitive development occur in stages. When it was observed that girls and women failed to reach the "higher stages" proposed in the theories, many assumed that this reflected a flaw in women's development rather than in the theory. Often the flaw was taken to involve one or more of the dichotomies noted: Girls and women were taken to be more subjective, and/or more emotional, and/or more concerned with particulars as opposed to universal principles than their male counterparts.

In anthropology, archaeology, economics, history, and political science, feminist scientists argued that the emphasis on what was perceived to be cultural, productive, and/or "public" effectively erased those aspects of social life associated with women (i.e., assumed to be natural, involving reproduction and/or the so-called private sphere). For example, cross-cultural studies undertaken in anthropology until the 1970s emphasized activities and behaviors associated with men (e.g., hunting rather than gathering in hunter-gatherer groups, although it would be discovered that gathering provides the majority of sustenance for such groups). Research in economics and political theory often assumed the public/private and

productive/reproductive dichotomies and focused on understanding activities associated with the first of each pair. Yet, feminists argued, the unpaid labor undertaken by middle-class women in the "private" sphere of capitalist economies deeply supported the practices and institutions in the public sphere.

The Implications of Androcentrism for the Philosophy of Science

The consequences of androcentrism (if and when it has a role in science) are relatively uncontroversial. In the foregoing examples, observations and explanations were at least incomplete, if not distorted. In addition, there was a lack of attention to issues of interest to women, although they were clearly relevant to accounts of social life—including reproduction, the so-called private sphere, rape, domestic violence, and job and wage discrimination.

However, there are disagreements about the sources and implications of androcentrism. In general, feminists argue that they reveal relationships between androcentrism and traditionally male-dominated science communities and between women's entering the social sciences following the collapse of barriers that prevented their participation and the recognition of androcentrism. They also view feminist engagements as having both a critical dimension (discussed in the previous section) and a decidedly constructive dimension. Scientists who view gender as a category warranting attention in their research, feminists point out, have identified new areas of research and proposed alternatives to traditional hypotheses. Hence, they propose a complex relationship between the sociopolitical context, on the one hand, and the directions and content of science, on the other. More substantive and detailed work on these issues is undertaken in feminist epistemology and feminist philosophy of science.

For more traditional thinkers, neither feminism nor gender does, or should, play a role in science. Cases of androcentrism are cases of "bad science," not typical of science. They also maintain that the critical and constructive developments feminists cite are the product of science's self-correcting nature, not feminism. Some charge that feminist arguments citing relationships between sociopolitical contexts and the content of science entail relativism by blurring the distinctions between science and values, and/or science and politics, and/or objectivity and subjectivity.

Somewhat ironically, feminist social scientists and philosophers cite developments within the so-called mainstream philosophy of science that, as early as the 1960s, challenged these distinctions, or at least understandings of them. These include the roles that theories have in shaping observations, that values have in scientific practice, and that the social organization and norms of a science community have in determining the weight given to views dissenting or different from those that are dominant. These developments reflect a more general recognition that, to be empirically warranted, the philosophy of science must study and reflect the actual practices of specific sciences, not idealize them.

Annales School

The *Annales* school refers to a group of historians in 20th-century France who have been described as the most influential historiographical movement of

the 20th century, not only in France but also internationally, particularly in Latin America and India. Peter Burke, in his book on the school, spoke of the group as having initiated a "historical revolution" in France. This revolution consisted in the turn from the established narrative history, focusing on politics, events, and great men, as practiced at the Sorbonne, to a problem-oriented interdisciplinary social and cultural history. Lucien Febvre (1878–1954) and Marc Bloch (1886–1944) laid the foundations of the *Annales* group with a journal, the *Annales d'histoire économique et sociale,* launched in 1929. Although an important study of the movement spoke of an "*Annales* paradigm," the *Annales* throughout its history was marked by considerable diversity, so that the term *paradigm* hardly applied. What held it, and also later what held the group connected with the journal, together was the commitment to exploring new historical interdisciplinary approaches. One can distinguish a number of stages through which the journal went between 1929 and now. But not only did the *Annales* assert an important influence on the reorientation of historical writing in France and elsewhere, it also was very much affected by new orientations internationally.

Febvre and Bloch had already gone in very different directions. Both were deeply influenced by the *Année sociologique* of Émile Durkheim (1858–1917) and the *Revue de synthèse* of Henri Berr (1863–1954), but in different ways and to different degrees. Durkheim's stress was on social and economic structures governed by an unconscious collective mentality; Berr, whose journal, founded in 1900, was in many ways a forerunner of the *Annales,* also sought a "synthesis" that broadened the historical outlook to include all aspects of society and culture, but in which the views and intentions of individuals still played an important role. This is reflected in Febvre's early work on human geography and later in his biography of Martin Luther and in his examination of François Rabelais and the problem of unbelief in the 16th century. In the latter work, the focus is not on Rabelais as an individual but on an impersonal factor, the language of the time, which structured religious thought and made unbelief impossible. By contrast, in Bloch's *Feudal Society* (1940) individuals hardly appear, but the worldview and the cultural context of the time are central.

Until the outbreak of World War II, the *Annales* were largely the work of Febvre and Bloch, who were relatively isolated in the French historical profession. Bloch was murdered in 1944 by the Nazis. Febvre succeeded after 1945 in giving the *Annales* a firm institutional basis in the newly formed Sixth Section of the *École Pratique des Hautes Etudes,* which was transformed in 1972 into the *École des Hautes Etudes en Sciences Sociales.* The title of the journal after it was revived in 1946 was changed to *Annales: Economies, Sociétés, Civilisations* to reflect its broadened perspective. The École was committed to integrating history and the social science disciplines within a comprehensive "science of man" (*science de l'homme*) that would include not only the traditional social sciences but also linguistics, semiotics, the sciences of literature, and the arts. The École became the most important center of historical and social science studies in France, and the *Maison des Sciences de l'Homme,* established in the Parisian Left Bank in 1963, became an integrated center for these interdisciplinary studies.

In the 1960s, the *Annales* followed the fascination with quantification current at the time in the social sciences. *Annales* historians increasingly wanted to be *scientists*. They often called their institutes "laboratories" and stressed that their work needed to be quantitative to be scientific. At the same time, in contrast to the *Annales* of the 1930s, which still gave attention to the problems of an industrial society globally, studies now largely avoided the contemporary world and turned to the Ancien Régime and the Middle Ages. Emile Labrousse's (1895–1986) exploration of the origins of the French Revolution emphasized economic forces and relied heavily on quantitative methods. Regional studies focused on demographic factors in premodern French societies. This reliance on the hard sciences was reflected in Emmanuel Le Roy Ladurie's (b. 1929) *History of Climate Since the Year 1000* (1967). Quantification played less of a role in the work of Fernand Braudel (1902–1985), who followed Febvre as director of the École. In his intercultural study of the Mediterranean in the Age of Philippe II, social structures to an extent determined by geographic factors occupied a central role. What mattered in history were not short-term changes but what Braudel called the *longue durée,* long-term structural aspects. The computer entered in the 1970s with the analysis by Michel Vovelle

(b. 1933) of thousands of wills from the 17th and 18th centuries to establish changing attitudes toward death as part of a process of secularization. In the 1970s and 1980s, this reliance on quantification and the search for large-scale social structures was challenged, as historical studies in general increasingly questioned social science approaches. The work of Le Roy Ladurie in this period reflects this reorientation. His *Peasants of Languedoc* (1967) applied a Neo-Malthusian model to analyze the interrelation of food prices and population pressures in the period from the Black Death in the 14th century to the 18th century, in which individuals and politics are hardly mentioned. Individuals reappear eight years later in his story of an early-14th-century southern French heretic village, *Montaillou* (1975), a foray into historical anthropology in which a set of narratives portrays men and women embedded in an age-old folk culture. An important collection of essays, *Lieux de Mémoire* (*Realms of Memory: Rethinking the French Past*), was initiated in 1984, stressing the role of memory rather than quantitative or documentary sources in reconstructing the past. In 1994, the subtitle of the journal *Economies, Sociétés, Civilisations,* which had consciously eliminated politics, was dropped and was replaced by *Histoire, Sciences Sociales*. A broadly global perspective, which included the role of politics and religion in the past and present, now occupied more space and left room for a broad diversity of the historiographical outlook. The *Annales* continues to exist, but the question nevertheless arises whether at this point one can still speak of a specifically *Annales* orientation.

Argumentation

This entry presents the field of argumentation, the major approaches that flourished within it, and its relevance to philosophy and the social sciences.

The study of argumentation, as distinct from the study of rhetorical theory focused on literature, has been a field of its own since 1958, when two pioneer works, Chaïm Perelman and Lucie Olbrecht-Tyteca's *Treatise on Argumentation* and Stephen Toulmin's *The Uses of Argument,* were published. These two books gave rise to distinct traditions, but both challenged models of reasoning inspired by logic and by geometry or other axiomatized sciences. Both approaches regarded juridical and judicial reasoning as more relevant in general patterns of everyday reasoning. Perelman's school in Brussels triggered numerous investigations on legal argumentation. Toulmin forged a model of argumentation as elementary and simple as the paradigmatic Aristotelian syllogism but better suited for the everyday types of reasoning (e.g., universal premises are replaced by general premises or "warrants" that tolerate exceptions). This model renewed communication studies, along with rhetorical theory in the work of Wayne E. Brockriede and Douglas Ehninger. Furthermore, Toulmin's identification of field-dependent aspects as distinct from field-invariant aspects of argumentation converged with Charles A. Willard's analysis of the sociological dimension of argumentation.

Numerous logicians, more or less explicitly in reaction against these antiformalist trends, have searched for what they call "informal logic," a phrasing that is somewhat paradoxical not only by definition but also because many of these scholars have been searching for *formal*—though *not axiomatic*—ways of modeling reasoning. One of the most successful scholars working in this vein is Jean-Blaize Grize, who has explored alternative ways of formally accounting for "the natural logic" of everyday reasoning, from Gerhard Gentzen's "natural deduction" to mathematical mereology. Researchers in computer science also search for new kinds of formal logic that are able to grasp the "nonmonotonic" aspects of everyday reasoning, namely, the frequent revision of principles—or "warrants"—and conclusions during the process of reasoning itself.

Other traditions were launched independently. Charles Hamblin, in particular, relying on an

impressive history of the various theories of fallacies from Aristotle to Stuart Mill, including the specifically Indian tradition in logic, focused on the fact that most alleged fallacies are communicative and not logical mistakes. He then opened the door to a significant renewal of the theory of fallacies, best represented by Frans Van Eemeren and Rob Grootendorst's "pragma-dialectic" theory, inspired by Paul Grice's theory of speech acts. John Woods and Douglas Walton's logical analyses have taken account of this significant pragmatic recovery of the analysis of fallacies to more precisely identify the specific role of formal logic in the analysis of everyday reasoning.

The pragmatic or speech act tradition has also inspired two closely related approaches. Oswald Ducrot and Jean-Claude Anscombre have ambitiously tried to reconstruct all of language analysis by using the basic idea that every word has an inherently argumentative aspect. In this approach, each word can be described as a particular "bundle" of commonplaces or *topoi* and each language as a structure of these *topoi,* or, in other words, of the various implicit cultural principles embedded in language and able to justify specific claims. Such an analysis is not far from Toulmin's idea of field-dependent warrants, but more than all these authors, Dan Sperber—relying on anthropological investigations—has highlighted the contextual dimension of meaning. The argumentative meaning of a myth (and, more generally, of any *topos* or warrant) depends significantly on the context of its utterance. However, unlike Grice, Sperber (along with Deirdre Wilson) has argued that not only do speakers not have to be aware of the most basic pragmatic rules allegedly guiding the interpretation of statements but these rules are reducible to a single principle, the *relevance principle* ("Be relevant when you speak!"), a functional principle of the mind. Sperber recently went further in his analysis of communication within this new cognitive framework by arguing that the emergence of reason itself might have been triggered by the intention to persuade others.

The theory of logical (and not communicative) fallacies has also been renewed by cognitive psychology (Amos Tversky and Daniel Kahneman). Stuart Mill's theory of fallacies—the last one before Frege and Russell's revival of logic—had greatly influenced one of the leading fathers of both contemporary economics and sociology, Vilfredo Pareto, who devoted a significant part of the *Tratta di Sociologia Generale* to lay out a treatise on social rhetoric. This aspect of Pareto's work has been rediscovered by Raymond Boudon and emphasized by Alban Bouvier, both in the continuity of cognitive psychology. Boudon and Bouvier have connected the study of argumentation to another general issue in the social sciences, namely, the relevance and the boundaries of rational choice theory to account for the apparent irrationality of collective beliefs.

Argumentation theory is now being reconsidered by social epistemology—or the *normative* social theory of knowledge—and by cognitive sociology—or the *descriptive* social theory of knowledge—as a double-sided part of their closely related domains (see Alvin Goldman, *Knowledge in a Social World*). Social epistemology, for example, deals with questions such as this one: How *should* the members of a jury proceed in court when they have to decide which expert is right out of two experts who disagree about the judicial responsibility of a defendant and to persuade the other jurors? Cognitive sociology (pioneered by Aaron Cicourel) deals with a complementary concern: How *do* they effectively proceed? This distinction between normative and descriptive aspects—essential to a theory of logical fallacy—was explicit in Toulmin's work but less clear in Perelman's. Evidently, the interactionist conception of communicative fallacies can be easily integrated into these complementary fields, which could unify argumentation analyses.

Finally, it should be mentioned that Jürgen Habermas has emphasized the necessary ethical dimension of argumentation, beyond pragma-dialectic rules as well as epistemological norms, and argued for argumentation ethics (or "discursive ethics") and for "deliberative democracy" in politics.

Artificial Intelligence

The first recorded use of the term *artificial intelligence* (AI) was in the proposal for the Dartmouth Summer Research Conference on Artificial Intelligence in 1956. This conference—essentially a month-long brainstorming session—is usually considered the birthplace of modern AI.

However, AI has many elements that predate this. Indeed, if one takes the possibility of the mechanization of thought as the key philosophical notion underlying AI, then this notion can be found in early works by Chinese, Indian, and European philosophers. Modern AI frequently acknowledges its debt to earlier thinkers, although often in a highly selective manner and frequently as part of factional disputes.

There have been many debates on the precise definition of AI in the years since 1956. The closest thing to an agreed definition of AI within the field is attributed to Marvin Minsky, an instigator of the Dartmouth Conference: *Artificial intelligence is the science of making machines do things that would require intelligence if done by men.*

This definition may be taken as a starting point and expanded. Even if we allow no sexist implication, many researchers would not wish to be restricted solely to human intelligence. Biological research on animal behavior during the 21st century strongly suggests that intelligence has evolved more than once on Earth. Many AI researchers are influenced by these discoveries in biology and might therefore prefer a definition that included things that require intelligence *if done by animals.*

It is important to distinguish the term *artificial intelligence* from the endeavor that is Artificial Intelligence. This is because much of AI research, AI technology, and AI theory may use different names. For commercial or political reasons, the term *artificial intelligence* has sometimes been thought to convey a negative image, so the endeavor has often been rebranded or referred to solely under the name of a component technology, such as machine learning, artificial life, robotics, or advanced computer science.

The endeavor that is AI has turned out to be as much engineering as science, if not more. Many of the technological successes of AI have come from building systems that solve specific problems, rather than from first developing an understanding of the scientific principles—particularly in the many areas where human intelligence is poorly or not understood. The attempt to reproduce human intelligent behavior in machines has often revealed a partial or complete ignorance of the way in which humans achieve such behavior. In this respect, AI has prompted and pushed the science of human intelligence rather than followed its development.

A better, expanded definition would therefore be as follows: AI is the study of intelligent behavior (in humans, animals, and machines) and the attempt to find ways in which such behavior could be engineered

in any type of artifact. It is important to include "any type of artifact" because some intelligent behavior is produced by the right sort of computer software, some by the physically right sort of robot, and some by a combination of the two. Indeed, much successful AI has only a virtual existence as portions of computer code within larger systems.

AI as a Science

The science of AI is essentially interdisciplinary—involving at least computing, neuroscience, biology, psychology, mathematics, and philosophy. It is closely related to the *cognitive sciences,* though the terms are not used interchangeably. As a field of study, AI is often involved in disputes over methods and areas with these more established areas of science. This can be aggravated by the tendency to use the term *artificial intelligence* only for the more experimental or speculative portions of the research, for reasons alluded to in the previous section. The tendency to give AI successes a different name also applies to AI as a science.

The science of AI can be seen as having progressed through three distinct phases. These phases are not properly to be called *paradigms* in Thomas Kuhn's use of the term, since they are compatible and modern. AI technology often utilizes an eclectic mix of ideas from all three phases.

The first phase is known as GOFAI (good old-fashioned AI). During this phase, the most important route to intelligent behavior was considered to be an appropriate algorithm. That is usually a clever programming technique capable of deducing or guessing the best solution to a problem. This is the phase of AI that most resembles conventional computing. It is important to stress that this was, and is, more than mere computation in that AI programs usually operate in areas where informed guesswork is necessary.

A good example would be game-playing AI, which, among other successes, has produced chess-playing programs capable of beating even the best human players. It is often believed that these programs play chess by calculating all possible moves. This is not the case. It is mathematically impossible to calculate all the moves available in a chess game. A chess-playing program must make informed guesses as to which moves are more likely to lead to a winning position. These informed guesses are known as *heuristics,* and they are refined by letting the program play games (usually against itself).

The second phase stemmed from an increasing realization that GOFAI methods, however successful, were very unlike the operation of natural brains, leading some researchers to explore very different approaches. This second phase was characterized by attempts to produce software that was more human or animal-like in its operation. This focus of interest used names such as *parallel distributed processing* or *connectionism.*

A crucial difference from GOFAI is that connectionist methods do not depend on sequential processing of information and rules. Instead, multiple processors make aggregate decisions in an imitation of the neurons in a human or animal brain. It is important to observe that this is a fairly loose imitation, as the operation of neurons is as yet incompletely understood.

Connectionist methods can often produce behavior that is much more brainlike than that produced by GOFAI methods. Features such as partial remembering or the ability to synthesize the missing portions of incomplete data also make these techniques useful in real-world applications.

The third phase was characterized by a much greater emphasis on the building of physical robots. This is usually known as *situated robotics* or *artificial life*. The change of emphasis in the third phase is an explicit rejection of producing intelligent behavior purely in simulation or from "disembodied software." It therefore focuses on *embodiment* as an essential component of intelligent behavior. This third phase has produced much more useful robots than the previous two phases—aided by concurrent developments in mechanical engineering and battery technology.

It is often argued that psychology has learned much from AI over the past 50 years. One way in which this can occur is in the building of computer models of human thought processes. The level of understanding of the mental processes required in order to do this has imposed a useful attention to detail, which would otherwise be lacking in psychological theories.

Many psychologists acknowledge the direct influence of AI. Even among those who claim to be not directly influenced by AI theories, it is generally

agreed that the development of AI has helped inspire the emergence of more scientific approaches to psychology.

AI as Engineering

No one who uses modern technology can have failed to notice that many devices are getting smarter. Much of AI technology is computer software that produces intelligent behavior in a particular application. This can be seamlessly and often invisibly integrated into computer systems that control larger systems—and human behavior—in the real world.

A good example would be the now common use of AI in traffic management systems. Rather than having human operators make a vast number of complex decisions in order to optimize traffic flows and minimize pollution levels from vehicle emissions, road systems are being increasingly turned over to automatic control. Automatic control is much faster and more reliable than human operators. The AI components in such systems are pieces of computer software that solve complex problems in real time. Without close examination, one would not know that this AI technology was there. Note that such systems also regulate human behavior in that drivers are legally required to comply with their instructions via traffic signals and variable speed limits.

This example illustrates many of the key features of AI as engineering. Without specialist inside knowledge, the public are often not aware of its existence—especially its presence in social life, controlling and enabling social action. In many cases, the developers, owners, and users of automated systems do not want the label "artificial intelligence" applied to their system. Such a system will be more acceptable to the public if it is described by what it does, without any mention of AI technology.

AI technology is involved in the monitoring of financial transactions and in detecting credit card fraud in real time. AI technology is essential for the routing of mobile phone calls. Many online advice and help systems use AI technology in a perhaps more obvious way. Car, aircraft, and railway engines are often monitored by AI programs. These applications are just as likely to use connectionist approaches or a mixture of GOFAI and connectionist methods.

Internet search engines are examples of applied AI. Similarly, the attempt to get intelligent behavior from robots, although at an early stage, has resulted in a number of toys that can learn and in military robots that possess a useful degree of autonomy. It is difficult, if not impossible, to exhaustively list the applications of AI as engineering, simply because it pervades so much modern technology.

The Myth of AI Failure

Despite the fact that AI technology is all around us, a myth has developed both inside and outside AI that it is a failed project. This myth is completely false—AI has been remarkably successful as both science and engineering. There are, however, many reasons for the emergence of such a myth.

An important reason within the field of AI is the tendency to promise major breakthroughs on ridiculously short timescales. This has led to disillusionment in funding bodies and to a number of so-called AI winters, during which it has been difficult to continue research.

Also important in the emergence of the myth has been the often highly skeptical response of some philosophers. Many philosophers have been unimpressed by the engineering successes of AI. They claim that these achievements do not in any way compose "real intelligence." The philosophical arguments might be characterized as whether the word *artificial* in "artificial intelligence" has the same force as in artificial light, which is "real light," or as in artificial flowers, which are but a crude imitation and lack most of the properties of real flowers.

Philosophical Responses to AI

The Turing Test

The expression *Turing test* is applied to a game introduced in an article, "Computing Machinery and Intelligence," published in 1950 in *Mind*—one of the longest-established British philosophy journals. It was written in 1948 by Alan Turing, a mathematical genius who had spent the war years of 1939 to 1945 at Bletchley Park engaged in secretly breaking the German Enigma code. By 1948, Turing had moved to Manchester, where an electronic computer—arguably the first modern computer—had been constructed. At the time when he was writing "Computing Machinery and Intelligence," Turing was also engaged in writing a program code for this machine. Importantly, this article is therefore

a philosophical article written by a mathematician turned code breaker turned computer programmer.

In "Computing Machinery and Intelligence," Turing says he wishes to discuss the question "Can machines think?" However, since this question is too vague, he proposes replacing it with a game. This game he called "the imitation game." It involves three people in separate rooms. They can communicate only by typing messages to each other. In the original version, there are a man, a woman, and an interrogator whose gender is unimportant. The interrogator, as the name suggests, can ask any question of the other two participants. The objective of the game is for both the man and the woman to convince the interrogator that they are the woman. The woman will be answering truthfully, and the man will be typing things like "Don't listen to him, I'm the woman."

Now what would we say, asks Turing, if the role of the man in this game were to be successfully played by a machine? That is if, after 5 minutes of questions, the average interrogator would not be able to recognize that he or she was communicating with a machine at least 30% of the time.

If the time comes when machines can achieve this level of success in the imitation game, then, so Turing claims, people will be happy to describe such machines as thinking machines. The imitation game has become known as the *Turing test,* and many people think that achieving Turing's level of success in the imitation game is a test of whether or not AI has finally been achieved.

Turing thought that it was a matter of *when,* not *if,* we would make such machines. He confidently predicted that by the year 2000, digital computers would be able to achieve this level of success in the imitation game. This achievement would change public attitudes so that it would become normal to talk of "thinking machines." However, no computer is anywhere near good enough to succeed in the imitation game in the foreseeable future. One important problem in building a machine capable of winning the imitation game is that the interrogator may ask absolutely any question and that humans seem to be very good at detecting implausible answers.

Unfortunately, using the imitation game as a test of AI is highly misleading. It has often distracted AI researchers into human imitation and methods of deceiving people. Such imitation is not central to AI as either science or engineering. Nonetheless, Turing's article has become central to the philosophy of AI. A key philosophical principle introduced in this article is that of *functional equivalence*. If a computer produces responses that are indistinguishable from those of a human, then in everyday speech, we would be inclined to say that it can think.

The Chinese Room

A much-cited objection to the claim that computers could ever think is attributed to the philosopher John Searle and has come to be known as the "Chinese room" argument, after the thought experiment he proposes. Despite many criticisms, the Chinese room argument continues to be discussed after more than 30 years.

Searle purports to show that an appropriately programmed computer cannot think. This may turn out to be true as a matter of science—though it seems unlikely on present evidence. Searle does not wait for science to resolve the issue: He claims to be able to show by argument alone the impossibility of a machine thinking as a result of following a program.

He asks us to consider a room that gives reliable and plausible answers to questions in Chinese. What is interesting about Searle's room is its internal working. Inside the room is a comprehensive set of instructions (written in English) detailing how to respond to any input with Chinese symbols. He (Professor Searle) sits inside the room following the instructions and, thereby, can respond appropriately to any input question, though he does so without ever knowing what any of the symbols mean or what the questions are about.

Searle does not mention Turing's imitation game explicitly but clearly thinks he has performed a *reductio* on Turing. Even the capability of answering any possible question does not entail that the machine is thinking. It may be simply *appearing to think* by following a program.

Many people in AI have responded to this thought experiment over the years, but Searle remains obdurate, dismissing them as "all wrong." Some of those responding think that the "Chinese Room" needs to be put into a real robot in the real world—as in the third phase of AI.

The most frequently made response is called by Searle as "the Systems Response." The main claim

of this response is that although the Searle in the room does not understand Chinese, the system as a whole does understand Chinese. The systems reply is obviously wrong also, says Searle, because just as there is no understanding in the Searle in the room, there is no understanding anywhere else in the system either. The book of instructions is just a book, and the room is just a room. Nothing in the system understands Chinese any more than Searle does, so it's pointless to look for understanding in the system. It is arguable that Searle's obduracy is mistaken, because it has often been observed (at least as early as in Leibnitz) that no *part* of a thinking system has to be able to think. Understanding therefore is probably not to be sought in any *part* of the Chinese Room.

The Chinese Room argument has proved enduring. Some of the reasons for this lie in its appeal to our intuitions. We do not feel as if our thoughts are, or even resemble, following a program. Nor does it seem plausible, at first glance, that the richness of mental lives could ever be reproduced by a machine that follows instructions. The notion of a thinking machine remains controversial, despite the success of AI.

The Ethical Implications of AI

Philosophical responses to AI have concentrated on the conceptual issue of whether or not AI can be said to really think and whether or not the idea of making a thinking machine is conceptually coherent. For this reason, there has been much less attention paid to the ethical implications of the changes being brought about by the actual use of AI. The invisibility of successful AI technology also contributes to a lack of awareness of the social and ethical issues around AI.

There is now a growing interest in some of the pressing ethical issues being thrown up by AI. Consider, for example, the use of AI in medicine. Modern knowledge-based systems have been shown to be superior to human doctors in certain specialized areas. There is also evidence that psychotherapy is sometimes more effective if performed by a computer than if performed by a human therapist. It would be unethical to resist the introduction of AI in these areas. However, there are no clear ethical principles established for the design and use of such systems. As yet, there have been no criteria agreed on as to who should be held responsible when things go wrong.

There is now international concern about the use of autonomous military robots, with some authorities calling for a moratorium on their deployment. The use of robots in caring applications—for example, in child care—and in "smart homes" for elderly people also raises ethical issues that remain unresolved.

Austrian Economics

The Austrian school of economics owes its name to the German historical school critics of the works of the Viennese economist Carl Menger in the late 19th century. Ironically, Menger had thought his work was a contribution to the German-language scientific literature in economics and, in fact, dedicated his *Principles of Economics* to William Roscher, leader of the older German historical school. He even concluded his preface by stating that he hoped his work would be viewed as building on the developments in political economy among German scientists and thus welcomed as a friendly greeting from a collaborator in Austria. Menger did not offer this dedication with any cynical intent but in sincere appreciation.

But Menger's was a theoretical contribution, and in particular, it concerned the deductive nature of pure theory, whereas the members of the younger German historical school had thought themselves free of abstract theoretical systems of thought, which only hindered progress in the study of humankind and, more to the point, progressive reforms in public policy. Menger's defense of the necessity of a theoretical framework for doing empirical social science sparked off the *Methodenstreit* in German-language economics. It was during this dispute that the economic ideas of Carl Menger—methodological individualism, subjective utility theory, marginal analysis, dynamic competition, relative prices, and especially the defense of the deductive method—were dubbed "Austrian." The name "Austrian school of economics" has stuck ever since.

Origin and Development of the Austrian School of Economics

The main contributors to the Austrian school of economics taught or studied at the University of Vienna from the late 19th century until the upheavals in Europe caused by Hitler in the 1930s. The list of economists associated with the Austrian school during this period is very impressive and includes many that are today considered as some of the leading economists worldwide during their time: Carl Menger, Eugen von Böhm-Bawerk, Friedrich Wieser, Joseph Schumpeter, Hans Mayer, Ludwig von Mises, Fritz Machlup, Oskar Morgenstern, Gottfried Haberler, and F. A. Hayek.

Schumpeter was the first to move outside Vienna, and he also sought to distance himself from his educational pedigree. But Schumpeter's core ideas about entrepreneurship, dynamic competition, and creative destruction were intimately connected to the teachings of his Viennese mentors. Machlup, Morgenstern, and Haberler all migrated to the United States and established teaching careers at Johns Hopkins, Princeton, and Harvard in the 1940s. But it was Hayek's move to the London School of Economics in the 1930s and the central role he played there in both the debate with John Maynard Keynes and that with Oscar Lange over socialism that began to spread the teachings of the Austrian school of economics throughout the elite of professional economists in the English language. Von Mises was the mentor for Machlup, Morgenstern, Haberler, and Hayek back in Vienna, and they all worked on various aspects of von Mises's ideas. But von Mises's work was not widely available in English until the 1940s, after he migrated to the United States and started teaching at New York University.

The Modern Austrian School

The modern Austrian school emerged in the 1950s and was centered around von Mises at New York University. When Hayek moved to the University of Chicago in 1950, he was not located in the economics department but in the Committee on Social Thought, and his work during that period was focused on methodology, intellectual history, and political and legal theory and history. The modern Austrian school of economics took its inspiration from two books written in the late 1940s by von Mises and Hayek—*Human Action,* by von Mises, published by Yale University Press in 1949, and *Individualism and Economic Order,* by Hayek, published by University of Chicago Press in 1948. It was these presentations of the method and methodology of economics that would inspire the work of a new generation of graduate students in economics, who would pick up the label "Austrian economics" even though they had never taken a class at the University of Vienna.

The two leading figures of the modern Austrian school were Murray Rothbard and Israel Kirzner, who while earning their PhDs in the 1950s would make significant contributions to economic science

through the 1960s and 1970s. Rothbard, for example, published his own comprehensive treatise of economics in 1962, *Man, Economy and State,* while Kirzner published more focused monographs, such as *The Economic Point of View* in 1960, *Market Theory and the Price System* in 1963, and *An Essay on Capital* in 1966. Rothbard also branched out and wrote an economic history of the Great Depression—*America's Great Depression,* published in 1963—which countered the conventional wisdom that capitalism is inherently unstable and argued instead that the Great Depression was a consequence of government intervention and policy errors. Rothbard also wrote political theory tracts, most notably *For a New Liberty* (1973) and *The Ethics of Liberty* (1981). Kirzner, on the other hand, was more narrowly focused on economic theory, and his most famous work, *Competition and Entrepreneurship,* was published in 1973. Through these works and, of course, the still looming influence of von Mises and Hayek, a group of students began to express an interest in studying Austrian economics in depth and contributing to the scientific tradition. Rotbhard and Kirzner organized a conference in the summer of 1974 with the Institute for Humane Studies.

Recent Developments

Then in the fall of 1974, Hayek was awarded the Nobel Prize in Economic Science, and new attention was paid to both the historical contributions of von Mises and Hayek and the group of new scholars influenced by Rothbard and Kirzner, who were joining the ranks of professional economists through the 1970s and 1980s. In addition to this renewed scientific interest, events and the tide of public opinion had turned in a way that was more receptive to the basic laissez-faire message of classical economics and the Austrian school. The stagflation of the 1970s and the collapse of communism in the late 1980s brought new adherents to the Austrian school of economics and its critique of Keynesianism and socialism. Works such as Hayek's *The Road to Serfdom* and *The Constitution of Liberty* were invoked by both Ronald Reagan and Margaret Thatcher, and then by the postcommunist leaders in East and Central Europe and the former Soviet Union. PhD programs were established at Auburn University and George Mason University, and of course, New York University was still the center of activity. In addition, professional scientific journals were established as well as book series. A professional scientific society was established—Society for the Development of Austrian Economics—which hosts an annual conference with well over 100 participants from throughout the world.

And since 2008, the business cycle theory of the Austrian school of economics has often been invoked by critics of government policies of easy credit during the housing boom and the bailouts of the big banks, as the major alternative to the more politically acceptable Keynesian demand management theory. Major policy intellectuals have been quoted as saying that they read von Mises at the beach—a rather absurd claim since *Human Action* runs close to 1,000 pages and is a rather densely argued philosophical as well as technical economics tract.

Epistemological Issues

The Austrian school of economics has evolved significantly since the founding period at the University of Vienna, but the basic building blocks of methodological individualism, methodological subjectivism, and market process theory—all pursued following the deductive method—remain. Substantively, you can divide the contributions of the Austrian-school economists into three categories: methodological, analytical, and ideological.

Methodologically, the Austrian school stands in opposition to both the formalist and the empiricist transformation of economics that took place in the mid 20th century. Austrian economists, because they tend to focus their intellectual attention on phenomena that defy strict formalism, will rely on verbal reasoning rather than mathematical. One way to summarize this position is that for the standard mathematical models to hold, the phenomena being studied must be assumed to be smooth, continuous, and twice differentiable, in order to lend themselves to the conventional mathematical techniques employed by economists. But according to the Austrian economists, the world consists of behavior that is "lumpy" and "discontinuous." In that world, the most logically rigorous approach may defy the formalism of the method of simultaneous equations.

Analytically, the Austrian school stands in opposition to the equilibrium-always textbook presentations of general competitive equilibrium or partial

equilibrium comparative statics. Instead, the focus is on processes of adaptation due to constantly changing circumstances. It is this focus on change and process that explains the preoccupation with entrepreneurship among Austrian economists—as the entrepreneur is by definition the agent of change in an economic system and also the agent of adjustment to those changed circumstances.

Ideologically, the Austrian school is the most consistent within the modern profession of economics in adhering to the classical liberal political economy of limited government. The main lesson of the teachings of the Austrian school, from Menger to Hayek to Kirzner, is that the market economy within the framework of secure private property rights, freedom on contract, sound money, fiscal responsibility, and free trade is not only self-correcting but also the source of generalized prosperity and improvements in the well-being of mankind.

The Austrian school of economics continues to exist both as a scientific tradition within professional economics and as an iconic rallying call for free-market activism in the political arena. The two different strands do not always exist without conflict. But from Menger onward, the Austrian economists have been committed to the proposition that policy relevance is a virtue and not a vice in economic discussions. On the other hand, the Austrian economists are also mindful of Claude Frédéric Bastiat's warning that "the worst thing that can happen to a good cause is not to be artfully criticized but to be ineptly defended."

Bargaining Theory

Bargaining is a universal social phenomenon. It takes place whenever humans are engaged in "antagonistic cooperation" and have to negotiate agreements on matters such as prices, wages, and regulations concerning personal, group, and international relations. Bargaining parties have partly opposing interests and need to negotiate how to compromise them to the advantage of all concerned. Bargaining theories characterize potential agreements descriptively and normatively. When and why cooperation will break down and what will, or should, be the shares after it stops in (dis)agreement are particularly relevant issues.

This entry focuses on "normative" characterizations of rational bargaining, analyzes its essential features, and points out its ethical implications. It also raises the question as to what extent the ideal theory coincides with real-world situations.

As a special case that can be generalized to $n \geq 2$ individuals, imagine two individuals, A and B, negotiating over a set of feasible outcomes. If they fail to agree, the outcome will be the status quo that each can realize without the agreement or cooperation of the other. Let $u = (u_A, u_B)$ be the pair of "cardinal" utility functions representing the preferences of A and B, respectively. Let S be the set of all "utility pairs" associated with those states that can in fact be realized. Let $d = (d_A, d_B) \in S$ be the utility pair, also called disagreement point, associated with the status quo that emerges if no agreement is reached. Only if some state of affairs $(s_A, s_B) \in S$ exist such that $s_A > d_A$ and $s_B > d_B$, there is a "bargaining incentive" for both individuals, A and B.

If S is convex and compact, the pair (S, d) is called a *bargaining situation.* It represents the underlying bargaining problem in a two-dimensional space of von Neumann–Morgenstern, "vNM," utility functions. John Nash axiomatically characterized a unique *solution function* f assigning a solution $f(S, d)$ to all situations (S, d) in the relevant utility space. For each situation (S, d), it selects the maximum of the function $(s_A - d_A)(s_B - d_B)$ within the individually rational subset S of all utility pairs such that all individuals at least realize their disagreement levels.

Nash assumes that the preferences of both actors should fulfill the vNM axioms for the existence of a class of utility functions that represent preferences. Propositions formulated relying on any such function u must remain true for $a \cdot u + b$ with $a > 0$, as the axioms do not allow us to discriminate between functions within the class. Nash's first additional axiom—beyond those guaranteeing the existence of a vNM utility representation of preferences—requires that the function evaluating the joint results should pick the same result for any positive linear transformation of each individual's utilities (at the same time avoiding interpersonal comparisons of utility in characterizing the result). The second axiom requires for a symmetric (S, d) that the solution $f(S, d)$ have identical utility components. The third axiom demands weak Pareto optimality of the solution of each situation. For each (S, d), there is no feasible point in S that would make everybody strictly better off than the one selected as a solution of (S, d). Fourth, the requirement of independence of

irrelevant alternatives means that, for a given status quo *d,* if the solution of a larger problem *S* is also part of a smaller set *S'*, then what is the agreement in the larger one should be chosen as the agreement in the smaller set as well.

That the loss of alternatives that are good for some person will not change the outcome as long as the former agreement is still available does not seem as plausible as the other axioms. In parallel to Nash, Howard Raiffa was working on a proportional solution concept that was not independent of "forgone" alternatives. Some 20 years later, Ehud Kalai and Meir Smorodinsky introduced the "ideal point," the pair of maximal utility values for each person in the individually rational subset of *S*. Substituting Nash's fourth axiom with their own, they compare situations with identical status quos and identical ideal points and require a monotonic reaction of agreement outcomes on enlargements of the feasible set. For the two-person case, they uniquely characterized a solution function on *S*. The selected solution point on the boundary of *S* has the property of assigning equal relative gains compared with the maximal gain between the status quo and the ideal point to both players, and these relative gains are maximal in *S*.

There is a wealth of spin-offs of the original approach. For instance, John Harsanyi has shown that in Frederik Zeuthen's model of concession making in negotiations, the concession process converges toward the Nash solution. David Gauthier used a different definition of a concession, where the ideal gain between status quo and ideal point is always in the focus when sizes of concessions are compared. He argues that rational players will compare and make concessions such that the process of stepwise concessions will converge toward the Kalai–Smorodinsky solution.

An examination of the normative justification of the axioms used in characterizations of bargaining solutions has obvious relations to ethical and other normative philosophical issues. At the same time, one may ask to what extent real-world bargaining empirically coincides with the ideal theory and how well, in particular, empirical processes of stepwise concession making cohere with, say, the Zeuthen–Harsanyi approach or, alternatively, aspiration adaptation and satisficing models. The project of modeling all the minute details of bargaining explicitly in noncooperative game theory and experimentally testing behavioral assumptions against the background of normative ones is still unfinished. Perhaps most extensively, so-called ultimatum bargaining has been used to check on the validity of the classical model of rational economic man in interactive decision making in the laboratory and in the field.

Bayesianism, Recent Uses of

Bayesianism, named after Thomas Bayes (1702–1761), is a family of related approaches in epistemology, philosophy of mind, Decision Theory, and statistics. In epistemology, philosophy of mind, and Decision Theory, Bayesians use probability theory to

represent rational agents' degrees of belief. In epistemology, Bayesianism is both a movement in its own right and a methodology for approaching various traditional problems. In statistics, Bayesianism is a view about statistical inference. It has been influential in most of the sciences and the social sciences, as well as in financial calculations, where probabilistic and statistical methods are standard.

The following section of this entry discusses Bayesian approaches to epistemology and philosophy of mind; the next section canvases Bayesian approaches to statistics; and the final section briefly surveys some applications of Bayesianism in the social sciences.

Bayesianism in Epistemology and Philosophy of Mind

In epistemology and philosophy of mind, Bayesianism's central tenet is that uncertainty should be represented probabilistically. While there are some intramural disputes, most Bayesians in these fields maintain that rational beliefs come in degrees that obey probability theory, beginning with a "prior" probability function before any enquiry and updating by repeatedly applying a particular rule as evidence comes in. As such, the view is associated with the "subjective" interpretation of probability (as opposed to "objective" interpretations such as frequentism).

Bayesians claim that rational degrees of belief obey probability theory. Probability theory imposes axioms on a *probability function P:* It is nonnegative, has a maximum value of 1, and is additive ($P(X \text{ or } Y) = P(X) + P(Y)$ if X and Y cannot both occur). For example, we might represent your uncertainty about how a fair die toss will land with a probability function P that assigns 16 to each of the 6 faces landing up, for which $P(\text{even number}) = P(2 \text{ or } 4 \text{ or } 6) = 16 + 16 + 16 = 12$.

The *conditional probability of X given Y* ($P(X \mid Y)$) is given by the ratio of unconditional probabilities:

$$P(X \mid Y) = PX \text{ and } YPY, \quad \text{provided } P(Y) > 0.$$

Thus, the conditional probability that the die lands 1, *given* that it lands odd, is 1/3:

$$P(1 \mid \text{odd}) = 1/3.$$

Suppose that your initial probabilities are given by P_{initial} and that you become certain of an event E (and of nothing more). What should be your new probability function, P_{new}? Bayesians favor updating by *conditionalization:*

$$\text{Conditionalization} \quad P_{\text{new}}(X) = P_{\text{initial}}(X \mid E), \quad \text{provided } P_{\text{initial}}(E) > 0.$$

For example, if you become certain that the die landed odd, your new probability for the die having landed 1 should be 1/3.

A famous result in probability theory is *Bayes's theorem:*

$$P(H \mid E) = P(E \mid H)P(H)/P(E).$$

H is a *hypothesis* and E, some *evidence*. $P(E \mid H)$ is the *likelihood*, and $P(H)$ and $P(E)$ are the *prior* probabilities. Bayes's theorem is often a convenient way to calculate the conditional probabilities that are required by conditionalization; thus, it is usually regarded as a cornerstone of Bayesianism. We stress, however, that Bayes's theorem is not *itself* an updating rule but rather a constraint on probabilities assigned by a single probability function or by an agent at a single time.

The picture of an ideally rational agent who assigns probabilities to various states of affairs, and who conditionalizes on the evidence as it comes in, goes back to F. P. Ramsey, Leonard J. Savage, and Bruno de Finetti. They also developed *Bayesian Decision Theory.* A rational decision is an action that maximizes *expected utility,* a weighted average of the payoffs associated with the action (for each possible state of affairs), the weights provided by the corresponding probabilities. These and other Bayesians have argued that an agent who violates Bayesianism's tenets will be susceptible to making bad decisions. *Objective* Bayesians impose further constraints on the agent's prior probabilities.

Bayesianism in Statistics

Bayesianism is an important and increasingly widespread view in statistics.

Suppose that we are interested in whether, and to what extent, a particular coin is biased toward heads and that we entertain various hypotheses about its bias. Suppose that we flip the coin 10 times, observing that it lands heads 7 times. What can we say about the probabilities of the various bias hypotheses, given these data? This is a question about statistical inference.

A Bayesian statistician begins with a *prior* probability distribution, before incorporating the data in question. (Note that this probability distribution need not be interpreted as any rational agent's degrees of belief, so a Bayesian statistician need not adopt a Bayesian philosophy of mind!) The prior might be based on the shape of the coin, previous observations of similar coins, and so on. This prior assigns some probability to each hypothesis regarding the coin's bias, and a likelihood for the actual data, given any particular such hypothesis. The prior is then combined with the data to obtain a *posterior* probability distribution—a synthesis of the two. (Bayes's theorem is typically used here.) Given a particular data set, a hypothesis has high posterior probability to the extent that (1) it has high prior probability and (2) the actual data are likely according to that hypothesis. The Bayesian statistician thus arrives at posterior probabilities for the hypotheses given the observed data.

The Bayesian approach to statistics is criticized for its reliance on prior probability distributions. Without clear guidelines about how to construct priors, the criticism goes, statistical inferences are too subjective. Bayesians counter this by attempting to provide the desired guidelines, by embracing the subjective nature of statistical inference, or by using data sets so large that all reasonable priors converge to similar posteriors. The main alternative to Bayesian statistics is *classical statistics*. In recent decades, improved computation has facilitated the increasingly widespread use of Bayesian techniques.

Bayesianism in the Social Sciences

The social sciences are largely concerned with human behavior. As such, they provide natural applications for Bayesian Decision Theory. Its early roots were in economics, and it continues to be influential there. Moreover, it complements *game theory*, the theory of strategic decision making by multiple agents in situations in which their profile of payoffs depends on what all the agents do individually. While John von Neumann and Oskar Morgenstern's seminal 1944 book *Theory of Games and Economic Behavior* assumed that all the relevant agents have the same probability distribution, Johann Pfanzagl in 1967 offered a Bayesian generalization by axiomatizing subjective probability and utility in their framework. Bayesian game-theoretic modeling is similarly important in political science, for example, in institutional design, voting theory, and auction theory (e.g., modeling electoral competition as an auction).

More generally, probability and statistics play an indispensable role in many branches of science and social science. As such, Bayesian methods are applied to areas as diverse as physics, biology, law, and sociology. Bayesian methods are also used as a tool for theory choice across the sciences and social sciences.

Bayesian networks (also known as directed acyclic graph models) provide a neat and intuitive way of representing causal relationships. They have a tremendous range of applications and are of particular use in modeling complex systems such as economies and the Internet. Bayesian networks are also used to develop management systems in a wide range of public policy areas, from water resource management to nuclear proliferation.

Bayesian models are often criticized for being highly idealized. In psychology, a large literature, pioneered by authors such as Ward Edwards and Herbert Simon, has explored how fruitfully these models may be deployed to understand actual human agents. A lively debate has raged over the extent to which we fall short of Bayesian ideals—Daniel Kahneman, Amos Tversky, and Gerd Gigerenzer have been the leading protagonists. Accordingly, some Bayesians have relaxed the traditional framework—for example, allowing degrees of belief to be imprecise, rather than sharp numbers. More recently, a trend has emerged of constructing Bayesian models of learning and cognition. For example, they have been used in psychology and linguistics to model language learning.

Behavioralism in Political Science

The behavioral movement, sometimes referred to as the behavioral revolution, was an important aspect of American political science during the 1950s and 1960s. It presented itself as a challenge to what it characterized as traditional and institutional approaches to the study of politics, and it became a contentious but increasingly ascendant position in the field. Despite its avowed commitment to a value-free stance, it continued to reflect the liberal democratic values embedded in what Bernard Crick had famously characterized as the American science of politics, in his 1958 book of that title. The term *behavioralism* was adopted by political scientists after a group of social scientists at the University of Chicago, who were devoted to developing a general scientific interdisciplinary study of human behavior, coined, in 1949, the label "behavioral sciences." The term was intended to suggest an attitude of scientific objectivity and, unlike "social science," to allay a persistent worry, revived during the Cold War, about confusion with the ideology of socialism. Although the term related to a long-standing interest, among Charles Merriam, Harold Lasswell, and others in the Chicago school of political science, in the psychological bases of politics, it did not signify any direct association with the theory of behaviorism.

Pendleton Herring, who became president of the Social Science Research Council in 1948 and who advocated the scientific study of political "behavior," had, since the 1920s, been a significant contributor to what was conceived as an empirical theory of pluralist democracy. This theory had emerged during the first quarter of the 20th century, and Herring, on the eve of World War II (in *The Politics of Democracy,* 1940), had stressed the need to ground democratic values in a scientific descriptive account of politics. This theme persisted during the early behavioral era in the work of individuals such as David Truman (*The Governmental Process,* 1951) and Robert Dahl (*Preface to Democratic Theory,* 1957; *Who Governs,* 1960), who not only advocated a more scientific mode of inquiry but also presented strong defenses of pluralist, or what Dahl referred to as "polyarchial," democracy in the United States and other Western societies.

David Easton, who came to Chicago in 1948 after finishing his degree at Harvard, became a principal theorist of the behavioral movement and the primary exponent of systems theory in political science (*A Systems Analysis of Political Life,* 1965). The first significant statement of the behavioral position was his 1951 article "Decline of Modern Political Theory," in which he criticized the "poverty" of theory in the discipline and ascribed this condition to absorption with the study of the history of past ideas and the consequent failure to take on the "task of building systematic theory about political behavior" as well as advancing relevant value theory. In 1961, Dahl claimed that the "behavioral approach" represented a "successful protest" against "conventional political science" and the work of speculative theorists, historians, legalists, and moralists and that it involved a "mood" or "outlook" that emphasized empirical modes of investigation and a focus on what

"is" as opposed to what "ought" to be. This sentiment was again apparent in Easton's 1962 statement of "The Current Meaning of 'Behavioralism,'" in which he defined it as a "science of politics modeled after the methodological assumptions of the natural sciences" (p. 17). Among the other "tenets" of the behavioral "credo" were a distinction between ethical claims and "empirical explanation" and the assumption that the achievements of "pure science" should precede the practical application of the knowledge. In the 1968 edition of the *International Encyclopedia of the Social Sciences,* Easton noted that "the methods of modern science had made deep inroads into political research, under the rubric of the study of political behavior" (p. 1295), which involved a sharp break with the past, the accumulation of large amounts of empirical data, the introduction of theoretical coherence, and a clear distinction between factual and normative claims.

A general commitment to a scientific study of politics was not an innovation in American political science, but the available philosophical accounts of science, often derived from the literature of American pragmatism, had been less than systematic, and in practice, a scientific approach often amounted to little more than data collection and the application of quantitative techniques. By midcentury, European scholars such as Rudolf Carnap and Carl Hempel, who were among the founders of the philosophy of logical positivism, had immigrated to the United States and offered a highly structured defense of the unity of science and a reconstruction of the logic and epistemology of science. This work gained hegemony in the literature of the philosophy of science, and often in secondary derivations, it served as a model for political scientists who sought both the authority of science and a guide to scientific practice. Beginning at least with Lasswell's collaboration with the philosopher Abraham Kaplan in the 1950 work *Power and Society,* it was apparent that what behavioralists meant by "science" pivoted on the positivist paradigm. For Lasswell and Kaplan, however, the purpose of pursuing a scientific study of politics was still, as for an earlier generation, to achieve the kind of epistemic credibility that would serve to bring "political theory and practical politics into closer harmony." This image of science was, however, vigorously opposed by numerous critics, including émigré scholars such as Leo Strauss and members of the Frankfurt School. The critics challenged the ideology of liberalism embedded in the behavioral program as well as what they charged was the manner in which scientism had led both to moral relativism and to a failure to confront contemporary political issues.

Only a year after his affirmation of the dominance of behavioralism, Easton, in his 1969 presidential address to the American Political Science Association, responded to the critics and announced a "new" or "postbehavioral" revolution in political science that sprung from a "deep dissatisfaction with political research and teaching, especially of the kind that is striving to convert the study of politics into a more rigorously scientific discipline" (p. 1051). Easton did not abandon the basic principles of behavioralism but instead called for a different distribution of emphasis whereby the pursuit of "the discovery of demonstrable basic truths about politics" would, in the short run, be subservient to the application of currently available knowledge to the "problems of the day." This new "policy turn" had begun, however, to fade by the end of the 1970s, and the underlying methodological agenda of behavioralism continued significantly to inform the future evolution of the field.

Behaviorism, Philosophical Conception of

According to behaviorism, everything there is to know or say about people with regard to their mental states can be known or said in terms of their observable behaviors (including verbal behaviors), and furthermore, all there *is* to mental states themselves are certain patterns of behavior or dispositions to behave. There are three core claims of behaviorism: (1) an epistemological claim (mental states are knowable only via behavior), (2) a semantic claim (mental-state words like *belief* have meanings definable in terms of behavior), and (3) a metaphysical claim (either there are *no* mental states, just behaviors and dispositions to behave, or there *are* mental states but they are identical to behaviors or dispositions to behave). Behaviorism as a movement in philosophy overlapped partially with a movement of the same name in psychology. This entry discusses philosophical behaviorism by discussing its history and some of the major arguments, both pro and con.

History of Philosophical Behaviorism

Philosophical behaviorism emerged from logical positivism and ordinary-language philosophy. Positivists believed in verificationism, according to which the meaning of a term is given by specifying the observable conditions that would verify its application. Ordinary-language philosophers were suspicious of philosophical theses, such as dualism, that were not stated in the terms of ordinary language. In the philosophy of mind, especially in the 20th century, many philosophers saw behaviorism as a viable early contender for a materialistic solution to the mind–body problem. Few contemporary philosophers of mind attracted to mind–body materialism subscribe to behaviorism, preferring instead one of its successors, such as functionalism and the mind–brain identity theory. While controversy surrounds applying the label of "behaviorist" to the philosophers who are often cited as being behaviorists, such citations occur frequently enough to merit mentioning as key behaviorists the philosophers Gilbert Ryle, Ludwig Wittgenstein, W. V. O. Quine, and Daniel Dennett.

Motivating Behaviorism

The private-language argument from Ludwig Wittgenstein's *Philosophical Investigations* has behavioristic conclusions. Wittgenstein attacked the alleged privacy of mental states. The conclusion of Wittgenstein's argument is that it is impossible for there to be a language that referred only to private things: a language about sensations that could only be understood by a single person. Suppose you devise a language in which there is a sign, "S," that you intend to stand for a particular sensation. According to Wittgenstein, no one, not you or anyone else, can distinguish between a correct usage and a mere *seemingly correct* usage of "S." However, where one cannot grasp a distinction between correct and incorrect uses, there is no place for a notion of correctness at all. Thus, "S," as well as the rest of the signs in this so-called private language, is meaningless.

Another line of thought with behavioristic conclusions is based on the verificationism central to logical positivism, according to which terms are defined by the evidence for their correct application. Given that the main evidence we have for correctly applying terms like *belief* and *desire* is behaviorial, verificationism entails that the meaning of such terms is definable in terms of behavior.

Against Behaviorism

One objection to behaviorism hinges on qualia, the subjective aspects of our conscious mental states, especially sensory states like seeing a red rose. If behaviorism is true, then it ought to be inconceivable for two beings to share all their behavioral dispositions but to differ in what qualia accompany their sensory interactions with roses (e.g., the way roses look to one differs from the way they look to the other). However, since such a situation is conceivable, behaviorism is false.

A second objection to behaviorism is based on the claim that it is part of our concepts of mental states that they can serve as causal explanations of behavior. For instance, one's opening of a refrigerator is explained causally by appeal to one's beliefs and desires (e.g., a desire to drink beer and a belief that there is beer in the refrigerator). However, by defining "belief" and "desire" by reference to such behaviors, behaviorism renders such explanations unacceptably circular.

A third objection to behaviorism is based on the claim that mental states cannot be individually connected with behaviors but can only be connected to behaviors in concert with other mental states. Whether a person's desire to avoid tiger attacks will result in her running away from a tiger instead of toward it (or not running at all) depends on her beliefs about where the nearest tiger is and whether it is more likely to attack a stationary person or a running one. The problem is that the project of saying which behavior a mental state is connected to is so complicated as to be totally intractable. Worse, the project of behavioral definition is thereby shown to be circular. Each mental state can only be connected to behavior by reference to other mental states, including the mental state that we started with, and thus we are led in a circle.

A fourth objection is the *perfect-actor* objection. For any set of behaviors one might engage in while in a mental state, a perfect actor can perform those very same behaviors without being in that mental state. Well-trained actors know techniques to help them appear sad even when they aren't actually sad. Thus, for any given mental state, no set of behavioral dispositions is essentially associated with it.

Behaviorism in Psychological Explanation

In 1890, America's first great psychologist, William James, famously proclaimed psychology to be the science of mental life, whose main aim is to determine the correlation of various kinds of thoughts and feelings with brain activity. Despite the prominence of James's proclamation, a competing school of psychology—*behaviorism*—emerged less than a quarter of a century later, which represented a seismic shift away from psychology as a science of mental life and toward a science of overt action.

From Consciousness to Behavior

No matter how compelling conscious mental experience was to James, rival theorists such as Ivan P. Pavlov, H. S. Jennings, and John B. Watson deemed such personal experience to be as useless as data for a scientific psychology as it would be for physics or chemistry. Why? It is not because behaviorists flatly deny the very existence of consciousness; rather, it is because they believe that private experience cannot be the proper subject of public science. In an oft-quoted expression, the mind is considered by radical behaviorists, like B. F. Skinner, as a "black box" in the sense that an alleged "internal" or "private" psychological entity, such as a conscious mind or its neural workings, could not be studied by science proper.

Can I see it? Can I measure it? Can I repeat my results? These three questions were to become a veritable mantra to Pavlov and his students in the aftermath of their initial, futile attempts to provide a "psychical" account of what they later termed conditioned reflexes. A natural science of behavior could not indulge the naive interpretation of animal behavior in terms of conscious human experience; what was necessary to explain both human and animal behavior was an objective account that sought the physiological mechanisms of what Pavlov called "higher nervous activity."

From Humans to Animals

It is surely no accident for the development of behaviorism that Pavlov, Jennings, and Watson had all assiduously studied the behavior of animals. With introspection thereby taken off the methodological table, overt behavior would have to be the focus of psychology as a natural science. So for behaviorists, the objective processes in behavior became of greatest interest in their own right. Discovering general laws of behavior—in both humans and animals—with the methods of natural science became the goal of behavioristic psychology.

Behaviorists saw this extrapolation of psychological science to animals to be especially important. It not only broadened the scope of scientific inquiry, but it also suggested that evolutionary principles of behavior might be as effectively applied to humans as to animals. This evolutionary extension was also controversial because it undermined the orthodoxy of the Cartesian belief that humans differed dramatically from all other animals. From a behavioristic perspective, it would no longer do to explain human behavior in mental terms and to explain animal behavior in physical terms. Only by objectively comparing the overt actions of both humans and animals can we effectively ascertain whether there is a continuity or a gulf between them. Charles Darwin unlatched the door to the possibility of "continuity" between humans and animals. Behaviorists flung it wide open and set their sights on collecting unimpeachable empirical evidence to rule on this provocative possibility.

From Theory to Practice

Behaviorists have been motivated not only by theoretical concerns but by practical problems as well. How might abnormal and ineffective human behaviors be best comprehended and remedied? Behaviorists have responded by carefully determining the origins of these behaviors and by devising ways of adaptively modifying the behaviors. Initially, Pavlov and Watson and, later, Skinner applied the principles of behavioral analysis to improving the human condition.

For example, behavior therapy seeks to alleviate behavioral dysfunctions by modifying the controlling conditions. Effective treatments for anxiety, enuresis, self-injurious behavior, stuttering, bulimia, depression, insomnia, and many other disorders have arisen from the basic scientific research of behaviorists. Also, applied behavioral analysis has proven to be successful in preventing the transmission of AIDS, promoting industrial safety and seat belt use, conserving natural resources, reducing littering, improving educational practices, and encouraging health and exercise.

Criticisms and Rejoinders

Despite these many important theoretical and practical achievements, many psychologists and philosophers now insist, as they have for several decades, that behaviorism is dead. Yet, much like Mark Twain's premature obituary, "the reports of behaviorism's death are greatly exaggerated."

What are these alleged failings, and why might they not be true?

Critics often contend that behaviorism offers an impoverished view of the individual and society, with no place for perceptual, cognitive, emotional, and spiritual mechanisms. In particular, how can any science of mind ignore consciousness? Behaviorists counter that objective science must deal with the observable. Such a focus may set aside spiritual and metaphysical matters, but the study of perception, cognition, and emotion remains very much on the table when viewed as behavior rather than as personal experience. Indeed, notable progress has been made with advanced behavioral methods in understanding the mechanisms of perception, cognition, and emotion in both humans and animals.

Another complaint is that many of our distinctively human qualities, like language, have an innate foundation; because behaviorism focuses on acquired actions, it can say little about many of those mental attributes that so decidedly distinguish us from animals. This claim too is incorrect. Even in its infancy, behaviorism appreciated the intricate interplay between ontogeny and phylogeny in the behavior of both humans and animals. Indeed, the very notion of innate behavior is undergoing a systematic reanalysis in light of recent research in developmental psychobiology.

A further rebuke is that behaviorism, as a deterministic approach to psychology, makes people into automatons lacking free will. Of course, humans and animals are subject to many illusions: Free will may be the most compelling. More to the point, behaviorists not only accept that life offers organisms

innumerable choices in behaviors and reinforcers, but they believe that there are lawful regularities in those choices that can be scientifically discovered. We surely are a long way from being able to say at any given time which of several choices an organism will make, but the hope is that a science of behavior is learning to predict such choices with increasing accuracy. What scientific strategy would critics propose instead?

In summary, behaviorists contend, "We are what we do." Understanding why we do what we do is the scientific quest.

Being-in-the-World

"Being-in-the-world" (*In-der-Welt-sein*) is the term of art coined by Martin Heidegger in his 1927 magnum opus, *Being and Time,* to describe the kind of existence specific to us, namely human beings, whom he calls *Dasein* (an otherwise ordinary German word meaning "being" or "existence").

The philosophical significance of Heidegger's use of these terms rests on two original and controversial claims. The first is what he calls the "ontological difference" between "entities" (*das Seiende*) and "being" (*das Sein*). Entities are whatever can be said *to be.* By contrast, that *in virtue of which* an entity is an entity, and that on the basis of or in terms of which we understand an entity to be, is its being. Heidegger's reason for drawing this distinction is to insist that being is not itself an entity and so cannot be investigated in the way the natural and human sciences investigate their objects. The question of being belongs exclusively to philosophy.

The second philosophical innovation behind Heidegger's introduction of the term *being-in-the-world* is his insistence that there are not just one but several ways or modes of being. That is, not only are there many things, and indeed many different kinds of things, but also several distinct and irreducible kinds of existence: What it means *to be* is not the same for everything that can be said to be. So, for example, what it means to be an "occurrent" (*vorhanden*) object (a stone, a tree, a molecule, a planet) is simply to be present at some particular point in time. By contrast, what it means to be an "available" (*zuhanden*) tool or piece of equipment (a shoe, a chair, a train, a coin) is to be useful in some practical context. Something's being *available* for use, Heidegger argues, is not just a special case of its being *occurrent* and then also having some special set of use properties added on. Rather, *being* available and *being* occurrent are two fundamentally different ways of being.

Dasein is neither occurrent nor available. Human beings are neither objects nor functional systems with human features in addition. More generally, a

human being is not a *what* but a *who*. For a human being to be is for it to inhabit a social and historical world in which it has intelligent skills to attend to things, orient itself, move, and undertake actions. The human being is a *being-in-the-world* (for which Heidegger also uses the German word *Existenz*). The central thesis of *Being and Time* is that each kind of being is intelligible in terms of its own kind of time—the instantaneous *now* for occurrent entities (as measured by clocks, for example) and the situational, pragmatic *now* for available things (time to eat, time to sleep). Human existence is temporal in a way fundamentally different from either of these two, for we are not confined to a discrete *now* or even to a flowing sequence of past, present, and future *nows*. Instead, our existence consists in our always having a future, understood as a horizon of possibilities into which we are constantly pressing or "projecting," thinkingly or unthinkingly, and a past, understood as the *already* of the given situation that we are "thrown" into, willingly or unwillingly.

Dasein's future-constituting possibilities are disclosed to it in what Heidegger calls "understanding" (*Verstehen*), by which he means competence or *know-how,* which includes not just intellectual capacities but also bodily skills, such as the ability to hammer a nail or ride a bicycle. Cognitive *knowing-that* is derivative of and dependent on practical and existential understanding. In addition to its propositional beliefs and judgments, we always have a pretheoretical, noncognitive understanding of our world, of our projects and commitments, and of ourselves and our being. *Dasein's* existential understanding embeds it in a practical world structured by a teleological significance constituted by means, goals, and ultimate meaning-giving ends, the point or "for-the-sake-of-which" we do what we do. The "world" of being-in-the-world is thus not a mere collection of objects but a familiar place where one can live or "dwell" (*wohnen*).

In addition to our projective understanding, we also have moods and emotions. That is, we are always affectively attuned to ourselves and to our world as an already constituted situation into which we are thrown. *Dasein* is exposed to its "thrownness" not by understanding but by mood or affect, which Heidegger calls "disposedness" (*Befindlichkeit*). Crudely speaking, whereas projection is active, thrownness is passive, and neither dimension of being-in-the-world is reducible to the other. Certain fundamental moods—above all, "anxiety" (*Angst*), but also joy and boredom—reveal the world to *Dasein* as a whole, including itself and its own being.

Human existence is also essentially social: Being-in-the-world, Heidegger maintains, is always also "being-with" (*Mitsein*). The philosophical problem of solipsism and other minds is a perverse effect that is misconceiving of *Dasein* as a "worldless" epistemological subject. We do not encounter others as alien subject–object anomalies in our own solitary world; instead, our most basic self-understanding is already an understanding of ourselves as among others and as defined by social norms. The world, Heidegger says, is always deeply articulated by "the one" or "anyone" (*das Man*) of normal, appropriate thought and behavior: That is, for the most part, we do what "one" does.

Being-in-the-world is also essentially "being toward death" (*Sein zum Tode*). Death in the existential sense is not an accidental occurrence that takes place at the end of our lives but a collapse of meaning and possibility that Heidegger believes is essential to the finitude of our existence throughout the duration of our lives.

Heidegger argues that the meaning of being-in-the-world is "care" (*Sorge*). For human beings, to be just is to care about something, for something to matter to us, that is, to be affected in mood and to project into the world as a domain of significance. Taking his inspiration from Heidegger, Hubert Dreyfus has criticized research on artificial intelligence by arguing that computers cannot exhibit anything like human understanding as long as they lack bodily skills and affective care.

Dasein can exist either "authentically" or "inauthentically," that is, either *owning up* to or fleeing from and effectively *disowning* its situation and itself in alienation and social conformism. "Authenticity" (*Eigentlichkeit*) involves what Heidegger calls "running forth into death," which means not suicide but embracing one's finitude in "resoluteness" (*Entschlossenheit*), or wholehearted commitment to what one cares about.

Biology and the Social Sciences

This entry charts the historical and thematic development of the conceptual relationship between biology and the social sciences.

Before World War II

Social science in the contemporary institutional sense began in the last decades of the 19th century. Of course, numerous philosophers and others before that time had thought systematically about the structures of human social interactions. Many, including Plato and Aristotle, appealed to biological models and metaphors in doing so. Before the invention and spread of industrial manufacturing, organisms with their specialized but integrated parts were the only kinds of objects that seemed to parallel human societies in functional complexity. Thus, before the industrial revolution, organic conceptions of society that depicted certain common forms, such as cities, as natural—rather than conventional or engineered—were dominant. The most influential model of this kind was that of Bernard Mandeville, whose *Fable of the Bees* (1705 and 1714) is generally regarded as an early literary expression of the idea of the invisible hand that preserves social order and economic productivity in ways that no individual intends or deliberately tries to produce. It is only when the world began to be economically dominated by production using industrial machinery that increasing numbers of thinkers started depicting unsocialized individuals as natural and social institutions as artificial constructions.

Social reflection also had an important reverse influence on biological thinking. The most important single stimulus to Charles Darwin's recognition of evolution by natural selection, the great organizing principle of all modern biology, was the work of the demographic theorist Thomas Malthus. In 1826, Malthus argued that human population was limited by the finite food-carrying capacity of available land and that lives would become miserable as this limit was approached. Darwin noticed that this reasoning implied competition and that less successful competitors would tend to be extinguished under the resulting selection pressure, taking with them the features that made them less competitively successful. If resources remained finite, such competitive pressure would always operate even if each generation were more efficient in resource utilization than the preceding one. Thus, Darwin concluded, both the natural and the social ecologies would tend to continuously evolve.

This Darwinian conception then fed back into social thinking. Social Darwinists, such as A. R. Wallace and Herbert Spencer, and normative organicists, such as Ernst Haeckel, maintained that winners of competitions to dominate society by commercial or political advantage thereby tended to improve society, just as the so-called selection of the fittest drove improvements in the adaptedness of successive plant and animal species. In this view, they misunderstood the more careful Darwin, who saw that natural selection was not necessarily a force for qualitative progress if environments continuously change, as they do. Darwin's understanding was too subtle for most nonbiologists, and so his science was widely invoked in the early 20th century by social reformers, both well-intentioned and otherwise, who promoted eugenics policies aimed at discouraging supposedly "inferior" kinds of people from reproducing.

Antibiology Backlash

The most extreme version of eugenics was practiced during World War II, when the Nazi leadership of Germany set out to exterminate whole populations of people—mainly Jews—whom they believed to be biologically distinctive from themselves and, on that basis, to also be morally inferior. The Japanese military government adopted a similar view and policy

with respect to the Chinese and others in Asia whom they briefly conquered. These terrible events, based partly on rampant confusion about human biology, led to a backlash in the years following World War II against all appeal to biological models or influences in conceptualizing the structure of society or the forces that drive social change.

This initial negative basis for a turn toward promoting the complete independence of the social from the biological was complemented by a positive idea from the ideological left. Some biologists in the Soviet Union had promoted the thesis—based on no sound evidence—that changes in the capacities of an organism could be inherited by its offspring. This encouraged optimism about the pace at which enduring revolutionary changes in human behavioral tendencies could be effected. Although this outright denial of basic Darwinism died with the Soviet leader Joseph Stalin in 1953, many promoters of radical social restructuring throughout the world continued to urge the autonomy of the social from the biological. This rested partly on misconceptions about nonhuman animals that were widespread among social scientists until comparatively recently: that such animals are genetically programmed to exclusively promote their individual welfare, that their social responses are stereotyped and shallow, and that there is little personality or other psychological variation among the members of any given nonhuman species. Thus, all the key preconditions for dynamic cultural and political change were widely considered to be missing in the biological domain.

Sociobiology and Evolutionary Psychology

The above reasoning takes optimism about humanity's capacity for change as an assumed premise. In the mid-1970s, a number of thinkers, including most famously the entomologist E. O. Wilson, called this optimism into question by drawing attention to numerous ways in which human habits seem to be anchored to, and to be explicable only by reference to, fitness maximization of social ground-dwelling apes. For example, humans seem intractably inclined to tribalism, the tendency to strongly favor small groups of genetic relatives and associated friendship networks, even in circumstances where more cosmopolitan attitudes would be more generally advantageous. During the decades since Wilson's promotion of this idea, it has been greatly enlarged upon through laboratory experiments conducted by behavioral economists. Combining testing methods from psychology with the use of monetary incentives special to economics, these researchers have examined the extent to which people identify self-interested rational solutions to strategic and other optimization challenges when forced to use their innate cognitive resources in relatively isolated and novel settings. The result has been a parade of respects in which people typically fall back on standard routines that are not ideally targeted to the unfamiliar tasks but that would make sense as evolved built-in biases given the ranges of problems that might have confronted our earlier hominid ancestors on the African savannah of the Pleistocene era.

Sociobiology was received as intensely controversial, not only scientifically but also politically and morally. This was partly because it seemed to imply limits on the transformability of society, but also more specifically because it could be taken as suggesting that some distinctions between the social roles of men and women are natural and permanent rather than culturally constructed and subject to intentional reform. These controversies continue, often under the label of the "nature/nurture debate." However, complete rejection of the idea that at least some statistically prevalent human behavioral dispositions and forms of social organization have their roots in the circumstances of hominid biological evolution is now seldom heard or taken seriously by most social scientists. At the same time, the label *sociobiology* has itself faded from usage. Since the 1990s, Wilson's methodological successors have referred to themselves as *evolutionary psychologists*. The main difference they emphasize in this rebranding is that they are clearer in distinguishing past adaptiveness of evolutionary biases from present normative functionality. (Arguably, Wilson was always equally clear about this.) More substantively, evolutionary psychologists develop their hypotheses on the basis of models of mental architecture from cognitive science. The human mind, they suggest, is not an all-purpose, rational problem-solving engine but a collection of special-purpose computers ("modules") that are activated to guide behavior through particular tasks cued by environmental triggers—especially social triggers. Failures of optimization are often diagnosed on the basis of imperfect integration among, or outright conflict between, these modules.

This picture of the mind is far from a consensus view. Some philosophers and social scientists argue that much of the supposedly discrete inner structure inferred from behavioral evidence by evolutionary psychologists involves projection in the wrong direction and, in fact, represents the recurrent sculpting of response patterns by strongly entrenched cultural articulation, to which individuals adapt during socialization. In effect, both the "nature" and the "nurture" sides of the debate have been driven by their dialectic to increasingly emphasize complexity: complexity of mental organization on the "nature" side and complexity of social structure on the "nurture" side.

Evolutionary Social Science

Despite their differences, both evolutionary psychologists and their critics tend to agree that evolutionary processes are critical to successful explanation of human social structures and social history. Evolutionary psychologists emphasize pressures of natural selection on individual genomes; evolutionary developmental theorists instead focus on the coevolution of genetic and cultural channels, operating simultaneously on individual organisms and on social structures. This has given rise to the development of "thick" historical narratives as a form of social explanation, which differ from similarly rich and historicist classic social science (e.g., Adam Smith, Alexis de Toqueville, Karl Marx) in being crucially informed by Darwinian modeling principles and, in many instances, by simulations in computer-generated dynamic virtual environments. In such so-called agent-based modeling, the researcher specifies behavioral rules that govern different types of simple individual agents, designs virtual environments that are idealizations of historical conditions of interest, and then programs rules that determine the relative success of agent types in reproducing themselves in subsequent generations, depending on the outcomes of their interactions with the environmental parameters and with one another in the current generation. In some such simulations, the evolving dynamics can also feed back to alter the background environment. (Biologists refer to this as *niche construction.*) Social scientists who build such models typically use evolutionary game theory as the mathematics for describing the relative stability of different combinations of agents, environments, and selection rules. Relatively stable, such combinations are at equilibrium. Causal dynamics of greatest interest are recurrent patterns of changes in variables that tip a simulated world out of one equilibrium and send it toward another one.

Evolutionary models of this kind, whether simulated or merely represented by equations on paper, are used both as exercises in the separate social sciences and as products of unified social science. For example, if the changing state variables in a model are relative exchange values and the principles of selection are relative asset balances measured using these values, then the model is an instance of evolutionary economics. Another model might vary the extent to which individuals form bonds with one another through spending resources on symbolic displays; this would be a case of evolutionary anthropology. Such models can be combined, creating unified social science. A major criticism of this approach is that as models become more complex and sensitive to specific simulation design parameters, they surrender the key scientific goal of generalizability.

Social Neuroscience and Neuroeconomics

The most important current arena of interaction between biological and social-scientific modeling has arisen thanks to new noninvasive technologies for probing and creating images of neural activity, such as functional magnetic resonance imaging. This has lately produced a wave of interest in the neuroprocessing basis of social affiliation (social neuroscience) and in the mechanisms by which brains compute and comparatively evaluate alternative rewards (neuroeconomics). Critics of these approaches caution against reductionism; emergent social structures might often restrict behavioral patterns to particular channels that then don't need to be explicitly represented in anyone's brain. It seems likely that this issue will dominate debates about the relationship between biological and social structures and processes over the years immediately ahead.

Capabilities

This entry introduces what is known as the capability approach and goes on to review various senses and uses of the notion of capability in philosophy, the social sciences, and policy.

The term *capability* is typically used to denote a potential, that is, the ability to achieve something that is possessed by a given entity. In philosophy and in the social sciences, the term is often used in connection with the "capability approach," proposed by Martha Nussbaum and Amartya Sen. The capability approach was first proposed in 1979 by Amartya Sen in a lecture titled "Equality of What?"—in which Sen tries to go beyond John Rawls's theory of justice and its use of "primary goods" as the relevant space in which to assess inequality.

Sen argues that by focusing on "primary goods," Rawls fails to take into account the differences between human beings. Different human beings will have different abilities to convert primary goods into well-being. Thus, Sen and Nussbaum argue that equality and well-being should be assessed in terms of the capabilities that human beings actually possess, which depend not only on the goods and resources they possess but also on the conversion factors that enable human beings to convert goods and resources into well-being.

Sen notes that there are other approaches that take into account the differences between human beings, such as utilitarianism (which underpins mainstream economics). However, Sen criticizes the use of utility as the space in which to assess equality and well-being. Sen argues that utility is a subjective measure, which depends on subjective preferences and may not reflect human well-being. For example, if our preferences become adapted to a given situation, our utility level may increase, but that subjective phenomenon does not mean that there is an increase in well-being. Thus, human well-being should be assessed in terms of the human functionings we have reason to value, where a human functioning is what a given human being is or does. The notion of functioning has Aristotelian roots; it has been developed especially by Nussbaum but has also been acknowledged by Sen.

Furthermore, the capability approach provides a multidimensional perspective on human well-being, since it focuses on various human functionings. However, Sen argues that equality should be assessed taking into account not only achieved functionings but also the *potential* to achieve. Thus, equality should be assessed in the space of the *potential* functionings that we have reason to value, which Sen and Nussbaum designate as valuable *capabilities,* that is, what a human being can be or do and have reason to value.

The capability approach has been adopted in developing concrete measures of well-being, most notably by the United Nations Human Development Programme, which publishes every year a Human Development Report, where the multidimensional approach of the capability approach is employed, going beyond the traditional measures that rely on the gross domestic product. The capability approach

also became influential in feminist studies and within political philosophy.

In business and management studies, the term *capability* is more often identified with the capabilities theory of the firm. This approach goes back to Edith Penrose and is connected to the resource-based view of the firm, where the term *capability* refers to the ability of a firm to use resources. Like in Sen's and Nussbaums's capability approach, the aim is to go from goods and resources to capabilities. However, in the theory of the firm, capabilities are seen as relevant to the competitive advantage of the firm rather than to assessing equality among human beings.

Capabilities also depend on the firms' routines, a concept developed within evolutionary perspectives, such as that of Robert Nelson and Sidney Winter, where the capabilities of the organization (organizational capabilities) depend on the routines of the organization (organizational routines).

In the theory of the firm, the term *competences* is also often used to denote a concept similar to that of "capability." Although much use of structural terms is made in the literature on the theory of the firm, there is little systematic account given of the different kinds of structural properties at play. One relatively unknown but potentially helpful account is given by Clive Lawson, who proposes a useful distinction between *capacity, capability,* and *competence*. A *capacity* is a more passive power of a structure to achieve something, a *capability* refers to an ability that has not yet been acquired, and a *competence* refers to an ability that has been acquired.

But across the various literatures on management, philosophy, and the social sciences, the term *capability* always denotes a potential that a given entity (such as a human being or an organization) possesses.

Capitalism

Capitalism is an idealized economic system consisting of legal protections of decentralized, cooperative social production; private ownership of resources; and free and open competitive markets for exchange of goods, labor, services, and material and financial capital. Capitalism can be contrasted with socialism, which promotes collective ownership of productive resources and labor, and with traditional, preindustrial economies, which determine production and distribution of goods and labor by traditional social roles. Capitalism dominates globally, promoting worldwide trade and labor mobility, but markets exist only in and through legal systems that are bounded by nation-states. These legal systems, along with the social norms that support and constrain each society's economy, create different approximations to the ideal of capitalism in different nations. While Karl Marx coined the term *capitalism* as part of a broader economic theory of production and distribution, neoclassical economic theory generally assumes the existence of capitalist markets, but heterodox economics and sociological and normative political theories provide a critical distance to critique capitalism as a system.

Private Property and Free Markets

Property rights are defined as the legal rights to possess, consume, use, trade, or destroy goods. Capitalism exists only where those legal rights allow private individuals to use goods (including material, intellectual, and financial goods), and to hire laborers to produce other goods, for trade. In a capitalist system, consumers

ultimately determine what is produced through their individual consumption decisions, and producers must compete against each other to appeal to consumer desires. Competition among producers leads to business failures and the creation of new businesses vying to create products that consumers will buy. This process, which the economist and political scientist Joseph Schumpeter called "creative destruction," leads not only to innovation in consumer goods but also to financial ruin and unemployment, at least temporarily, for producers and workers. It also leads to unequal ownership of goods among individuals and to periodic social upheavals. Socialism prohibits private ownership of large-scale production, which requires government intervention in productive and market activities. When property ownership, production, or trade is very highly taxed, a market-based system can be a hybrid between capitalism and socialism, known as *market socialism.* Variants of (pseudo) capitalism include *state capitalism,* where the state supports certain industries against competition, and *oligarchic capitalism,* where the means of production are owned exclusively by a small sector of society, determined by forces outside the market. Without a market system to allow individual choice to determine what will be produced and who will consume it, such decisions must be made and enforced collectively. Although it was a commonly held view among economists until the mid 20th century that such decisions could be effectively coordinated, the collapse of communist economies has cast serious doubt on that proposition.

Global Trade

Capitalism and the concomitant growth of industry and transportation have accelerated the global spread of culture, wealth, and persons through trade. Although property rights and markets are governed by the legal systems of the countries within which trade takes place, when trade crosses national boundaries these transactions are governed by bilateral and multilateral agreements between and among the participating nations. Given the different conceptions of just social distributions and different social norms and beliefs about legitimate rules for consumer and labor protection, disagreements about property rights and market restrictions inevitably arise between nations. The basic tenet of welfare economics holds that trade increases overall welfare and that as long as it is unforced, it cannot decrease any individual trader's welfare. However, trade agreements between nations necessarily benefit some nations and some individuals more than others, creating internal and external friction. In the post–World War II era, transnational institutions were developed to reduce tariffs and trade wars and foster international economic growth and development. These institutions include the World Trade Organization, which adjudicates trade disputes between nations; the International Monetary Fund, which is the global lending organization of last resort; the World Bank, which aims at promoting economic development and poverty reduction in the developing world; and the International Labor Organization, which promotes the rights of laborers. Human rights questions and disputes that arise in the context of global capitalism, such as in the matter of human trafficking, are scrutinized by the United Nations.

Controversies of Global Capitalism

Normative and social scientific study of capitalism raises many urgent questions about how capitalism relates to economic development, human rights, the growth of inequality, and the destruction of the natural environment and traditional cultures. Capitalism has been the dominant economic system during a time of unparalleled growth in material well-being for much of the world. Life expectancy has gone from around 30 in 1800 to upward of 65 years in nearly every nation, and is higher than 80 years in most of the developed world. Child mortality and women's fertility rates have likewise declined precipitously. Claims about moral progress are less easily quantified, but the past century of global capitalist domination has seen the end of legal slavery and the enactment of formal, legal rights for women in much of the world. Capitalism by its nature promotes social mobility, in that traditional forms of status do not determine the social role of individuals from birth. However, despite these positive gains, massive absolute poverty and inequalities in wealth and life opportunities remain, though to what degree and extent is controversial. These facts raise questions about how much good capitalism has done, how capitalism might be altered or constrained to do more good, and whether another economic system would lead to better outcomes.

One trenchant critique of capitalism since Marx has been that the hypercompetition of capitalism requires business to exploit vulnerable workers, resulting in massive child labor and human

trafficking. Likewise, businesses are motivated to exploit the natural environment when it is to their benefit, at the social cost of environmental degradation. Marx also criticized capitalism for its tendency to bring about cyclical market failures, a prediction that has been borne out by devastating worldwide depressions and recessions. Although economic science has increased understanding of how government intervention can dampen these cycles, recent experience suggests that they cannot be eliminated.

Another criticism of capitalism is that it destroys traditional culture by encouraging and enabling social mobility, motivating rural to urban migration, and creating a homogenizing global culture. While capitalism clearly affects cultural evolution, whether that is for good or ill remains highly controversial. For communitarians, the destruction of traditional value is an evil in itself, while for liberals, cultures are the instruments of the individuals who comprise them, and the important question is whether capitalism coerces individuals to act in ways they would not choose for themselves.

Causal Explanation, in Philosophy of Science

The truism that scientific inquiry aims not merely to *describe* phenomena but to *explain* them gives rise to one of the central questions of philosophy of science: What makes some claims about some phenomenon *count* as a scientific explanation of that phenomenon? Since at least the late 1970s, the dominant approach has endorsed this answer: Explanatory claims must provide information about the *causes* of the given phenomenon. Here, we'll look at some motivations, challenges, and open questions for this approach.

Causal accounts grew up in response to the dominant approach that preceded them: The deductive-nomological (DN) account was championed by logical empiricists such as Carl Hempel. On this latter view, we explain some phenomenon by producing a valid derivation of it (more exactly, of a sentence describing it) from true statements, at least one of which states a law of nature; the DN account adds that each such law-premise must be essential to the derivation, in that its removal renders the derivation invalid. Example: A certain pendulum has a certain period. Why? What explains this fact? Answer: The pendulum has a certain length, and there is a law that gives the period of any pendulum as a function of its length; from these two facts (but not from the first fact alone), the period of the given pendulum can be validly derived.

The DN account faced devastating counterexamples—what's more, counterexamples that seemed to uniformly point in the direction of a *causal* account as the best alternative. For example, the law that gives the period of any pendulum as a function of its length likewise gives the length as a function of the period; but for all that, we cannot explain why some pendulum has the length it does by citing its period. Evidently, what goes wrong in this example is that an *effect* is being used (together with a relevant law) to "explain" its *cause*. Again, from an effect A of some cause C, one may be able to deduce (via suitable laws) a *distinct* effect B; one does not thereby *explain* B by reference to A. (The barometer reading does not explain the subsequent storm.) Or some event C may be poised to bring about effect E if E's *actual* causes fail to do so; a mere backup such as this does not explain E, even if it can, with suitable laws, be used to derive the occurrence of E. (The victim received a fatal dose of poison but in fact died from gunshot wounds; so the poisoning does not explain his death.)

Hence the alternative, which avoids these counterexamples in the most straightforward manner: Leave laws and derivation out of the picture and insist, instead, that an explanation of some phenomenon consists in some amount of information about its causes. Still, a variety of challenges remain for any such causal account. Some can be met by

developing the account with sufficient care and flexibility. For example, scientists often seek explanations for *regularities*—which, unlike *events,* do not even seem to be the sorts of things that *have* causes. A reasonable response: We give a causal explanation of a regularity by articulating not its *causes* but rather common patterns in the causes of each of its *instances*.

Other challenges are more stubborn, and of these, the most significant is probably also the simplest: Just what *is* causation, anyway? It's no good pretending that our ordinary notion of causation is so clear and sharp that the question can be safely ignored. Consider—to cite just one of many examples testifying to its lack of clarity and precision—the controversy surrounding the question of whether "omissions" can be causes. Billy promises to water Suzy's plants and fails to do so; the plants die. Did his failure to water them *cause* their death? We might ordinarily say so, but it is far from clear, even so, that we mean the same sort of thing that we would report by saying that his trampling the plants caused their death. It thus seems an urgent question to augment a causal account of explanation with an account of causation itself.

The best contemporary approach to attempts to connect causation to *counterfactual dependence* is roughly as follows: A cause of some event E is some earlier event C where *had C not occurred, E would not have occurred*. Even this simple account fits a remarkably wide range of cases remarkably well; still, it won't do, and two reasons are especially noteworthy. First, there are cases where an event would have happened *anyway,* even had one of its causes failed to materialize; our earlier example of the poisoned assassination victim was just such a case. Second, it turns out—frustratingly if predictably—that the crucial conditional connective "had X been the case, then Y would have been the case" hides complications that themselves need to be addressed.

Very often, these conditionals submit to a fairly simple recipe for evaluation. Example: At noon, Suzy throws a rock at a window, which breaks a few moments later. What would have happened had she not thrown the rock? We answer this question by constructing a "possible world" in which, at noon, every material condition is exactly as it is in the actual world, with only the exception that Suzy is not throwing her rock (but is instead, say, standing idle); we then consider how the underlying laws of nature would have yielded an alternative future from this alternative starting point. (Presumably, in this alternative future the window does not break; hence, we may assert that if Suzy had not thrown her rock, the window would not have broken.)

A good and well-motivated recipe, as far as it goes. The trouble is that it does not go far enough for all of our scientific purposes. For in the social sciences in particular, we often seek causal explanations for phenomena, where these explanations reside in factors that cannot be intelligibly "counterfactually varied" while holding all *other* factors *fixed* in the way our recipe evidently requires. For given how intertwined and even inter*defined* different social, political, economic, and cultural factors can be, there may be no remotely realistic way to envisage *one* being different while all *others* remain as they actually are. For that reason (among others), it remains an important open question how best to develop the insight that explaining is a matter of detailing causes, so that this insight will prove as illuminating of practice in the social sciences as it already has of practice in the "hard" sciences.

Causation, Philosophical Views of

The social sciences seek causes, such as the cause of the obesity epidemic. Social scientists find causal explanations for such phenomena and use them

to predict their future development. They find and model causes to make social policy interventions to control such phenomena. What is it that the social sciences are trying to find, model, and use?

The philosophical literature on causation offers a variety of views. These have grown in sophistication since David Hume analyzed causality by appealing to effects regularly following their causes. We know now that such regularity does not always imply causation: Night follows day, but day does not cause night! And causes do not always produce their effects: Not everyone who lives in an obesogenic environment becomes obese.

This entry offers a guide to elements of the philosophical literature of interest to the social sciences. First, an important division in approaches to causality is examined: dependence or difference-making views versus production views. Then, three difference-making views are explained—probabilistic causality, the counterfactual theory, and interventionism—followed by two production views—processes and mechanisms. Finally, the relevance of these distinctions to social science is discussed.

Difference Making and Production

Ned Hall points out that many recent philosophical views fall into one of two categories:

1. *Difference-making* causes make a difference to their effects (if Jack *hadn't* grown up in an obesogenic environment, Jack *wouldn't* have been obese; or obesity rates *vary* with obesogenic factors in the environment).
2. *Production* causes are connected to effects (obesogenic factors interact with human psychological and physiological mechanisms to produce obesity).

Many take these approaches to be incompatible, but each is thought to capture something vital about causation.

Difference Making: Probabilistic Theory

Hans Reichenbach, I. J. Good, and Patrick Suppes were among the first to champion probabilistic views of causation. The simple idea is that causes raise the probability of their effects. Probability raising is a particular kind of difference making. It can be expressed formally using probability theory, as can more complex, related notions. One advantage is that this notion of causation is closely tied to science, which uses probabilistic relations extensively. Also, it can cover cases where the effects do not always follow their causes: Living in an obesogenic environment raises the probability that Jack will become obese but does not make it certain.

Unfortunately, not all causes raise the probability of their effects. Suppose Jack has a gene that strongly predisposes him to obesity, so that the probability of Jack's being obese is close to 1. Then, abundant high-calorie foods might causally contribute to Jack's obesity, without increasing the already very high probability of his obesity.

Difference Making: Counterfactual Theory

Reasoning counterfactually is common. In social science, we might claim, "If Jack had not been raised in an obesogenic environment, then he wouldn't have become obese." This is a *counterfactual conditional* because it is a contrary-to-fact conditional. A conditional is an if-then claim, and this one is counterfactual because, as a matter of fact, Jack *was* raised in an obesogenic environment. But we suppose, contrary to fact, that Jack was not raised in such an environment, and imagine what would have happened differently.

David Lewis made this kind of reasoning precise. He suggested that to assess whether a counterfactual conditional is true, we compare the actual situation with other similar "possible worlds." In similar possible worlds—such as ones where Jack's counterpart has a similar physiology and psychology but where he is not raised in an obesogenic environment—he does not become obese. Lewis then gives an account of causation in terms of counterfactuals. Effects counterfactually depend on their causes: If the cause hadn't been, then the effect wouldn't have occurred either. The account can be extended to probabilistic cases. Counterfactual dependence is the second kind of difference making.

This is a nice reasoning strategy, but Lewis claimed that possible worlds are real. There really is a world where Jack's counterpart grows up in a nonobesogenic environment. It is just not the actual world. Many philosophers reject this metaphysical claim and treat possible worlds as *fictions* we use to structure our reasoning.

Furthermore, there seem to be cases of causation without counterfactual dependence. Suppose Jack's mother is anxious and inclined to overfeed him, even at the expense of the rest of the family. Even if the family lived outside the obesogenic richer nations, Jack might still become obese. So the counterfactual "If Jack had grown up in a nonobesogenic environment, Jack would not have become obese" is not true. Even so, when Jack does grow up in the rich obesogenic world, the abundant availability of high-calorie foods is a contributing cause of Jack's obesity.

Difference Making: Intervention

James Woodward gave an account of causation that tied it closely to the kinds of experimental manipulations we use to find causes. The intuitive idea is that if we wiggle the cause, we affect the effect. If we increase the availability of high-calorie foods, we increase obesity; if we reduce the availability of high-calorie foods, we reduce obesity.

More formally, for Woodward, obesogenic factors cause obesity if the relationship between obesity and obesogenic factors is invariant under intervention on these factors, given a specific context, such as a particular age-group in a particular country. The relationship between, say, abundant high-calorie foods and obesity is invariant when it is not disrupted when we intervene to alter the system, by changing the availability of foods or slightly altering the context, such as the age-groups we assess. To "intervene" properly, we have to be able to affect the abundance of high-calorie foods without disturbing other causes of obesity, such as parental behavior. Invariance under intervention is the third kind of difference making.

When such relationships can be found, they are useful, particularly for effective policy. However, satisfying the requirements is difficult in the social sciences. Causal relationships are often sensitive to slight changes in context, so that what works for 10-year-olds might fail for 15-year-olds. And policy interventions often alter the delicate causal structure we are examining. Regulations reducing the availability of high-calorie foods to children are likely to alter parental behavior as well. For example, reassured parents may reduce their supervision of their children's diet—which may make the policy ineffective.

Production: Process

Production accounts focus on a link between cause and effect, rather than on causes making some kind of difference to their effects. For a difference-making relation to hold, it doesn't matter *how* it holds. The link between cause and effect can be left unexplained so long as a probabilistic, counterfactual, or invariant relationship between cause and effect can be detected. Production accounts focus on the *how.*

Wesley Salmon and Phil Dowe hold the view that *processes* are continuous world-lines in space-time. Causal processes are those that, when they intersect, exchange conserved quantities. This is what happens when billiard balls collide. Airplanes' shadows crossing on the ground do not exchange anything and remain unaltered after the interaction. They are therefore pseudo-processes, not causal processes.

This gives a nice account of a causal link and is the first of the two production accounts that we consider. However, it is far from clear how to apply it to anything except certain areas of physics—and certainly not to social science. If processes are important to social science, a different account is needed.

Production: Mechanism

When social scientists find a correlation (a probabilistic relationship) that they don't understand, like that between a mother's education and infant mortality, they naturally wonder whether there is a plausible *mechanism* by which a mother's education can affect infant mortality. This is another way of looking for a connection, and the second production account.

Major philosophers working on mechanisms include Peter Machamer, Lindley Darden, and Carl Craver (MDC), and Stuart Glennan. They broadly agree that mechanisms are found in three steps. For example, suppose the mechanism for a mother's education improving infant mortality is sought:

> *Phenomenon:* We want the best description of the phenomenon we can get. When does it happen? In what subpopulations? For example, just mothers' education or fathers' too? How young do the children have to be to be affected? Do you have to improve education a lot or just a little?
>
> *Parts and what they do:* Who takes children to the doctor and follows the doctor's instructions? Does

education help them understand when to consult the doctor and how to follow orders? What are the other influences on infant mortality, such as nutrition? How does maternal education affect those? Are the educated just more likely to have access to doctors and be able to afford medicine and good food anyway?

Organization: Links between access to doctors, the ability to understand instructions, and other factors like nutrition

When the whole picture is built up, and the sequence of interactions between parts is experimentally established, the mechanism has been discovered.

MDC and Glennan agree that when there is a mechanism, there is at least one causal relation. But only Glennan gives an analysis of causation in terms of mechanism: Causes are connected by mechanisms (except perhaps the causes in fundamental physics).

This view is more widely applicable than that of Salmon-Dowe and connects nicely with real scientific practice. But there is no guarantee that when a mechanism is found, an overall causal relation also exists. Mechanisms may cancel out each other's effects. When regulations limiting children's access to high-calorie foods make parents reduce their supervision, mechanisms of parental control cancel out the effect of mechanisms of regulatory control. Finally, it is often difficult to find such mechanisms, and there is no guarantee that they will always be available in social science.

Conclusion

Difference-making views and production views seem incompatible. Whatever difference-making view is used, it is possible to have causation in its absence: If there is a mechanistic link between high-calorie foods and obesity, then there may be a causal relation, even if it does not show up probabilistically, counterfactually, or in invariance under intervention. On the other hand, it seems that there can be causation without production. If nonobesity is probabilistically related to, and/or counterfactually dependent on, the absence of high-calorie foods, then this absence is a candidate cause of nonobesity. But it is difficult to see what mechanism could connect an *absence* with nonobesity.

This leaves us with a conundrum: How exactly is causation related to difference making and production? It is currently very much up in the air as to the correct response to this question.

However, even with such problems, these distinctions are useful to clarify thinking about *evidence* for causal claims. Suppose we have evidence of a correlation between obesogenic factors in the environment and obesity, across a variety of age-groups and social conditions, such as city/country and so on. This is population-level probabilistic evidence. What Jack's doctor wants to know is what to recommend *to Jack*. How should Jack alter his behavior? What past actions would have altered Jack's current situation? This is a single-case counterfactual dependence. The gap between these two concerns might be unbridgeable—or it might not. Perhaps there is evidence concerning the operation of mechanisms in Jack, or very similar individuals, which might be brought to bear. The distinctions explained here help clarify such questions.

Causation in the Social Sciences

Learning the cause, or causes, of something is often important for explaining it and for designing effective plans for changing it in desired ways. Not surprisingly, then, questions of causation are usually at issue when social scientists offer explanations or policy advice. For example, economists might attempt to learn about the causes of economic recessions in order to explain why they happened when they did as well as to offer helpful suggestions to politicians about how to reduce the chance that one will occur in the near future. There are, however, a number of long-standing philosophical issues related to causation.

One group of issues concerns the concept of causation itself: A variety of conflicting theories about the nature of causation exist, and a few philosophers have even argued that the concept is bankrupt and should be dispensed with altogether. A second class of issues has to do with how knowledge about cause and effect can be acquired. It is generally agreed that correctly inferring cause-and-effect relationships in social science is very difficult, and philosophers and social scientists have offered a number of, sometimes competing, proposals about how, or whether, those difficulties may be overcome.

This entry treats these two issues in turn, discussing some interconnections between them and some implications for social science methodology.

Skeptical Challenges to Causation

One of the most fundamental questions about causation is "What is it?" We normally think of causation as something "out there" in the world. It seems an obvious and objective fact of nature that some things make other things happen. But several illustrious figures in the history of Western philosophy have argued that this commonsense idea of the objective reality of causation is an illusion. In particular, both David Hume and Bertrand Russell argued that causation, as it is normally understood, does not exist in the physical world but is instead largely a projection of the human mind onto experience.

Hume asks us to consider examples of cause and effect, for instance, one billiard ball colliding with another and sending it into the corner pocket. When we examine such examples as carefully as we can, Hume says, we only observe three basic features: (1) temporal priority (the cause happens before the effect), (2) contiguity (the cause is adjacent to the effect in space and time), and (3) constant conjunction (events like the cause are always followed by events like the effect). According to Hume, this is all causation really is in the world. This is Hume's first or "philosophical" definition of causation. But Hume points out that our ordinary concept of cause and effect involves more than just this. It includes the idea of a necessary connection between cause and effect: We think that given the cause, the effect *had to happen*. But Hume claims that, try as we might, we cannot observe any such connection between objects in the world. According to Hume, the source of our idea of necessary connection is internal rather than external. After having repeatedly observed events of Type A being followed by events of Type B, we *feel,* upon seeing a new instance of A, a strong and vivid expectation of B. Our mind then projects that expectation onto external objects. This leads to Hume's second or "natural" definition of causation, namely, that *c* is a cause of *e* if *c* is prior and contiguous to *e* and the observation of *c* "determines the mind to form" a vivid idea of *e*. Thus, Hume thinks that causation as normally understood is, to a significant extent, an illusion: We think it is "out there" in the external objects, but the most important element of it—necessary connection—is something that our mind projects on what we observe.

Bertrand Russell agreed with Hume's arguments about necessary connections not really being "out there" in the world. But Russell took skepticism about causation one step further. He argued that Hume's first, or "philosophical," definition of causation does not correspond to anything physically real either. More specifically, Russell argued that Hume's first definition of causation cannot correspond to anything in the world if modern physics is true. Russell claimed that laws of physics (here he was thinking primarily of Newtonian mechanics) do not include any reference to time; they do not say things such as "When *A* happens, *B* follows." Rather, they state relations among features of the world at a given instant. For example, Newton's law of gravitation says that the gravitational force between two objects is directly proportional to the product of their masses and inversely proportional to the square of the distance between them.

Moreover, any empirical generalization of the form "When *A* happens, *B* follows" that could be stated by humans would have exceptions. The reason is that some event might intervene after the occurrence of *A* to prevent *B*.

Thus, Russell reasoned, if we accept Hume's first definition of causation, it follows that trying to discover cause and effect (and telling scientists that this is what they should be doing) is a waste of time, or worse. Our best option, Russell thought, is to jettison the notion of cause altogether. Instead of causation, Russell thought that it would be best to talk about the sorts of functional dependencies represented in physical laws, such as Newton's law of gravitation. Another variant of this type of view, which also appeared around the turn of the 20th century, was advocated by the statistician Karl Pearson, who argued that the notion of causation should be replaced by the (then) newly invented statistical concept of correlation.

The Causal Renaissance

It is hard to overstate the impact of Hume and Russell on subsequent discussions of causation in philosophy and statistics, and subsequently on social science. One effect was to cast a shroud of metaphysical suspicion over causation, suggesting that it is something best avoided. However, causation began to make a comeback as a respectable philosophical concept in the second half of the 20th century. In what might be regarded as the first wave of this causal renaissance, a number of philosophers proposed updated versions of Hume's first definition of causation. One example of this type of proposal asserts that *A* is a cause of *B* if *A* raises the probability of *B* even when a set of other background conditions *C* is controlled for. This concept of causation is relevant to social science, because it suggests that it would be possible to discover causes of social phenomena (e.g., recessions, political insurrections, social cohesion, etc.) through a careful examination of statistical data. However, philosophers quickly uncovered a number of difficulties in attempts to define causation in terms of probabilities. For example, suppose there are two causal pathways linking *A* to *B*: one pathway that increases the chance of *B* and the other that lowers it. Then it is possible that *A* is a cause of *B,* yet this does not raise (or lower) its probability overall. To cite one commonly given example, taking birth control pills increases the chance of thrombosis (the formation of blood clots that block blood vessels), but birth control pills also decrease the chance of pregnancy, which is a risk factor for thrombosis. Thus, despite the causal relationship between the pills and thrombosis, it is possible that taking the pills would make no difference to the probability of thrombosis. As a result of this and other objections, the idea that causation could be defined by probabilities was mostly abandoned.

The gradual demise of probabilistic definitions of causation led to a variety of alternative proposals. One line of thought focused on the mechanisms, or pathways, through which causal influence is transmitted. One of the best-known theories of this type, developed by Wesley Salmon, is founded on the concepts of *causal process* and *causal interaction*: Causal processes are objects capable of transmitting "marks," while causal interactions occur when two causal processes intersect and both are modified as a result. For example, a cue ball is a causal process that one could "mark" with momentum by hitting it with a cue stick. The cue ball could transmit this momentum to a stationary 8-ball, imparting momentum to the 8-ball and, thereby, causing it to roll into the corner pocket. One difficulty facing this theory is that it is unclear how its two key concepts can be defined without already presupposing the notion of causation. A second difficulty is that the mark transmission theory provides little help for distinguishing those chains of causal interactions that are relevant for explaining an outcome from those that are not. For instance, striking the cue ball with the stick also made a sound, which consists of vibrations in the air that also intersect with the 8-ball.

A third approach to causation emphasizes the link between causation and intervention, proposing that causal relationships differ from mere correlations in terms of indicating effective strategies for altering an outcome. Theories of this type often explicitly abandon the philosophical project of defining causation in strictly noncausal language and, instead, aim to explicate the relationship between causation and a cluster of related concepts, including intervention, explanation, and probability. James Woodward developed an approach to causation along these lines, according to which the distinctive feature of causal generalizations is that they are invariant, or continue to hold true, when subjected to interventions. Woodward conceives of an intervention as

an ideal experimental manipulation that targets a single variable without directly affecting anything else. One objection to Woodward's theory is that it is unclear how it would be applied in cases in which interventions are not possible to perform.

Causation and Social Science Methods

Each of the theories about causation described in the previous section can be helpfully thought of in relation to corresponding methods for discovering causes, methods that can be employed in social science. Probabilistic definitions of causality suggest that causes of social phenomena can be learned by carefully sifting through social statistics in just the right way. Mark transmission theories suggest that causation can be established by tracing a chain of interactions from cause to effect. In social science, this might translate into ethnographic-style analyses of social interactions, for instance, of processes through which teenagers decide to finsh high school or drop out. Finally, theories of causation that focus on intervention can be thought of in connection with experiments, either deliberately designed or naturally occurring. Moreover, methodological disputes about the necessity or relative importance of these methods in social science are not uncommon.

For example, a number of philosophers and social scientists have argued that establishing a causal relationship in social science is only possible when a mechanism has been traced from cause to effect. According to this view, for example, no amount of statistical data showing that people who regularly attend religious services tend to be happier could demonstrate a causal link between the two unless a mechanism linking them has been provided. A plausible mechanism in this case would be that regular attendance at religious services makes a person more likely to be integrated into a social support network. Without carefully documenting such a mechanism, the argument goes, we can never be sure that the correlation is not due to some unmeasured third factor that is a cause of both attending religious services and happiness. Critics of this argument respond that tracing a mechanism is not the only possible way to rule out alternative explanations.

It is possible, however, to combine at least some key ideas from separate theories of causation in ways that can illuminate connections between distinct methodological approaches. For instance, a quickly expanding interdisciplinary body of work on causation in philosophy, statistics, and computer science utilizes graphical models known as Bayesian networks to represent causation. This approach can formulate assumptions implicit in probabilistic theories of causation and can explore the extent to which those assumptions would enable causal conclusions to be inferred from statistical data. But the approach can also be used to represent interventions and hence can examine what can be learned about causation in (possibly imperfect) experiments, as well as what can be predicted about the result of an intervention from a presumed causal hypothesis.

Causes Versus Reasons in Action Explanation

The debate whether human action is the result of, and can be explained by appeal to, reasons as opposed to causes has been of central importance both to the

philosophy of action and to the philosophy of the social sciences. The debate was particularly significant to the latter, especially because it was thought that if reasons for actions are not causes, then the social sciences cannot be assimilated to natural sciences and understanding intentional behavior is distinct from explanation of physical phenomena.

Causation

Philosophers theorizing about causation have by and large followed David Hume in construing it as a relation between events in succession such that, given the types of events they are, once the first occurs the second is bound to follow. Most today reject the so-called Humean regularity thesis of causal relations and Hume's claim that this causal necessity is a "determination of the mind," a human "habit," and not found "in the objects themselves." The dominant picture is that general laws governing events of certain types "subsume" causal relations between particular instances of those types. It is also part of this view that causal relations and the laws that govern them are found in nature, independently of our particular ways of identifying them, and that we discover these relations through experience and experiment.

There are good reasons for rejecting at least some of the orthodoxy just outlined about the "nature" of causation. It seems to depend on the idea that the nouns *cause, causation,* or *causality* name something general and abstract, and it is the metaphysician's business to enquire into its nature. A more satisfying but underappreciated view is that "causation" names nothing: It is an umbrella or "concept" term that "collects" a variety of uses of expressions that resemble one another in disparate ways. Rather than speculating about the nature of the object or the property allegedly named by the abstract noun, it is the philosopher's job to trace the contours and details of these uses and compare and contrast them with neighboring concepts, with which they abut, crisscross, and overlap. This kind of investigation reveals that, like all expressions that are collected by general concepts that have their home in our everyday practices, causal terms change their inflections from one circumstance to another. Therefore, we can and should talk about "central" cases: those that are at some remove from the center and those located toward the periphery. These can be compared and contrasted with the multifarious uses of expressions we collect under the umbrella term *reasons for action.*

In its central uses, the concept of causation is inextricably bound with explanation and prediction. Construing causation as an "external" relation between events—a relation "in the world" that occurs independently of our ways of conceptualizing or describing it—has the effect of severing causation from causal explanation, and the metaphysical analysis is thus allowed to float free from the role the concept plays in our lives, with most unsatisfactory results. Concentrating on the genuine role the concept plays will reveal that our acquaintance is not with a general relation, namely, that of "causation," *in itself,* that holds between particular events and even less with the natural laws that subsume them.

Although necessity enters into our understanding of causation in central cases—unnecessitated causes are the exception and not the norm—it is not as a mysterious metaphysical glue holding together the events themselves or as an entailing power in the universal laws that subsume them.

That is, *for us and in the particular circumstances we are considering,* and not in other "conceivable" ones, there is no more scope for avoidance in, say, getting wet when swimming than for failure in constructing a heptagon with a compass and straightedge. Both the natural and the mathematical impossibilities are equipollent for us.

Primary cases of causation, then, seem to involve a circumstance-dependent, nonidealized notion of necessity and the notion of one object or event bringing about or having an impact on another. In the central cases, we learn of these interactions through experience and experiment.

Explaining

Does this short description of causation tell us what we need to know about explanation, generally construed, as some philosophers seem to think? In order to see why the answer is negative, consider the following questions and answers.

1. Why do we need 120 wine glasses? Because we have 30 guests and 4 tastings.
2. Why did he become so angry when we offered to help him with the bill? Because he is proud.

3. What makes you think Christmas falls on a Sunday? Because New Year's Day is on a Sunday and they are a week apart.
4. What makes him a bachelor? Because he is unmarried.
5. Why is this animal a mammal? Because it is a whale.

In contrast, consider the following:

6. Why was he right to concede the match? Because there was no way he could win.
7. Why add the olive oil so slowly to the beaten egg? Because otherwise it will curdle.

We can imagine situations in which the reasons given in each of these answers will satisfy us by making the phenomenon to be explained unmysterious. The explanations given are backed by or grounded in (either explicitly or implicitly) diverse considerations: the first, on a mathematical calculation; the second, on a trait of character; the third, on the conventions set out in a calendar; the fourth, on the meaning of a word; the fifth, on a biological or zoological taxonomy; the sixth, on the rules of a game; and the seventh, on past experience or to an established regularity.

But notice how few of these "becausal" explanations we would categorize—without rewriting them—as *causal* explanations. It would sound odd to say, for example, that the multiplication of 30 guests times 4 tastings caused the requirement for 120 glasses or that the man's pride caused his becoming upset. Instead, the multiplication provides justification (or proof) for the suggested number of glasses; getting upset when others offer to help is one of the manifestations, or is indicative, of a man's pride.

Nor would we be tempted to claim that New Year's falling on Sunday causes Christmas to fall on the same day or that being a whale causes it to be a mammal. Rather, the calendar determines the day on which each holiday falls, and biological or zoological taxonomy grounds the claim that whales are mammals. An (unidealized) element of necessity is present in some but not all of these cases, but in none do we have the idea of one object or event causing another.

The first six cases are different in kind from the explanation for why the oil is added slowly to the egg mixture. The reason given in this case—"because otherwise it will curdle"—does suggest a causal claim that grounds the explanation, namely, that adding oil too quickly to whipped egg yolks causes the mixture to curdle. The grounds for this claim involve past experience, or trial and error, with two substances that interact in different ways depending on how they are combined.

This shows that not all explanations are causal and only some have causal backings.

Reasons Versus Causes in Action Explanation

What about explanations of action? Example 6 is about an agent's action: that of conceding the match. Example 7 is about a rule (in this case, a recipe for mayonnaise) that governs an action: Oil should be added only very slowly to the egg yolks.

The other examples can be set out explicitly as explanations of action. Why did you put 120 glasses on the table? Why did he slam his hand on the table when we offered to pay the bill? Why did she tell them that Christmas is on a Sunday, that he is a bachelor, or that the whale is a mammal?

Does rewriting them thus require a different answer from the ones given? It depends on what we are looking for, and this, of course, depends on what is puzzling us. The very same answers will satisfy us about a person's *reasons* for calling a whale a mammal, for serving 120 glasses of wine, for pouring the oil very slowly into the egg mixture, and so on, if we are concerned about what justifies the claim or action: why someone in the same situation *should* do the same.

Ludwig Wittgenstein, John Wisdom, Gilbert Ryle, Elizabeth Anscombe, and others were keen to point out the circumstance dependence of explanation: what counts as a successful one depends on whom it is for and how this understanding informs one's abilities and practices. Explanations come to an end somewhere, Wittgenstein reminds us. Knowing a law of nature or an inference rule, Ryle suggests, depends on knowing how to use this law in making explanations or predictions or in implementing the rule in deducing a conclusion from a set of premises. Explanations, as it were, do not sit in some metaphysical heaven to be intuited by the mind: They are woven into the fabric of our daily practices. Even so, these philosophers distinguished between different kinds of explanation. Ryle accepts

a certain picture suggested by the use of "cause," in which causal laws are established by experiment and the relata that enter into causal relations are independently observable and describable. This he contrasts with a phenomenon that is partly constitutive of another, as the headside of a penny is part of what makes it the penny it is, but is not a separately existing agency that causes it to be so. For Wittgenstein, a crucial contrast is between what is discovered on the basis of experiment versus the rules we lay down. Anscombe famously traced the logical or grammatical ties between the concepts of intentions, motive, reason, and voluntariness, contrasting the kind of explanation facilitated with that given by citing "mental causes."

Today, however, philosophers tend to see causes and even causal *explanation* as quite independent of human contingencies and practices. Objectivity and discovery are the bywords for scientific investigation, which, many hold, seek out natural laws that allow us to explain events in terms of their causes by construing these relations as instances of more general patterns in (mind-independent) nature. Reasons, by contrast, provide explanations that allow us to see, in the paradigm case, human action as making sense based on how the agent conceives it, as well as (how she conceives) her goals, desires, beliefs, and values. (Teleological explanation, in which natural events are seen as arising from the purposes of God, Mother Nature, or evolution, sits in between this too stark division.)

If causation falls within the province of the natural sciences and if the "special sciences," such as psychology, sociology, or anthropology, are to aspire to the same measurable, repeatable, and in this sense objective standards, then what seems to be a matter of subjectivity and interpretation needs to be reconciled with the opposite aims of the natural sciences. Donald Davidson, though inveighing against the idea that there are natural laws of psychology, was nonetheless responsible for giving hope to many that there could be a science of the mind. He famously challenged the positions of Wittgenstein, Anscombe, A. I. Melden, and others by arguing that for a true explanation of an action, we need to know what events *caused* it as well as the agent's conception, values, goals, and so on, that make the action *reasonable,* at least from her point of view.

Anscombe's insightful contribution to action theory was to point out, among other things, that a human action is *intentional* or that someone acts with an *intention to act* when the question "Why did she do it?" can be meaningfully answered only by citing her *reasons* for action, and these, for Anscombe, are not causes. Furthermore, she pioneered the important idea that an action is intentional *under a description* that cites the actor's reasons or intention, while this is perfectly compatible with the same action being seen—because, for example, it is constituted by bodily movements, such as an arm rising—as a physical event *under a different description.* But the latter will not amount to an explanation of an intentional action. In addition, others, like Melden, for example, argued that intentions or reasons to act are not Humean causes, for the latter involve, as we have seen at the start, a model of causation as an external relation holding between two distinct events, whereas, by contrast, intentions are not *logically* distinct from the resulting actions—they (intending and acting) are not two logically distinct events. Citing an intention requires expressing it as "the intention to do x," where "x" describes the action—that is, once we describe an intention, we already refer to the action—thus violating the standard Humean model of causation requiring separateness of event-descriptions.

To those working in the philosophy of the social sciences, this account of action whereby reasons to act were not Humean causes provided an additional argument in favor of the nonassimilation of the study of the social world to the study of the physical world as carried out by the natural sciences. Action as meaningful behavior requires understanding the reasons behind it, not a causal explanation. Parallel to this, Peter Winch's influential thesis about rule following reinforced this anticausal stance.

Davidson, however, challenged the thesis that reasons are not causes and argued that a reconstructed rationalization of the kind he himself favored (in which reasons are "reduced" to beliefs, desires, and weighted value judgments) is still not enough to explain the agent's action, for it fails to give us *the* reason that explains the action: the reason, that is, *for which* the agent acts. His argument is that more than one rational reconstruction is possible, any one of which will provide an "anemic justification" for the action. We can, he continues, imagine cases in which the agent acts because of one of these reasons instead of another. Short of a better story, he suggests, we may as well construe the connective "because" in explanations citing reasons as signifying a *causal* relation.

Davidson himself construed causation in the Neo-Humean way—outlined at the beginning of this entry—namely, as a relation between "real-world" events, which occur independently of our way of describing or conceptualizing them. His argument that reasons are causes became extraordinarily influential in supporting a view of the mind that was also gaining momentum independently: the view that "mental states" (which, he argued, though nonreducible are nonetheless identical to tokens of or particular physical events) are individuated or identified as the kind of mental state they are by virtue of their causal role in mediating between stimulus or input, behavior or output, and other mental states. (This is the view in philosophy of mind called *functionalism,* married with *token physicalism.*) This view itself was given support from the same implicit assumption about language described earlier, that mental concepts name something—to wit, mental states, events, or properties. More precisely, Davidson held that mental verbs such as "believes," which have as their subject a pronoun or proper noun and are followed by an accusative noun or a "that . . ." clause—such as "John believes that it's time to decant the wine"—signify something: John's belief. (This in turn is construed as, e.g., "John's hat" might be—as naming a property of John, but since, unlike his hat, it is nonphysical under its description as a "belief," it becomes a property about the nature of which it is the philosopher's job to enquire). If reasons involve a rational reconstruction of "content-bearing" or "propositional-attitude" states, such as beliefs and desires and these states themselves are (identical to) physical states in the brain, then the philosopher becomes additionally burdened with the puzzle of how something in the brain could bear representational "content"—in other words, be "about" something.

As a result of his influential arguments that reasons are causes, today's orthodoxy is that a rational reconstruction of an agent's action can be given by adverting to "cognitive" and "conative" states: colloquially, her beliefs and her desires or other "pro-attitudes." The explanation why the person put 120 wine glasses on the table, on this construal, would provide us with information about what she wanted to achieve by her action (in this case, to provide enough glasses for the number of tastings) and what she believed would be necessary to meet that goal (that 3 tastings multiplied by 40 guests requires 120 glasses).

There are, however, a number of problems with the standard view. Note, first, how this reconstruction changes the original example, which is plausibly paraphrased as asking the right with which the woman put 120 wine glasses on the table. An answer to this question is not given by asking after the agent's beliefs, because these may be false. Indeed, it seems clear that we would, in the normal case, retreat from the "facts" to the agent's beliefs when her action cannot be given the normal justification (e.g., Why did she put out 80 glasses of wine? Because she believed, wrongly, that there would only be 2 tastings). Citing a person's beliefs and desires as her reasons for performing a particular action does not answer the question whether, in those circumstances, she was right or justified in doing so, or why someone else in her situation should do the same. And this is, as we have seen, one of the things we might be wondering when enquiring into someone's reasons for acting.

Second, if the action is based on a miscalculation, misinformation, wishful thinking, or something not rationalizable in the full-blooded sense, then the anemic sort of justification obtained by pinpointing what the agent mistakenly believed or perversely described is not given by looking at the causal mechanism of her mind/brain; it is given by a rational reconstruction that takes into account the less-than-ideal circumstances ("She thought there would only be 2 tastings" or "She forgot how to multiply" or "There were only 80 glasses available" or "She wanted to ruin her husband's party"). If these are not obvious, we may find the answer by asking her. Thus, Anscombe's proposed criterion, what the agent would say in response to the question "Why did you do this?" or "What were you thinking?" is also something we may mean when we ask about someone's reasons for acting. The reasons for which she acts become, on this construal, the ones she would give in answer to the question.

Third, construing reasons as causes in the primary sense, as one thing or event having an impact on another, puts reasons, as it were, in the wrong logical/grammatical/ontological category: Questions we ought to be able to ask about events (e.g., When did it occur? How long did it last?) make no sense in many of the central cases in which we enquire into a person's reasons for acting. Fourth, nor is there the element of necessity between reasons and actions that seems to attend causal claims: even the nonidealized kind. Fifth, nor is the relation between reason

and the action it justifies the one that we learn about from experience and experiment.

Furthermore, sixth, construing reasons as causes does not solve the "mind–body" problem: It resurrects it. It creates a mystery about the nature of mental stuff such that it can affect other stuff, whether mental or otherwise. Seventh, construing reasons as the causal antecedents of an agent's action introduces the problem of self-knowledge: How could an agent possibly know what her reasons are if they are at bottom physical (neurophysiological) processes?

Of course, agents cause things: The captain caused the shipwreck by showing off, and in showing off, he navigated too close to the shore. One might say that his bravado caused the shipwreck, or perhaps, to be more candid we might say that the shipwreck occurred because of it. In saying the former, we would be speaking relatively loosely and would not commit ourselves to the idea that after a thorough investigation of things in the world having an impact on one another—navigation instruments, ship mechanisms, heavy metal, and rock outcrops—there will be at least one more thing that had an impact, the captain's bravado, about the nature of which it is the philosopher's job to enquire. But unless the shipwreck was intentional on his part, he did not have a reason for causing it. Even if he did—he wanted to destroy the cruise liner in order to wreak havoc on the company and did not care if lives were lost in the process—reasons are not "things" or "processes" either; they are not to be found among the things, like the ship and the rock that played a causal role in the shipwreck.

Chicago School (Economics)

The Chicago school of economics was a post–World War II group of economists, often associated with the University of Chicago, who shared a commitment to using the analytical tools of price theory to test economic policies against their empirical outcomes. Chicago economists, however, did not develop increasingly complex mathematical models or models with more realistic assumptions to predict policy outcomes. Instead, they used analytically simple models based on the basic principles of the market performance of rational individuals to identify how various government interventions in free markets created inefficiencies in the allocation of resources across the economy.

Arguing that the basic principles of economic rationality reliably predict the outcomes of individuals' actions in market settings, Chicago economists focused their attention on the structure of opportunity costs and policy-created constraints that surround economic actors, rather than on changes in tastes, values, and preferences. Often, the Chicago school's examination of a policy defied the conventional wisdom of economists, other social scientists, and legal scholars and showed the unintended (and usually negative) consequences of the policy. A classic example of the Chicago approach is the argument against minimum-wage laws. Regardless of its good intentions, legislation that creates a floor below which wages cannot fall ends up hurting the people it was created to help. Higher wage costs lead employers to reorganize their workflow and substitute capital investments for labor in order to make fewer workers more productive. The lowest productive workers would become perpetually unemployed under such legislation and might drop out of the workforce eventually.

By the 1960s, Chicago economists realized that their logic could be extended into other policy arenas. Sociological issues like discrimination, crime, urban problems, and education came under the lens of the Chicago approach, as did public and bureaucratic choices. The Chicago school spearheaded the movement of "rational choice" theory into sociology and political science. And in public sector analysis, they were closely allied with public choice scholars. Inroads into legal theory began with the transaction cost approach to economic organization and its extension into the examination of the social costs of negative externalities. Questioning the traditional argument against concentrations of market power, Chicago law and economics researchers, as well as its industrial organization theorists, argued that market dominance was fleeting unless supported by government action and regulation. Courts and legislatures should be less concerned about the market actions of corporations than previous industrial organization theorists had suggested. In most cases, activities previously considered anticompetitive were actually responses to consumer demand and transaction costs. In response to the Chicago approach, mergers, acquisitions, long-term contracts, resale price maintenance agreements, price discrimination, bundling of services, and other activities have come to be seen as legitimate activities of firms in open markets.

The Chicago school is best known in the media for its role in monetary and financial theory. Both monetarism and the theory of efficient financial markets were built upon the same basis of applied price theory as Chicago's other policy evaluations. Monetarists argued that in an economy featuring a large degree of economic freedom, the best long-term monetary strategy was a rule dictating a rate of money supply growth approximately equal to the long-term, real economic growth rate. Efficient market theorists argued that financial markets that were free and diversified would efficiently process all available market information without regulatory control. New firms and new financial products would enter the financial markets to provide participants with better means of capturing available returns, as they do in consumer markets. The monetary stability of the 1990s and early 2000s, as well as the concurrent expansion of the financial markets and diversification of financial derivatives, is often attributed to the theories of the Chicago school.

Three types of criticisms have been brought against the Chicago school. Each type of criticism, while focused on the school's policy evaluations, bears the marks of an underlying philosophical difference with the school's approach. The first and most common criticism is the charge that ideology trumps scientific inquiry in the school. The criticism came to the forefront of public attention when policymakers in the United Kingdom, Latin America, Israel, post-Communist Russia, and elsewhere turned to the Chicago school for insights on liberalizing their economies. Because the Chicago approach almost always returns the policy advice to lessen social control and expand market freedom, the critics have ample opportunity to wonder if the inquiry leads to the conclusion or the conclusion drives the inquiry.

The second type of criticism focuses on the school's use of simple price theory models to evaluate policy outcomes. The argument here can take several directions. Many have argued that economics advances by developing models with more nuanced assumptions, in terms of either their realism or their generalizability. Another common argument is that a social scientist cannot ignore changes in values and preferences, and in social influence on these changes.

The final type of criticism is the most fundamental philosophically: the school's dependence on the combination of an instrumental conception of rationality (homo economicus—the rational economic

person) and an individualistic conception of society. Any social scientific approach that views humans as more than rational calculators or society as more than a social contract will find the Chicago school problematic at some level.

And yet the Chicago school was remarkably successful in the latter half of the 20th century. Even when economists today disagree with some aspects of the school's findings, their underlying approach to policy evaluation is deeply influenced by the school's legacy.

Classical Computationalism, Connectionism, and Computational Neuroscience

Computationalism is the view that cognitive capacities have a computational explanation or, somewhat more strongly, that cognition is (a kind of) computation. For simplicity, these two formulations will be used interchangeably. Most cognitive scientists endorse some version of computationalism. Thus, when cognitive scientists propose an explanation of a cognitive capacity, the explanation typically involves computations that result in the cognitive capacity. But cognitive scientists differ on how they apply the notion of computation to the study of cognition. Their three main research traditions are classical computationalism, connectionism, and computational neuroscience.

This entry introduces the notions associated with cognition construed as computation and reviews in detail the three traditions.

Some Notions of Computation

Computationalism is usually introduced as an empirical hypothesis that can be disconfirmed. Whether computationalism has empirical bite depends on how we construe the notion of computation: The more inclusive a notion of computation, the weaker the version of computationalism formulated in its terms.

At one end of the continuum, some notions of computation are so loose that they encompass virtually everything. For instance, if computation is construed as the production of outputs from inputs and if any state of a system qualifies as an input (or output), then every process is a computation. Sometimes, computation is construed as information processing, which is somewhat more stringent, yet the resulting version of computationalism is quite weak. There is little doubt that organisms gather and process information about their environment.

The best computational theories appeal to a well-defined kind of computation. Historically, the most important version of computationalism appeals to *digital* computation—the kind of computation performed by digital computers. Other versions appeal to *analog* computation or computation *in a generic sense,* which encompasses both digital and analog computation, among others, as species.

Three Research Traditions: Classical Computationalism, Connectionism, and Computational Neuroscience

Computation: Origins

The view that thinking has something to do with computation may be found in the works of some modern materialists, such as Thomas Hobbes in the 17th century. But computationalism properly so called could not begin in earnest until a number of 20th-century logicians (most notably Alonzo Church, Kurt Gödel, Stephen Kleene, Emil Post, and especially Alan Turing) laid the foundations for the mathematical theory of computation.

Turing analyzed computation in terms of what are now called "Turing machines"—a kind of simple processor operating on an unbounded tape.

The tape is divided into squares, which the processor can read and write on. The processor moves along the tape, reading and writing on one square at a time depending on what is already on the square as well as on the rules that govern the processor's behavior. The rules state what to write on the tape and where to move next, depending on what is on the tape as well as which of the finitely many states the processor is in.

Turing argued convincingly that any function that can be computed by following an algorithm (i.e., an unambiguous list of instructions operating on discrete symbols) can be computed by a Turing machine. Church offered a similar proposal in terms of general recursive functions, and it turns out that a function is general recursive if and only if it can be computed by a Turing machine. Given this extensional equivalence between Turing machines and general recursive functions, the thesis that any algorithmically computable function is computable by some Turing machine (or, equivalently, is general recursive) is now known as the *Church-Turing thesis*.

Turing made two other relevant contributions. First, he showed how to construct *universal* Turing machines. These are Turing machines that can mimic any other Turing machine by encoding the rules that govern the other machine as instructions, storing the instructions on a portion of their tape, and then using the encoded instructions to determine their behavior on the input data. Notice that ordinary digital computers, although they have more complex components than universal Turing machines, are universal in the same sense (up to their memory limitations). That is, digital computers can compute any function computable by a Turing machine until they run out of memory.

Second, Turing showed that the vast majority of functions whose domain is denumerable (e.g., functions of strings of symbols or of natural numbers) are actually *not* computable by Turing machines. These ideas can be put together as follows: Assuming the Church-Turing thesis, a universal digital computer can compute any function computable by algorithm, although the sum total of these Turing-computable functions is a tiny subset of all the functions whose domain is denumerable.

Modern Computationalism and Neural Networks

Modern computationalism began when Warren McCulloch and Walter Pitts connected three things: (1) Turing's work on computation, (2) the explanation of cognitive capacities, and (3) the mathematical study of neural networks. Neural networks are sets of connected signal-processing elements ("neurons"). Typically, they have elements that receive inputs from the environment (input elements), elements that yield outputs to the environment (output elements), and elements that communicate only with other elements in the system (hidden elements). Each element receives input signals and delivers output signals as a function of its input and current state. As a result of their elements' activities and organization, neural networks turn the input received by their input elements into the output produced by their output elements. A neural network may be either a concrete physical system or an abstract mathematical system. An abstract neural network may be used to model another system (such as a network of actual neurons) to some degree of approximation.

The mathematical study of neural networks using biophysical techniques began around the 1930s. Before McCulloch and Pitts, though, no one had suggested that neural networks have something to do with computation. McCulloch and Pitts defined networks that operate on sequences of discrete inputs in discrete time, argued that they are a useful idealization of what is found in the nervous system, and concluded that the activity of their networks explains cognitive phenomena. McCulloch and Pitts also pointed out that their networks can perform computations like those of Turing machines. More precisely, McCulloch-Pitts networks are computationally equivalent to Turing machines without tape or finite-state automata. Modern digital computers are a kind of McCulloch-Pitts neural network. Digital computers are sets of logic gates—digital signal-processing elements equivalent to McCulloch-Pitts neurons—connected to form a specific architecture.

McCulloch and Pitts's account of cognition contains three important aspects: (1) an analogy between neural processes and digital computations, (2) the use of mathematically defined neural networks as models, and (3) an appeal to neurophysiological evidence to support their neural network models. After McCulloch and Pitts, many others linked computation and cognition, though they often abandoned one or more aspects of McCulloch and Pitts's theory. Computationalism evolved into three main traditions, each emphasizing a different aspect of McCulloch and Pitts's account.

The Three Traditions: Classical Computationalism, Connectionism, and Computational Neuroscience

One tradition, sometimes called *classical computationalism,* emphasizes the analogy between cognitive systems and digital computers while downplaying the relevance of neuroscience to the theory of cognition. When researchers in this tradition offer computational models of a cognitive capacity, the models take the form of computer programs for producing the capacity in question. One strength of the classicist tradition lies in programming computers to exhibit higher cognitive capacities such as problem solving, language processing, and language-based inference.

A second tradition, most closely associated with the term *connectionism* (although this label can be misleading; see below), downplays the analogy between cognitive systems and digital computers in favor of computational explanations of cognition that are "neurally inspired." When researchers in this tradition offer computational models of a cognitive capacity, the models take the form of neural networks for producing the capacity in question. Such models are primarily constrained by psychological data, as opposed to neurophysiological and neuroanatomical data. One strength of the connectionist tradition lies in designing artificial neural networks that exhibit cognitive capacities, such as perception, motor control, learning, and implicit memory.

A third tradition is most closely associated with the term *computational neuroscience,* which is one aspect of theoretical neuroscience. Computational neuroscience downplays the analogy between cognitive systems and digital computers even more than the connectionist tradition. Neurocomputational models aim to describe actual neural systems, such as (parts of) the hippocampus, cerebellum, or cortex, and are constrained by neurophysiological and neuroanatomical data in addition to psychological data. It turns out that McCulloch-Pitts networks and many of their "connectionist" descendants are relatively unfaithful to the details of neural activity, whereas other types of neural networks are more biologically realistic. Computational neuroscience offers models of how real neural systems may exhibit cognitive capacities, especially perception, motor control, learning, and implicit memory.

Although the three traditions just outlined are in competition with one another to some extent, there is also some fuzziness at their borders. Some cognitive scientists propose hybrid theories that combine explanatory resources drawn from both the classicist and the connectionist traditions. In addition, biological realism comes in degrees, so there is no sharp divide between connectionist and neurocomputational models.

Understanding the Three Traditions

The debate between classicists and connectionists has been somewhat confusing. Different authors employ different notions of computation, which vary in both their degree of precision and their inclusiveness. Specifically, some authors use the term *computation* only for classical computation—at a minimum, algorithmic digital computation over language-like structures—and conclude that (nonclassicist) connectionism falls outside computationalism. By contrast, other authors use a broader notion of computation, thus including connectionism within computationalism. But even after we factor out differences in notions of computation, further confusions lie in the wings.

Classical computationalism and connectionism are often described as being at odds with one another, because classical computationalism is committed to the idea that the vehicles of digital computation are language-like structures and, it is assumed, is also committed to the idea of autonomy from neuroscience—two theses flatly denied by many prominent connectionists. But many connectionists also model and explain cognition using neural networks that perform computations defined over digital structures, so perhaps they should be counted among the digital computationalists.

Furthermore, both classicists and connectionists tend to ignore computational neuroscientists, who in turn tend to ignore both classical computationalism and connectionism. Computational neuroscientists often operate with their own mathematical tools, without committing themselves to a particular notion of computation. To make matters worse, some connectionists and computational neuroscientists reject digital computationalism—they maintain that their neural networks, while explaining behavior, do not perform digital computations.

In addition, the very origin of digital computationalism calls into question the commitment to autonomy from neuroscience. McCulloch and Pitts

initially introduced digital computationalism as a theory of the brain, and some form of computationalism or other is now a working assumption of many neuroscientists.

A further wrinkle in this debate derives from the ambiguity of the term *connectionism*. In its original sense, connectionism says that behavior is explained by the changing "connections" between stimuli and responses, which are biologically mediated by the changing connections between neurons. This original connectionism is related to behaviorist associationism, according to which, behavior is explained by the association between stimuli and responses. Associationist connectionism adds a biological mechanism to explain the associations: the mechanism of changing connections between neurons.

But contemporary connectionism is a more general thesis than associationist connectionism. In its most general form, contemporary connectionism, like computational neuroscience, simply says that cognition is explained (at some level) by neural network activity. This is a truism, or at least it should be. The brain is the organ of cognition, the cells that perform cognitive functions are (mostly) neurons, and neurons perform their cognitive labor by organizing themselves in networks. Neural activity is computation at least in a generic sense. Even digital computers are just one special kind of neural network. So even classicists, whose theory is most closely inspired by digital computers, are committed to connectionism in its general sense.

The relationship between connectionist and neurocomputational approaches on the one hand and associationism on the other turns on a distinction between strong and weak associationism. Strong associationism maintains that association is the only legitimate explanatory construct in a theory of cognition. Weak associationism maintains that association is a legitimate explanatory construct along with other constructs such as the innate structure of neural systems.

To be sure, some connectionists profess strong associationism. But that is beside the point, because connectionism per se is consistent with weak associationism or even the complete rejection of associationism. Some connectionist models do not rely on association at all—a prominent example being the work of McCulloch and Pitts. Weak associationism is consistent with many theories of cognition, including classicism. A vivid illustration is Alan Turing's early proposal to train associative neural networks to acquire the architectural structure of a universal computing machine. In Turing's proposal, association may explain how a network acquires the capacity for universal computation (or an approximation thereof), while the capacity for universal computation may explain any number of other cognitive phenomena.

Although many of today's connectionists and computational neuroscientists emphasize the explanatory role of association, many of them also combine association with other explanatory constructs, as per weak associationism. What remains to be determined is which neural networks, organized in what way, actually explain cognition and which role association, and other explanatory constructs, should play in a theory of cognition.

Yet another source of confusion is that classical computationalism, connectionism, and computational neuroscience tend to offer explanations at different mechanistic levels. Specifically, classicists tend to offer explanations in terms of rules and representations, without detailing the neural mechanisms by which the representations are implemented and processed; connectionists tend to offer explanations in terms of highly abstract neural networks, which do not necessarily represent networks of actual neurons (in fact, a processing element in a connectionist network may represent an entire brain area rather than an actual neuron); finally, computational neuroscientists tend to offer explanations in terms of mathematical models that represent concrete neural networks based on neurophysiological evidence. Explanations at different mechanistic levels are not necessarily in conflict with each other, but they do need to be integrated to describe a multilevel mechanism. Integrating explanations at different levels into a unified multilevel mechanistic picture may require revisions in the original explanations themselves.

Different parties in the dispute between classical computationalism, connectionism, and computational neuroscience may offer different accounts of how the different levels relate to one another. One traditional view is that computational explanations do not describe mechanisms. Instead, computational and mechanistic explanations are independent. This suggests a division of labor: Computations are the domain of psychologists, while the implementing

neural mechanisms are the business of neuroscientists. According to this picture, the role of connectionists and computational neuroscientists is to discover how neural mechanisms implement the computations postulated by (classicist) psychologists.

This traditional view has been criticized as unfaithful to scientific practices. It's been pointed out that (a) both psychologists and neuroscientists offer computational explanations; (b) far from being independent, different levels of explanation constrain one another; and (c) both computational explanations and mechanistic explanations can be given at different levels.

One alternative to the traditional view is that connectionist or neurocomputational explanations simply replace classicist ones. Perhaps some connectionist computations approximate classical ones. In any case, some authors maintain that classicist constructs, such as program execution, play no causal role in cognition and will be eliminated from cognitive science.

A more neutral account of the relation between explanations at different levels is provided by the mechanistic account of computation. According to the mechanistic account, computational explanation is just one type of mechanistic explanation. Mechanistic explanations provide components with such properties and organization that they produce the phenomenon. Computational explanation, then, is explanation in terms of *computing* mechanisms and components—mechanisms and components that perform computations. Mechanistic explanations come with many levels of mechanisms, where each level is constituted by its components and the way they are organized. If a mechanistic level produces its behavior by the action of computing components, it counts as a computational level. Thus, a mechanism may contain zero, one, or many computational levels, depending on what components it has and what they do. Which types of computation are performed at each level is an open empirical question to be answered by studying cognition and the nervous system at all levels of organization.

Conclusion

Computationalism is here to stay. We have every reason to suppose that cognitive capacities have computational explanations, at least in a generic sense. Moreover, everyone is (or should be) a connectionist or computational neuroscientist, at least in the general sense of embracing neural computation. Nonetheless, much work remains to be done.

The computational study of cognition will require that we integrate different mechanistic levels into a unified, multilevel explanation of cognition. We also need to characterize the specific computations on which cognition depends: whether—and to what extent—the satisfactory explanation of cognition requires classical computational mechanisms as opposed to nonclassical digital computation and whether we need to invoke processes that involve nondigital computation (Figure 1).

It may turn out that one computational theory is right about all of cognition, or it may be that different cognitive capacities are explained by different kinds of computation. To address these questions in the long run, the only effective way is to study

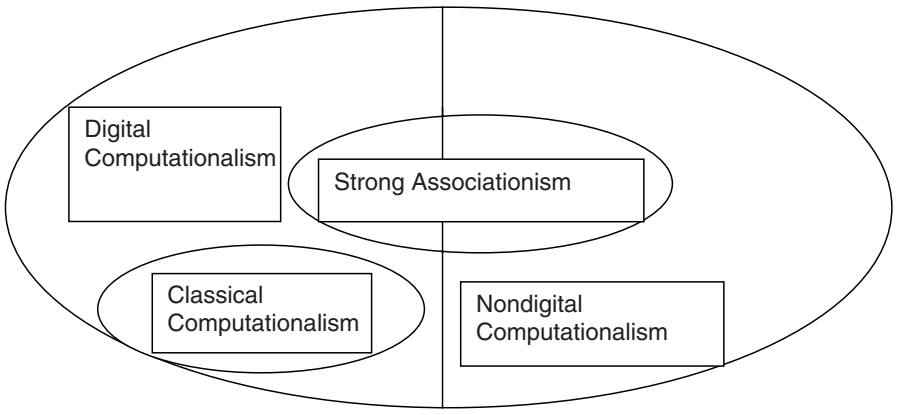

Figure 1 Some Prominent Forms of Computationalism and Their Relations

Coalition Logic

Coalition Logic (CL) is a modal logic for reasoning about cooperation, more specifically about *coalitional ability.* The main construct of CL is of the form $[C]\varphi$, where C is a group of agents (a coalition), meaning that coalition C can by some collective action bring about a state of the world where φ is true, no matter what other agents choose to do. In game-theoretic terms, $[C]\varphi$ means that C is *effective* for φ. Basic CL as well as epistemic, temporal, strategic, quantified, and other extensions of it can be used to formalize properties of social choice mechanisms in a natural way.

The Language of Coalition Logic

CL extends propositional logic with a family of modalities [C], one for each coalition C. Formally, the language of CL is parameterized by a finite set N of *agents* and a set of *atomic propositions*. *Formulae* are defined as θ follows. An atomic proposition $p \in \theta$ is a formula, and if φ and ψ are formulae, then $\neg\varphi$, $\varphi \wedge \psi$, $\varphi \vee \psi$, $\varphi \rightarrow \psi$, $\varphi \leftrightarrow \psi$, and $[C]\varphi$ are formulae, where $C \subseteq N$. The meaning of the operators $\neg$, $\vee$, $\wedge$, $\rightarrow$, and $\leftrightarrow$ are as in propositional logic.

Coalition Logic and Social Choice

CL can be used to formally specify properties of mechanisms for social choice. As an example, consider the case that we are interested in a mechanism with the following properties. Two agents, a and b, should be able to collectively choose between one of two possible outcomes, p and q, but not both at the same time. However, none of the two agents should be able to choose any of the two outcomes individually. These properties can be formally specified in CL as follows: $a, bp \wedge a, bq \wedge \neg a, bp \wedge q \wedge \neg ap \wedge \neg bp \wedge \neg aq \wedge \neg bq$.

CL provides a formal language with a precise and well-defined meaning. In addition to making formal reasoning about social choice mechanisms possible in general, a formal logic also builds a bridge to the concept of *computation.* This connection, first, opens the door to computational tools developed in artificial intelligence and computer science to be used to automatically reason about the logical principles of a social mechanism, to specify and automatically verify properties of a social mechanism, and to automatically synthesize social mechanisms. Second, it is useful for understanding and implementing computational social choice mechanisms.

Semantics and Axioms

The meaning of CL formulae is defined in terms of neighborhood semantics. A *coalition model* is a tuple $M = \langle S,E,V \rangle$, where S is a set of *states*, $V{:}\theta \rightarrow 2S$ is a *valuation function* assigning atomic propositions to states, and for each state $s \in S$,

$E(s): \wp N \rightarrow \wp\wp S$ is an *effectivity function* assigning a set of sets of states to each coalition in state s. That $X \in EsC$ means that C can perform some collective action such that the outcome is ensured to be a state in X. Each effectivity function E(s) is required to be a *playable* effectivity function, that is, to have the following properties: (1) $\emptyset \notin E(s)(C)$, (2) $S \in E(s)(C)$, (3) $S \backslash X \notin Es\emptyset \Rightarrow X \in EsN$ (N-maximality), (4) $\forall X \subseteq X' : X \in EsC \Rightarrow X' \in EsC$ (outcome monotonicity), and (5) $\forall C1 \cap C2 = \emptyset : X1 \in EsC1$ and $X2 \in EsC2 \Rightarrow X1 \cap X2 \in EsC1 \cup C2$ (superadditivity).

These properties correspond exactly to a natural type of *effectivity* in strategic games. A *strategic game* is here a tuple $G = \langle N, \{\Sigma i : i \in N\}, o, S\rangle$, where N is the set of agents, S the set of states, Σi the nonempty set of strategies for i, and $o : \Pi i \in N \Sigma i \rightarrow S$ maps each strategy profile to an outcome state. The α-*effectivity function* EG of a strategic game G is defined as follows: $X \in EGC \Leftrightarrow \exists \sigma C \forall \sigma N \backslash Co(\sigma C, \sigma N \backslash C) \in X$. An effectivity function is playable if and only if it is the α-effectivity function of some strategic game and if it is assumed that the state space is finite. Without the finiteness assumption, an additional property is required for the correspondence to hold: (6) $\forall X \subseteq S : X \in EsN \Rightarrow \exists x \in X\ x \in E(s)(N)$ (crown).

Given a formula φ, coalition model M, and state s, we write $(M,s) \models \varphi$ means that φ is true in s, defined as follows: When $p \in \theta$, $(M,s) \models p$ iff $s \in V(p)$. The propositional connectives are interpreted as usual. Finally, $(M,s) \models [C]\varphi$ iff $\{s \in S : (M,s) \models \varphi\} \in EsC$.

The set of all *valid* formulae, true in every state in every coalition model, is completely axiomatized by the following axioms and inference rules.

All substitution instances of propositional tautologies
$\neg[C]\bot$ (where $\bot$ is a propositional contradiction)
$C\neg\bot$
$\neg[\emptyset]\neg\varphi \rightarrow [N]\varphi$
$[C](\varphi \wedge \psi) \rightarrow [C]\psi$
$([C1]\varphi 1 \wedge [C2]\varphi 2) \rightarrow [C1 \cup C2](\varphi 1 \wedge \varphi 2)$
From φ and $\varphi \rightarrow \psi$ derive ψ (*Modus ponens*)
From $\varphi \leftrightarrow \psi$ derive $C\varphi \leftrightarrow [C]\psi$ (Equivalence)

Extensions

Several extensions of the basic language have been proposed in order to, for example, be able to express more sophisticated properties of situations involving social choice. Alternating-Time Temporal Logic (ATL), developed independently from CL, extends CL syntactically with *temporal modalities* and semantically with *strategies*. *Epistemic* extensions of CL and ATL add epistemic modalities. Examples of formulae: $Ki\varphi \rightarrow iKj\varphi$ (i can communicate her knowledge of φ to j) and $CG\varphi \rightarrow G\psi$ (common knowledge in coalition G of φ is sufficient for G to ensure that ψ). Quantified Coalition Logic (QCL) adds quantification over coalitions. Consider a mechanism with the following properties. An electorate of n voters should be allowed to choose between two outcomes p and q, using majority voting. No nonmajority coalition should be allowed to choose an outcome, and any majority coalition should be allowed to choose any outcome. These properties can be succinctly described in QCL as follows: (majnp) $\wedge$ majnq $\wedge \neg\neg$majnp $\wedge \neg\neg$majnq. Here, majnp means that for *any* coalition C satisfying maj(n), that is, any majority coalition, Cp holds. $\neg$majnp means that *there exists* a coalition C satisfying $\neg$majn: that is, a nonmajority coalition such that Cp holds.

Cognitive Anthropology and Mental Architecture

Cognitive anthropology studies the collective structures, and their content, that make up culture. This entry introduces the novel field of cognitive anthropology; explains the importance of the notion of mental architecture in studying concept acquisition and concept extension, especially in social contexts involving essentially collective conceptual categories; highlights the importance of cognitive anthropology and cognitive sciences cross-fertilizing each other; and presents in detail the kind of groundbreaking approach to the collective cognitive structures underlying social interaction, particularly in different cultures, which this discipline has put forward.

"Mental architecture" can refer to several things, such as how the brain is structured, how the mind is structured, or how mental entities are structured, and how collective concepts (the properties of a community—distributed and varyingly shared within that community) are structured. Of this list, it is only the last item that is directly in the province of cognitive anthropology, though psychological theories about the structure of mind and mental entities are appealed to by some scholars, too. The idea of mental architecture is often associated with *modules,* or a modular approach wherein each entity is bounded, having its own structure.

Contemporary cognitive anthropology undermines certain traditional assumptions held by many students of semantics with regard to two topics. The first topic involves the explanation of certain universal conceptual categories—traditionally spoken of as "natural kinds": Here, the received view was that the acquisition of universal conceptual categories may be innate whether what is innate could be the knowledge of them itself or the attributes and contexts of knowledge by means of which we form these common concepts, such as, for example, "animate," or "living." The other traditional topic has to do with the nature of *collective cognitive* (including linguistic) *categories*. Is their structure one of categories bounded once and for all, or is it a "prototype-extension" structure, with much creative flexibility in patterns of extension—that is, permitting extension to the range of applicability of such concepts or, in other words, extending the denotation or referents of such concepts? Of these two assumptions undermined by contemporary developments, the latter is the one that involves a topic most basic to cognitive anthropology, namely, collective cognitive categories. Nevertheless, the former issue is also pertinent to our topic.

In this entry, after a discussion of the aforementioned undermined assumptions, three further issues important to any treatment of collective cognitive structures will be presented.

Natural Kinds (Undermining the First Traditional Assumption)

The *natural-kinds argument* states that there exist certain classes of natural, substantive categories—that is, concepts referring to physical substances, such as landscape features (e.g., mountains, rivers), living things, or plant genera (e.g., oak, pine), that we are innately programmed to recognize. Although it is natural to assume that there is such an innate disposition, since all people recognize something like these categories, the question concerns whether the knowledge of them itself (i.e., "this is what a plant genus looks like") is innate or whether, alternatively, we are born with only the ability to recognize attributes (e.g., mass, edges, continuity vs. discontinuity, apparently internally generated change over time, apparent volition, etc.) from which we further infer such categories.

The difference matters because some anthropologists and others have claimed that our recognition of a natural category, such as "oak," is intrinsically different from our recognition of a culturally constructed category, such as "table." What is thus crucial is that work within cognitive anthropology on semantic and pragmatic categories suggests that *no such difference exists*. Even nursery rhymes ("The fork ran away with the spoon") imply that when instances of inanimate, culturally created object categories (forks and spoons) are given the right attributes (such as volition and the ability to act) we have no trouble imagining those instances as animate. And complex machines (e.g., computers and cars) are sometimes felt to be animate even while we know, intellectually, that they are not (consider Hal, the rogue computer, in the movie *2001*).

Collective Cognitive Categories (Undermining the Second Traditional Assumption)

In the following discussion, "term" (cf. *morpheme* or *lexeme*) is used to refer to a *signifier* (a sound

concept) and "referents," to refer to various *signifieds* (concepts); both kinds of concepts may be "realized" in the world as experienced by language-using human beings. "Word" is used to refer to a *sign*—Ferdinand de Saussure's union of a *signifier* and a *signified* (a relationship often misunderstood in discussions of "structuralism"). Understanding the nature of the two Saussurean concepts and the relationship between them is important because the one-to-one connection between *signifier* and *signified* that characterizes "componential semantics" is broken in extensionist approaches, as discussed below.

Componential Categories

Classically, semantic categories were considered—by early cognitive anthropologists and those who strove for rigorous formal semantic definitions—to be bounded, "all and only" chunks of semantic space. This approach was embodied in the componential analysis of kin terminologies by early cognitive anthropologists: A term's set of referents is defined by the intersection of a set of semantic components. The only alternative to this formal view was seen as a kind of accidental concatenation of incidental links among the *signified*s tied to any particular *signifier,* captured by Ludwig Wittgenstein's idea of "family resemblances." The problem with the "unstructured incidental links" alternative is that our shared use of language is too complex and apparently regular; it has to depend on a system. However, the "all and only" categories alternative would leave us with woefully insufficient vocabularies. Since our vocabularies are individually learned but have to be learned in an identical way by enough of us to enable effective communication in social contexts, we do not have the experience or time that it would take to learn an adequately dedicated vocabulary for talking about all of the things we have occasion to communicate about; that is, in the normal course of events, we have occasion to speak of a great many more concepts than such a fixed vocabulary can capture. New speakers only learn words via their frequency of use in conversations, and it takes ample frequency to keep these words active in the language. Frequently spoken of innovations, whether technological (e.g., computers), social ("rave" parties), style related ("A-line"), or whatever, all lead to new signs in the language, while, in contrast, significantly less frequently used terms (such as "quill" for a pen, or "syke" or "stell" as kinds of watercourses) drop out of people's active vocabularies—even if, in modern literate languages, they are technically maintained in dictionaries. For example, we needed some way less awkward than the paraphrase "a new writing implement that works sort of like a pen" to talk of ball-point pens when they first began to emerge (before their own label became widespread and, thus, common).

Prototype Extension

Developing out of Floyd Lounsbury's studies of kinship semantics and O. Brent Berlin and Paul Kay's study of color terms, a third alternative approach to semantic categories has gradually emerged, the *prototype-extension* approach. In this approach, basic or default definitions apply to prototypic referents of terms, and it was the communicative usefulness of easy reference to these referents that generated the words in the first place. Prototypic referents are what terms are presumed to refer to in the absence of other information, and it is only to them that the "essential properties" of the words necessarily apply.

In this approach, *semantic extension* provides the solution for the problem of how we can talk of many more referents than we have specifically dedicated terms for. We are able to use familiar terms in systematic (and contextually sensitive) ways for referents that do not rate their own dedicated terms. *Denotative extension* is based on the similarity of the extended referent to the defining-form attributes of the prototype (joined with functional or connotative relevance); such extensions (e.g., extending the term *cousin* from the prototypic first cousin to more distant ones) are considered true referents of the term in question. *Connotative* extension is based on a direct similarity of function but where the extended referent lacks key attributes of the prototype (as when a senior family friend is called "uncle"). *Figurative* extension involves extending a term (with its key contrasts) from one domain to another in order to use the connotations of the term. Such extension can range from very conventional usage (say our use of "brother" variously for monks and for members of one's fraternity) to quite ad hoc metaphors (the "plumpness" of one's academic department as it awaits its looming fiscal "diet"). At the same time, such extensions must be sufficiently systematic and based on general understandings for hearers to be able to recognize (and

in most normal conversation, they must be able to *automatically* recognize) what the speaker intends them to communicate in context. Extension is not one that applies to a term in isolation but one that operates in the context of a term's focal contrasts (e.g., "brother" vs. "sister," "father," "son," etc., or "uncle" vs. "aunt," "father," "nephew," etc.). In this approach, conjunctive definitions remain important, but their focus of application is different from that in the componential approach.

In cognitive anthropology, *semantics* refers to the ways in which words are defined in structural linguistics and in the anthropology that grew out of it. These definitions are couched in terms of relations of contrast (or opposition), by means of which words are distinguished from one another, and inclusion, by means of which they are grouped into higher-level categories. Such information includes what distinguishes a "father" from an "uncle" or a "son"—as kinds of "relative" or "kin," an "oak" from a "pine"—as kinds of "trees," a "tree" from a "bush"—as kinds of "plant," and a "chair" from a "table"—as kinds of "furniture." But obviously our use of these terms depends on much other information, such as the facts that an "uncle" is a "father's" (or "mother's") brother, that mothers and fathers have special responsibilities for their children that uncles and aunts (in Western culture) do not have, and that an emotionally close older nonrelative, in America, can be spoken to or of as "uncle" but not "father." Similarly, we know that oak makes more solid furniture than does pine. This wider sort of presumptively shared knowledge about the world that informs our use and understanding of words can be spoken of as *pragmatics*. Pragmatics thus defined is *not limited to language* (as is semantics) but extends out to the similar kinds of presumptively shared knowledge we have of how to treat an uncle or a friend, or a person we are standing next to in a supermarket line. This wider universe of knowledge that both our speech and our social interaction (whether cooperation, competition, or ignoring) depend on can be seen as the *cognitive* version of what anthropologists speak of as "culture."

Three Further Issues

Kinds of Collective Cognitive Structures

From the perspective of cognitive anthropology, both semantics and pragmatics represent kinds of *collective cognitive structures,* emphasis being placed on all three terms, jointly and individually, at the same time: *collective, cognitive,* and *structure*—that is, mental architecture.

Semantics can be seen as a single system paralleling the more exclusively linguistic systems of phonology, syntax, and perhaps the lexicon. But pragmatics can be broken into a number of distinct subsystems (or modules); these include inter alia Edward Hall's *proxemics* (the ways people in different cultures space themselves out in different social situations or how space is perceived in different cultural contexts), cultural-values systems, culturally shaped modes of emotional response (Gregory Bateson's *ethos*), "cultural modes of thought" (conceptual *bauplan*s—basic ways of imagining and ordering conceptual relations in a culture (cf. Bateson's *eidos*), "cultural conceptual systems" (formally organized conceptual systems such as folk taxonomies or kinship terminologies), and "cultural models of action" (models for how to behave in a given situation, e.g., going on a date or building a house—often spoken of simply as "cultural models," associated with the work of Naomi Quinn and Claudia Strauss, among others). Early cognitive anthropology had a significant impact on the initial development of the new discipline of cognitive sciences, and more recently, insights from cognitive sciences have helped shape developments in cognitive anthropology.

Collective Knowledge Systems and Individual Knowledge

The relationship between collective knowledge systems and individual knowledge is a tricky one. In any direct sense, all there is is individual knowledge, since there exists no collective mind or collective consciousness. But at the same time, we all constantly act as if there exist *collectively* held cognitive systems—such as the proper grammar of a language, the proper pronunciation and meaning of words, the correct way to show respect for an elder, what counts (socially and culturally, vs. legally) as justifiable homicide, and so forth. We presume these collective systems in our communication and interaction. What makes these putative collective systems effectively real is our constant reference to (or dependence on) them, joined with the fact that we know how they differ from our personal systems (e.g., "my accent" or "I prefer to say it this way") and the fact that we agree more with each other

about what are generally considered "correct" or "normal" usage, views, values, and so on (even if we ourselves do not necessarily adhere to these) than we do regarding our personal actions or preferences.

As individuals learning a cultural or linguistic system, we keep trying to construct a representation of it in our minds that allows us to generate acceptable performance and judgments, enabling us to make sense of the messages and behavior that we experience from others. Mostly, this learning process and the knowledge it produces are subconscious, but occasionally bits of the learning or the knowledge on which we are momentarily focused will rise to consciousness. We thus each have in our minds our *individual* knowledge (i.e., individual representations) of each of the various *collective* representations that make up our language and culture—including dialects, subcultures, and so forth, and the system variants that go with each social entity within which we participate or with whose members we interact.

Our separate individual representations of these communal cognitive systems are kept consistent with each other because our social interactions depend on them—but only to the degree to (and in the situations in) which that interaction is actually relevant. Thus, we all pretty much agree on what unicorns look like but don't seem much to agree on the nature of their feces; and more prosaically, English speakers agree on what a cousin is, but that agreement falls apart when we get into kinds of cousins (such as "first cousin, once removed" vs. "second cousin"). Note that we are talking about basic cultural *knowledge,* not about matters of taste or opinion—which vary even more. The details of how such systems are learned, organized, kept straight, and stored are topics of ongoing study.

Cognitive Structures and Social Units

For structures to be collective, they have to inhere in some kind of social units. At the same time, it is the shared systems of language and culture that enable membership in social units to be recognized and to function. In this sense, culture (including language) and society can be said to be mutually constitutive. However, collective cognitive structures pertain not just to society as a whole but to the full gamut of (and variety of hierarchies of) social units, whether formal or informal, face-to-face or indirect, continuing or ad hoc; and so they delimit a matching variety of pragmatic subcultural cognitive structures. The anthropological study and modeling of the systematic relationships among such subcultural cognitive structures is still in its infancy.

Cognitive Archaeology

Cognitive archaeology, or the archaeology of mind, has been broadly defined by Colin Renfrew as the study of past *ways of thinking* through the material remains of the past. What does this mean? Why ask an archaeologist about the mind? Above all, what is it, specifically, that archaeology can bring to the study of mind and human cognitive evolution?

Two major points may be made by way of answer: First, as our stated working definition makes clear, the archaeology of mind is not concerned with *what* people were thinking in the past but, instead, with *how* they were doing their thinking. Cognitive archaeology is primarily interested, in other words, to learn about the different situated processes, rather than disembodied contents, of human thought as they emerge and take shape in the different cultural trajectories of our species. This is important because as archaeology may well testify, significant episodes of the story of mind appear relatively recently in the archaeological record and can certainly be seen as the emergent products of various cultural trajectories rather than innate biological capacities. Indeed, the image of the human mind that emerges from the perspective of cognitive archaeology so far resembles that of a hybrid bio-cultural entity constituted in a double way: It is partly the product of biological evolution and partly an artifact of our own making.

How did we humans get to be so different then? This brings us to our second major point, which can be found by looking at three key topics that characterize, more than anything else, the archaeology of mind as an *epistemic culture:* time, change, and material culture. Starting with the early Paleolithic stone tools some 2.6 million years ago and moving to the more recent and ever more refined forms of artifacts and technologies, cognitive archaeology sets out not only to understand the workings of the minds that created them but also to explore the possible role that these objects might have played in extending our minds and redesigning ourselves. This coevolutionary process of deep enculturation and material engagement, which continues into the present, occupies the principal focus for cognitive archaeology. The recently developed field of *neuroarchaeology,* in particular, is primarily preoccupied with understanding the long-term developmental mechanisms by which the bidirectional, mutual constitution of brain and culture occurs. To this end, a basic commitment to some broadly defined, embodied and interactionist view of mind might protect us from sliding into neural determinism and thus from mistaking the properties of the sociocultural system for the properties of the individual or the brain.

Meanwhile, cognitive archaeology's special preoccupation with the world of things and long-term change signifies not only what differentiates it from the other disciplines in the field of contemporary cognitive sciences but also the point of intersection between these disciplines, to which cognitive archaeology may have some interesting contributions to make. For instance, one important contribution can be seen in the way cognitive archaeology has made clear that the science of mind and the science of material culture are two sides of the same coin. It is now understood that the way we think is not only changed but also partly constituted through the social experience of action and material engagement activities. New forms of engagement with the material world bring about new possibilities and constraints for the mind. Another, and closely related, contribution of cognitive archaeology can be seen in the recognition that the hallmark of human cognitive evolution may be based not on the ever-increasing sophistication or specialization of a modular mind but on an ever-increasing representational flexibility that allows for environmentally and culturally derived plastic changes in the structure and functional architecture of the human brain.

Naturally, the task of trying to reconstruct the prehistory of mind has not been an easy one. Establishing testable, empirical, but also culturally sensitive and philosophically informed, links between brain structure, cognitive function, and

archaeologically observable behaviors remains a central challenge. But since the emergence of cognitive archaeology in the early 1980s, there have been some radical advancements as well as changes in perspective in the way we approach, interpret, and understand the ancient mind *through the material record*. Especially in the past decade or so, the archaeology of mind has apparently come of age with a series of remarkable theoretical advances and a growing number of new empirical findings. The initial skepticism about "paleopsychological" investigations gave way to a systematic research endeavor that fuses different schools of thought and research strands together in a highly interdisciplinary and rapidly growing research field.

New, important steps have been made toward an understanding of the basic principles of brain evolution and of human brain–culture coevolution. As a result, we can now make better sense of the evolutionary changes (structural/functional) that occurred, the ways in which human brains differ, as well as the manner in which these differences evolved. In this context, new methodological advances in the field of paleoneurology enable a more nuanced interpretation of the observed variation in endocranial morphology and a better understanding of the patterns of growth (changes in size) and development (changes in shape) of the brain as reflected in the available record of fossil endocasts. Moreover, a new hypothesis on the role of enhanced working memory in the emergence of modern human cognition has been proposed.

Last but not least, important theoretical developments in phenomenology and cognitive science assist us in rethinking our conventional ideas about the boundaries between cognition and material culture, and the embodied character of human experience. Archaeologists have learned a great deal about the social and cultural basis of the human mind while working with anthropologists, philosophers, and social and cognitive scientists. Conversely, cognitive archaeology, probably more than any other field of cognitive research, has the ability to develop a systematic understanding of the relationship between cognition and material culture from its own unique perspective. The temporal depth and historical diversity of the archaeological object, coupled with this systematic examination of the interaction between mind and matter in the course of human cognitive evolution, may well furnish some key insights into the nature of human condition: who we are and how we got here.

Cognitive Phenomenology

The term *cognitive phenomenology* refers to the idea that the phenomenal quality of experience is not limited to the sensory or feeling states but that there is, in Thomas Nagel's phrase, "something it is like" to engage in higher-order cognitive acts like thinking, judging, or evaluating. The claim that there is a phenomenal or experiential aspect to thinking is controversial, with some philosophers arguing against the idea (e.g., David Braddon-Mitchell and Frank Jackson, Peter Carruthers, Michael Tye) and others arguing in favor of it (e.g., Terence Horgan and John Tienson, Charles Siewert, Galen Strawson, or Dan Zahavi). A related but distinguishable issue is whether phenomenal consciousness is conceptual or nonconceptual or, more precisely, whether the conceptual aspects of thinking contribute something to phenomenal experience even if the phenomenality in question is sensory.

Those who support the idea that thinking does involve a phenomenal or experiential aspect claim that just as there is something it is like to taste a lemon, there is something it is like to think about a lemon and that these two phenomenal states are different. There is a difference between what it is like to actually taste a lemon and what it is like to remember what it is like to taste a lemon, just as there is a difference between what it feels like to throw a lemon and what it feels like to calculate how far I might be able to throw it.

Intentional states have a phenomenal character, and this phenomenal character is precisely the "what it is like" of experiencing a specific propositional attitude vis-à-vis a specific intentional content. Change either the attitude type (believing, desiring, wondering, hoping, etc.) or the particular intentional content, and the phenomenal character thereby changes too.

Likewise, Alvin Goldman suggests that when we think about something, we are implicitly (nonreflectively) aware of our thinking. This seems to imply that thinking has a phenomenal feel to it. This may mean that there is a specific qualitative feel to having a specific thought, or it may mean that thought processes, like associating or inferring or speculating, may have different feels. One might claim, however, that there is *nothing* that it is like to think, except that one is aware that one is thinking. Nor is it clear how specific the awareness or feeling is. Solving a math problem may feel different from planning a road trip, and engaging in either of these cognitive tasks may feel different from evaluating the motives of your best friend. But does solving a simple arithmetical problem feel different from doing calculus? Does planning a road trip to Memphis feel different from planning a holiday trip to Crete? Does evaluating someone's motives feel different from evaluating their physical health? On the one hand, even if one cannot pick out a phenomenal difference in every thought (or attitude type), the lack of phenomenal difference does not necessarily mean a lack of phenomenality. If we say that Thought A feels no different from Thought B, this doesn't mean that they have no feel at all to them. On the other hand, if one can pick out a difference in each of these thoughts, then it seems possible that the phenomenal experience is linked to the intentionality or the content of thinking.

One could take this idea further and claim that the difference between doing arithmetic and doing calculus is not about the doing but about the complexity

of the problem that's being considered, or that what it feels like to think about something depends entirely on the something that is being thought about. In this regard, there are three possibilities: (1) the differences under consideration are not differences in the phenomenal aspects of thinking but rather simply differences in intentional content, and the phenomenal aspects are completely distinguishable from the intentional aspects; (2) the differences under consideration are differences in the phenomenal aspects of consciousness but are linked to intentional differences because the phenomenal and intentional aspects are related or even inseparable; and (3) the differences are in some way purely phenomenal differences that don't depend on intentional content.

Those who argue against the idea that thinking has a phenomenal feel suggest that the idea confuses thinking with the possible inner speech or visual imagery that might accompany thinking. Inner speech or visual imagery may be phenomenally conscious, but the thinking itself intrinsically (i.e., nonrelationally) has no phenomenal quality. But one might object that someone who rehearses a bit of inner speech, for example, "La porte est rouge," but who isn't thinking that the door is red, because she doesn't know what these words mean, would have a different phenomenal experience from someone who understands the words. In that case, the thinking itself seems to make a difference. The question, as Carruthers and Veillet (2011) have recently put it, is whether, with regard to some phenomenal experience, a concurrent thought "makes a constitutive, as opposed to a causal, contribution to the phenomenal properties" (p. 3). On their view, no one would deny that thinking about something may play a causal role in generating phenomenal experience. The central question, however, is whether the thinking is constitutive of the phenomenal experience, that is, whether thinking is instrinsically phenomenal or not.

The debate about cognitive phenomenology is ongoing. Both sides have appealed to introspection, both have appealed to inference to the best explanation, different sides have contested whether phenomenal aspects of cognition facilitate self-knowledge (knowing what mental state one is in), and disagreements abound about the importance of this issue to questions about representational content. Everyone does agree, however, that the purported fact that making arguments on one side feels more convincing than making arguments on the other side, which apparently involves no feeling at all, is not decisive.

Cognitive Sciences

Cognitive science is the interdisciplinary attempt to understand mind and intelligence by combining insights from psychology, neuroscience, linguistics, artificial intelligence, and anthropology.

What are the relations among the cognitive sciences, such as psychology and neuroscience, and the social sciences, such as economics and sociology? This broad question raises many subordinate issues, such as the following: What distinguishes the cognitive sciences from the social sciences? Are theories and explanations in the cognitive sciences different from those in the social sciences? Can the cognitive sciences be reduced to the social sciences, or are the social sciences methodologically independent from or even conceptually prior to the cognitive sciences? What is the relation between social entities such as companies and nations and the individual people in them?

This entry outlines some of the main answers that have been given to these questions, thus tracing the intricate relationship between cognitive and social sciences.

Origins

The term *cognitive science* was coined in the 1970s to advocate a common set of concerns and ideas that form the intersection rather than just the union of all the fields that might be called cognitive sciences. There is no analogous interdisciplinary field called *social science* but rather a host of largely independent disciplines, such as sociology, economics, political science, anthropology, and psychology. Several fields are often placed among *both* the cognitive and the social sciences, including psychology, anthropology, and linguistics. This double placement is natural for fields that are concerned with the operations of individual minds *and* with the operations of minds in social contexts, as occurs in subfields such as social psychology, cognitive anthropology, and sociolinguistics.

Cognitive Sciences and Social Sciences: Relationship

Despite this overlap, there is an obvious difference in primary focus between the cognitive and social sciences, with the former concerned with the mental processes of individuals and the latter concerned with the social processes (mostly) of groups, such as companies and nations. Hence, we can use the term *mind–group problem* for the set of issues about the relation between the cognitive and social sciences. Progress in both the cognitive and the social sciences requires dealing with these issues, as is evident from recent interdisciplinary developments. For example, cultural psychology has been challenging the presuppositions of individualist cognitive psychology, and behavioral and neural economics have begun to provide alternatives to traditional approaches to economic analysis.

Dealing with the mind–group problem must begin with an understanding of the nature of the theories that are used to explain cognitive and social processes. Little is to be gained by viewing theories as sets of formalized universal statements, as the logical positivists advocated, because theories in both the cognitive and the social sciences rarely have this kind of structure. Instead, there is growing appreciation that cognitive and social theories can be better understood as descriptions of mechanisms, which are systems of parts whose interconnections produce regular changes. From this perspective, explanations of both cognitive and social phenomena consist of describing the mechanisms—parts and interactions—that causally produce the changes that require explanation. The relevant mechanisms are not just the simple push–pull interactions of Newtonian physics but can involve all the complexity of biological systems, including feedback relations and chaotic unpredictability. Then the mind–group problem takes on this form: What are the relations among the mental mechanisms relevant to explaining individual behavior and the social mechanisms relevant to explaining social behavior? This formulation is obviously controversial for practitioners of the cognitive and social sciences, who claim that explanations of human behavior cannot be mechanistic because they need to rely on introspection of self or empathic interpretation of others.

Three Views of the Relation Between Cognitive and Social Sciences

There are several alternative views of the relation between cognitive and social mechanisms: cognitive reduction, social construction, autonomy, and interaction. Reductionism is the view that social changes

can be explained in terms of psychological mechanisms, which in turn can be explained by neural mechanisms. Social constructionism, in contrast, makes social explanations fundamental on the grounds that all knowledge is socially constructed. Autonomy is the view that the cognitive and social sciences do and should operate independently from each other, so that neither psychology nor sociology, for example, needs to pay attention to ideas from the other field. The interactionist view may be seen as preferable, namely, that there are many important connections between the cognitive and social sciences that can be understood in terms of interacting mechanisms.

In order to adjudicate among these views, we need multiple examples of the kinds of mechanisms that currently appear to have the most explanatory potential at both individual and group levels. Modern approaches to cognitive science arose in the 1950s because ideas about computing provided an alternative to behaviorist explanations, whose inadequacy was increasingly becoming evident. Behaviorists in psychology and linguistics thought that explanation of the performance of humans and other animals should only concern how behavioral responses result from environmental stimuli that produce learning by reinforcement. Psychologists such as George Miller drew on new ideas about computer programs to argue that behavior could be better explained by supposing that animals from humans to rats employ mental representations and algorithmic processes that operate on the representations. This approach is clearly mechanistic: The parts are representations, the interactions are computational operations, and the behavioral changes result from applying the operations to the representations. For example, one important kind of explanation in cognitive science proposes that the most important mental representations are IF-THEN rules that can be used to solve problems by means of algorithms for selecting and applying rules in particular situations. A navigational problem can be solved by reasoning that operates with rules such as "IF you want to get to Australia, THEN arrange a flight."

Advances in Cognitive Science

Connectionism or Parallel Distributed Processing

Many other kinds of representations have also been proposed as important to explaining human cognition, including concepts, images, and analogies. These representations also function as parts of systems for processing information via computational interactions. In the 1980s, a new approach to cognitive explanations became influential, called *connectionism* or *parallel distributed processing*. Inspired in part by neural processing in the brain, connectionists view thinking as resulting from simple neuron-like processers connected by excitatory and inhibitory links. Computational models using neural networks, rules, concepts, images, and analogies have been used to simulate and thereby explain a wide range of kinds of thinking, including inference, problem solving, learning, and language use.

Contemporary Advances: Cognitive Neuroscience

In the 21st century, by far the most striking trend in cognitive science is the increasing prominence of *cognitive neuroscience,* which has both experimental and theoretical sides. The experimental side has exploded because of the availability of brain-scanning technologies such as functional magnetic resonance imaging. These technologies make it possible to examine what is happening in the brain while people perform complex tasks such as solving problems. Brain-scanning experiments produce vast amounts of data that need to be explained using new theories about how brains process information. The field of theoretical neuroscience develops computational models that simulate how interactions of large numbers of neurons can produce mental changes. These models are more biologically accurate than the earlier connectionist models, through employment of neural networks that are closer to those in the brain with respect to firing and connection properties. Explanations of thinking employed by cognitive neuroscience are obviously mechanistic: The parts are neurons, the interactions are the electrical and chemical ways in which neurons influence each other, and the resulting changes correlate well with the mental changes revealed in behavior.

Brain–Mind and Brain–Mind–Group

These advances in cognitive neuroscience make all the more pressing the traditional philosophical issue of the relation between body and mind, which becomes the *brain–mind problem*. This problem concerns the relation between neural mechanisms and mental ones and hence is similar to the mind–group problem concerning mental mechanisms and

social ones. Connecting these together, we get the *brain–mind–group* problem, whose solution would provide answers to a host of questions concerning the cognitive and social sciences. Before approaching this extended problem, we need a brief characterization of the kinds of social mechanisms that need to be connected with mental and neural ones.

Social Mechanisms

Social scientists are much less accustomed than biologists or cognitive scientists to describe explanations in terms of mechanisms, but it is easy to view social processes as consisting of interacting parts. At the first level, the parts are persons, and the interactions are all the forms of communication that occur between them. These include not just verbal conversations but also electronic messages and the full range of nonverbal communication, such as the transfer of emotional information by bodily signals. The social interactions that result in social changes can take many forms, such as power relations in which some individuals use verbal or nonverbal communication to induce emotional reactions in others that make them act in ways that the powerful want. For example, a political leader can wield power over a population in many ways, such as making them fear a foreign power or convincing them that the leader is the solution to their economic problems. Hence, power is a social mechanism that depends on cognitive mechanisms by which the powerful induce emotional reactions in the weak. Higher levels of social mechanisms concern group–group interactions, for example, in international relations where multiple countries cooperate and compete.

Neural, Psychological, and Social Mechanisms

If that understanding of social mechanisms is correct, we can approach the brain–mind–group problem by considering the relations among neural, psychological, and social mechanisms. There are two main reasons for rejecting the reductionist views that social phenomena are fully explainable by psychological mechanisms and that psychological phenomena are fully explainable by neural mechanisms. First, the phenomena to be explained are so complicated that it is difficult to see how a full account of them could be given just in terms of lower-level mechanisms. Consider, for example, social movements such as feminism and environmentalism. These involve the interactions of large numbers of people formed into identifiable groups that help determine who interacts with whom. There is no obvious way to identify social entities such as groups with psychological or neural entities. Second, causal explanation does not always operate in the reductionist direction from lower mechanisms to higher phenomena but sometimes can proceed from higher mechanisms to lower phenomena. For example, it might be a part of the explanation of why there is neural firing in the dopamine pathways of a fervent environmentalist to say that he or she is happy to be interacting with other members of an activist organization. In this case, the social causes the neural.

Recognition of social causation is not the imperialistic position found in some postmodernist social scientists that *all* knowledge is socially constructed, which implies that psychology and the other cognitive sciences can be ignored. Social processes undoubtedly contribute to all scientific developments, but so do psychological processes such as problem solving, as well as the neural processes that enable human brains to think. Experimentation in psychology and neuroscience, not to mention physics and chemistry, is sufficiently robust for the claim that scientific knowledge is *only* socially reconstructed to be hugely implausible.

Cognitive and Social Sciences: Interactions

Perhaps, then, we should conclude that the cognitive and social sciences are simply independent of each other and can pursue their own agendas. In the early decades of cognitive science, it was common to suppose that psychology was largely autonomous from neuroscience in that it dealt abstractly with information processes in common with computers, concerned with software functions rather than the underlying hardware. Advances in brain-scanning technologies, however, have utterly undermined this view, and since the 1990s, cognitive psychology has increasingly been integrated with neuroscience. Similarly, there are growing signs of recognition of the relevance of the cognitive sciences to the social sciences, for example, in the subfields of cognitive sociology and neuroeconomics. The social sciences are not so successful in their explanations and predictions that they can afford to ignore what psychology and neuroscience have to say about how people behave in social contexts. For example, the financial

collapse of 2008 was inexplicable in terms of the economic views of idealized individuals assumed by rational choice theories, but it begins to make sense from the perspective of psychological theories of human cognitive and emotional limitations.

In the other direction, the cognitive sciences do not hesitate to draw on the social sciences for many kinds of explanatory factors that contribute to explanations of how people behave in interaction with others. There is increasing recognition that social processes are an important part of intelligence, even in computer science, where the subfield of multi-agent systems looks at how artificial intelligence can be distributed across multiple interacting machines. Hence, the autonomy view is implausible as an account of the primary relation between the cognitive and the social sciences.

The weaknesses in the reductionist, social constructionist, and autonomy views show the need for the development of a richer account of how the cognitive and social sciences can fruitfully interact. Consider the important phenomena that involve ideological change, for example, the rise of new social movements such as communism and fascism or, more recently, the Tea Party and Occupy Wall Street interest groups in the United States. Such ideological developments are social phenomena observable in rallies and demonstrations, but they are also cognitive phenomena rooted in the beliefs and attitudes of the participants in the movements.

Cognitive and Social Mechanisms: Interrelation

What cognitive mechanisms are responsible for the adoption and maintenance of ideologies by individuals? Ideologies are appealing as the result of processes of emotional coherence, in which people form their beliefs and attitudes in response to their goals as well as the available evidence. The main psychological mechanisms include motivated inference, in which people marshal evidence in ways that suit their goals, and fear-driven inference, in which people arrive at beliefs that scare them because anxiety causes them to focus on the limited evidence for those beliefs.

These cognitive mechanisms are complemented by social mechanisms that transmit both cognitive and emotional forms of information. Here are some of the relevant mechanisms that bridge the cognitive and the social:

1. *Verbal communication,* in which people make statements and perform other kinds of speech acts
2. *Neural mirroring,* in which observation of the experience of another person can produce the same neural activity that would be produced by having the experience oneself
3. *Emotional contagion by mimicry,* in which people mimic the facial expressions of those with whom they interact, inclining them to acquire similar emotional reactions because emotions are in part responses to bodily changes
4. *Attachment-based learning,* in which emotional attitudes are acquired from people, such as parents, to whom a person is emotionally attached
5. *Empathy,* in which people acquire an emotional response from others by imagining themselves in the others' situations and experiencing emotions similar to theirs
6. *Altruism and sympathy,* in which people can acquire emotional responses directed toward the well-being of others
7. *Social cuing,* in which people's facial expressions, such as anger, can cue negative emotions, such as guilt, in their targets
8. *Power manipulations,* in which one person gains power over others by offering them something they desire or by offering to protect them from something that they fear

All of these social communication mechanisms depend on underlying psychological and neural mechanisms but do not reduce to them, because their description requires reference to the social processes of different people interacting with each other. Hence, explaining the spread of an ideology through a population requires attention not only to the cognitive/emotional mechanisms operating in individual brains but also to important social events, such as conversations, meetings, rallies, demonstrations, and occupations. These events provide the occasions by which social mechanisms ranging from verbal communication to power manipulations can affect the psychological and neural mechanisms operating within individuals.

The spread of ideologies in groups exemplifies the principle that the actions of groups result from the actions of individuals who think of themselves as

members of groups. On this principle, the explanation of group behaviors is

(a) not individualist, because groups are not reduced to mental representations;
(b) not holistic, because the psychology of individuals is considered;
(c) emergentist, because the actions of groups are different from the properties of individuals and depend on complex interactions between the individuals, including their representations of the group and each other.

Emergence

The concept of emergence is a hotly contested one in the philosophy of science, but a reasonable and nonmystical version is available: Emergent properties belong to the wholes, do not belong to any of the parts, and are not aggregates of properties of the parts. A social group, such as a political party, can have emergent properties, such as coming to power, that are not just aggregates of the people in the party because they depend on interactions between the members of the party and interactions between the party and other social groups. Similarly, a key aspect of a solution to the brain–mind problem is appreciation of how psychological properties such as representation, emotion, and even consciousness emerge from neural mechanisms.

Conclusion

In sum, the following principles describe the key relations between the cognitive sciences, which deal primarily with individual thinkers, and the social sciences, which deal primarily with group action: (a) the social does not reduce to the cognitive or the cognitive to the social; (b) explanation of social and cognitive phenomena will require attention to the mechanisms at both levels and to the interactions among them; and (c) social groups can have emergent properties that are neither reducible to nor independent from the psychological properties of their members but rather emerge from them as the result of cognitive and social mechanisms. Philosophy can serve a valuable role by helping cognitive and social scientists make the conceptual and methodological connections that should someday lead to an integrated cognitive social science.

Collective Agents

Collective agents are groups of agents who act together. We speak of groups of agents as doing things and of what they do as collective actions. Collective agents do things both intentionally and unintentionally. Electing a new president is something that citizens do intentionally, but poisoning the environment is something that they do unintentionally. The minimal social unit consists of a group of agents who do something together intentionally. Understanding collective agents and collective agency is therefore central to understanding social reality.

Collective agents sort into two broad categories. Plural group agents are picked out using plural referring terms (e.g., "we," "they," "the President's men," etc.), and their membership is invariable. Singular group agents are picked out using grammatically singular referring terms (e.g., "the Paris Mob," "the Supreme Court," "the British Parliament," "General Motors Corporation," etc.). They can survive changes in their membership and could have had different membership from their present one. These include institutional agents—corporations, governments, armies, clubs, and so on—defined in terms of a structure of institutional roles for individuals, as well as more informal groups such as mobs and crowds.

There are two main questions about collective agents. The first question is whether to understand collective agency we must admit the existence of irreducibly group agents over and above individual agents. Individualists argue that talk of collective agents can be understood entirely in terms of individual agents. Although individualists do not deny that there are groups of agents, they deny that groups are themselves agents. Anti-individualists, in contrast, maintain that collective agency requires (at least in some cases) a group agent over and above the individual agents who constitute it. The second question is how to understand the psychology of group action. Two subquestions arise. First, if we must admit irreducibly group agents, must we attribute to them psychological states, such as desire, belief, and intention; if so, how can we make sense of this? Second, what is the difference between the intentions with which agents act as individuals, I-intentions, and the intentions of agents who participate in intentional group behavior, we-intentions?

Motivations for anti-individualism are divided into three sorts.

The first is the claim that ordinary discourse about collective action entails that there are genuine group agents. The referent of "I" in "I rowed the boat ashore" is the agent of the action expressed. Similarly, it seems, the referent of "We" in "We rowed the boat ashore" is the agent of the action expressed in it. In addition, many actions seem to be things that no individual can be said to have done. When three men lift a piano, no one is the agent of the lifting. A joint declaration of war by Congress cannot be performed even in principle by a single individual. Furthermore, while plural group agents are individuated by their members, singular group agents (e.g., the U.S. Congress) survive changes in their membership, act over periods longer than the life span of any of their members, and could have had different members than they in fact have had.

The second is the claim that we must admit group agents as such to make sense of our practices in assigning praise and blame for collective actions. We seem often to attribute to groups responsibility for what they do (in the form of praise or blame) when it is not clear that any of the individuals who make up the group are candidates for the kind or degree of responsibility in question. For example, in a stoning, no one person who participates is responsible for the death. Or a government may be responsible for what one of its agents does or fails to do, though the agent is excused because of personal obligations that the state does not have.

The third is the claim that some institutions, such as corporations, are complex enough to have the functional organization of an agent. If functional organization is sufficient for being an agent and corporations have the relevant functional organization, it would follow that they were agents in their own right.

Individualism is motivated by the view that the mechanism of joint action lies in the joint expression of individual agency, so that no superagent should be required in order to understand what groups of agents bring about. Individualists can either accept an error theory about ordinary discourse or argue that, on analysis, discourse about group actions does not commit us to group agents but only multiple individual agents contributing to bringing about events. Plausibly, for example, the surface form "We rowed the boat ashore" is misleading. It admits of a

distributive and collective reading. On the distributive reading, we interpret it to mean "Each of us is such that he is an agent of an event, which is a rowing of the boat to shore." We get the collective reading by reversing the order of "an event" and "each of us": "An event is such that each of us is an agent of it, and it is a rowing of the boat to shore." A similar, though more elaborate, strategy would be required for discourse about singular group agents. With respect to the argument from the moral autonomy of group agents, individualists must argue that all moral praise and blame must be distributed over individual members of the groups that act; for example, in a stoning, while no one person is causally responsible for the killing, it might be said that all are equally morally responsible for it, because they act in concert with others with the joint aim of killing the victim. Finally, with respect to the functionalist argument, individualists may charge, even laying aside doubts about the adequacy of a functionalist theory of mind, that the case has not been made that any organization does have the functional organization of a person. The requirement that in attributing any propositional attitude to an agent many supporting attitudes and capacities need to be attributed means that the burden on the functionalist is very heavy. For example, it may seem innocent enough to think of the corporation as such intending to paint its headquarters red, but to possess the concept of redness requires visual experience, for which the corporation, as opposed to the agents who realize it, clearly does not possess the capacity.

Collective Emotions

Among social phenomena that raise important philosophical as well as social-scientific issues is the phenomenon of collective emotions. The main purpose of this entry is to present a classification of collective emotional phenomena in terms of their degree or level of *collectivity,* using existing theoretical concepts of collective emotions as examples of different types of collective emotions. The functions of collective emotions in social groups will also be highlighted.

Collective emotional phenomena have been conceptualized in many ways in philosophy and the social sciences. In addition to "collective emotion," notions such as "group emotion," "shared emotion," "collective effervescence," and "emotional climate" have been used in different discourses. These notions are partly overlapping, but there is no wide interdisciplinary agreement on the definition of "collective emotions." Therefore, this concept will here be used as an umbrella term for collective phenomena that are characterized by *intentional aboutness* and *affective experiential quality,* as distinct from other affective phenomena such as moods or feelings, which lack the intentionality of emotions.

Even if intentionality and affectivity are phenomenologically inseparable in the emotional content,

we can distinguish the question about the intentional structure of collective emotions from the question about their affective quality. Intuitively, collective emotions are collective in both respects—their intentional structure is collective in some robust sense, and their affective experience is collective in the sense of being shared by several individuals. However, these aspects of collective emotions may require different kinds of explanation. The subject, object, and content of emotion are important for the collectively intentional structure of emotions, whereas physical proximity of individuals and psychological and biological mechanisms of various kinds, such as attentional deployment, facial mimicry, neural mirroring, behavioral entrainment, and emotional contagion, are relevant for the emergence of collective affective experiences.

The Intentional Structure of Collective Emotions

Following Margaret Gilbert, we can divide theoretical accounts on the *intentional structure* of collective emotions into three types: weakly aggregative accounts, strongly aggregative accounts, and collective subject accounts. The subjects of the first two types of collective emotions are individuals, while the main difference between these emotions lies in their content. Weakly aggregative collective emotions are about the subject's own actions or events that matter to a subject on the basis of his or her private concerns, whereas the content of strongly aggregative collective emotions is associated with the subject's *group membership* and the shared concerns that come with it. Finally, collective subject accounts suggest that even if there are, ontologically speaking, no group minds but only individual minds, collective emotions nevertheless have a "collective subject" in some robust sense.

Weakly aggregative collective emotions are collective in a weak sense of being based on overlapping private concerns of individuals. These concerns may be about survival, security, attachment, health, wealth, happiness, and so on. An example of a weakly aggregative collective emotion is the panic of shareholders about the fall of stock prices. Individual shareholders share the same type of emotion about the same event. However, the content of their similar emotions is individual, because each shareholder is concerned about his or her own wealth. A theoretical concept of this type is J. M. George's "group affective tone." Here, it is sufficient that an aggregate of individuals experience the same type of emotion, such as fear or anger or joy, in a group context, such as at a bus stop or workplace, with mutual awareness that others are feeling the same.

Strongly aggregative collective emotions are experienced by a subject in the role or position of a group member, with mutual awareness that other group members are feeling the same type of emotion. The content of emotion is collective, because the emotion is about an event that matters to the individual on the basis of his or her membership in a particular social group or category, such as a political party, sports team, religious sect, artistic ensemble, workgroup, or ethnic group. Empirical and philosophical theories differ from each other in terms of how they understand the required group membership. Empirical theories, such as the *Intergroup Emotion Theory* of D. M. Mackie and E. R. Smith, emphasize the psychological mechanism of group identification, whose intensity determines the relative importance of different groups for individuals. However, from a philosophical perspective, the intensity of identification does not distinguish between those groups whose membership is founded on individuals' private commitment to the group or its ethos—certain constitutive goals, values, norms, or beliefs of the group on the one hand—and those groups whose membership is founded on the group members' joint commitment to the group or its ethos on the other (as in Raimo Tuomela's theory). From a normative point of view, the latter kind of collective emotions are more robustly collective than the former kind of collective emotions. The "membership emotions" Margaret Gilbert identifies provide an example of the more robust type of strongly aggregative collective emotions.

Accounts in terms of "collective or plural subjects" argue that the subject of collective emotions is in some sense a "we" rather than a mere aggregate of individuals who ontologically constitute the specific "we." Margaret Gilbert suggests that members of a plural subject can jointly commit themselves to feeling particular emotions as a body. The object of commitment is an evaluative judgment that for Gilbert constitutes the content of emotion, whereas feelings are only contingent concomitants of emotions. Therefore, having a collective emotion does not require experiencing it but merely acting and talking in ways that are consistent with the evaluative content of the emotion. If, for instance, a group of

people have jointly committed themselves to feeling guilt, then they have jointly committed themselves to judging the object of their emotion, a certain action of theirs, as morally wrong, as well as to talking and behaving in accordance with this judgment.

H. B. Schmid rejects Gilbert's plural subject account, because it undermines the affective dimension of emotions. However, he retains the idea of a collective subject, which in his model emerges as a phenomenological frame in which individuals interpret their feelings as "our" feeling. A phenomenological fusion of feelings requires that individuals share the same concern, such as survival, attachment, or welfare, but their emotions need not have the same object. Schmid also suggests that the feelings of individuals may differ from each other in terms of their intensity and quality without undermining the possibility of a phenomenological fusion.

The categories of weakly and strongly aggregative collective emotion relate to real emotions at various levels of collectivity. A phenomenological fusion of feelings also seems possible, but it need not alone indicate a high level of collectivity because such fusion may emerge even in the context of weakly aggregative collective emotions. Instead, the plural subject account of Gilbert does not appear to refer to any genuine collective emotion, for it is not psychologically possible to summon an emotion by means of a joint commitment to feeling it. Nevertheless, Gilbert's plural subject account of collective emotions is plausible in the sense that it refers to feeling rules—rules of appropriateness for distinct emotions—which individuals can, in some circumstances, produce by jointly committing themselves to such rules. Feeling rules are important in the regulation of emotional states and expressions, but they are emotions themselves. Strongly aggregative collective emotions that are felt for reasons emerging from a jointly committed group membership represent then the highest level of collectivity as far as the intentional structure of collective emotions is concerned.

Collective Affective Experience

The emergence of collective affective experiences requires the copresence of individuals, either physical or virtual. The key to such experiences is an extensive *synchronization* of several individuals' emotional responses: their physiological changes, facial expressions, action tendencies, and subjective feelings. Several psychological and biological mechanisms contribute to such synchronization. These mechanisms include attentional deployment, facial mimicry, neural mirroring, behavioral entrainment, and emotional contagion. The sociologist Randall Collins maintains that the synchronization of individual emotional responses typically occurs in the context of interaction rituals, such as songs, dances, chants, games, and other activities, in which the participants are separated from others; they share a common emotional mood, their attention is focused on the same object or activity, and they are mutually aware of sharing the same mood and focus of attention with each other. The result of extensive synchronization of individuals' emotional responses is collective effervescence, "a high degree of absorption in emotional entrainment."

The Functions of Collective Emotions in Social Groups

Collective emotions have several functions in the emergence and maintenance of social groups. First, collective emotions contribute to the emergence of social groups as well as to the formation of their goals, values, and intentions—a certain group ethos. For instance, shared anger at oppression or shared guilt about collective wrongdoing to a third party contributes to the emergence of social and political movements. Second, collective emotions motivate expressive and purposive behavior in support of the group ethos. Shared anger motivates protests, and shared guilt motivates apologetic and reparative actions toward a violated outgroup, for instance. Third, collective emotions manifest and reinforce group members' commitment to the group and its constitutive ethos. Group members feel shared emotions when their group ethos is affected favorably or adversely, thus *experiencing* their being "in the same boat" with each other. Fourth, collective emotions affectively "glue" group members to each other as fellow group members. Collective emotional experiences are intrinsically pleasant and rewarding as they involve feelings of solidarity, which foster affective bonds, cooperative ties, and group loyalty, especially if the shared emotions are hedonically positive rather than negative. There is some evidence that strongly collective emotions are capable of serving these functions more efficiently than weakly collective emotions, but this hypothesis requires further support

from empirical research that would pay closer attention to the various types of collective emotions.

Collective Goals

The concept of a "collective goal" is central to several problems relating to collective action. For example, it has been argued that collective actions are brought about when a group of individuals orient themselves around a collective goal. Similarly, a collective intention is characterized—at least in part—by a desire on the part of a group of individuals to bring about a collective goal. To take another example, Margaret Gilbert has influentially argued that the collective goals of a group play an important role in determining the beliefs that are held by the group.

Despite its centrality, there have been relatively few full-length treatments of this concept in the collective action literature. Notable exceptions are Raimo Tuomela and Kaarlo Miller, who emphasize the differences among various kinds of goals, including collective goals. According to Tuomela, a collective goal must satisfy two conditions. First, it must be accepted in the "we-mode"; this means that each person aims to achieve the goal as a member of the group. Second, it must satisfy the "collectivity condition": if the goal is met for anyone in the group, it is met for everyone in the group. These conditions are echoed by other authors, including Christopher Kutz, who argues that for a goal to be collective, there must be a nonempty intersection of states of affairs that satisfy those collective ends.

The clearest way to understand these conditions is by contrasting collective goals with goals that are not collective and with group behaviors that merely resemble those brought about by collective goals. For example, a collective goal is not merely a goal that happens to be shared by more than one agent. So if you and I each have the goal of going to a particular restaurant at noon, we do not thereby have a collective goal to do so. Even though there is a state of affairs in which our goals are satisfied—namely, the state of affairs in which we are both at the restaurant at noon—our goals can be satisfied without being in the "we-mode," that is, without our aiming to meet our goals cooperatively as a group. As Tuomela observes, this distinction between a goal that happens to be shared by all the members of a group and a truly collective goal corresponds to Rousseau's distinction between the "will of all" and the "general will."

To take another example, we may have the goal that a certain table be moved from one end of a room to another. If we are indifferent as to how the table is moved—that is, if we don't care who moves it—then it is not a collective goal. In other words, if the goal can be met by my moving the table by myself, then the goal cannot be collective. In contrast, a truly collective goal that we move the table *together* can be satisfied only if the table is moved as a result of our cooperative action. Such a collective goal would be thwarted if one of us were to move the table alone.

It is also useful to note the differences between meeting a collective goal and merely coordinating our behavior. This contrast is informative because it shows that important conditions that are frequently discussed in theories of collective action are insufficient for characterizing collective goals. For example,

consider the coordinated behavior of driving on the right side of the road in some countries. As individuals, we each have the goal of driving on the right, and our goals are mutually interdependent in the sense that they are justified by our knowledge that others have the same goal. In this respect, the example is different from the case where we each want the table to be moved; in the latter case, the rationality of my goal did not depend on your having the same goal. But in this case, it would be irrational for me to have the goal of driving on the right side of the road if nobody else had the same goal. But despite this interdependence, it is generally accepted that there is no collective goal to drive on the right side of the road.

Furthermore, collective goals share a particular self-referential property with intentions. For example, my intention to break a window is clearly not satisfied if you throw me through the window, thereby causing me to break it. Similarly (to adapt one of Michael Bratman's examples), our collective goal of going to New York together is not satisfied if we are both abducted and brought to New York together in the back of a van. In this way, a collective goal is self-referential in the sense that it is met only if the appropriate state of affairs is brought about by virtue of our having the collective goal.

Collective Identity and Cultural Trauma

An important feature of social life is traumatic experiences felt by collective actors when public meanings get shattered or drastically rearticulated. This entry charts the various aspects of cultural trauma and how it relates to groups and in particular to collective identity, discusses the role of emotions, and explains cultural traumas as essentially processes. As well as being destructive of established social or national (and other) identities, traumas may also be conducive to, or productive of (renewed), collective identities.

Cultural trauma is a discursive response to a tear in the social fabric, when the foundations of an established collective identity are shaken by a traumatic occurrence and are in need of re-narration. The process of cultural trauma can be understood as a meaning struggle, where individual and collective actors attempt to define the situation and impose a particular meaning on it. Within this meaning struggle, various individuals and groups construct narratives in which trauma is an organizing notion.

Cultural trauma should be distinguished from the classical and commonsense notions of trauma, which have in common the naturalistic assumption that trauma results from a wound inflicted on the body or the mind through an overwhelming event that imposes itself on a victim. This naturalistic notion roots trauma in direct individual experience, one that leaves an indelible mark that will later cause the appearance of otherwise inexplicable behavior. By contrast, cultural trauma involves discursive practices, collectivities, collective memory, and collective identity.

Definitions

In an insightful discussion of the difference between individually rooted psychological and cultural trauma, Neil Smelser finds one essential difference in the fact that cultural traumas are made, not born. He goes on to define a cultural trauma as "an invasive and overwhelming event" that is believed as undermining a whole culture as such or some of its essential ingredients. Though he acknowledges the discursive aspect of cultural trauma, Smelser grounds the process in an event. Others (e.g., Ron Eyerman) argue that an event is also a discursive

product and distinguish between a traumatic occurrence and a cultural trauma. This is also suggested in Smelser's theory with the insertion of the phrase "believed to undermine," a notion that undercuts any idea that an event could be traumatic in itself.

This proposition opens two vital questions: (1) Can any occurrence or event be made traumatic, so that it is "believed to undermine" an established collective identity? (2) If not, what is it that permits some occurrences to become traumatic in this sense and not other seemingly equally powerful or shocking occurrences? The first question points to the power to create belief. A cynic might argue that given the ultimate power to persuade, one could turn any occurrence into a "trauma." This would be to push the idea that "traumas are made, not born" to its limits. At the other extreme, a strong naturalist or lay trauma account would make the claim that certain events are traumatic in themselves, that is, they are the direct cause of traumatic affect. A more moderate position might argue that certain occurrences create conditions conducive to setting in motion a process of cultural trauma, without necessarily being traumatic in themselves. Such a process will not happen without the aid of mediating, meaning-making forces, such as the mass media and other more specifically defined carrier groups, such as intellectuals, who articulate the suffering and influence the formation and direction of a process of cultural trauma. However, not all or any interpretative frame will "fit" or make sense; there must be some relation, real or perceived, to some referent—an occurrence, experience, or event—which itself appears "always there."

Cultural Traumas as Processes

Cultural traumas are not things but *processes* of meaning making and attribution, a contentious contest in which various individuals and groups struggle to define a situation and to manage and control it. It can also be added that these forces are unlikely to create a trauma out of nothing; there is likely to be some powerful, shocking occurrence that creates the possibility, providing the opportunity to mobilize opinions and emotions. There are thus two sides to a cultural trauma: an emotional experience and an interpretative reaction. Shocks arouse emotion by breaking everyday routines (behaviors as well as cognitive frameworks) and as such demand interpretation, opening a discursive field where well-placed individuals can play a determinative role. In modern societies, access to the mass media is significant in this process. The polarity between perpetrator and victim is what distinguishes cultural trauma as a discursive process. In this sense, cultural trauma is a contentious struggle to define the meaning of a shocking, unforgettable occurrence framed by a dichotomy between perpetrator and victim, where the foundations of a *collective identity* are shaken.

Traumas and Public Emotions

Yet cultural traumas are more than a struggle between competing actors to define a situation, to distinguish between perpetrator and victim, and to identify the nature of the pain. That would limit the process to instrumental or strategic interaction. Cultural traumas are a response to deeply felt emotions that are publicly expressed and represented in this very same process, which implies an expressive and communicative aspect that makes claims to authenticity and sincerity connected to *collective identity* and *memory.* Anything connected to identity falls within the realm of the sacred and as such is bound up with powerful emotions. There are deeply rooted emotions and scripted identities to be drawn upon in such a situation.

One can think, for example, of ethnic or national identities that may lie under the surface but that can be mobilized in the face of a shocking occurrence, such as a political assassination. This was the case with the assassination in 1914 of Archduke Ferdinand of Austria, and the process started by this occurrence spiraled into a world war that fundamentally altered the political geography of Europe.

"Believe to Undermine or Overwhelm" Collective Identities

We can now return to the question of how it is that a collective comes to *believe* that an occurrence "overwhelms" their already established collective identity. Collective identities are rooted in beliefs that are maintained in everyday life through routine practices. Routines provide confirmation and security in that they allow beliefs to be taken for granted, to be in a sense forgotten. An example of Eyerman's may help illustrate this. One of the first public statements made by the Swedish prime minister after the assassination of Foreign Minister Anna Lindh in 2003

was "This is an attack on our democratic society." That Sweden is a democratic society is a fundamental belief and value grounding modern Swedish collective identity. This belief is not only taught in schools but is also bound up with routine practices such as voting every several years to elect the government. The fact that Sweden is a "democracy" is normally taken for granted. The murder of Anna Lindh was shocking not only because she was a well-known member of the collective but also because she was a political figure, a representative of that democratic process. At least for the prime minister, another representative figure, her murder presented a threat to that fundamental value/identity, as well as to the political process that underpins it. It was thus important for the security and the stability of that identity not only that the murderer be caught, which was a police matter, but also that the rules and procedures of the political system that would guarantee stability were immediately put on display. This was even clearer in the assassination of Prime Minister Olof Palme in 1986, where the same radio bulletin that announced the murder to the public also confirmed that the government was already meeting to ensure the succession of his replacement. Since shocking events like political assassinations, or the explosion in the center of Oslo, Norway, and the subsequent massacre at nearby Utøya Island on July 22, 2011, break everyday routines and can call into question fundamental taken-for-granted beliefs that ground individual and collective identity, it is important that those in positions of authority act quickly to reaffirm those basic identities. To act in this manner is one way of assuring, or attempting to ensure, that the shock caused by a political assassination will be contained and limited to an institution or set of institutions, in this case that of politics and law enforcement, and not involve the society at large. Failure to do so, or failure of such performances of authority, increases the risk that a shocking occurrence will become a cultural trauma.

This returns one to Smelser's discussion of cultural trauma—of shocking occurrences as being "potentially" traumatic—which must be successfully "endowed with negative affect" in order to be fully realized. Central in the meaning struggle and thus to the making of a cultural trauma is the successful attribution of a term such as *national tragedy, national shame,* and *national catastrophe* and its acceptance by a significant part of the collective. This is what is meant by the phrase *come to believe to undermine*: that a significant number, who can say how many, of members of a collective come to believe that the shock is a "national tragedy" and has undermined the fundamental values that have defined the collective. This is what turns or transforms a shock into a cultural trauma and leads to Smelser's (2004) more formal definition:

> A cultural trauma is a memory accepted or given credence by a relevant membership group and evoking an event or situation which is (a) laden with negative affect, (b) represented as indelible, and (c) regarded as threatening a society's existence or violating one or more of its fundamental cultural pre-suppositions. (p. 44)

The Collective

Even when speaking of a collective, one must ask "trauma for whom?" Imaginary collectivities, such as nations or ethnic groups, are rarely unified or univocal. One effect of a traumatic occurrence can be to provide a sense of coherence and collectivity, even if this is also imaginary and temporary. The attack on New York's World Trade Center in 2001 appeared to unify the American nation into an emotional collective, producing ritual practices that helped sustain it, just as the phrase "9/11" is meant to evoke and signify shared experience and collective understanding. But digging beneath that ephemeral surface, in large part facilitated through mass-mediated representations, one would undoubtedly find individuals and even groups that would dissent from that feeling. In this sense, a traumatic occurrence has the potential to both unify and divide, to create both insiders and outsiders.

This potential must, however, be realized, and it is here that what Jeffrey Alexander, following Max Weber, called *carrier groups* play an important role. Such groups articulate and represent trauma, making it available for communication and shared understanding. They help transform emotional response into words and images that can be dispersed and remembered. Artists, writers, journalists, and political and religious leaders are important social categories in this articulation and play an important role in the trauma process. Potential carrier groups are broader than these professional categories, however. Carrier groups, such as family members and friends, for example, can be preexisting or may form

in response to a particular traumatic occurrence, even while it is likely that professional categories, like those mentioned above, will become significant agents within the process of cultural trauma. Carrier groups not only are central to the making of cultural trauma, they are important in its continued affect. Carrier groups are bearers of memory and can, through their actions, elicit emotional recall in distant others.

Cultural trauma is thus a process through which collectivities are articulated, formed, and re-formed in light of traumatic occurrences. Traumatic occurrences and the cultural trauma process need not only have negative outcomes for all concerned; they can create as well as shatter collectivities.

Collective Intentionality

Explanations of human agency, both in everyday contexts and in the context of social scientific research, often appeal to intentions, beliefs, and other mental states of individuals. But humans act together, forming social groups that engage in a variety of activities. *Collective intentionality* is a subfield of social philosophy that attempts to answer questions regarding the nature of social groups, group action (collective agency), and whether a group can be held responsible for its actions (collective responsibility). This entry focuses on the philosophical debates surrounding collective intention and collective belief as they play a dominant role in discussions of group agency and responsibility.

Philosophical Debates About Collective Intention

Consider the attribution of intention to groups such as teams, corporations, committees, and organizations. One might attempt to explain the collective intention expressed by the phrase "We intend to win the soccer game!" by reducing it to the sum of individual intentions (to win) had by members of the group. On this view, a group intends to X if and only if each member (or perhaps a majority of the members) intends to X, or each individual intends to do his or her part in bringing about X and to do so under conditions of common knowledge. But the existence of individual intentions to do one's part even under conditions of common knowledge has seemed, to some philosophers, to be insufficient to explain collective action and our attributions of collective intention. According to John Searle, for instance, collective intentions cannot be explained in terms of individual intentions because the collective intentions are primary. Even if each member intends to do his part to bring about X, these individual intentions seem to derive from the collective intention. It is because there is a collective intention that individuals are able to form individual intentions to

do their part. But are collective intentions the intentions of some supra-individual or group mind?

Like many others working in the area of collective intentionality, Searle is committed to a form of ontological individualism. Ontological individualism is the view that individuals are the primary and sole units of agency. There are no collective minds or supra-agents that are intentional agents in any real sense. Because there is no supra-agent that is the subject of the collective intention and all intentionality is to be found in the heads of individual human beings (and animals), Searle posits the existence of "we-intentions." We-intentions are states of individuals, not groups. Just as an individual can intend from the first-person perspective, one can also intend from the third-person-plural perspective. From we-intentions, one derives specific intentions of the form "I intend to do my part to bring about X." Searle offers a similar analysis of collective belief. Collective beliefs are not the beliefs of a group but the beliefs of group members, individuals have the ability to believe in the "we-mode."

For some, this does not sufficiently explain joint action and our attributions of intention to groups. There is something about collective intentions that coordinates individual, independent actions into a joint action. But isolated we-intentions do not, by themselves, seem to be enough to direct and coordinate the individual intentional actions that make up joint action. This suggests that the individual intentional states that underlie collective intentions should be suitably interrelated.

Michael Bratman provides an account of collective intention in terms of the intentions of the individual participants and their interrelations. Bratman's account also preserves a form of ontological individualism. However, on his view, while collective intentions are not the intentions of some supra-agent, they are not located in the heads of individuals either. Rather, shared intentions are states of affairs that consist in a set of individual intentional states and their interrelations. On Bratman's account, when individuals share an intention, each individual has the intention of the form "I intend that we X," and these intentions are formed because of and by way of the intentions of others. Bratman's analysis also requires that subplans of individuals (the means by which they plan to do their part to bring about X) do not conflict or fail to mesh. In recent work, Bratman has developed this account to explain more complicated forms of collective action and introduced the notion of shared value.

Bratman and Searle's analysis of collective intentions has been subject to the following objection: Normally, one cannot intend to do what one does not have control over. Consider again the following collective intention ascribed to a soccer team: "*Purple Storm* intends to win the game." Since no one individual has control over the actions of his teammates, it is difficult to explain how any individual could have the intention "We intend to win." An individual might have the intention to do her part by scoring a goal or assisting others. The actions required to fulfill these intentions are within her control. But she cannot intend that others score goals and make assists. She can wish and hope that they do so. But she cannot intend that they do so. The individual who does the intending is normally the same individual who fulfills the intention. If an individual can only intend what is within her control, then contrary to Searle and Bratman, individuals cannot have we-intentions or intentions of the form "I intend that we X."

The distinction between intending *to* and intending *that* has been appealed to in order to respond to this criticism. Although an individual cannot *intend to* get married (because such an act requires the action of another that is out of one's control), she can *intend that* she and her partner get married. In a similar vein, Christopher Kutz argues that joint action can be explained by appeal to a special type of intention called a "participatory intention." These are not intentions *to do* something but individual intentions *to do one's part* in a collective action. Seumas Miller avoids these difficulties by explaining collective action in terms of collective goals or ends, rather than appeal to the notion of intention.

Philosophical Debates About Collective Belief

We often attribute beliefs to groups such as corporations, and social scientific research might appeal to a group's beliefs in order to explain its behavior. In some cases, such ascriptions will identify beliefs held in common. That is, to say that when group G believes that *p*, it might mean that all or most of the members of G believe that *p*. But in other cases, the ascription of group belief might attempt to identify something beyond a shared belief. Margaret Gilbert, for instance, argues that there are cases when we

ascribe a belief to a group even when no individual member of the group has the belief being ascribed to the group, or at least such cases are conceivable. Thus, for a group to be said to believe that *p,* it need not be the case that all or most of the members believe that *p*. In some cases, group members might accept that *p* is the belief of the group and act in accordance with that belief as group members. Or as Gilbert describes it, there may be a joint commitment to believe that *p* as a body or as a group. When individuals jointly commit to believing that *p* as a group, there is a plural subject that believes that *p*. Joint commitments are the glue that forms plural subjects, and joint commitments cannot, according to Gilbert, be reduced to individual commitments to believe that *p*.

Raimo Tuomela offers an extensive taxonomy and analysis of different types of collective belief. In some cases, our ascriptions capture shared we-beliefs. In the case of we-beliefs, each member believes that *p,* and it is common knowledge that each member believes that *p*. But in some cases, our ascriptions of collective belief move beyond we-beliefs. Tuomela appeals to the distinction between the I-mode and the we-mode in order to capture a different form of collective belief. Just as we can personally believe something (the I-mode), we can believe a proposition from the we-mode. Tuomela has also developed an influential account of corporate beliefs. Collective beliefs in the case of large groups such as corporations can be explained by relying on the notions of rule-based social positions, tasks, and positional beliefs. Positional beliefs are the views held by a person qua position holder, as one with decision-making authority. They are views that one accepts as a basis for action, without necessarily being views that one personally believes. Positional views, then, need not be truth related. We may accept false beliefs and adopt positional views that we know to be false.

The accounts considered thus far attempt to explain collective intention and collective belief in terms of other concepts such as acceptance, joint commitment, and we-beliefs. According to most accounts, collective intentionality is not the intentionality had by groups but a special form of intentionality had by individuals as group members. But one might argue that collective intentions and beliefs are to be understood as states of the group *itself*. There are two ways to go about this. One might argue that intentional states such as belief and intention should be understood functionally: Though collective intentions and beliefs are realized by states of individuals and their interrelations, they are had by the group because they play the same functional role within the group that individual intentions and beliefs play within the individual mind. Another approach would be to adopt a form of instrumentalism: Intentions and beliefs are not states of the brain or mind at all but are mere explanatory constructs that are useful in explaining and predicting the behavior of certain kinds of systems. Deborah Tollefsen has argued that instrumentalism lends itself nicely to the idea that groups, too, can be the subject of intentional state ascription, such as belief and intention. To the extent that one takes the intentional stance toward certain types of groups and doing so helps explain and predict collective action, groups themselves "have" beliefs and intentions.

The Role of Collective Intention and Belief

Theories of collective intention and belief have had an impact on a number of philosophical and social scientific issues and debates. Searle's theory of collective belief and intention serves as the foundation for a theory of social facts. Collective intentions confer status functions on artifacts and turn them into social facts. The bits of paper we call money serve a particular role in our lives. Money is money because we accept it and intend it to serve a particular role. Others have explored the role that collective intentionality, either collective intentions or beliefs, plays in political philosophy and moral theory. Gilbert, for instance, argues that her account of collective intentionality provides a richer account of political obligation and social rules than competing theories. Tuomela has developed accounts of rule-governed social practices and fads by appeal to collective intentions and beliefs. Fields as diverse as cognitive ethology, evolutionary psychology, developmental psychology, jurisprudence, economics, and sociology have appealed to work in collective intentionality to explain both human and animal behavior.

Collective Memory

The entry introduces the meaning of the term *collective memory,* traces its origins and explains its anti-reductionist or anti-individualist nature in social ontology, and goes on to review recent formulations of it.

Meaning

Collective memory denotes the totality of a collective entity's mnemonic practices. While personal memories relate to an individual's experiences with the past, these experiences—to the extent that they are mnemonically re-created in the present at all—represent a small slice of past social reality, the rest of which is forgotten. Collective memory transcends the sphere of the individual in that individual experiences with the past relate to the experiences of others so as to render the past meaningful to both the individual and the collective; acts of remembrance (and forgetting) are collective performances, and the impact of remembrance is collective. The late 20th and early 21st centuries are said to have experienced an enduring "memory boom" centered on the Holocaust, marked not only by an increasing number of memorials but also by a plurality in memory.

Origin

When the French sociologist Maurice Halbwachs coined the term *collective memory* to designate a social phenomenon that emerges from social interaction, he stood in the tradition of Durkheimian sociology. Halbwachs's mentor Émile Durkheim noted that collective representations of the world, including those of the past, have their origins in interactions in collective entities from the beginning and *cannot be reduced* to the contributions of individuals. Remembered events and experiences are hardly ever constituted by individuals divorced from other individuals or from a social framework that constitutes a generative milieu for the events and experiences. Rather, they result from *collective acts,* and the memory of events and experiences is reconstituted and affirmed in collective acts of remembrance. Entities that relate to the past in this way can vary in scope from small groups to entire nations and even the global community, as can the entities affected by remembrance; that is, the impact of collective memory is social as well as individual.

Developments

In conceptualizing collective memory, scholars such as Jörg Assmann differentiate between communicative memory and cultural memory. *Communicative memory* is tied to living or recent generations. Traditions are passed on mostly orally and thus depend on communicative transmission among persons. Communicative memory tends to be more fluid, less formal, and more tied to daily life than cultural memory. *Cultural memory* provides a long-term storage function for the types of knowledge that help shape a society's collective identity and from which individuals derive their cultural capital. The distinction between communicative and cultural memory points to the importance of forms of literacy, communication media, collective time horizons, and the social functions of collective memory: Oral cultures draw on and perpetuate living memory; elite literacy is tied to the creation and distribution of manuscripts and serves to recover lost wisdoms; mass literacy and the availability of print media allow the reconstruction of a past distinct from the present; and literacy tied to electronic media in the

digital age facilitates the deconstruction of representations of the past.

Literacy constitutes one element in the cultural settings of action that frame how, where, and when past events are remembered. At a macro-social level, such settings may be part of larger memory regimes. Memory regimes reflect the ways in which national histories, politics, and culture have shaped commemorative practices, and over the course of the past century they have varied greatly, but the engagement with the past is also often intensely local. That is, whether the past is remembered at all, and to what extent, is an issue that relates not only to the germinating effects of culture but also to the activities of local memory entrepreneurs and agents as well, seeking to imbue selective elements of the past with cultural significance.

Some scholars note that the interplay of national and regional memory regimes and local memory agents has taken on a new quality in the digital age, in which collective memory is increasingly constituted via electronic media. Representations of the past, the historian Pierre Nora has argued, are no longer tied to what he calls *milieux de mémoire,* or lived memory that is a part of everyday life and reconstituted in traditional rituals, but are rather embodied in "sites of memory" (*lieux de mémoire*), or any place, practice, object, or concept that serves as a symbol by which a social entity relates to its past. For Nora, sites of memory are not necessarily material, but they are always socially constructed, and he deems them central to national identity formation. Postmodernist thought has taken this argument further, referring to a rapidly changing order, a disbelief in the linearity of time, the prominence of simulations, and constancy and continuity found only in the experience of transience itself, conditions that lend themselves to memories being dominated by images and their reproductions.

A "memory boom" since the late 20th century has led to the emergence of numerous new sites of memory. A considerable number of sites relate to the Holocaust, some entirely virtual. In the decades following World War II, memories of the Holocaust served different functions: In Israel after the Eichmann trial in 1961, they were employed to advocate a need for a strong state that could militarily defend itself in the face of adversity; in the United States, they gradually became part of a more general narrative of success in the American quest to liberate the world from evil; in Eastern Europe, they were suppressed by communist governments or considered part of a larger group of memories of victimhood, lest they detracted from a state-sponsored focus on resistance fighters as antifascist heroes; in Austria, they were quickly set aside in a national attempt to claim the status of first victim of Nazi Germany or became part of a narrative of attributing the Holocaust to Germany in order to absolve the nation from culpability in participating in it; in West Germany, the assumption of responsibility for the Holocaust helped the government reintegrate German society back into the fold of Western nations. More recently, as part of a trend toward the memorialization of trauma, the Holocaust as a historically unique atrocity has become a generalized symbol of human suffering and moral evil. Some see the generation of knowledge about it and the memorialization of its victims as opportunities for humanistic learning in a global memory culture proffered by the formation of cosmopolitan memory.

Collective Moral Responsibility

This entry discusses an important feature of collective entities and social life in general, that of moral responsibility ascribed to collective agents or plural subjects. It first explains the distinctive feature of collective moral responsibility and then goes on to examine briefly three main theories about it.

What Is Collective Moral Responsibility?

Collective moral responsibility is a species of moral responsibility. Here, we need to distinguish *moral* responsibility (including collective moral responsibility) from *causal* responsibility. A person or persons can inadvertently cause a bad outcome without necessarily being morally responsible for doing so. For example, a careful and competent driver who is obeying all the rules of the road might, nevertheless, accidently and unavoidably hit and maim a child who suddenly and unpredictably runs onto the road and in front of the moving vehicle. Moral responsibility typically requires not only causal responsibility but also an *intention* to cause harm (or at least the knowledge that one's action will or may well cause harm).

Collective moral responsibility is the moral responsibility that attaches to *structured* and *unstructured groups* for their morally significant actions and omissions. Thus, an organized gang of thieves who carry out a million-dollar bank heist is said to be collectively morally (and, presumably, legally) responsible for the theft. Again, a number of bystanders who act jointly to save a child trapped in a burning house are said to be collectively morally responsible for saving the child's life. Notice that sometimes it is the *members* of a group that are said to be collectively responsible and sometimes it is *the group or other collective entity per se*; for example, the Mafia might be said to be collectively morally responsible for a crime wave in southern Italy.

Theories of Collective Moral Responsibility

There are three prominent kinds of theories of collective moral responsibility. The first of these conceives of collective moral responsibility as a convenient way of referring to what is in fact simply a set of individual responsibilities. I will refer to it as the atomistic account. The second holds that it is the group or collective itself that is the bearer of moral responsibility. I will refer to this view as the collectivist account. The third theory is a relational account. The only bearers of moral responsibility are individual human persons (or like creatures) but, unlike individual moral responsibility, collective moral responsibility is to be understood in relational terms.

Atomism

Advocates of atomism with respect to collective moral responsibility include H. D. Lewis, R. S. Downie, Stephen Sverdlik, and Jan Narveson. The strength of atomism is that it does not postulate suprahuman collective entities as the mysterious bearers of moral responsibility and of the psychological states (e.g., beliefs and intentions) necessary for moral responsibility. Moreover, since it ascribes moral responsibility only to individual human beings, it has no tendency to let the members of collective entities, such as criminal organizations or negligent corporations, off the hook by relocating moral responsibility at the suprahuman level.

The weakness of atomism is that it does not seem to be able to accommodate the full range of cases in which we pretheoretically ascribe collective moral responsibility. For example, in our above million-dollar bank heist example, robber A might be individually responsible for planning the heist, robber B for driving the getaway car, C for blowing the safe, D for taking $100,000, E for taking a second $100,000, and so on. However, arguably none of the robbers was individually causally responsible—and, therefore, individually morally responsible—for stealing $1,000,000. Again, we pretheoretically hold BP morally responsible for the massively environmentally damaging oil spill in the Gulf of Mexico in 2009. But here we seem to be doing something above and beyond simply ascribing individual moral responsibility to each of the BP personnel who did something wrong and aggregating them. BP's moral responsibility seems to be more than the set of individual responsibilities.

Collectivism

In this view, "collective responsibility" should be understood in the sense of a collective's responsibility. Whether the members of a collective, the people

who constitute the collective in question, are individually responsible is a separate question. When it comes to collective moral responsibility, the collective itself is the bearer of the moral responsibility. In David Copp's terminology, this claim is equivalent to the claim that a collective can be an independent moral agent. An important corollary of the collectivist view is that collectives are capable of bearing moral responsibility for outcomes, even when none of their members are in any degree *individually* morally responsible for those outcomes. Other prominent representatives of the collectivist approach include Peter French and Margaret Gilbert.

Perhaps unsurprisingly, collectivism tends to be regarded as being able to accommodate many of the problems that beset atomism but to lack the virtues of atomism. Thus, to return to our examples, collectivism will ascribe moral responsibility to (respectively) the gang of robbers as a collective entity and to BP per se (and not merely to some individual BP personnel for their individual moral failings). However, in so doing it admits suprahuman collective entities (the gang, BP) that (somewhat mysteriously) bear moral responsibility (and, therefore, the associated psychological states) and have the potential to get (respectively) the individual gang members and BP personnel off the moral hook. Potentially at least, BP is morally responsible, but none of its managers, employees, and so on have any moral responsibility; and the same goes for the individual gang members, at least as far as the theft of the $1,000,000 is concerned (as opposed to, say, driving the getaway car or stealing $100,000).

Relational Accounts

Relational accounts try to square the circle. Theorists of a relational persuasion include Larry May, Gregory Mellema, and Seumas Miller. On the one hand, relational accounts claim to have the virtues of atomism and to lack the vices of collectivism. Thus, relational accounts do not postulate suprahuman collective entities as the mysterious bearers of moral responsibility and have no tendency to let the members of collective entities off the moral hook by relocating moral responsibility at the suprahuman level.

On the other hand, relational accounts seem to be better equipped than atomistic accounts to provide a plausible account of the ascription of moral responsibility to structured and unstructured groups.

For example, Miller has developed an account of collective responsibility as joint responsibility. On Miller's view, at least one of the central senses of collective responsibility is responsibility arising from joint actions and omissions. Roughly speaking, a joint action can be understood thus: Two or more individuals perform a joint action if each of them intentionally performs an individual action but does so with the (true) belief that in so doing they will jointly realize an end that each of them has. On this view of collective responsibility as joint responsibility, collective responsibility is ascribed to individuals. Each member of the group is individually morally responsible for the outcome of the joint action. However, each is individually responsible, jointly with the others; hence, the conception is relational in character. Thus, in our million-dollar bank heist example, each member of the gang is responsible jointly with the others for the theft of the $1,000,000, because each performed his contributory action in the service of that collective end (the theft of the $1,000,000).

On this kind of relational view, BP can be ascribed collective moral responsibility for the Gulf oil spill to the extent that BP personnel jointly acted—or, more likely, jointly (and culpably) failed to act—in ways that led to the disaster. Here, the network of joint actions and omissions could be quite wide and complex without involving all, or even most, BP personnel. Moreover, some joint actions or omissions might be of greater moral significance than others and some individual contributions, such as those of managers, of greater importance than others.

Collective Rationality

Collective rationality is a property of a group of agents. In one sense, it is the rationality of each member of the group, but in another, common sense, it is the rationality of the group itself.

This entry treats the rationality of the group itself but also describes its relation to the rationality of each member of the group. Being normative, collective rationality falls into philosophy's province. Because groups often aim for the collectively rational, collective rationality figures in the explanation of their acts and so assists the social sciences. The entry's first section explains collective rationality, and the other sections treat its application to collective acts.

Agents and Rationality

Groups act; a group's acts may be rational or irrational. A group may pass a resolution to raise dues. Its act may be rational because the group needs more revenue to balance its budget. A group may adopt a policy of not accepting new members. The policy's adoption may be irrational because the group needs new members to survive.

As for individuals, the standards of rationality for a group are sensitive to the group's situation. Suppose that the members of a group vote rationally, although they do not vote in the best way because of their ignorance. The group then votes rationally, although not optimally. Its members' ignorance may excuse the group's shortcoming.

Collective rationality is a technical term in some literatures. In economics, it often means efficiency, or Pareto optimality (after the Italian economist Vilfredo Pareto), and in some contexts, it means maximization of collective utility, taken as a sum of utilities for individuals. This section explains each of these technical senses of collective rationality, starting with Pareto optimality.

Suppose that a group has two options and the first is better than the second for each member of the group. Then, the first option is strictly Pareto superior to the second option. A group's act is weakly Pareto optimal if no alternative is strictly Pareto superior to it. Suppose that a group has two options and the first is better than the second in some cases and at least as good as the second in all cases. Then, the first option is Pareto superior to the second option. A group's act is Pareto optimal if no alternative is Pareto superior to it. A group benefits from achieving Pareto optimality. However, in some cases a group composed of rational people may fail to achieve Pareto optimality. The members of the group, because of nonculpable ignorance, may not know which of their options would be Pareto optimal.

An act's utility for a group is the sum of the personal utilities that the group's members attach to the act. Their personal utilities depend on how strongly they want the group to perform the act. An act that maximizes collective utility is such that no other act achieves greater collective utility. Typically, giving each member of a group a resource has greater collective utility than withholding the resource from each member of the group.

A Pareto-optimal act may not maximize collective utility. For example, in a typical case, every way of dividing a sum of money among a group's members achieves Pareto optimality. Every alternative gives less money to some member, and so none is Pareto superior. Typically, not all divisions maximize collective utility, however. For example, giving equal shares to the group's members yields more collective utility than giving all the money to the flush members and nothing to the needy members.

Achieving Pareto optimality seems insufficient for collective rationality, so instead of taking collective rationality to be Pareto optimality, some theorists take it to be maximization of collective utility. Being sensitive to a group's circumstances, rationality excuses some failures to maximize collective utility. A group composed of rational people, through nonculpable ignorance, may fail to

maximize collective utility because they fail to see which of their options maximize collective utility. Their failure to maximize collective utility may not be collectively irrational, all things considered.

The standard of collective-utility maximization requires a way of putting personal-utility assignments on the same interpersonal scale before summing them to obtain collective utility. Some theorists object to interpersonal utilities because it may be difficult to measure them accurately. The standard of Pareto optimality is easier to apply than is the standard of collective-utility maximization.

Standards of collective rationality apply to the traits of a group, such as a group's customs and traditions. Some customs may be rational and others irrational. Standards also apply to a group's acts, such as electing a president. A group's act is often called a collective act.

What counts as a collective act? Because ordinary usage does not settle the question, theorists are free to define collective acts in any fruitful way. Some hold that a collective act requires a collective intention in a sense that does not require a group to have a mind. They hold that a person's having an intention to perform an act is a functional state of the person that normally generates the act. In this functional sense, whatever plays the role of an intention in generating a group's act counts as a collective intention. In a restrictive sense, only those acts a group performs because of a collective intention count as collective acts.

A liberal view of collective acts counts all sets of acts of a group's members, with one act per member, as collective acts. If Arthur breaks a pencil in England and Luis breaks a pencil in Uruguay, then between them they break two pencils. Neither breaks two pencils, but the two of them break two pencils. Together they break two pencils, although they did not coordinate to break them. Given the broad view of collective acts, not all of a group's collective acts count as the members coordinating, cooperating, or collaborating. The broad view acknowledges special types of collective acts, such as coordination, that require a group's members to take account of each other. Some, but not all, collective acts achieve coordination.

To make standards of collective rationality as far-reaching as possible, a broad theory of collective rationality adopts the liberal view of collective acts. It evaluates for rationality even unconnected acts of a group's members.

This entry treats the rationality of collective acts and puts aside evaluation of a group's traits. What standards of rationality apply to collective acts? Some standards for individuals suggest extensions to groups. One suggestion holds that a rational collective act comes from the top of a collective preference ranking of acts. This principle requires a definition of collective preference, however, and no satisfactory general definition using only the preferences of the group's members exists, as Kenneth Arrow shows.

Utilitarianism offers another way of aggregating personal assessments of options to form a collective assessment. It suggests that as a person's act maximizes personal utility if it is rational, a group's act maximizes collective utility if it is rational, at least if conditions are ideal for collective action. If contrary to the principle's presupposition, interpersonal utilities for a group's members do not exist in all cases, the principle may restrict itself to cases in which the interpersonal utilities exist.

The principle to maximize collective utility faces a serious problem. It may require sacrificing a member of a group. This happens if the group can prevent the deaths of many members its enemy holds hostage by exchanging for the hostages one hunted member its enemy will execute. The member then rationally blocks maximization if possible. The principle pits collective rationality against individual rationality. This makes the theory of rationality inconsistent. The theory tells a group to maximize collective utility but tells a member to block maximization. The theory should issue consistent directives to the group and to its members.

An alternative principle for evaluating collective acts holds that the rationality of every member of a group ensures the rationality of the whole group. If each member acts rationally, then the collective act that their acts form is also rational. For example, if all the members vote rationally, then the group's vote is also rational. This principle of evaluation is general and ensures consistency. According to it, rationality's directives to a group are not contrary to its directives to the group's members.

Granting the principle of evaluation, the rationality of all members of a group suffices for the group's rationality. Is the rationality of all members also necessary for the group's rationality? No, in some cases a group's act is rational, although some

members' contributions are irrational. For example, a committee using majoritarian methods to vote on resolutions may rationally vote in favor of a sensible resolution, even though some members irrationally vote against it. Because a rational act by the group requires only a majority of rational votes, a few irrational votes do not make the group's act irrational. What makes the group's voting rational despite the irrational voting of some members? The group's act is rational because it is the same collective act that the group would perform if all its members were to vote rationally.

A group's profile of votes is a description of every member's vote. Even a few irrational votes make a group's profile of votes defective. In the example, the group's profile of votes is irrational, one says, although its voting for the resolution is rational. To accommodate this point, a theory of rationality may distinguish the group's profile of votes from the group's voting for the resolution. Although the group's profile of votes constitutes the group's voting for the resolution, the collective acts differ because they are individuated according to the propositions that express them. Two acts that have the same realization by physical events may differ because they have different propositional expressions. One may be rational, while the other is irrational. A group's profile of votes may be irrational, although the group's voting for the resolution is rational.

The Prisoner's Dilemma

In the Prisoner's Dilemma, each of two agents, who cannot communicate, decides whether to act cooperatively. If both act cooperatively, they each do better than if each acts noncooperatively. However, each does better acting noncooperatively whatever the other agent does. Each agent prefers the outcome in a pair that is better for him. A principle of rational preference, the principle of strict dominance says that if one option is better than another in every case, then the agent should prefer it to the other option. The principle requires that each agent act noncooperatively even though the combination of their noncooperative acts is not Pareto optimal. It is not Pareto optimal because each agent prefers the combination of his or her cooperative acts. Because some theorists take collective rationality to require Pareto optimality, they conclude that the principles of individual rationality conflict with the principles of collective rationality. The principle of dominance and the principle of Pareto optimality are at odds in the Prisoner's Dilemma. The first requires that each agent act noncooperatively, whereas the second requires that the pair of players act cooperatively to achieve a Pareto-optimal combination.

Collective and individual rationality do not conflict, contrary to the foregoing account of their application to the Prisoner's Dilemma. Collective rationality does not always require Pareto optimality. Sometimes obstacles stand in the way, obstacles such as the inability to communicate. In the Prisoner's Dilemma, agents cannot communicate. Conditions are not ideal for collective action. Hence, collective rationality does not demand that the agents achieve Pareto optimality. Collective rationality, as individual rationality, is sensitive to circumstances. It excuses failures to optimize given the obstacles to optimization.

Group Minds

Groups literally act but lack minds and so do not literally have beliefs and desires, or intentions, and do not literally make decisions. A technical definition of collective preference may be helpful, nonetheless, in special cases where restrictions prevent problems. Take a definition of collective preference according to which a group prefers the first of two options if a majority of the group's members prefer the first option. This definition leads to cyclical collective preferences if advanced generally. To prevent cycles, the definition may restrict itself to cases in which the group's members have preferences that are single-peaked. This restriction requires that according to some ordering of alternatives along the horizontal axis of a graph, a plot of each individual's preference ranking of alternatives, with height representing position in the ranking, has a single peak. With the restriction in place, the majoritarian definition of collective preference works well. An account of the group's behavior may treat the group as if it had collective preferences.

Game Theory

In a game of strategy, each player chooses a strategy, and the combination of strategies chosen settles the outcome for each player. Strategic reasoning suggests that a player choose a strategy in light of his beliefs about the strategies that other players will choose. A profile of strategies is a set of strategies with exactly one strategy for each player. A solution

to a game is a profile of strategies such that each strategy is rational given the other strategies in the profile. Realization of a profile of strategies is a collective act. How are the profile's being a solution and its being collectively rational related?

In ideal games, agents are fully rational and have unlimited cognitive power so that they reason flawlessly and know all the logical and mathematical truths. They also have correct beliefs about others' strategies. These beliefs may arise from their common knowledge of their game and their rationality. Here, common knowledge has a technical sense according to which common knowledge that a proposition holds entails that all know the proposition, all know that all know it, and so on.

Because in ideal games each player has correct beliefs about the other players' strategies, if each player's strategy maximizes utility, the players' strategy profile is what is known as a Nash equilibrium (after John Nash). Each player's strategy is a best response to the other players' strategies. A player's strategies in a game may include mixed strategies, that is, probabilistic mixtures of the player's pure strategies. Every game with a finite number of players and pure strategies has a Nash equilibrium if the players may choose mixed strategies. Game theorists propose that a strategy profile is not a solution unless it forms a Nash equilibrium, assuming that the game has a Nash equilibrium. Some games have multiple Nash equilibria. Theorists propose principles for selecting the Nash equilibria that qualify as solutions. A common requirement is that a solution be a Nash equilibrium that is Pareto optimal among Nash equilibria.

Because a game's solution is a strategy profile in which each player's strategy is rational given the other players' strategies and because the rationality of a player's strategy depends on the player's information, the strategy profiles that are solutions depend on the players' information about their game and each other. An adequate representation of a game specifies the players' information.

The definition of a solution uses conditional as opposed to unconditional rationality. Each player's part of a solution is rational if each player knows that the solution will be realized. This result need not hold for a profile of rational strategies. A player's strategy in the profile may be rational only because the player thinks that other players will perform strategies outside the profile. For example, in the game of Matching Pennies, the player going for a match may rationally show heads because he thinks his opponent will show heads. The player going for a mismatch may show tails because she thinks her opponent will show heads. The two strategies are each rational in this case, although they are not each rational if both players know about them. Given that knowledge, the player going for a match should not show heads.

Given that the rationality of each player's strategy ensures the collective rationality of the players' strategy profile, a collectively rational profile may fail to be a solution. In the example, the matcher's showing heads and the mismatcher's showing tails is a profile of rational strategies and so is collectively rational, but it is not a solution. However, if a strategy profile is a solution, then given the players' awareness of their participation in the profile, each player's participation is rational and the player's realization of the profile is collectively rational.

Many theorists argue that in some games the players' rationality does not ensure a solution. In the game Hi-Lo, the players have two ways of coordinating, one better for each player than the other. Each has a reason to pick High, his part in the better way of coordinating, if the other player picks High. If neither player is told what the other will do, it may seem that none has a reason to pick High. Nonetheless, each player's picking High appears to be the game's solution.

Must collective rationality demand more than the rationality of each player if it is to generate a solution? If the game has fully rational ideal players who are prepared for coordination, an argument exists that each player chooses High. One player may intend to pick High because forming the intention gives the other player a reason to pick High. The first player then has a reason to pick High because the second player will. The players' rationality in preparing for optimal forms of coordination leads to the profile in which each player picks High.

By describing solutions to ideal games, theorists flesh out an account of collectively rational behavior. Because players infer the profile realized, realizing a solution ensures the players' collective rationality.

Collective Values

This entry gives an account of the epistemological and ontological issues behind the notion of collective values, explains its difference from that of shared values, and shows the importance of admitting collective values in social ontology.

On March 16, 2011, Rajav Shah, the head of the U.S. Agency for International Development (USAID), presented his budget proposal to the House Subcommittee on Foreign Affairs. He argued that foreign assistance from USAID "keeps our country safe, develops the markets of tomorrow, and expresses our collective values." While appeals to our *collective values* are often politically expedient, the content of such appeals is often ambiguous at best. Of course, collective values must be *values,* not mere common expectations or shared understandings of joint activities. They require treating activities, entities, or practices as worthwhile or essential to what we do together. Furthermore, collective values are not merely agent-neutral values; they must be grounded in our collective concern with activities such as the elimination of sex trafficking, the prevention of deforestation, and the promotion of education.

But while the authors of this entry value such things, and one suspects that most other U.S. citizens do as well, this does not mean that they are *American values*—values that are not just mine and yours, his and hers, but *ours*.

If the methodologically and ontologically individualistic assumption that *there are no collectivities* is true, then there are no collective values; rather, appeals to collective values are literally false, though often elliptical for true claims about aggregations of individual values. Perhaps the claim "Justice is an American value" might be better paraphrased as "Every U.S. citizen values justice" or as "Most U.S. citizens value justice."

Unfortunately, such paraphrases threaten to flatten an important distinction between *shared* and *collective* values, which can be exemplified in the difference between the members of an academic department who all happen to value good baseball games, and the department's valuing of a specific deliberative procedure. The baseball value could be kept private; but even when it is made public it does not have an impact on department-relevant behavior. The valuing of a deliberative procedure, a *collective* value, by contrast, grounds the practices and projects of the department *as such*. So while "shared values" and "collective values" are often treated as interchangeable, they are logically distinct.

Collective and shared values are significant for understanding some collectivities. For example, someone who does not understand their near-religious exaltation of cheese curds and Usinger's sausage may not really understand Wisconsinites. Moreover, shared and collective values are significant for decision making, as when marketing to a particular demographic requires considering their shared values. However, the fact that people *happen*

to share a value is unlikely to affect action in any way that extends beyond the action guidance of individual values.

Of course, a more sophisticated form of methodological individualism might couple the individualistic requirement on explanation with a nonindividualistic conception of *value* (e.g., as Max Weber famously did). The seeming paradox of this position dissipates with the recognition that networks of social practice can be seen as the structural scaffolding upon which individual values can be constructed or as the holistic conceptual background against which individual practices of valuing can emerge. For example, valuing the vintage New England Patriots football logo requires the existence of numerous social institutions (e.g., facts about national and local history, the existence of the National Football League, and fashion trends at the time of the American Revolution). But such a value is not a *collective* value; while social institutions are necessary to explain how such values are possible, the individual is still the locus of valuation and the locus of action.

In short, genuinely *collective values* require (a) a collective agent capable of goal-directed behavior and (b) collective values that are implicated in, required for, or constitutive of that behavior. This does not require an ascription of value *to the collectivity,* and some collective values are likely to be dependent on, though not reducible to, individual values. Such values arise where the social institutions that are a necessary condition for individual valuing are grounded in the collective nature of a joint activity. Call these "we-values" (to parallel "we-intentions"). Unlike values contingently shared by group members, we-values depend on a complex set of relationships that can modulate the ways in which individuals reflect upon these values, consider conflicting values, and recalibrate their individual and collective actions to accord with those values. Some we-values are analytically constitutive of the group itself (e.g., the Society for the Preservation of Greek Heritage must treat Greek culture as worthy of value), while other we-values achieve their status as a result of the necessity of the value for continuing a collective endeavor. For example, it is an essential part of belonging to the modern scientific community that one values seeking the truth, replicating results, and preserving methodological transparency.

These we-values may be relatively thick or relatively thin. A rabbit values her life because all of her actions accord with this value, and such relatively thin values thus offer a way of categorizing and describing her behavior. Similarly, we might say that a particular corporation values an increase in its profits because its actions accord with this value. Such "free-floating values," however, are insufficient to explain the role of valuing in individual and collective deliberation. Agency in a thicker sense may well require reflecting on one's values, considering how they interact and conflict, and attempting to bring one's actions into accord with one's values. Thick values, unlike their thin counterparts, provide structure for deliberations and play an integral role in practical reasoning.

This brings us to the most *robust* collective values, values that are properly predicated *of the collectivity itself* (as Margaret Gilbert claims). In such cases, *the collectivity* must be able to reflect on its values, consider how they interact and conflict, and evaluate the extent to which individual actions should be brought into accordance with these values. For example, a university that has plans and projects designed to ensure that its actions (e.g., admissions and hiring decisions) increase diversity, and endeavors to alter its actions where they do not align with this value, can be properly said to value diversity.

Collective values provide action guidance that stretches well beyond the recognition of aggregates of individual values. They change the deontic status of particular actions for group members. Although a new member of an academic department, for example, has no more reason to value fine wine after learning that her colleagues do so than she does when she learns that some loose aggregate of her friends do, when she learns that her colleagues value improving gender equality in her profession, she gains new reasons for action (and there is a chance that—as a member of this group—she will have to give up some reasons that she used to have). Of course, the fact that something is valued by a collectivity to which one belongs does not imply that such values ought not be changed or challenged, but as a group member such challenges are the exception, not the rule. Perhaps less obviously, collective values also can change the deontic significance of actions for nonmembers, making actions more egregiously wrong than they would be if merely shared by a random set of agents. For example, there is an

additional reason to respect an artifact that is valued by a group for its role in their collective activities, history, or self-understanding that goes beyond the reason to respect a similar artifact that is valued by a similar number of disconnected individuals. So the fact that a value is collective rather than merely shared can be morally significant both for members and for those external to a collectivity.

Commitment

This entry explains the notion of commitment and its significance in philosophical accounts of social agency and presents the three received accounts of it.

The Notion of "Commitment"

The English word *commitment* has many meanings and is without equivalent in other languages. In the sense that is particularly relevant to philosophy and the social sciences, the term refers to an agent's choice or disposition to self-impose limitations on her agency ("self-commitment"). While changes of options and elimination of alternatives occur as a side effect or unintended consequence of almost any choice, it is usually assumed that in the special case of commitment, the agent *identifies* with these self-imposed bounds of her agency as expressive of her will. Commitments are a central feature of human agency and a basic building block of the social world.

The Received Accounts of Commitment

Received accounts of the nature and role of commitment can be distinguished according to how far they depart from the standard rational choice model of action (the standard model assumes that an agent's choices maximize the satisfaction of her desires, given her beliefs). Broadly, the received conceptions of commitment can be divided into three groups: (1) according to the *conservative view,* commitment leaves the standard model more or less intact; (2) proponents of *revisionist accounts* claim that the view of practical reason has to be widened in order to accommodate commitment; and (3) *revolutionary conceptions* claim that in view of the structure and role of commitment in action, an altogether different theory of practical reason is required.

Conservative Accounts

Diverse theorists such as Thomas C. Schelling or Jon Elster analyze a classical paradigm case of commitment: the capacity to remain steadfast in the face of temptation. In their view, this is explained by the human capacity to causally influence the range and utility of future options, as illustrated in Odysseus's case of having himself tied to the mast of his ship so as not to be able to give in to temptation. In political theory, the role of constitutional constraints imposed on collective action is sometimes analyzed along similar lines. Commitments are seen as a special case of rational choice, as the source of the commitment is placed in the preferences of the user of the "commitment device" rather than in the exertion of a different dimension of evaluation.

Revisionist Accounts

According to revisionist authors, the kind of self-control involved in commitment requires the exercise of a special type of mental capacity or practical reason rather than the merely causal power that an agent has over his own future self. Commitment does not *remove* options from the menu of available

alternatives but involves a different, noninstrumental type of *evaluation* according to which choices are made. In these accounts, "commitment" refers to an agent's ability or disposition to be bound—and guided in the course of her actions—by what she takes herself to have a *reason* to do, independently of other motivations he or she might have. While the Kantian allusions are certainly not coincidental, it is important to note that according to most revisionist accounts, an agent's commitments need not express her acceptance of universal moral or rational principles but may stem from the particular loyalties, values, or other normative bounds (or plans) that she endorses either as a matter of an autonomous act of will or as an effect of socialization. Some variants of these conceptions concentrate on the "deep," temporally stable normative bounds that are claimed to be constitutive of an agent's personhood, authenticity, or integrity (e.g., "identity-conferring commitments"), while other accounts focus on ubiquitous kinds of commitments involved in any case of rule following or acting in accordance to a plan. Margaret Gilbert has developed an account of joint commitment that she claims to be constitutive of social facts. A joint commitment to x is created if the participant individuals implicitly or explicitly express the willingness to participate in the group's joint x-ing, and it puts the members under an obligation to perform their parts, independently of changes in their motivation. A joint commitment may not be unilaterally rescinded.

Revolutionary Accounts

At the revolutionary extreme of the spectrum are those philosophers (known under labels such as "interpretivists," "holists," or "social externalists") who hold that for any intentional (mental) state to have content (e.g., for "choice" to be "of" something in the sense that the agent has any grasp *of what* it is that she chooses), the agent needs to be committed to a rule. Thus, commitment is seen as a basic and irreducible feature of mind and action. Most prominently in the philosophy of social science, Peter Winch claims that in order to understand an agent's behavior as an action the interpreter must understand the agent as committed to the rules that constitute the meaning of the action in question. Along similar lines, proponents of inferentialism and normative pragmatism, such as Robert Brandom, argue for a view of practical reason in which endorsement and commitment are the central features of rational agency, rather than notions such as desire or preference, traditionally understood as the referents of the "springs of action."

An account of commitment that is especially important for the social sciences can be found in Amartya Sen's critique of standard rational choice theory. Sen claims that committed action is pervasive in social life (e.g., linguistic communication, cooperation, adherence to moral codes and loyalties) and that it cannot be accommodated in standard rational choice explanations. Sen distinguishes commitment from *sympathy.* A sympathetic agent furthers another's welfare because it correlates with his own. A committed agent, by contrast, may act in other people's interests independently of any such effect on his or her welfare. Commitment thus drives a wedge between choice and welfare and involves the possibility of "counterpreferential choice." In this context, Sen advanced the radical claim that committed agents should not be construed as pursuing their own goals. While some interpreters have linked this idea to the role of social identities and shared goals, Sen has later explained his claim as referring to an agent's conforming to a norm independently of how the agent takes this to affect his own or other agents' welfare.

Common Goods

This entry considers an important category of collective entities known as *common goods* and reviews the different notions, distinctions, and problems related to such a collective item. The entry raises questions about what it means to be "common" in this case and how it relates to the issues of jointly held rights to such common goods, which are jointly produced or are the result of joint activity.

Common (or collective) goods have been theorized by philosophy, by political theory, by jurisprudence, as well as by social sciences, such as economics.

There is evidently a family resemblance between notions such as *common good, collective good, public good, common interest, collective interest, public interest,* and so on. Such goods or interests attach to or are enjoyed by groups or other collectives, such as, for example, the British people, the members of the Wagga Wagga local community, the teachers' union, or the pharmaceutical industry. So the contrast here is with a single individual's interest or a benefit that is or could be produced and/or enjoyed by a single individual. Historically, notions of the common good, common interest, and the like in the political sphere are associated with philosophers such as Aristotle, Thomas Aquinas, Thomas Hobbes, and Jean-Jacques Rousseau.

Notions of Common Goods

There is a distinction to be made between the common good and specific common goods. Perhaps security, clean air, and an efficient transport system are all examples of common goods. We can presumably, at least in principle, offer a definition of the notion of a common good and draw up a list of such goods. By contrast, *the common good*—which is often, but not necessarily always, what is in the common interest—is something to be determined anew in a multiplicity or ever-changing circumstances. The common good is an unspecified, or at least underdetermined, state to be realized by collective action.

Economists typically speak of a species of common goods, namely, so-called public goods. They define public goods as being nonrival and nonexcludable. If a good is nonrival, then my enjoyment of it does not prevent or diminish the possibility of your enjoyment of it; a street sign, for example, is nonrival since my using it to find my way has no effect on your using it likewise. Again, a good is nonexcludable if it is such that if anyone is enjoying the good then no one can be prevented from enjoying it—for example, national defense. The public goods in question are typically relativized to the nation-state but increasingly to the global economy.

Nonrivalness and nonexcludability are relevant to the characterization of common goods, albeit the notion of a common good is not necessarily defined in terms of them. Other properties that are relevant to the notion of a common good include equality and jointness of production. Many common goods are jointly produced (or maintained or renewed). And perhaps if a common good is enjoyed, it is enjoyed equally by all; if not, it should be.

There are further distinctions to be made in relation to common goods (sometimes referred to as *collective goods*).

As Joseph Raz points out, there are *necessarily* common goods and ones that are merely *contingently* common. A right of access to a water supply might only be contingently common. This would be so if when the water supply is cut off, everybody's supply is cut off. But under a different system, selective cutting off is possible. By contrast, a tolerant society is necessarily a common good. The tolerance of the society is not something that could be channelled to certain individuals only.

Following Denise Reaume, in respect of necessarily common goods, we can further distinguish between those that an agent can choose not to enjoy himself and those that he cannot choose not to enjoy. Perhaps clean streets are of the former kind and a law-abiding society of the latter. A recluse could not be prevented from enjoying clean streets or a law-abiding society, but he could choose not to enjoy clean streets by never going out. On the other hand, even by staying at home he cannot choose not to enjoy a law-abiding society.

Jointly Produced Common Goods and the Question of Rights

Let us now further explore common goods that are *jointly produced* (or maintained or renewed). Perhaps the territory occupied by the people of the Netherlands is a common good in this sense, since

much of it would be under water were it not for the elaborate system of dykes put in place, maintained, and extended over hundreds of years by the people of the Netherlands.

What is the relationship, if any, between moral rights and jointly produced common goods? Presumably the participants in the joint enterprise in question have a joint moral right to the common good. Accordingly, even if the good considered in itself is not a common good, each of the individual (jointly held) rights to it is a right to it qua common good. For example, by using two boats and a single large net we could jointly catch 100 fish. By prior agreement, we could possess individual rights to 50 fish each. But this agreement is something additional to the joint right, and indeed presupposes it. Imagine that unexpectedly the good produced could not be parcelled out in the manner envisaged in the agreement. Perhaps we caught only one very large fish or no fish but instead a rare and valuable old ship. If so, each individual could still claim an individual (jointly held) right to the good and therefore legitimately insist on making some different agreement (or perhaps no agreement).

Jointly produced common goods give rise to the so-called free rider problem. The problem arises for goods that can be produced even if some members of the group do not contribute; that is, they free ride. The problem is that each knows he or she can free ride and it is in his or her interest to do so. However, if all act on their self-interest, then the good will not be produced, something that is ultimately in no one's interest. The problem is particularly acute for rational egoist theories (e.g., Hobbes's classic one), since such theories assume that rational human action is always self-interested or, at least, that where self-interest and the common good conflict, self-interest always wins.

Common Goods Produced by Joint Activity

Thus far, our discussion of jointly held rights to jointly produced goods has implicitly assumed that the good produced is not constituted by the actions that produce it. Let us now consider goods that consist of the *joint activity* undertaken to produce them. Reaume claims that such goods are *necessarily collective* in the sense of goods such that an agent that contributes to their production cannot be excluded from their enjoyment, either by another agent or by the agent himself. Examples are political participation and cultural participation. We might refer to such goods as *participatory* common goods.

Arguably, social institutions are an important means by which common goods that ought to be produced are in fact produced. Indeed, on some accounts of social institutions, the production (or maintenance or renewal) of common goods is the raison d'être of social institutions.

On Seumas Miller's account, the collective ends pursued by organized joint activity are common goods by virtue of their possession of the following three properties: (1) they are produced, maintained, or renewed by means of the *joint activity* of members of organizations such as schools, hospitals, welfare organizations, agribusinesses, electricity providers, and police services—that is, by institutional role occupants; (2) they are *available to the whole community:* for example, clean drinking water, a clean environment, basic foodstuffs, electricity, banking services, education, health, safety and security; and (3) they *ought* to be produced (or maintained or renewed) and made available to the whole community since they are desirable (as opposed to merely desired) and such that the members of the community have an *(institutional) joint moral right* to them.

Common Knowledge

While you are working in the library, the loudspeaker announces that the library will close in 15 minutes, inviting the public to move toward the exit. The public announcement makes you and everyone else in the library aware that the library is about to close for the day. You realize that all users in the library have heard the announcement and know that the library is about to close. The state of group knowledge in which all members of a group know that something is the case is called *mutual knowledge*.

The subject matter of this entry, common knowledge, is a far richer epistemic state than mere mutual knowledge. After hearing the announcement, you realize not only that everybody in the library knows that the library is about to close but also that everybody is in a position to come to the same realization, since the announcement was publicly made. Thus, everybody knows that everybody knows that the library is about to close. But everybody can realize also that everybody else can realize that the public announcement has made everyone aware that the library is about to close. Thus, everybody knows that everybody knows that everybody knows that the library is about to close. The chain of "realizations," inferences, awareness, and knowledge can, in principle, go on indefinitely. Thus, everybody knows that the library is going to close, everybody knows that everybody knows that, everybody knows that everybody knows that everybody knows that, and so on ad infinitum. This state of group knowledge is called *common knowledge*.

In this entry, we will describe the pervasiveness of common knowledge, offer two characterizations of it, and illustrate applications relevant to the social sciences.

Common knowledge is ubiquitous. As we have seen above, public announcements generate common knowledge. But common knowledge is also implied by the fundamental psychological mechanism of joint attention, and it is assumed in our linguistic exchanges: Definite references presuppose common knowledge, as does meaning in Gricean accounts (after the British philosopher Paul Grice). The philosopher who introduced the notion in his 1969 book on social conventions, David Lewis, argues that common knowledge is necessary for social conventions to exist. In the context of group agency and political obligation, Margaret Gilbert claims that common knowledge is necessary for a joint obligation to arise in a group of agents.

However, common knowledge is also elusive. It entails an infinite amount of epistemic states, which, of course, cannot possibly occur in finite agents. It entails perfect sharing of public announcements or events, which cannot always be assumed: Did the person who was listening to her iPod in the library hear the library loudspeaker announcement? It entails that agents be symmetric reasoners: If an agent infers p in a given situation, everyone else in that situation will infer p. Moreover, it requires that it be common knowledge that agents are symmetric reasoners. (This raises the question "Where does *that* common knowledge come from?") David Lewis ingeniously proposes that in our daily interactions common knowledge represents an infinite number of *potential* knowledge states, which translate into only a few steps of *actual* ones: In practice we seldom go over the first two or three levels of mutual knowledge.

The infinitary character of common knowledge can be characterized by a finite definition exploiting the circularity inherent in a publicly shared situation. A classic definition of common knowledge goes like this:

p is common knowledge in a group G if

1. E obtains,
2. E entails that everyone in G knows that E, and
3. E entails that everyone in G knows that p.

Consider the library example again: E is the announcement on the loudspeaker, p the event that the library will close in 15 minutes. It is easy to see that by repeatedly applying (3) to (2) and appropriately using

modus ponens, it is possible to derive the whole common knowledge hierarchy.

The above characterization of common knowledge can be compressed in the so-called fix-point account, used mainly by logicians and computer scientists. While common knowledge can be a valuable logical notion to use, most logical systems do not allow for infinitely long formulas, hence computer scientists investigating multi-agent architectures and philosophers investigating epistemic logic by and large base common knowledge logics on the fix-point account. In a nutshell, Conditions 1 to 3 above are summarized by a unique logical formula that, in English, reads "Everyone in *G* knows *p* and everyone in *G* knows **σ**," where **σ** refers to the whole expression between scare quotes.

Applications of common knowledge are widespread, and it will only be possible to give here three brief and partial references. First, in economics, one of the earliest and seminal results involving common knowledge is Robert Aumann's agreement theorem. Aumann proves that if two agents have a common prior probability distribution and they have common knowledge of their posterior distributions, then no matter how disparate the information on which they updated their priors, their posteriors are equal. The result has been generalized to no-trade theorems, showing the impossibility of speculative trade between rational agents. Second, in game theory and its philosophical foundations, much has been discussed about the role that common knowledge plays in the selection of action in strategic interactions between rational players: Cristina Bicchieri has developed this line of thought. Third, in the philosophy of social sciences, there is an ongoing debate on the role played by common knowledge in game-theoretic accounts of social convention. While authors influenced by the evolutionary approach stress that common knowledge is not necessary for conventions to arise, others argue that common knowledge is crucial to create expectations supporting coordinating action.

Common Sense (in the Social Sciences)

From the Latin *sensus communis,* common sense came to refer to a body of self-evident truths or first principles presupposed by the practical judgments of every sane individual. Deviating from this universal capacity, the philosophical understanding of common sense oscillated between ontology and epistemology, means and ends, judgment and knowledge, certainty and ambiguity, sensory experience and cognitive categories. Across philosophers as diverse as Aristotle, Giambattista Vico, Shaftesbury, Thomas Reid, Immanuel Kant, Henri Bergson, G. E. Moore, Ludwig Wittgenstein, Hans-Georg Gadamer, and Richard Rorty, common sense has been subject to competing, often terse, analyses and counteranalyses.

Sensus Communis

A humanist appeal is made to the sensus communis as the communal basis of reason, truth, and moral sense, in contrast to the convolutions of abstract theoretical knowledge. The Third Earl of Shaftesbury pointed to the lively wit and ridicule of the sensus communis as evidence of human sociability and morality. As it passed through the Scottish common sense philosophy of Thomas Reid, the universality of tacit common understanding represented the supreme court of appeal, while the philosophical "way of ideas" led ineluctably to "ridiculous" and "absurd" forms of "metaphysical lunacy." Reid argued that philosophers who cast doubt on our knowledge of reality, like David Hume, routinely adhere to commonsense principles in daily life.

Realist assumptions about universal common sense mean that individual experience cannot be deceived or doubted. Intellectual authority derives from direct observation and the combined senses of individuals bound together in community. Morally, all sane human beings are believed to be congenitally predisposed to the "good sense" of universal rules of conduct. Socially, common sense anchors individuals intersubjectively to others in specific social worlds. Psychologically, it provides ontological security to stabilize a unified sense of self caught up in the flow of life. Common sense also offers protection against the narrowing horizon of intellectual expertise generated by scientific overspecialization.

Duality of Common Sense

Social science adopts contrasting approaches to common sense. On one side, common sense is understood as a precondition of social solidarity and social action. Social science is thought to be continuous with common sense, an umbilical cord that can never be cut but simply needs to be more systematically ordered by self-conscious reason. On the other side, common sense is reproached as a constraint on critical reason and autonomy. Social science qua science strives for a discontinuous "break" with the self-evident biases and distortions of common sense.

With its emphasis on the social conditioning of sound judgment as a universal disposition, common sense entered the social sciences by a number of circuitous routes. In Britain and much of southern Europe, common sense possessed a critical, moral, and civic quality, underpinning rationalist and positivist assumptions in social thought. In the United States, commonsense philosophy was refracted through the Scottish school and pragmatism. "Critical commonsensism" formed a bridge between self, society, and science, helping found an alternative social psychology to John Locke's cognitive individualism. Commonsense universality provided the grounds for modern democratic challenges to arbitrary authority, from Tom Paine's 1776 pamphlet "Common Sense" to Martin Luther King Jr.'s 1963 "I Have a Dream" speech. The most celebrated economic tract of the 20th century, John Maynard Keynes's *The General Theory of Employment, Interest and Money* is indebted to the indeterminate possibilities of ordinary-language philosophy developed by his Cambridge colleagues G. E. Moore, Frank Ramsey, and Ludwig Wittgenstein.

This critical egalitarian understanding of common sense found little resonance in German metaphysics. Commonsense judgment was consigned to the lower functions of mind, languishing beneath an elevated scholastic cognitive tradition. For Immanuel Kant, the sensus communis provided the indeterminate ground for the universal judgment of aesthetic taste rather than specific truths of scientific reason or morality. Even in Enlightenment France, common sense came to be identified with the childlike credulity, prejudice, and superstition of the vulgar masses, in contrast to the enlightened reason, tact, restraint, and taste of cultivated intellectuals.

Common sense was excised from the pure analytical conceptions constructed by classical sociology. Émile Durkheim formulated a scientific "break" with the "previsions" of common sense by establishing a distinctive methodology and conceptual framework, from "social facts" to describe the impersonal norms of common sense and the "conscience collective" of highly integrated, premodern social systems. Drawing on the German hermeneutic tradition of Wilhelm Dilthey and Heinrich Rickert, Max Weber made subjective observation of purposive social action broadly continuous with common sense through the "sympathetic magic" of *aktuelle,* or "direct understanding." However, this was always subordinate to Weber's project to found an "objective social science" through ideal models of typical causes and motives of instrumental social action.

From Karl Marx's premise that being-in-the-world determines consciousness, Marxism found great difficulty assimilating common sense depending on whether social structures or sensual-practical subjectivity was emphasized. For Georg Lukács, empirical common sense represented a barrier to objective knowledge and class consciousness because it spontaneously reified the social world of universal commodity production. Louis Althusser reduced common sense to insidious ideological representations, from which only by a rigorous effort of scientific labor could one break free—exemplified by the later work of Marx.

In contrast, for Antonio Gramsci common sense represents the "folklore" of philosophy. Since it emerges among historically formed groups in specific cultural conditions, common sense for Gramsci (1971) represents "a chaotic aggregate of disparate conceptions" (p. 422). It is "ambiguous, contradictory and multiform" (p. 422) rather than a flat realm

of ideological transmission or reification. Common sense spontaneously provides the contradictory but fertile ground through which "the good sense" of class consciousness is channeled by the "philosophy of praxis" (Marxism).

Phenomenological Sociology

Synthesizing Edmund Husserl, Henri Bergson, pragmatism, and hermeneutics, Alfred Schütz developed a phenomenological approach to the "natural attitude" of common sense in the "life-world." For phenomenological sociology, common sense performs an axiomatic function that makes intersubjectivity possible in the first place. Routine, prereflexive common sense puts the social world "at hand" without much further ado as real, meaningful, and coherent. Phenomenological sociology is more concerned with the necessary preconditions of social worlds than with the explicit meanings or rationalizations of agents themselves, an insight developed independently by the later Wittgenstein. George Herbert Mead's "social theory of mind" acted as a pragmatic-behaviorist bridge to phenomenological sociology. For Mead the common socio-sensory capacities of individuals are essential for the completion of self by the "generalized other" through cooperation and conflict.

Phenomenological concerns with commonsense preconditions gave rise to a wide and varied intellectual tendency in postwar sociology, ranging from ethnomethodology, Erving Goffman's model of social action, the social construction of reality, through to feminist standpoint theories of gender, race, and class differences. Jürgen Habermas recentered critical theory's concern with the systemic loss of consensual good sense in the bourgeois public sphere through the malign construction of "public opinion."

Synthesizing phenomenology and classical sociology, Pierre Bourdieu developed a critique of scholastic disdain for common sense by theorizing the logic of *sens pratique* ("practical sense") as a concrete "feel for the game" of the embodied dispositions of habitus. This does not refer to a universal sense, as in the Kantian judgment of taste, or the contingent identities valorized by postmodernism, but to a common, prereflexive sense of unequal positions structured across social space.

Communication Studies

Communication studies is a multifaceted area of academic inquiry in which scholars explore how humans share symbols to create meaning. The subject includes investigations into topics such as understanding, interaction, transferring meaning, and reducing uncertainty in various contexts. Communication studies is an interdisciplinary academic area, and theoretically applied topics of investigation frequently overlap with scholarship conducted in other academic disciplines including psychology, sociology, history, education, health care, political science, and business. While researchers in other academic disciplines consider communication to be a secondary process within their content area, communication scholars consider communication to be the primary content and other fields as secondary. Communication has a long history dating back to antiquity and includes a range of topics that may be examined from both humanities and social science perspectives.

History

Early Greek and Roman philosophers including Plato, Aristotle, Cicero, Quintilian, and others emphasized the importance of communication

in everyday life. They were interested in the use of persuasive arguments to influence others in the public sphere (*rhetoric*) and examined both in the practice of communication as well as various parts of the communication process. In fact, rhetoric and the logic of persuasion became a *topos* of systematic philosophical analysis in the hands of Aristotle but also a bone of major philosophical contention between the sophists, on the one hand, and Socrates and Plato, on the other—with important repercussions for ethics and the theory of knowledge.

One of the earliest models of communication codified the five canons of rhetoric. While some scholars emphasized the civic practice of combining these components to deliver a persuasive argument, other scholars engaged in the formal theoretical investigation of a particular segment of communication. Thus, each canon has a practical and theoretical aspect. Invention (Latin *inventio*) relates to identifying the content of an argument that one will make to other people and is informed by theoretical investigations into the nature of knowledge and knowing. Style (Latin *loqui*) refers to the language choices one selects to best convey ideas and is enriched by theories relating to the nature of language. Arrangement (Latin *dispositio*) considers how ideas are arranged or organized within one's speech and is enhanced by theories about the processes by which information could be ordered and related. Memory (Latin *memoria*) relates to one's ability to remember and recall information and is guided by theoretical content related to processes of information storage and retrieval. Delivery (Latin *pronuntiatio*) focuses on the recitation or presentation of the content and is enhanced by theories about message transmission.

Following the classical period, the medieval and Renaissance periods saw a decline in scholars' interest in formal communication theory. Communication scholars emphasized issues of practical concern in prescriptive and nontheoretical works, such as manuals on letter writing and preaching. The theoretical study of communication reemerged with the secularization of thought in the 1600s and included four major areas of inquiry. Classical scholarship on communication reintroduced and elaborated on the earliest works in rhetoric, reversing the prescriptive trend. Epistemological-psychological approaches raised questions about how humans know, believe, and act in different situations, emphasizing the mental processes involved in communication.

Belletristics (French *belle lettres,* "fine writing") opened up theoretical interest in the study of literature, poetry, and drama as communication, prompting the investigation of the relationship between language arts and broader society. Elocutionist scholarship emphasized the practical aspects of delivery, stimulating theory about the verbal and nonverbal behaviors one can use to enhance a presentation.

Contemporary Issues

The 20th century saw the rise of communication technologies, including radio, television, the telephone, satellites, and computer networking. This further broadened communication inquiry to include the use of mass communication channels to share information and seek to improve society. Along with scholars, members of society in general became interested in myriad communication topics, including communication as a psychological and social process, persuasion and influence, and decision making in groups. In keeping with societal changes, postmodern scholarship in communication studies is highly eclectic in both topics of investigation and the forms of scholarship used to investigate those topics.

Communication studies has been approached by scholars both as an area in the humanities and as a social science. The epistemological choice a scholar makes determines the research approach taken. Within the humanities, scholars consider the philosophical and rhetorical grounds of human communication, including topics such as meaning and truth, interpretation, representation, and speech acts. Humanities scholars may approach communication from various philosophical traditions (semiotics, hermeneutics, phenomenology, critical theory, etc.) or rhetorical traditions (various types of rhetorical criticism, including dramaturgical, genre, feminist, etc.). Approaching it as a social science, researchers employ both quantitative and qualitative methods to investigate communication topics such as attitude change, relationship development and deterioration, decision-making processes, and media effects. Some social science scholars choose to triangulate research methods and data analysis techniques—using quantitative or qualitative data-gathering techniques—to produce data that may be analyzed statistically or interpretively.

Communication studies is a term that includes a variety of topics that may be considered in any

number of ways. Domains of communication inquiry include intrapersonal, interpersonal, group, organizational, and public communication. Furthermore, communication in each domain may occur face-to-face or through a mediated channel in either private or public settings. Scholars examine how communication is symbolically structured and functions within each area. They also attend to factors such as a person or group's gender, ethnicity, culture, able-bodiedness, sexual orientation, age, ethics and religious value systems, and so forth. The forms of inquiry in communication studies are very broad and include the depth and breadth of subjects related to the human exchange of symbols to create shared meaning.

People have been interested in human communication since antiquity. The dynamics of communication include a variety of domains and range of topics that may be studied from a humanities/philosophical perspective or using social science methods.

Communicative Action Theory

Jürgen Habermas's theory of *communicative action* is central to his version of critical theory and a powerful alternative to theories of rational action and rational choice, which have been influential in the social sciences. It is also exceptionally relevant to this encyclopedia because it is located on the borders of philosophy and social theory.

In the 1970s, Habermas (1929–) had been attracted by the idea of using the theory of language developed in analytic philosophy and speech act theory as a basis for the social sciences. By 1981, when he published his *Theory of Communicative Action,* he had abandoned this aim, and he presents his theory as a social theory rather than as a metatheory. In its focus on a particular conception of rationality, however, it is, like rational action theory, taking up central philosophical themes. As Habermas stresses in the first chapter of *Theory of Communicative Action,* a concern with rationality is central both to philosophy and to the social sciences. In social science, and in a more informal way in everyday life, we make sense of other people's speech and behavior in terms of models of rationality ("I see why you said that"), we test these understandings against rational criteria ("But you completely misunderstood the situation"), and we make judgments about how far a person or a larger collectivity really has been rational.

Rather as the term *discourse* has been stretched far beyond a linguistic concern with speech and writing to include more complex systems of belief and practice (as in Michel Foucault's analyses of medical and psychiatric discourse), Habermas understands by communicative action a form of action oriented toward agreement, whether about states of affairs in the external world, normative claims about what should be the case, or proposals for action. Anyone engaging in communicative action is implicitly claiming that what he or she says is intelligible, true, sincere, and justified. Even a request, if it is more than just an instruction (like the pilot's order to the cabin crew to switch the "doors to automatic"), opens itself up to a possible process of justification. In Habermas's example in Volume 1 of *Theory of Communicative Action,* if he asks a seminar participant to fetch him a glass of water, he is making the implicit claims that there is a reasonably convenient source of water, that he really wants it and is not just attempting to belittle the student, and that the request is a reasonable and appropriate one that he is entitled to make; any or all of these claims may be contested by the addressee of the request.

In Volume 2, Habermas uses a similar example to make the point that communicative action is not just communication or a process of reaching understanding: It is also an ongoing element of sociation, engaging individuals' definitions and understandings of situations and their own identities. This time, the example is of an older building worker sending a

younger recent recruit to fetch beer to go with the midmorning snack. Again, the exchange makes sense against the background of a whole set of shared assumptions that may be problematized if the younger worker does not understand the custom or the expectations associated with his or her place in the team hierarchy.

Habermas makes the same sort of claim for the primordial character of communicative action as other theorists would make for self-interested or, in Habermas's terms, strategic action. Both, he insists in a reply to critics in 1986, have a teleological component. What distinguishes them is not so much the actor's orientation as such but what Habermas calls "the combination of actor attitudes (orientation to success vs. orientation to reaching understanding) and forms of coordinating different action plans (influence vs. consensus)." It is all right, in other words, for me to argue vigorously with you for my point of view about what is true or what is to be done about some matter of concern, but not for me to try to persuade you by rhetoric or manipulation, for example, by falsely suggesting that "there is no alternative."

Bargaining, manipulation, and so on, he argues, are all parasitic on communicative action, as are the sociological models of normatively oriented action (i.e., action shaped by a shared value system), derived from the functionalist sociologist Talcott Parsons, or the "dramaturgical" model of action developed by Erving Goffman, in which the idea of role-*playing* is taken seriously as a model of the "presentation of self" in social life. He was not, he insisted, saying that people choose or want to act communicatively but that they *have to*.

Armed with this model of communicative action, Habermas presented an outline history of Western modernity, following Marx and Max Weber, in which social arrangements came to be questioned in light of reason (the "Enlightenment"), only to be removed from the scope of rational discussion and possible agreement by the growth of capitalist markets and bureaucratic administration. There can be no argument if you have reached your credit limit or if your case is not eligible according to the rule book. This process of rationalization or reification, which for a time Habermas referred to as the "colonization of the life-world" by formal systems, might not have been inevitable: There might have been, or might still be, more communicative or cooperative alternatives.

Habermas went on to develop a *discourse theory of morality,* also less precisely called "discourse ethics," according to which norms are valid if all those affected could in principle come to agree on them. This is a theoretical justification as he presents it, but he also wants to claim that the more such discussion actually takes place and the closer it approximates to the ideal vanishing point, which for a time he called the "ideal speech situation," the better. In a society like ours, where there is no longer (if there ever was) a single shared view of the world and of how we should behave in it, the only way we can achieve a shared understanding is by bringing our interpretations into line with one another in a process that is "risky" but also promises greater rationality. There are echoes here of Max Weber's image, in which in the modern world we are faced by the rival demands of warring gods and demons; there are also philosophical echoes of Hegel's critique of Kant's abstract account of morality and his own—more sociological emphasis on the way it is necessarily embedded in the ethical life (*Sittlichkeit*) of a real human community.

Following a long engagement with legal theory, Habermas extended his model into a discourse theory of law and democracy, in which law gives teeth to morality but also demands democratic justification. Here, Habermas converged with theories of deliberative democracy as it was developed initially with reference to states and then, beyond state borders, in models of cosmopolitan democracy.

Critics of Habermas's model have tended to see it as excessively rationalistic, though it is worth noting that his friend Karl-Otto Apel's more Kantian version of discourse theory is more directly vulnerable to this charge. Approaches such as those of Michel Foucault or Pierre Bourdieu, which put more emphasis on power and strategic action, or analyses of political discourse, which give more attention to rhetorical and "agonistic" aspects, may seem to be more realistic. Analysts of discursive democracy, often focusing on deliberations in the European Union, have argued for the importance of acceptable compromises setting limits to, while still incorporating, the pursuit of self-interest. Habermas himself has no objection to majority voting, so long as a prior agreement has been reached that this is an acceptable way to decide an issue, for example, where pressure of time rules out further search for a consensus. Academic committees, for example, may

see voting as a last resort, whereas political ones may be happier to take a formal vote, even where there is unanimous agreement.

The distinction between communicative and strategic action may itself not be as clear-cut as Habermas assumes. The aesthetic dimension of social life also receives little attention in Habermas's model. Albrecht Wellmer, in particular, who had contributed substantially to the communicative action model, has come to stress this aspect, generalizing it to the argument that the "negative freedoms" of a liberal democracy should include the right "not to be completely rational." More concretely, some critics have detected a latent authoritarianism in the stress on the pursuit of agreement and the requirement of rational justification.

The early critiques along these lines by French intellectuals may have been misdirected, but the demands by religious and/or ethnic minorities for their "difference" to be respected without the need for formal justification pose a more substantial challenge to someone like Habermas, who has always been deeply respectful of different ways of life, even in relation to unpromising contexts such as the South of the United States before the Civil War. The title essay of *The Inclusion of the Other* (see Further Readings, below) is a partial response to these issues, as is his later engagement with questions of religious belief. Seyla Benhabib has taken up these themes in a number of important recent works.

Complex Networks Theory and Social Phenomena

This entry introduces the emerging interdisciplinary field of complex networks, which incorporates insights from physics and mechanical engineering as well as computer science into an account of social networks and social interconnecting in general. Complex networks theory attempts to explain in mathematical and topological terms not only social networks but also social institutions (e.g., markets) or social practices (traffic) on the analogy of properties found in the natural world.

Background and Definitions

Complex networks theory is the study of physical systems and social phenomena represented as networks, with nodes representing the actors (entities) of the system and links encoding the interactions between pairs of nodes. With roots in mathematics, physics, computer science, and biology, complex networks theory marks a departure from the perception, previously widely held within those fields, that either random networks—links occurring between pairs of nodes with equal probability—or regular lattices were appropriate mathematical approximations of networks occurring in the natural world. A *complex system* can be informally defined as a system where components acting and interacting

according to simple rules results in nontrivial global behavior. The aspiration of complex networks theory is to understand and describe how the simple, local interactions of individual nodes and actors result in empirically observed intricate network structures and dynamics on multiple scales.

Structure

Complex networks theory grew out of two central studies, each one pointing out fundamental structural properties of real-world networks.

In 1998, Duncan Watts and Steven Strogatz showed that two interesting structural properties were both present in a number of real-world networks. First, all networks were so-called small worlds, where almost every node can be reached from every other node in a small number of jumps. This finding drew on earlier work by the American social psychologist Stanley Milgram and is reflected in the commonly known idea of *six degrees of separation*. Second, they showed that if we consider the neighbors of a typical node, we will tend to find more connections between them than one would expect at random; this property is known as *clustering*. Social networks, in particular, are known to be highly clustered: Two of your friends are more likely to be friends with one another than would be the case with two randomly chosen nodes.

Soon thereafter, studying the distribution of a number of connections per node, the node's *degree,* Albert-László Barabási and Réka Albert found that the degree distributions observed in many empirical networks tend to follow *power laws*. As a statistical distribution, the power law is radically different from the *Poisson distribution* that describes the connectivity of random networks; the power law degree distribution is characterized by a few highly connected nodes, sometimes called *hubs,* and a vast majority of nodes with low degree. These broad degree distributions have profound consequences for network properties, related to—for example—robustness and stability, epidemic threshold, and search.

Since these initial results, researchers have discovered structure on almost any scale between single nodes and the total network size. Starting from the properties of pairs of nodes, it soon became clear that in some networks, nodes of high degree systematically connect to nodes of low degree—this *disassortative* behavior increases overall robustness and is often seen in biological networks. Social networks tend to be *assortative*—nodes of high degree tend to link other nodes of high degree, while low-degree nodes tend to connect to other low-degree nodes. If we consider *motifs* of three to five nodes and the links between them, it turns out that some motifs occur much more frequently than one would expect at random. Other motifs never occur, although one would expect to see them often had nodes been linked to each other by chance. The specific motifs that are upregulated, as well as those that are suppressed, provide information about the function of the individual networks. On the meso scale—between motifs and the entire network—networks are typically organized into communities. *Communities* are sets of densely connected nodes—in social networks, they correspond to groups of friends, families, coworkers, and so on. Finally, many networks are organized according to a hierarchy that describes how the various structural elements are combined: how nodes are linked to form motifs, how motifs are combined to form communities, and how communities are joined to form the network itself.

Social Phenomena

Complex networks theory does not exist in a vacuum—networks have been studied in many other contexts. Starting with the work of Jacob L. Moreno in the 1920s, an entire branch of sociology, *social network analysis,* has been devoted to understanding social networks. In that larger context, the single component that truly distinguishes complex networks theory is *scale:* Fueled by analytical and computational methods from physics and computer science, complex networks theory has specifically added to our understanding of social phenomena, when it comes to understanding social systems at the largest scales.

Seen from this perspective, Watts's and Strogatz's strongest contribution consists not in revealing the presence of clustering in many networks and the small-world effect—both were previously known phenomena—but in showing explicitly that these effects are expressed in a global sense and in proposing quantitative explanations for why this is the case. Knowing that it is a "small world" is one thing, but understanding the overall network properties that are responsible for short path lengths and network navigability requires insight into the global structure of the system.

The power law degree distributions discovered by Barabási and Albert are naturally statistical descriptions of entire systems—which is the reason why their discovery is without a precursor in social network analysis. The consequences of the power law degree distributions are particularly important when expressed on the societal scale. For example, networks with power law degree distributions often occur in nature because this configuration is more robust to random node deletions. The effects of power laws also extend to dynamical processes; for example, the spread of an infectious disease displays very differently on a power law network than is expected by the standard assumptions of epidemiology. Many other network properties (e.g., communities) have impact processes occurring on the network.

While complex network theory remains a discipline primarily driven by empirical discoveries, recent developments in the theory focus primarily on two tasks: One central challenge is to strengthen the understanding of networks with many different types of nodes as well as multiple link types, potentially coexisting between any pair of nodes. The second central problem is to develop a unified framework for describing the dynamical aspects of complex networks—and how the dynamical aspects interact with the questions of *multiplexity* (the overlap of roles, exchanges, and affiliations in social relationships).

Complexity

The term *complexity* derives etymologically from the Latin *plexus,* which means "interwoven." Intuitively, this implies that something complex is composed by elements that are difficult to separate. This difficulty arises from the relevant *interactions* that take place between components. This lack of separability is at odds with the classical scientific method—which has been used since the times of Galileo, Newton, Descartes, and Laplace—and has also influenced the fields of philosophy and engineering.

In recent decades, the scientific study of complexity and complex systems has initiated a paradigm shift in science and philosophy, proposing novel methods that take into account relevant interactions. At the same time, complexity is relevant to the social phenomena studied by social science. A number of issues in studying complexity, such as the question of irreducibility or systems theory, are directly relevant to social science.

This entry reviews the basic aspects of the notion of complexity, both scientific and philosophical, explains its uses and definitions, discusses the prospect of a science of complexity, and delineates the possibility of a "philosophy of complexity."

The Limits of Reductionism

Classical science and engineering have successfully used a reductionist methodology, that is, separating and simplifying phenomena in order to predict their future. This approach has been applied in a variety of domains. Nevertheless, in recent decades, the limits of reductionism have become evident in phenomena where interactions are relevant. Since reductionism separates, it has to ignore interactions. If interactions are relevant, reductionism is not suitable for studying complex phenomena.

There are plenty of phenomena that are better described from a nonreductionist or "complex" perspective. For example, insect swarms, flocks of birds, schools of fish, herds of animals, and human crowds exhibit a behavior at the group level that cannot be determined or predicted from individual behaviors or rules. Each animal makes local decisions depending on the behavior of its neighbors, thus interacting with them. Without interactions—that is, with reductionism—the collective behavior cannot be described. Through interactions, the group behavior can be well understood. This also applies to cells, brains, markets, cities, ecosystems, and biospheres.

In complex systems, having the "laws" of a system, plus initial and boundary conditions, are not enough to make a priori predictions. Since interactions generate novel information that is not present in initial or boundary conditions, predictability is limited. This is also known as *computational irreducibility;* that is, there is no shortcut to determine the future state of a system other than actually computing it.

Since classical (nonquantum mechanical) science and (versions of) philosophy assume that the world is predictable in principle, and relevant interactions limit predictability, many people have argued that a paradigm shift is required, and several novel proposals have been put forward in recent years.

The Complexity of "Complexity"

There is a broad variety of definitions of complexity, depending on the context in which the term is used. For example, the complexity of a string of bits—a sequence of zeroes and ones—can be described in terms of how easy it is to produce or compress that string. In this view, a simple string (e.g., "010101010101") would be easily produced or compressed, as opposed to a more "random" one (e.g., "011010010000"). However, some people make a distinction between complexity and randomness, placing complexity as a balance between "ordered" and "chaotic" dynamics.

A well-accepted measure of complexity is *the amount of information required to describe a phenomenon at a given scale.* In this view, more complex phenomena will require more information to be described at a particular scale than simpler ones. It is important to note that the scale is relevant to determine the amount of information, since, for example, a gas requires much more information to be described at an atomic scale (with all the details of the positions and momentums of molecules) than at a human scale (where all the molecular details are averaged to produce temperature, pressure, volume, etc.).

Complexity has also been used to describe phenomena where properties at a higher scale cannot be reduced to properties at a lower scale—in other words, when the whole is more than the sum of its parts (as in the notion of "emergence"). For example, a piece of gold has color, conductivity, malleability, and other "emergent" properties that cannot be reduced to the properties of gold atoms. In other words, there is a potentiality of novel behaviors and properties: A system with coordinated interacting elements can perform more complex functions than the independent aggregation of the same elements. Emergent properties cannot be reduced to the components of a system, because they depend on interactions. Thus, an approach to studying complex systems requires the observation of phenomena at multiple scales, without ignoring interactions. Formalisms such as multi-agent systems and network theory have proven to be useful for this purpose.

Complexity Science?

The scientific study of complexity, under that label, started in the 1980s. Some people argue that it is a science in its infancy, since it has been only a few decades since its inception and has yet to reveal its full potential. However, some people argue that complexity will never be a science in itself, because of its pervasiveness. Since complexity can be described in every phenomenon, a science of complexity would be too broad to be useful. A third camp defends the position that complexity is already a science in its own right. This debate certainly depends on the notion of what a science is.

Moreover, one can argue that all three viewpoints are correct to a certain degree. A scientific study of complex phenomena exists; this is not in dispute. People also agree that this study is offering new insights in all disciplines and has great potential, already yielding some fruits. The pervasiveness of complexity is also agreed upon. A scientific approach where interactions are considered (i.e., as nonreductionist) has been propagated in all disciplines. Whether or not people call this approach "complex" is irrelevant. The ideas and concepts of

the scientific study of complex systems are being propagated. Perhaps there will never be a science of complexity itself, but complexity is pushing paradigm shifts in all the sciences.

Toward a Philosophy of Complexity

Science has greatly influenced philosophy. For example, Newtonian physics led to philosophical materialism and mechanism. Perhaps unknowingly, the reductionist worldview stemming from classical physics seeped into ontology, where people argued that the only real phenomena were those described by physics—the laws of matter and energy—while all the rest were only epiphenomena, reducible to Newtonian dynamics in the times of Laplace and to elementary particles in recent decades.

Complexity has shown that reductionism is limited, in the sense that emergent properties cannot be reduced. In other words, the properties at a given scale cannot always be described completely in terms of properties at a lower scale. This has led people to debate on the reality of phenomena at different scales. This is crucial for social scientific explanations. For example, interactions are not necessarily describable in terms of physics, but they can have a causal effect on the physical world. An example can be seen with money, the value of which rests simply on an agreement between people; it is not describable in terms of physics. Still, money has a causal effect on matter and energy.

Complexity has also shown the relevance of the observer in the description of phenomena, since depending on the scale at which a phenomenon is described, its complexity will change. This is in contrast to classical epistemology, which seeks in objectivism the path to find the "true" nature of phenomena.

It should also be noted that the novel information generated by interactions in complex systems limits their predictability. Without randomness, complexity implies a particular nondeterminism characterized by computational irreducibility. In other words, complex phenomena cannot be known a priori.

An interesting feature of the philosophy of complexity is that it is very close to certain Asian philosophies, which were not influenced by reductionism and do consider the relevance of interactions. It could be said that Western philosophies are rediscovering the ideas of Eastern philosophies through the scientific study of complexity.

Complexity and the Social Sciences

Phrased in an encapsulated form, the essential element of the *complexity turn* across science can be summed up in the common English expression "The whole is greater than the sum of its parts." That is to say, complexity is concerned with emergence, with what physical scientists refer to as "the failure of superposition." The essence of emergence is that entities may have properties that apply to them as a whole and are not explicable in terms of properties of the components that constitute the entities.

This entry reviews the origin and meanings of the notion of complexity and its principal uses in current social theory.

Complexity

It is important not to confuse the idea of complexity with methodological holism. Holism of this sort asserts that there are properties that belong to entities as a whole and are not explicable other than by reference to the entity as a whole. Complexity considers that an essential source of the properties of an entity are the interactions among its components. In the most developed version of complexity theory, such interactions are considered to operate among the components of the entity, among the components with the entity as a whole, and among the components of the entity, the entity as a whole, other entities, and the components of other entities.

Complex entities are generally understood as being *systems* that possess the *emergent* properties. Emergence is not a new idea. Its origins can be traced back to G. H. Hughes in the 1880s, and it has informed unconventional positions in philosophy and the philosophy of science since that time. Emergence is a radical challenge to the *reductionist* program in scientific explanation. Reductionism seeks to explain the properties of more "complex" entities/systems solely in terms of the properties of simpler entities. Ultimately, reductionism seeks to explain all of reality, including social reality, in terms of fundamental physical properties of matter and energy, although of course this is not a real program in any science. Complexity does not deny the validity of the reductionist program in relation to simple systems, but rather, it argues that it cannot cope with complex systems with emergent properties and asserts that much of reality, not only social reality but also biological reality and in particular the intersections of the "natural" and the "social," can only be understood if we pay attention to emergence and develop a strategy of investigation that recognizes its implications. So complexity theory is fundamentally not a testable theory describing an aspect of reality but rather an ontology asserting the nature of most of reality itself.

Complex Systems

The history of complexity in social science is itself complex. It stems (a) in part from the tradition of systems theory in sociology associated with Talcott Parsons, although it is radically different in form; (b) in part from the General Systems Theory proposed by Ludwig von Bertalanffy; (c) in part from cybernetics and in particular from the debates associated with the Macy seminars of the 1950s, described by Katherine Hayles; (d) in part from developments in the physical and biological sciences that began with the turning of attention to ideas of *chaos* and the use of computing technology to explore deterministic chaos using *nonlinear* modeling and simulation approaches, often associated with the work of the U.S. Santa Fe Institute; and (e) in part from a rather different European scientific approach to chemical systems associated with the work of the physicist Ilya Prigogine.

All these approaches, with the exception of the general tendency, but not the full content, of Parsons's account, are concerned with systems understood as being *open* and *far from equilibric*. Such systems are open in the sense that they receive information and energy from their environment and pass waste and other information back to their environment. They are far from equilibric, not in the sense of general chaotic systems, where very small changes in the values of control parameters can generate massive differences in trajectories over time, but rather in the sense of possessing the capacity for radical change while maintaining their integrity. They can undergo *phase shifts*—qualitative changes of kind. The idea of trajectory is crucial. Complex systems are dynamic. They develop and change through time. The idea of phase shift—of qualitative transformation—can also be expressed by saying that change in them is nonlinear. This represents a considerable challenge to those quantitative social sciences, and in particular econometrics, that have developed linear models in which changes in system state are proportionate to changes in system inputs. Likewise, the notion of a far from equilibric system is contrary to neoclassical economics' emphasis on equilibrium.

Social Complexity: The Current Debate

Across the social sciences, there are a variety of current and often conflicting approaches to complexity. The sociologist Niklas Luhmann draws on the very strong epistemological arguments of the philosophically minded biologist Humberto Maturana, asserting that complex social systems are closed rather than open. In contrast, Paul Cilliers, while explicitly engaging with postmodernist traditions and in particular the work of the deconstructionist philosopher Jacques Derrida, argues for a much more fluid and open approach that sees complex systems as intersecting, with boundaries that are both real and socially constructed. This has much in common with the arguments for a synthesis of complexity and critical realism, advocated by David L. Harvey and David Byrne. It also resonates with the approach of Manuel DeLanda, who draws on the work of the philosopher Gilles Deleuze and in particular the idea of assemblage.

It is impossible to separate philosophical argument about the role of complexity in the social sciences from methodological debate, a debate in considerable part driven by the development of simulation approaches. R. Keith Sawyer goes so far as to argue that simulation through agent-based modeling represents a third wave of complexity, but

this position is rejected by those who see this kind of approach as a kind of comfort-zone scientism, corresponding to what Edgar Morin calls "restricted complexity," in contrast to a general-complexity frame of reference, which represents a radical break with the program of science as it has been understood since Newton. Simulations are plainly an important tool in exploring complexity, but a clear distinction has to be drawn between simulations that are based on purely abstract propositions and those (far less common in the literature) in which rules are calibrated using real data. In a general-complexity frame, the latter can provide empirically grounded narratives, but these have no greater status than any other form of narrative as scientific description. Good narratives will generally be multisourced, and part of the complexity program is a breaking down of the distinction between quantitative and qualitative scientific description and explanation, with these modes being understood as complementary rather than contradictory.

Concepts

Human beings are makers and users of representations. Prominent among these are concepts, or the representations we employ in higher thought. When we formulate plans; construct theories, explanations, and narratives; deliberate over a course of action; and reason more generally, we are engaging in processes that manipulate concepts. Indeed, having concepts is necessary even to form a belief, a desire, or an intention. To believe that the earth revolves around the sun requires possessing the concepts *earth* and *sun*; to intend to sign a mortgage contract requires the concept *mortgage*; and to desire a gin and tonic requires the concept *gin*. Without possession of those concepts, and the means of combining them, thinking these thoughts would be impossible. Thus, concepts have often been termed *the building blocks of thought*.

This entry first looks into concepts considered as mental items in the head, then moves on to discuss the role of concepts in philosophical methodology (e.g., conceptual analysis), and will conclude by explaining vagueness, open texture, and essential contestability exhibited by some concepts. The latter feature, in particular, is one considered crucial in social theory.

Concepts and Categorization

Among psychologists, concepts are thought of as the mental representations that enable individuals to categorize objects in one way or another. For example, having the concept *elephant* enables one to recognize elephants as such; to sort elephants from other creatures, such as rhinoceroses and woolly mammoths; and perhaps to label elephants verbally. Categorization may be thought of as making a mental judgment that this thing is an F or as thinking that all of these Fs are Gs, as when one categorizes elephants as animals.

Psychologists who study concepts have focused on the structure of these representations and

how they are learned and processed. The classical theory of concepts assumed that concepts are like definitions: They consist of sets of necessary and sufficient conditions for belonging to a certain category. To have the concept *elephant*, *electron*, *prime number*, or *mayor* is to grasp such a definition. This view derives in part from the idea that understanding what it is to be a certain kind of thing involves grasping the essential features of that thing, which is what proper definitions are supposed to summarize.

The classical view fell out of favor in the wake of Willard van Orman Quine's attack on the existence of analytic definitions, as well as many empirical studies suggesting that people do not represent most categories in terms of necessary and sufficient conditions. Instead, people appear to treat many categories as if they were organized around similarity to a prototype. Prototypes are representations of the statistically typical or "normal" member of a category: The typical raven is black, but there are also albino ravens; typical tables are four legged, but there are also three-legged designs; and so on. When we think of ravens and tables, we often think of them in terms of these prototypical features, not in terms of a definition. Whether we take something to be a member of a category depends on how similar it is to the prototypical category member, not on whether it possesses the category definition. Similarity-based views of concepts can explain many facts about people's judgments, including the greater speed and accuracy with which people categorize prototypical category members, the existence of borderline cases, and the fact that certain inductive inferences are facilitated for more prototypical categories.

Another perspective on concepts says that they are organized around theories. The theory-based view (sometimes called the "Theory theory"—not to be confused with the "Theory Theory" of folk psychology, pertaining to the area of the philosophy of mind) says that concepts either *are* theories of a certain domain or are *embedded* in them. Theoretical concepts like *quark* get their meaning from the theories they are a part of (e.g., the Standard Model of particle physics), and so also, on this view, do ordinary concepts like *elm* and *computer*. A central part of these ordinary theories is that they are committed to psychological essentialism. *Essentialism* means that people tend to believe that categories possess hidden or unperceived essences that determine the kind of thing they are and that normally cause or produce their superficially observable traits. In distinction from the classical view, however, it is not assumed that we know what these essences actually are. Essentialist beliefs seem to emerge early: Children will judge that something is really a cat even if it is painted and scented to appear just like a skunk and will assume that something is a skunk if it has skunk parents, no matter whether it looks and acts like a skunk. Concepts belonging to many domains seem to go beyond simple perceivable prototypical features, contrary to what many similarity-based views would predict.

As this brief sketch indicates, the psychological role of concepts is a complex one, and explaining how we use them to categorize will require appealing to many types of processes, including abstraction, judging similarity, and causal-explanatory reasoning.

Concepts, Publicity, and Possession Conditions

Concepts are widely believed to be public, meaning that it is possible for many thinkers to possess the very same concept. This requirement of publicity goes back at least to Gottlob Frege, who argued that thoughts must be the kinds of things that can be grasped by many individuals and by the same individual at different times. Publicity is important because in offering psychological explanations we appeal to the thoughts that people have: Someone's behavior is explained by his or her having certain beliefs and desires, for instance. These explanations have a degree of generality built into them, in that anyone who thought the same would behave the same. So psychological explanations, insofar as they are intended to be general, assume that concepts and thoughts are public. In light of this, theories of concepts need to explain their possession conditions in a way that satisfies publicity.

Many theories of possession conditions are *inferentialist*. Inferentialism is the claim that possessing a concept is a matter of being able to draw the right sorts of inferences. For example, someone who possesses the concept *squirrel* can infer from how something looks and acts that it is a squirrel and infer from the fact that it is a squirrel to the fact that it is a certain kind of animal, that it caches and eats nuts, and so on. To have the concept *plus*, one

needs to be poised to infer that 2 plus 2 equals 4, as well as indefinitely many other arithmetical propositions. An *inferentialist* holds that what it is to have a concept is just to be poised to use it in making such inferences.

Inferentialists must tell us something about which inferences a person needs to be able to make in order to possess a concept. Here, there are two possible positions: *holism* and *localism*. Holistic theories claim that possessing any concept necessarily requires being ready to make many inferences involving that concept, and thus, possessing any concept requires possessing vastly many others. To have the concept *apple*, and thus to be able to think that something is an apple, one needs to understand, among other things, that apples are a certain kind of edible fruit, that fruits contain seeds and have a certain characteristic reproductive and life cycle, that they have a range of salient properties and uses, and so on. On holistic views, even grasping such a seemingly simple concept requires having a vast web of interrelated concepts and beliefs.

However, since concepts are individuated by their place in this web, any change anywhere necessarily alters some or all of the concepts that one possesses. Holistic theories have difficulty satisfying publicity, since almost no individuals will share all of their network of beliefs, and hence, no two individuals will share exactly the same concepts. A task for holistic theories, then, is to explain what it means for concepts to be similar enough to share across differing belief systems.

Localistic theories claim that possessing a concept requires being poised to draw some inferences, but not anywhere near as many as holists claim. Hence, localism says that possessing any concept requires having some others but not a large number. The paradigm examples here are well-defined concepts: Having *bachelor* requires only having *unmarried male*, since that is all that a bachelor is; the concept *lamp* might be exhausted by saying that it is *designed to give off light*. Perhaps while *red* is not a definable concept, one could not possess it without also possessing *color*. These concepts are ones that can be had simply by being poised to draw a few crucial or central inferences.

Localistic theories impose more stability than do holistic ones, since not every change in a person's beliefs also changes all of his or her concepts. However, localistic theories are also committed to the existence of analytic or conceptually necessary connections: These are the inferential links that are part of the very meaning of a concept. Many philosophers are skeptical of the existence of any such connections. As noted above, Quine argued forcefully that there is no reliable criterion for when we have a genuine conceptually necessary connection, as opposed to merely a deeply held empirical belief. The price of adopting localism is accepting the existence of strong analytic conceptual connections.

Atomistic theories take a different approach in opposition to inferentialism. They claim that concept possession is not based on the inferences one draws with a concept but rather with what that concept picks out in the world. Concepts for atomists are fundamentally a kind of category detector. A detector is a device that goes off or indicates to a creature when something is present in the environment. Having the concept *cat* or *red* is just a matter of having a mental detector that reliably tracks, covaries with, or otherwise carries information about the presence of cats or red things in the environment. Because these detectors can reliably inform a creature about the world around it, this approach is sometimes termed "informational semantics," and so atomism may be thought of as an information-based approach rather than an inferentialist one. Informational views and inferentialist views differ on whether the fundamental role of concepts is to detect categories in the environment or to facilitate inferences concerning categories.

The ability to reliably detect a category does not presuppose the possession of any other concepts in particular, so atomists do not need to posit the existence of conceptually necessary connections. Moreover, a detector for cats or red things can exist even if its connection to other concepts and beliefs changes; so atomism does not face the stability problem that holism faces. However, it is unclear whether many concepts are best thought of as detectors. Concepts like *recession, art, truth, quark, good, economic equilibrium,* and *negative number* are ones that it is hard to imagine simply detecting conditions in the environment, since they pick out highly abstract and theoretical categories that are by their nature difficult or impossible to detect.

Informational theories may be correct for some concepts then but not all of them.

Innateness and Concepts

The normal adult has a rich repertoire of concepts for living things and material substances, actions and other occurrences, tools and artworks, kinship and other social groupings, scientific and technical categories, and the framework of ordinary life in general. Infants and young children, however, possess very few of these, and certainly none that depend on language, acculturation, and pedagogy. Two important questions in understanding conceptual development are (1) What is the initial conceptual endowment that children begin with? (2) What processes exist to enrich that initial endowment?

The first question, in particular, arises in debates about nativism. Nativism itself is a contested notion, and there is no general agreement on what it means to call a psychological characteristic innate. However, it can be useful to understand claims of innateness as meaning that a characteristic is acquired by a non-psychological process—in particular, that it is not a *learned* characteristic. If it is agreed that learning is at least one way to enrich our conceptual repertoire, the first question becomes "Which concepts do we learn, and which do we acquire without needing to learn them?"

A classic answer advanced by empiricists such as John Locke and David Hume is that our innate concepts are just our sensory concepts—those that pick out immediately perceivable categories such as particular colors, textures, shapes, tangible and audible qualities, and so on. These only require the right sort of experience to be "awakened" in us; all our other concepts are then complex logical constructions out of these sensory primitives. *snowball*, for example, might be a complex representation partly consisting of *white, cold, round*, and *hard*. The empiricist ideal is to extend this model to all our concepts, such that everything in the mind is ultimately analyzable in terms of concepts derived directly from sensory experience. On this view, there would be relatively few primitive concepts and many complex ones.

Rationalists such as René Descartes and Gottfried Leibniz argue that empiricists are wrong to suppose that most of our concepts can be analyzed in sensory terms. Experience with the world may be needed to give us these concepts, but they are not, properly speaking, learned from these experiences. Modern-day rationalists like Jerry Fodor have turned this into an argument for the impossibility of learning any concepts whatsoever. Fodor's argument runs as follows: Assume that to learn anything is to acquire evidence in favor of a certain proposition. To learn that grass is green, for instance, is to find evidence that confirms this generalization about the natural color of grass. Learning, then, requires the ability to entertain this proposition. To do this requires having certain concepts—the concepts *grass*, *green*, and so on. But if this is so, we must already possess these concepts so that we can frame the proposition to be confirmed. Similarly, with the case of learning a new concept, there must be some hypothesis involving the concept that we are trying to confirm. But going by the reasoning given above, any such hypothesis must be represented by the learner; which is to say that the learner must already have the concept that she is trying to learn in order to frame the hypothesis in the first place. So there cannot be any such thing as learning a concept, since any such act of learning presupposes the concept to be learned. This leads to a kind of radical concept nativism.

The contemporary debate between defenders of empiricism and rationalism has two major axes. First, there is the issue of how much of our conceptual repertoire is "copied" from sensory experiences. Neo-empiricists argue, by appeal to psychological and neuroscientific evidence, that all our concepts are ultimately grounded in the senses. If they are right, higher thought turns out to be a complicated form of perceptual simulation. Their opponents maintain that most, if not all, of our higher thought takes place in an amodal system that is independent of these lower-level perceptual systems. This remains a live question, in part since the notion of what should count as evidence that a psychological process is "perceptual" versus "amodal" is unclear and contested.

Second, there is the issue of whether we can learn any genuinely new concepts. Advocates of concept nativism think that the very idea of such learning is incoherent. Their opponents hold that the notion of learning as hypothesis confirmation is unnecessarily restrictive. They propose a variety of other models

on which we can acquire new concepts in a way that is appropriately adaptive and responsive to experience but that does not assume that we already have the concepts in question. These "bootstrapping" processes might treat concept learning as akin to learning a new skill or adding a new vocabulary item to a language. Neither of these obviously involves hypothesis confirmation in any problematic way. It remains open whether learning a concept is relevantly similar to these processes and whether they can avoid the radical nativist's argument.

Conceptual Analysis and Folk Concepts

Concepts have played a significant role in philosophical methodology. A central tenet of so-called analytic philosophy is that the proper task of the philosopher is to analyze important concepts such as *cause, action, person, knowledge, free will, truth, meaning, good, justice*, and so on. A common goal of philosophical analysis is the discovery of noncircular necessary and sufficient conditions for falling under a concept. Hence, the traditional analysis of *knowledge* claims that knowing that *p* involves having a justified true belief that *p*. Analyses of this kind play an important role in philosophical debate.

Analyses of concepts are often tested against thought experiments: real or fictional scenarios in which certain properties that are part of the analysis are present. In such scenarios, one asks whether the concept being analyzed properly applies in that situation or not. If not, then this shows that the analysis is somehow defective, since something may have the properties picked out by the analysis but not have the concept being analyzed. For instance, if *knowledge* simply is *justified true belief*, nothing could fall under the latter and not under the former. But as Edmund Gettier showed, seemingly decisively, there are cases of justified true belief that are not also cases of knowledge, and so the traditional analysis must be defective.

In recent years, experimental philosophers have challenged this method of doing philosophy. They have argued that the judgments that are elicited by these thought experiments are much less stable than philosophers have normally assumed. For instance, some of them show significant cross-cultural variation between Asian and Western populations, while others may vary across gender, degree of philosophical experience, and so on. Many conceptual analysts have assumed that their own intuitive judgments are representative of "our" concepts in general. But if these judgments are highly variable and unstable, this assumption is false. The "folk" may not think the way philosophers have assumed that they do or the way philosophers themselves do. If this is true, then concepts may not be as public as has often been thought; and if philosophers remain interested in analyzing concepts, they must decide which population's concepts are of interest and sample them more systematically. Seen in this light, there may be little reason to treat the concepts and intuitions of philosophers as being of any special interest. One response would be to continue to pursue the project of conceptual analysis but to broaden it to cover a more inclusive set of empirically gathered intuitive judgments. Alternatively, philosophers might adopt a conception of philosophy that does not see it as primarily being in the business of analyzing concepts by means of thought experiments.

Open Texture, Vagueness, and Contestedness

Many of our concepts are neither sharp nor precise. This imprecision comes in several forms. Friedrich Waismann argued that most terms in natural language are "open-textured," by which he meant that the rules or conditions that govern their application do not determinately cover every possible case. We might encounter things that have some of the characteristics associated with falling under a concept, such as *cat*, but others that are so irregular or eccentric that we are unsure whether to count them as category members or not. (Imagine something that looks and acts like an ordinary cat but that keeps growing to a gigantic size or appears and disappears seemingly at random or occasionally transforms into something doglike.) While for ordinary cases questions of category membership seem settled, there are indefinitely many cases where our concepts simply do not specify how we are to "go on." The notion of open texture was also famously invoked by the legal theorist H. L. A. Hart to describe the way in which laws necessarily fail to cover every possible future case that might fall under them (e.g., "No vehicles in the park" depends on what may count as a vehicle in the future—are Segways and hoverbikes included?).

Vagueness exists where there are borderline cases of category membership. Whether a person is tall

or bald is a vague matter, since while there are clear end points where membership is determinate, there are also many cases where it is not. A person with no hair is clearly bald, but many people are shy of a full head of hair, yet they are obviously not bald. We may want to say that there is no fact about whether they are bald or not or that the judgment that they are bald does not have a truth-value. Vagueness and open texture differ in subtle ways. Both involve indeterminacy of application and, hence, involve borderline cases. Vagueness in a concept can be eliminated by adopting some precise standard that fixes the boundaries of its application on a particular occasion of use, whereas open-textured concepts have indefinitely many possibilities for indeterminacy in their application, and these possibilities are unpredictable in advance. In other words, we usually know the dimensions or features that must be made more precise to resolve vagueness, but for open-textured concepts, we have no set list of qualities to make precise.

A different kind of demarcation problem is raised by what the political theorist W. B. Gallie referred to as "essentially contested concepts." Essentially contested concepts possess five features: (1) they are used to praise activities or achievements, (2) these achievements have internally complex features, (3) these features can be weighted in several possible ways to determine how the achievement is assessed, (4) the way these features can be modified or weighted is empirically sensitive and open-ended, and (5) the concept plays a dialogic role in which each user of the concept knows that his or her use will be contested and challenged by other concept users.

Gallie's examples of essentially contested concepts include *art, democracy, social justice*, and *christian life*. All of these denote a certain kind of complex, multidimensional activity that possesses the relevant open-ended empirical character, but one where the component dimensions may be assigned different weights by different people. Moreover, these concepts have both aggressive and defensive uses, with partisans of differing value schemes pitted against one another. Consider debates over whether Marcel Duchamp's readymades, Jackson Pollock's action paintings, or Damien Hirst's "The Physical Impossibility of Death in the Mind of Someone Living" (a tiger shark floating in a glass and steel tank full of formaldehyde) fall under *art*. In legal philosophy and the social sciences, the notion of essential contestedness has found wide application. Further widely discussed examples include concepts such as *rule of law, power, racism*, and *medicine*.

While essential contestedness is similar to open texture and vagueness, there are important differences. Like cases of open texture, essentially contested concepts do not have their empirical domain of application settled in advance. There is room for new exemplars to alter the extension of the category that they pick out. Thus, John Cage's *4'33"* may change what counts as a composition. On the other hand, open-textured concepts typically have a single, unitary, and widely agreed-on core of application. Essentially contested concepts do not, or at least need not. Partisans of two notions of *art* or *democracy* need not agree on the central exemplars of those concepts, since they may give the relevant evaluative features different weights.

In terms of the psychological theories of concepts discussed earlier, vagueness can be captured by many similarity-based theories of concepts, since these inherently allow for borderline cases. Essentially contested and open-textured concepts, on the other hand, have a complex internal structure reminiscent of the theory-based view. The essentially contested nature of many philosophical concepts may also explain the fact that traditional philosophical debates seem so peculiarly intractable.

Consciousness

The term *consciousness* applies to several distinct phenomena, each pertaining to aspects of the mental functioning of people or other creatures. We describe people and other creatures as *conscious* when they are awake and sentient, as against being asleep, knocked out, or comatose. We also use the word *conscious* to describe a creature as being conscious or *aware of* something. And we describe thoughts, feelings, desires, and perceptions as being conscious in contrast with *unconscious* states of those sorts. All these phenomena have been the subject of extensive recent investigation in philosophy, experimental psychology, and neuroscience and the subject also of some heated debate in those fields. This entry discusses these types of consciousness and the major approaches to understanding them.

Awakeness and Awareness

An individual's being conscious, as against being asleep, anesthetized, and so forth, consists in that individual's being awake and receptive to sensory input and perhaps also having the ability to engage in voluntary, purposive movement. Investigation of this type of consciousness primarily concerns what aspect of *neural* functioning determines whether an individual is conscious or not. Understanding the neurological difference between conscious and unconscious conditions is important for determining the effects of various methods of anesthesia and for the clinical evaluation of patients in an apparent vegetative state, who have no discernible voluntary control of movement.

An individual when conscious has at least the ability to sense things and to have desires or intentions. Some argue that no creature is conscious in this way unless it actually senses or perceives, and perhaps such sensations or perceptions must be conscious states. But psychologically primitive creatures, such as snakes, may sometimes be awake and have the ability to sense things even when no actual sensing is taking place. It is likely that the conditions for a creature's being conscious cannot be settled except by appeal to reliable neurological correlates for such consciousness, established by appeal to uncontroversial cases.

Being conscious or aware of something often consists in an individual's sensing or perceiving that thing. If a person sees, hears, or smells an object, the person is conscious of that object. But even if one does not sense or perceive something, having a thought about that thing is also a way of being conscious of it, at least if one thinks about the thing as being present. It is less natural to describe somebody as conscious of something if the thought represents the object as distant in time or space.

There are cases in which a person perceives something *subliminally*—that is, without being aware of

perceiving it. Subliminal perception is perception that is below the threshold of conscious awareness. There is dispute about the correct way to describe such cases, but it is natural to think that in subliminal perception one is aware of the stimulus but not consciously aware of it. Such cases have been extensively investigated in experimental psychology, mainly by presenting individuals with stimuli that are degraded in some way—for example, they are very brief or faint—or stimuli that occur just before or after another stimulus that blocks conscious awareness of the target. The stimulus that does the blocking in such cases is said to be a *mask*.

Participants in these experiments report consciously seeing the mask but not the masked stimulus, though when the mask does not occur, participants do report consciously seeing that stimulus. But despite participants' denial that they see such masked stimuli, there is evidence that they do see it, since masked stimuli often have an effect, known as a *priming effect,* on subsequent psychological processing. Thus, participants may make a subsequent choice or have a faster reaction time in ways that reflect the character of the masked stimulus, despite claiming to be unaware of it.

Mental States and Consciousness

Despite evidence that perceptions occur in these subliminal cases, individuals report being unaware of any such perceptions and deny having them. So it is natural to describe those perceptions themselves as not being conscious. A conscious mental state, by contrast, is then a state an individual is aware of being in and can under ordinary circumstances report.

Subliminal perception is not the only case of mental states that individuals are unaware of. The best explanation for people's behavior is sometimes that they have acted on beliefs and intentions they deny having; experimental psychologists in these cases may posit unconscious beliefs and intentions. There is even evidence from social psychology that people sometimes do not have the beliefs and desires they claim explain their behavior. Rather, people confabulate having beliefs and desires that make sense of their behavior or fit with others' expectations or preconceptions.

There is also neuropsychological evidence that the neural events thought to correspond to decisions to do things occur before people are aware of making those decisions, at least one third of a second, and perhaps significantly more, in advance. This suggests that decisions occur and exert their causal influence in guiding behavior before one comes to be aware of the decision—that is, before the decision becomes conscious.

These findings show that mental states of all sorts occur without being conscious. So they encourage the view that a mental state's being conscious requires that one be aware of that state, and that if one is not so aware, the state is not conscious. This view of what it is for a thought, feeling, or perception to be conscious fits well, moreover, with our everyday understanding about mental states' being conscious. We sometimes take ourselves to see that another person thinks or wants something or feels a particular way, even though that person is unaware of doing so; those thoughts, desires, and feelings are unconscious.

Holding that a mental state is conscious *only if one is aware of it* also fits comfortably with psychoanalytic theory. The unconscious states that Freudian theory and its descendants posit are states that there is clinical reason to believe an individual is in despite the individual's being unaware of them. It is reasonable also to see the actions performed under post-hypnotic suggestion as due to volitions that the individual is again unaware of.

The idea that a mental state's being conscious requires that one be aware of that state is reflected in what psychologists call a *subjective measure* of consciousness, which holds that a mental state is conscious if it seems subjectively to one that one is in it. Some psychologists operate instead with an *objective measure* of consciousness, on which a state is held to be conscious only if there is evidence, independent of any subjective impression, that the state occurs. On this measure, an individual consciously perceives something only if that individual behaves in ways that reflect such perceiving. It is unclear, however, whether an objective measure can accommodate the occurrence of perceiving that is not conscious, since that would likely result in the same behavior as conscious perceiving. Another difficulty with the objective measure is that we can perceive things peripherally and also consciously, although such perceiving may have no measurable effect on behavior.

Qualitative Consciousness

It is reasonably natural to see people as having thoughts and volitions that are not conscious; actual and likely behavior points to their occurrence. But many profess difficulty in understanding how sensations, perceptions, and other states that exhibit *qualitative* character ("It feels like …") could occur without being conscious. That may be partly because an inference from behavior to qualitative states seems less compelling. But many theorists also regard qualitative states as having a special tie to consciousness; indeed, the term *consciousness* is sometimes used simply to refer to conscious *qualitative* states.

In this spirit, Ned Block has posited a type of consciousness distinctive of qualitative states, which Block calls "phenomenal consciousness." Phenomenal consciousness occurs when there is something it is like to be in a mental state, as with conscious perceptions, bodily sensations, and emotions. Block distinguishes this from what he calls "access consciousness," which consists in the representational content of a mental state's being available for the control of action, speech, and rational thought. When an individual cannot report being in a qualitative state, Block argues, it shows only that the state lacks access consciousness, not that it lacks phenomenal consciousness as well.

Some in philosophy have urged that special problems affect our understanding of conscious qualitative states. Even if we had accurate correlations of particular types of mental quality with types of neural state, we might be unable to explain why one type of neural state should occur in connection with a particular type of mental quality, or indeed any mental quality at all. Such an explanatory gap would presumably occur only for qualitative states that are conscious; if qualitative states can occur without being conscious, nothing would impede explaining such correlations.

It is also held by some in philosophy that there is no way to tell whether the mental quality that characterizes one person's seeing a red object is the same as the mental quality that occurs when another person sees such an object. Perhaps one person's mental quality when seeing red is the same as another person's on seeing a green object (this goes back to John Locke's hypothesis for the possibility of an undetectable "inverted spectrum of colors"). This concern stems from thinking of mental qualities as fixed solely by the way they present themselves to conscious awareness; otherwise, we could tell in some objective way whether such interpersonal quality inversion occurs. So this concern also pertains only to qualitative states as they occur consciously.

Perceiving prima facie involves mental states with mental quality. So evidence for subliminal perception puts pressure on the denial that qualitative states must always be conscious. Theorists who deny that qualitative states can occur without being conscious might urge that subliminal perceptual states never fail altogether to be conscious; they might maintain, for example, that subliminal states lack only access consciousness but not phenomenal consciousness. But it is arguable that subliminal perceptions also lack phenomenal consciousness, since there is nothing it is like for one to be in a state that one is wholly unaware of.

Instead of denying that subliminal perceptions fail to be conscious, a theorist who holds that qualitative states are always conscious can instead deny that subliminal states involve qualitative character. Perhaps they are simply neural states and not mental at all. But that is unlikely. Subliminal perceptions affect subsequent psychological processing in ways that appear to reflect differences in qualitative character, much as conscious perceptions do. It is natural to conclude that subliminal states have qualitative character and so qualitative states are not invariably conscious. Phenomenal consciousness is simply the special case of mental states being conscious where the states exhibit mental qualities.

The insistence that qualitative mental states are always conscious stems from the view that the very nature of mental qualities is determined solely by how they present themselves to conscious awareness. This insistence is captured vividly in Frank Jackson's famed thought experiment of somebody knowing everything about neural function and color perception but having never seen red and so not knowing what it is like to see red (though she knows the whole gamut of chemical theories about colors, neurological theories of perception, etc.). But knowing what it is like to see red is simply consciously having that experience. So the thought experiment gives no independent reason to hold that the nature of mental qualities is solely a matter of how they present themselves to conscious awareness. And subliminal perception shows that we know about

mental qualities not just by way of consciousness but also by the role they play in perceiving; mental qualities are the mental properties in virtue of which we sense and perceive things. Since we perceive both consciously and subliminally, there is no mystery about the occurrence of qualitative mental states that are not conscious.

Theories of Consciousness

Those impressed by evidence that mental states occur without being conscious tend to favor a theoretical approach that can explain the difference between mental states that are conscious and those that are not. One widely adopted approach builds on the idea that a mental state one is wholly unaware of is not a conscious state. A state is conscious, on this approach, only if one is aware of that state; theories that explain in this way what it is for a state to be conscious are known as *higher-order theories*. An apparent problem with such theories is that we seldom seem subjectively to be aware of our conscious mental states. Higher-order theorists usually argue that this is because the higher-order states by virtue of which we are aware of conscious states are seldom conscious states, so we are seldom aware of those higher-order states.

Another type of theory explains how conscious states differ from unconscious mental states by appeal to the effect that conscious states can have on psychological processing but that unconscious states cannot. On these *global-workspace theories,* as with Block's notion of access consciousness, a state's being conscious does not involve any awareness of the state; rather, a state is conscious if it is accessible to many significant types of psychological processing. And as with Block's notion of access consciousness, such theories face a difficulty similar to that which is faced by objective measures of consciousness, that peripheral perceptions can be conscious but have no significant effect on psychological processing. It may also be that repressed mental states, though not conscious, often do have a significant effect on psychological processing.

Theories like global-workspace theories, on which a state's being conscious does not involve any awareness of the states, are *first-order theories*. Other first-order theories maintain that a state's being conscious consists simply in its making one aware of something; on still others, a state is conscious if it involves attention; in no case does a state's being conscious require awareness of the state itself. Unlike global-workspace theories, it is unclear whether these types of first-order theory can accommodate mental states that are not conscious, as in subliminal perception. And it has been shown experimentally that states that are not conscious can involve attention and that attention is lacking in many conscious states, for example, conscious peripheral perceptions.

There are several versions of higher-order theory, which differ principally on what kind of higher-order awareness figures in states' being conscious. The theory prevalent in traditional philosophy is the *inner-sense theory,* on which a state is conscious if one is aware of it by sensing or perceiving it. Since none of the ordinary sense modalities can figure in such higher-order perceiving, a special inner sense is posited. Inner sense explains the apparent immediacy of our awareness of our conscious states, since perceiving and sensing always seem unmediated. But it is doubtful that any sense modality could make us aware of all the types of mental state that occur consciously, including perceptual states of different sense modalities. Nor is it clear what mental qualities could characterize such an all-purpose modality of inner sense.

On an alternative theory, we are aware of conscious states by having *thoughts* about those states. This avoids the problems facing inner sense, since thoughts can be about mental states of whatever kind and thoughts involve no mental qualities. This *higher-order-thought theory* explains the apparent immediacy of the way we are aware of conscious states, by hypothesizing that higher-order thoughts occur without any conscious mediation, for example, without relying on conscious inference or observation.

Another type of higher-order theory seeks to accommodate the considerations that motivate first-order theories by positing that the higher-order awareness by virtue of which mental states are conscious is *internal* to the conscious states themselves. Such theories must provide an independently motivated way of individuating mental states, on which such higher-order awareness is internal to the states we are aware of. It is unclear whether any method of individuation that had that result could square with the finding that many mental states at least occur measurably in advance of our becoming aware of them.

A theory of consciousness should address what *function* there is for a creature's mental states to be

conscious. It is natural to expect that there is some *utility* to a mental state's being conscious, since so many mental states are conscious. But we must distinguish the utility of a state's being conscious from the utility of states that happen to be conscious. When a conscious state has utility, that utility might be due not to the state's being conscious but to its other mental properties, such as what it represents or causes independently of its being conscious. So care must be taken in determining whether there is significant utility for mental states' being conscious.

Contemporary French Philosophy and the Social Sciences

Contemporary French philosophy has long been associated with the names of Jacques Derrida, Michel Foucault, Louis Althusser, Gilles Deleuze, Michel Serres, and Jean-François Lyotard (to which the name of Jacques Lacan, a psychiatrist and psychoanalyst exceptionally well-read in philosophy, has often been added), to name only the most renowned ones starting to flourish in the 1960s. There were close and complex interactions among these thinkers, often dating back to their education at the École Normale Supérieure (ENS), a most selective higher-education establishment near the Sorbonne and the French equivalent of an Oxford or Cambridge University, where older scholars frequently trained the younger ones (e.g., Althusser was Foucault's teacher and Foucault taught Derrida).

Frequent references to linguistics, ethnology, psychoanalysis, and Marxism are a typical feature of these philosophers. These references, however, played quite distinct roles in each case. A few thought that either conceptual analysis or philosophical intuitions could help improve specific domains, such as Marxism (according to Althusser), psychoanalysis (according to Lacan), Marxism *and* psychoanalysis (according to Deleuze and Félix Guattari or to Lyotard), or their relationships with natural science (Michel Serres). Others (e.g., Derrida) contended, rather, that disciplines such as linguistics and poetics could provide them with tools helpful for their own intrinsically philosophical concerns. Still others (Foucault and, even more radically, Deleuze) wanted to substitute a more "joyous" conception

of knowledge (cf. Friedrich Nietzsche's *The Gay Science*), free of asceticism, which has long been, according to Nietzsche, the psychological basis of the scientific spirit.

Doubtless, all these French scholars have written original works. What is more controversial is whether these works truly have been philosophically and scientifically influential or had an overall impact. They frequently and deliberately favored sophisticated rhetoric and convoluted literary phrasing, in contrast to the more typically French style with its characteristic clarity and simplicity, still exemplified at the beginning of the 20th century by the eminent French philosophers Henri Bergson (1859–1941) and Leon Brunschvicg (1869–1944) but already being challenged by Jean-Paul Sartre's work, which mixed philosophy and literature. The "collective effervescence" emerging from these often prolific scholars, however, never involved all the French philosophers interested in the social sciences. The philosopher Paul Ricoeur is a case in point, as it can be said that he was even deliberately marginalized. And far more sober works—*pace* Nietzsche—were written, which may have been more fruitful in the long term.

All these works—seductive or not—arose against an older philosophical and scientific backdrop. The rupture with Jean-Paul Sartre's existentialism, introduced by the eminent anthropologist Claude Lévi-Strauss's structuralism, played a crucial role. But Sartre's former fellows at the ENS and the Sorbonne—in particular Maurice Merleau-Ponty (1908–1961), Raymond Aron (1905–1983), Georges Canguilhem (1904–1995), and Jean Cavaillès (1903–1944)—happen to have initiated still lively trends entirely independently.

Lévi-Strauss

One can hardly understand the relationship of French contemporary philosophy with social science from the late 1950s onward if one does not mention the preeminent role of Claude Lévi-Strauss's anthropology. Although Lévi-Strauss (1908–2009) was educated—in philosophy and in law—at the same time as Jean-Paul Sartre (1905–1980), his work became influential in philosophy only after Sartre's. The latter's reputation was already at its peak immediately after World War II (Sartre's major work, *Being and Nothingness,* was published in 1943), while Lévi-Strauss's work became known to a wider audience in France only in the early 1960s. *Structural Anthropology* introduced a new paradigm in social science. Its philosophical presuppositions quickly seemed to many almost entirely opposed to Sartre's.

Structuralism in Lévi-Strauss's mind meant that the most relevant method in any social domain (from inquiries into marriage rules to the meaning of myths) is to study any element of such a domain not in isolation but always in relation to other elements and to focus on the relationships between them more than on any single elements. The role of a father in a family is variable depending on the kinds of societies in question, and similarly, other family members may also have very variable roles depending on the contextual social structures in which those roles were embedded in a distinct way in each society under study. These roles cannot be understood well without examining all close relatives' roles. When maternal uncles regularly exert authority over their nephews, as it happens in certain matrilocal societies, fathers exert a more playful role toward their children, thus inverting traditional Western roles in the same general structure exhibited by such functional relationships.

Lévi-Strauss strongly distanced himself from Sartre. He focused on the unconscious dimension of social phenomena (i.e., structures and functions as opposed to individual agents), unlike Sartre who had tried to describe the whole range of conscious mental states, especially in everyday interactions, and had strongly criticized the relevance of psychoanalysis. Lévi-Strauss did not ascribe particular significance to unconscious—possibly sexual—wishes; rather, he highlighted the unconscious social rules. He emphasized the almost deterministic strength of these unconscious rules, again in strong opposition to Sartre's emphasis on the individual's responsibility and freedom. Finally, he counterbalanced the high significance given by Sartre to history in the explanation of social facts by focusing, on the contrary, on social structures at a given time.

Lacan and Derrida

Lévi-Strauss claimed that his method had been already employed, in an exemplary fashion, by Nikolai Troubetzkoy and Roman Jacobson. These two Russian linguists admired the French-speaking Swiss linguist Ferdinand de Saussure, who had

provided linguistics with a new base (his *Cours de Linguistique Générale* was published in 1916). Saussure had anticipated structuralism with an exceptional awareness of the revolution introduced by the idea that languages should not be studied only in a historical way (as in German linguistics). On the contrary, one could display the structure of a given language at a given time (synchronic linguistics) and then compare two structures of the same language at distinct times (diachronic linguistics). Describing the progressive transformation from one structure to another structure would be a further program.

Jacques Lacan's main principle was that psychoanalysts did not have direct access to the analysands' dreams—the interpretation of which had been supposed by Freud to be the royal way to childhood's memories and to deep-down unconscious wishes—but only to the narratives of dreams. Consequently, Lacan (1901–1981) searched for interpretative tools in Jacobson's analysis of metaphors and metonymies. Furthermore, Lacan adopted Lévi-Strauss's view, according to which unconscious social rules, especially those regarding familial relationships, had to be understood in a structuralist way. This means, for example, that what plays the main formative role for a child is not necessarily his or her biological father but the one who fills the father's place in the social-familial structure.

Lévi-Strauss had not ignored the role that psychoanalysts could play in Western societies, as shamans do in other societies, and he certainly did not promote a purely abstract view of societies, in which men and women would be destined to play interchangeable roles in invariant structures. With similar concerns, Lacan thought that certain philosophers, in particular G. W. F. Hegel and Martin Heidegger, could help us understand how psychoanalysts might reveal the deep human subjecthood ("I"), based on drives (the "id") but hidden under false social identities ("ego") and irreducible to Sartre's authenticity.

Jacques Derrida (1930–2004) found specific intellectual tools in Saussure and Freud in order to refine his analysis of the presuppositions behind great philosophical works. Derrida was not searching for logical presuppositions, though; instead, his interest was in presuppositions hidden in metaphors, analogies, rhetorical questions, and the like. He called this specific method of analysis "deconstruction," which implied always viewing philosophical (and scientific) works as literary texts. According to Derrida, one of Western philosophical tradition's main presuppositions—explicit in Saussure—is the emphasis on the role of voice instead of writing (*Of Grammatology*). Derrida argued that, on the contrary, writing had extremely interesting features, in particular because it allows us to keep "traces" of the past. As a consequence, the past can be revivified as the present, in various senses. This topic is closely related to Edmund Husserl's phenomenology of time and Heidegger's ontology (*Writing and Difference*). Derrida's deconstruction of philosophical works coherently led him to explore progressively all rhetorical tools at his disposal to express his own thoughts. Doing so, he clearly went as far as the very boundaries of philosophy, as the Russian constructivist Casimir Malevich did in painting. Not surprisingly, Derrida's dialogue with John Searle, one of analytical philosophy's main representatives, was a dialogue of the deaf (*Limited Inc)*.

Althusser and Bourdieu

Lévi-Strauss also influenced Pierre Bourdieu (1930–2002), who studied philosophy almost at the same time as Derrida. First an ethnographer, then a sociologist, Bourdieu adopted Lévi-Strauss's structuralism, but unlike Lévi-Strauss, he wanted to explain how sociological and ideological structures are transmitted. He did not return to Sartre's views, however, but to the phenomenologist Maurice Merleau-Ponty's idea that usual practices and common values are often unconsciously incorporated (habitus) and so have unconscious effects. In a manner characteristic of Marxist analysis, he focused mainly on "dominating"/"dominated" relationships in social structures. Along with Jean-Claude Passeron (1930–), he adopted Gaston Bachelard's views on the necessary radical distance (break) between commonsense and scientific explanations. Later, Passeron would return to a view in favor of continuity, insisting rather on the specificity of the social sciences in comparison with the natural sciences (*Le raisonnement sociologique: L'espace non-poppérien du raisonnement naturel*, 1991).

Marxism had been renewed a little earlier by Louis Althusser (1918–1990), who distanced himself considerably from Sartre's existentialist reading of Marx. He focused, on the contrary, on the decisive break (*rupture*) constituted by *Das Kapital* in the emergence of social science, following Bachelard,

who emphasized discontinuities in the history of sciences. Althusser had a huge, although indirect, influence on the political involvement of many brilliant philosophy students during the public events of May 1968. His theoretical work, however, was almost exclusively programmatic, as the titles of his books indicate (*For Marx* and *Reading Capital*).

Foucault, Deleuze, Guattari, and Ricoeur

Michel Foucault (1926–1984), as both a historian and a philosopher, was the second French scholar after Lévi-Strauss to have influenced French philosophy greatly. The relevance and respective validity of phenomenology, psychology, and psychoanalysis had been much debated in France since the immediate postwar years. It is within this broad context that Foucault wrote his *History of Madness*.

Foucault argued that the history of the notion of madness could not be understood without being related to the emergence of modern rationality. Foucault investigated several strata of collective presuppositions, from those shared in the Middle Age—when madmen were still integrated in everyday life—to those shared in the 17th century—when madness was, according to Foucault, assimilated to absolute irrationality (an issue much debated)—and further on to those presuppositions emerging in the early 20th century—when poets like Antonin Artaud expressed in symbolism another conception of madness.

Foucault's main idea was that it made sense not to focus on the mere succession of ideas, institutions, and practices but rather to study ideas, institutions, and practices coexisting in the same period of time, even in very distant fields, and to search for their possible common hidden presuppositions. These constituted the intellectual a priori of this specific time, their "épistémè," which "archaeology" had to highlight. In *The Order of Things: An Archaeology of the Human Sciences,* he claimed that natural history in the 17th and 18th centuries had to be compared with Port Royal's general and rational grammar and Adam Smith's analysis of wealth, before being studied as the ancestor of Darwinism. Given the huge scope of his analyses, however, it has been easy to prove that Foucault's assessments were historically controversial in many cases.

Furthermore, Foucault's viewpoint was not only descriptive but also normative, and Foucault's political opinions obviously often crucially biased his assessments (e.g., on the role of asylums and prisons). Foucault's normative viewpoint was not in line with Marx's (or Freud's) but with Nietzsche's. He wanted to emphasize everything that expressed the power of life. Madness itself is sometimes correlated with creativity.

History of Madness was well received by antipsychiatrists such as David Cooper and R. D. Laing. But Foucault's work was merely historical. On the contrary, Gilles Deleuze (1925–1995), together with Félix Guattari (1930–1992), a psychiatrist and psychoanalyst initially trained by Lacan, set up a theory of schizophrenia in their joint work, *Anti-Oedipe,* published in 1972. They related this theory to a novel criticism of capitalism, inspired by Nietzsche and based on a new ontology (*Difference and Repetition*). Deleuze emphasized the relentless "flux" of life and the multiplicity of beings. Lacan, they argued, was still too concerned about the unity of subjecthood and too committed, like Lévi-Strauss, to finding invariant familial structures under cultural variations. By comparison, Deleuze and Guattari were clearly antistructuralists. They were also opposed to Hegel and to what remained Hegelian in Marx, especially dialectics as an emphasis on the permanent identity underlying temporal differences. They are sometimes viewed (by other philosophers, e.g., Vincent Descombes) as having achieved the project of synthesizing Freud and Marx more successfully than did Jean-François Lyotard (1924–1998).

Freud's theory was also examined and criticized in a more academic way by Paul Ricoeur (1913–2005) in *De l'Interpretation: Essai sur Freud,* an implicit criticism of Lacan's reading of Freud's theory as semiological. Ricoeur, in particular, pointed to the biological dimension of Freud's thought. He returned, however, to the phenomenological trend and to what had been left aside by both Lévi-Strauss and Foucault. He focused on methods in history and, more generally, on the nature of narratives, thus justifying the relevance of "hermeneutic" methods (*Time and Narrative*). Ricoeur became the doyen of this new school of hermeneutics and has been quite influential in discussions on the philosophy of the social sciences, especially in the Anglophone philosophical world. One of the main influences was the use made of Ricoeur's hermeneutics in the philosophical battle against those who wished to assimilate the social sciences to the natural sciences.

Canguilhem's, Cavaillès's, and Bachelard's Hidden Legacy

As stated above, Foucault's work was influenced not only by Nietzsche but also by the French context of distrust toward psychology, inherited in particular from August Comte and Émile Durkheim. This distrust would be challenged in French social sciences only in the 1980s by a type of anthropology congenial to experimental cognitive psychology, as practiced by Dan Sperber (1942–). Foucault's main mentor at the university was Georges Canguilhem. Canguilhem studied both philosophy and science (medicine), as did his own teacher at the Sorbonne, Gaston Bachelard (who had studied physics), and his ENS colleague Jean Cavaillès (trained in logic), who was killed by the Nazis. Canguilhem wrote numerous articles on the history of medicine, biology, and psychology, in a very sober and meticulous style. Ian Hacking (1936–), the Canadian doyen of the Stanford school of philosophy of science, while crowning his academic career as a professor in Paris (at the Collège de France), rediscovered this aspect of Foucault's heritage, which leaves relativist and Nietzschean aspects of Foucault's viewpoint entirely aside.

Gilles-Gaston Granger (1920–), who was trained by Cavaillès and influenced by Ludwig Wittgenstein and Rudolf Carnap, played a very significant role in the French philosophy of social science by distancing himself from Marx quite early on. Although admiring Lévi-Strauss for his use of formal models in the social sciences, he broadened attention to other domains of social science, such as Keynesian economics and Decision Theory (*Pensée Formelle et Sciences de l'Homme*). A generation later, Jacques Bouveresse (1940–), in line with Wittgenstein as well, sharply criticized the rhetorical abuses of certain French philosophers and sociologists (such as Bruno Latour), as well as their relativism.

Michel Serres (1930–), who was also trained in the same intellectual climate, was, however, more specifically influenced by Gaston Bachelard. Bachelard was interested not only in science but also in the study of myths as expressing another dimension of human beings. Serres brilliantly illustrated conceptions close to Foucault's episteme (*Hermès*). To some extent, he went further than Foucault on this path, by arguing that natural science, such as thermodynamics, should be studied jointly with literature—for example, Jules Verne's novels—because they might express the same implicit presuppositions during a certain historical period. His way of writing, however, is not analytic, conceptually speaking, but very literary, as are Lacan's, Derrida's, Foucault's, Deleuze's, and, to some extent, Bourdieu's. He claimed to be searching for bridges from social sciences to natural sciences (*Le Passage du Nord-Ouest,* 1980) but tended to comment poetically on this passage more than to construct real bridges.

Aron's Paradoxical Legacy

In the long term, Raymond Aron might have had the deepest influence on contemporary French philosophy of social science. Politically oriented to the right, he nevertheless admired Marx's work. For many, he turned out retrospectively to have often made more accurate assessments than Sartre regarding the significance of both political events and emerging ideas. As he was more open to ideas coming from the English-speaking world compared with other French scholars, left-wing as well as right-wing PhD students found inspiration in his work. Typically, the Norwegian Marxist social scientist Jon Elster (1940–) preferred to write his PhD thesis—on Marx—under Aron's supervision rather than under Althusser's.

Aron also reintroduced the work of Max Weber in France and rediscovered Alexis de Tocqueville, who had been forgotten during the dominance of Marxism in France. Within the same tradition, Raymond Boudon (1934–), also educated as a philosopher at the ENS, introduced mathematical modeling into the practice of French sociology. He has also conducted an ongoing critical analysis of the fundamental concepts and logical presuppositions of contemporary social sciences (including a sharp criticism of structuralism), based on an in-depth knowledge of these disciplines.

Paul Veyne (1930–), formerly a regular attendee at Foucault's seminars, is both an outstanding historian and a subtle philosopher of social science. He has recognized that he shares Aron's views on history. Like Boudon's (and Elster's), this kind of philosophy of social science is intimately connected with the practice of the social sciences.

Conclusion

Comparable with German philosophy, yet unlike American philosophy, French philosophy has often been closely connected to the social and human sciences. Ethnology and psychoanalysis, in particular,

have long captured the attention of French philosophers. These two disciplines seemed to blaze a third trail between natural science and a social science inspired by natural science, such as economics. But unlike German philosophy, the so-called French theory has often deliberately tried to mix philosophy with literature, sometimes successfully if considered in accordance with aesthetic canons. The way was thus opened to a French vogue that swept many departments of literature in universities in the United States. French philosophy of social science, however, is much broader, encompassing works that abide strictly by epistemological rules, very much in line with the prevailing French tradition of René Descartes, Nicolas de Condorcet, and Antoine Cournot.

Context of Discovery Versus Context of Justification

The basic assumption behind the discovery/justification (D-J) or "two-context" distinction, as employed by Hans Reichenbach and the Logical Empiricists—but also by Karl Popper—is that there exists a general logic of justification in science but no *logic* of discovery. This entry explains the aim of the upholders of this distinction (once considered important for genuine scientific method and thus shaping official philosophy of science for a certain period), reviews criticisms against it, and assesses some positive uses of it.

Aim

For these methodologists, creative acts, such as inventing hypotheses or composing piano sonatas, are idiosyncratic and to be left to psychologists and historians to study. Since these philosophers

conceived scientific method as the logic of science, and since there did seem to be a routine method for testing hypotheses against data, one analogous to the systematic method of checking logical proofs, they employed the distinction invidiously to *restrict* scientific method and epistemology to the logical structure of theories, predictions, explanations, and so on, already on the table. Accordingly, these philosophers rejected the foundationist views of Bacon, Descartes, and Newton, according to which using the correct method of discovery itself is the strongest form of justification. Since the Logical Empiricists and Popper shaped modern, academic philosophy of science, the D-J distinction became entrenched, leaving creative activity as an *exogenous* factor in philosophical models of science.

Criticisms

The D-J distinction and its applications invited several criticisms.

1. The distinction is unclear. Its typical formulations harbor several distinctions that do not stand or fall together. For example, if the context of justification is understood as a temporal phase of research rather than as a timeless logical relation of theoretical to observation statements, then the context of justification is filled with discovery tasks such as searching for predictions that the theory implies and inventing the experimental means of checking them. Artificial intelligence (AI) experts were the first to emphasize this point, noting that even the discovery of a deductive logical proof is an inductive search task—a discovery task—one that needs to be guided by heuristics to be efficient.

2. By switching the emphasis from romantic notions of theory formation to problem solving as the central activity of scientists, AI experts made the search for systematic discovery methods a more reasonable enterprise. For Herbert Simon and colleagues, discovery is problem solving, and problem solving is a search through a space of possible solutions. Hence, discovery is ubiquitous in research. There cannot exist a pure context of justification in the temporal sense.

3. Logical empiricist attempts to formulate a theory of confirmation in logical or probabilistic terms were failures. Besides generating paradoxes, an untenable distinction between a pure observation language and a theoretical language undercut these efforts.

4. Norwood Russell Hanson retained the D-J distinction but asserted the possibility of a logic of discovery. He revived Charles S. Peirce's topics of abductive logic of discovery and economy of research and posited an intermediate stage of preliminary evaluation between the contexts of discovery and justification, an idea developed by later writers under labels such as "prior appraisal," "pursuit," and "heuristic appraisal."

5. By the 1960s, most philosophers were abandoning logical empiricism. Historically oriented analysts such as Thomas Kuhn, Paul Feyerabend, Stephen Toulmin, and Imre Lakatos denied that there is a systematic logic of justification any more than there is a logic of discovery and insisted that the products of science cannot be fully understood in isolation from the process that produced them.

6. Kuhn often took the viewpoint of research scientists who constantly engage new problems at research frontiers, a pro-discovery stance excluded by the positivists' use of the D-J distinction.

7. Henceforth, philosophers paid more attention to creativity and invention in the history of science and drew on the resources of AI and other cognitive sciences, as well as the heuristic power of rhetorical tropes (analogy, similarity, metaphor, and resemblance) and their application in modeling. Some turned upside down the positivist view of heuristics as mere temporary scaffolding, regarding such guides as fundamental to the advance of knowledge.

8. Although the new social studies of science avoids the term *discovery,* given its apparent commitment to theoretical realism (the view that the sciences are approaching the final truth about reality), much work in this field pertains to "science in action" and hence to "discovery" in the broad, pragmatic sense of scientists' invention or social construction practices at research frontiers.

Positive Implications

Despite these largely negative responses to the invidious use of the D-J distinction since the 1960s, some applications of it remain useful. General confirmation theory still thrives in the form of subjective Bayesian probabilistic approaches. Evolutionary epistemology

also motivates a D-J distinction. Donald Campbell has argued that all innovation, all inductive increases of fit, must be the product of undirected variation plus selective retention, a generalized Darwinian selectionist process defended by Popper as well. For at the frontier of knowledge, scientists can proceed only by trial and error—by a variation–selection process. While the variant ideas and practices produced in the search for new problems and solutions are always constrained by current knowledge to some degree, thereby cutting down the search space, the remaining space can be explored only by trial and error. This remaining element of blind guessing falls within the context of discovery, while the testing phase falls within the context of justification. AI experts have devoted much attention to both contexts, and to pursuit as well, in the form of economy of research—the study of which search strategies are best for problems of a given kind. Indeed, the field of evolutionary computation, including genetic algorithms, has turned selectionism into a powerful approach to automated discovery, thus reviving to some degree the old idea of methodology of discovery.

Conventions, Logic of

This entry traces the conceptual and logical origins of convention, a ubiquitous social phenomenon, by presenting four main theoretical accounts of it.

One of the earliest attempts to delineate a role for conventions in social analysis was David Hume's influential discussion of justice in *A Treatise of Human Nature*. His ideas have resurfaced in theoretical contributions to economics, sociology, and law, as well as being the inspiration for David Lewis's seminal philosophical study of convention. As this entry will show, Hume's ideas are fertile, and subsequent analyses that claim to develop them have focused on different elements. However, a common theme that most modern approaches share is a preoccupation with understanding *social rules* that are both *normative* (in the sense that we should follow them) and *arbitrary* (in the sense that they might have been otherwise).

Classic examples of social conventions include the convention of driving on the right in some countries but not in others, various rules of etiquette and dress, and also language, fiat money, and the foundations of law (at least for legal positivism).

Hume on the Origins of Justice

Hume tells us that justice—which he understands very minimally as a system of property rights—is an "artificial virtue" because it cannot be established by the unhampered interaction of the natural passions. Yet systems of property—while nonnatural in the sense that they do not flow directly from the operation of innate dispositions—exist. According to Hume, this is made possible by a human "artifice" or *convention*. The artifice is fortuitous, because the narrow self-interest of those who manage to move from an unstable, impoverished state of nature to a society with rules of property ownership tends to be well served. Individuals can engage in a collaborative project that extends beyond the family and allows them to enjoy the fruits of their labor safely.

Hume defines conventions as "a general sense of common interest" expressed by all the members of society to one another. This shared sense of common interest motivates them into regulating their conduct in accordance with certain rules. Crucially, conventions depend on reciprocity and mutual recognition

for their force and thus can exist prior to contracts or promises. As Hume (1978) notes,

> This may properly enough be call'd a convention or agreement betwixt us, tho' without the interposition of a promise; since the actions of each of us have reference to those of the other and are perform'd upon the supposition, that something is to be perform'd on the other part. (p. 490)

In Hume's state of nature, primitive conventions are the primary mechanism for neutralizing the potentially conflicting interests of nonsocialized individuals. Conventions come about in situations where a number of people each stand to gain by adopting a principle that regulates interaction between them. In the case of property rights, Hume describes a principle of reciprocity: Individuals agree not to take the goods that another has rightfully gained, provided that their own goods will not be taken in a similar manner. However, once the principle is transgressed, the system breaks down because it is not underwritten by moral obligations. He also assumes that the adoption of principles such as these must involve some linguistic interaction: People must be aware that mutual interdependence exists. This communicative element is essential because there is no preexisting framework of obligation, right, or duty—without signaling, it is unclear why primordial men would be motivated to take the risk of being exposed to transgressions.

Although he was primarily concerned with justice, Hume suggested that language, money, and a host of other social institutions are conventions. In order to explain these, he introduced a second version of convention, which is exemplified by the example of rowers seamlessly *coordinating* in order to propel a boat across a river. Here, Hume introduced a new intuition about conventions—that they can arise gradually by small adjustments in behavior prompted by a *shared goal.* The rowers are not in the same situation as primordial men because they have a common, unique, and immediate objective—to move the boat through the water. We can easily imagine a situation in which given a number of possible rowing techniques, they would be completely indifferent between them. Moreover, they can coordinate their behavior without declaring interests because their mutual desire for coordination is trivial. In this situation, principles no longer seem to play a role—conventions can be established by channeling expectations, a simple regard for precedent, and a method for identifying transgressions.

While the first version stresses the mutual expression of interdependence of *selfish* interests, Hume's second version of convention shows how conventions arise out of a type of *inductive,* trial-and-error-based reasoning where language is not essential. It was a development of the latter interpretation by philosophers that has generated the greatest volume of philosophical and social-scientific research on conventions in recent years.

David Lewis and Game Theory

David Lewis, the pioneer of the game-theoretic approach to convention, acknowledged his debt to Hume by suggesting that the formal structure that he elaborated was "merely scaffolding" that restated earlier Humean ideas. Nevertheless, it is his formalization of earlier intuitions that has held sway in recent debates in both philosophy and the social sciences.

Lewis sees conventions as arising from situations where agents have a mutual coincidence of wants, and he analyzes these situations as *coordination games.* He defines a coordination game as an interdependent decision by two or more agents where there is a coincidence of preferences and two or more "proper" coordination equilibria. A coordination equilibrium strategy is one where players would not have wanted to act otherwise after the outcome has been reached. For game theorists in the Lewisian mold, potential participants in a convention are faced with the following problem: How should they coordinate around one of a number of equally satisfactory possible outcomes given that any coordinated behavior is preferable to a failure to coordinate?

Their answer relies heavily on the importance of *precedent.* If information about past iterations of the game is available to players, then they would have a reason to coordinate by employing a "salient" strategy that has been employed in the past. The past equilibrium provides them with a focal point for future coordination. Lewis (1969) summarizes the essence of the game-theoretic conception as "a self-perpetuating system of preferences, expectations, and actions capable of persisting indefinitely" (p. 42). Precedent thus leads to the formation of

expectations about future behavior, which, in turn, leads to *conformity* in the actions of individuals. This system of expectations and actions is represented by a behavioral regularity that conforms to one of the possible equilibrium strategies of the game.

The only way for agents to conform to a convention is through calculations based on their expectations of other people's behavior. However, this can lead to an infinite regress of higher-order expectations, which would normally be resolved by a contract or promise. It is because (following Hume) game theorists reject this option that convention becomes dependent on precedent. Yet the theory needs a further "common knowledge" assumption in order to avoid infinite regress. Lewis tells us that x is common knowledge in a population y if every member of that population knows x and knows that everyone else knows it, and so on. His model thus requires that for a given population to sustain a convention, it must be common knowledge that a particular behavioral regularity is the convention.

More recently, the game-theoretic rendering of convention has gained in mathematical sophistication and scope within economics, and evolutionary games have supplanted classical games. In this context, agents are assumed to be uniquely backward looking, basing their decisions solely on the observation of past behavior. Agents are also reactive, following precedent unthinkingly while remaining unaware of potential alternatives and unable to effect change through deliberation. The revised structure allows modelers to "predict" which out of a number of competing behavioral regularities will emerge as the convention. Though "deviant" behavior is possible, the system as a whole will converge on a unique, long-run equilibrium. Evolutionary games account for the emergence of conventions, without relying on standard rationality assumptions or the coincidence of preferences. Instead, conventional behavior is modeled as a *self-organizing system* that is independent of its own history.

Agreement Theory

Lewis's aim was to show how rational agents could follow conventions *without prior agreement*—purely on the basis of precedent. However, critics of the game-theoretic approach have identified a tension in his analysis. They claim that game theorists wishing to adhere to a classical (economic) conception of rationality cannot accept a Lewisian account of coordination through precedent. This is because classical rationality is exclusively forward looking: A strategy is rational at time t if and only if it maximizes expected utility from t into the indefinite future. Precedent might allow agents to coordinate expectations, but once the rationality of agents is common knowledge in a given population, expectations must be based on the canons of rationality rather than on the reproduction of past behavior. For a rational convention follower, past conformity cannot be an adequate reason for present conformity, nor would she expect another rational convention follower to conform in the present just because she has conformed in the past. Common knowledge of precedent will not, therefore, suffice to generate either expectations of conformity or actual conformity.

This argument (among others) has led one of Lewis's critics, Margaret Gilbert, to develop an alternative conception of convention. In doing so, she abandons one of the basic assumptions of game theory—the idea that conventions can be established without prior agreement or communication. The result is what we might call *an agreement theory of convention,* which emphasizes the *quasi-moral* features of coordination. Gilbert observes that conventions, despite their informal and ephemeral nature, are ubiquitous and influential in everyday life. Though they are rarely consciously followed and lack the rigidity of moral prescriptions, the conventions of a community are usually described in moral language, which permeates the analysis of the concept. Like agreements, conventions have positive and negative implications once adopted—we feel that we "ought" to abide by the prevailing conventions and that we "ought" to avoid behavior that violates them. Our attitudes are not exclusively based on individual cost–benefit calculations. Harking back to Hume's first version of convention, agreement theory explains this quasi-moral aspect of conventions by claiming that they are conditional on the tacit joint acceptance of principles of action. These principles take a fiat form—they are stipulated by participants in the conventional practice rather than justified by reference to a higher-order normative framework, such as the common good or self-interest. Thus, agreement theory replaces assumptions about individual calculative rationality

with the myth of an original contract and explains coordination through this *contractarian* device.

A Keynesian Alternative

We have now seen how two divergent themes that emerge from the Humean account of convention have been reinterpreted and transformed in recent philosophical and theoretical work. A third influential approach is the Keynesian tradition within economics, which also treats convention as a basic theoretical tool, though it eschews the Humean framework. This should not come as a surprise, because Keynes's interest in convention was derivative of his desire to understand an economy characterized by radical *uncertainty*. Keynes believed that investment decisions (and many other economic choices) were made under conditions of radical uncertainty. That is to say, he thought that calculating the probability of future states of the world and assigning quantifiable risks to them was not possible. Furthermore, Keynes argued that uncertainty was not only an inevitable feature of economic psychology, it was also ontologically grounded—the economy is a nonergodic system (i.e., a system where the statistical rates true of the ensemble of actors do not correspond with, or are not equal to, statistics true of a given individual actor, e.g., an investor).

According to Keynes, under true uncertainty the only way rational agents might avoid paralysis is to follow a convention. In order to illustrate this, he provided a typology of conventions that, he claimed, operate in the financial markets. They include the assumptions that (a) the present is a "serviceable guide" to the future, (b) the existing state of opinion (as expressed by prices) accurately sums up future prospects, and (c) individuals attempt to conform to the behavior of the majority. Thus, Keynes treated conventions as *coping mechanisms* used by fallible agents in volatile and unpredictable socioeconomic environments. Subsequent Keynesian analysis has developed this theme by conceptualizing conventions as stabilizing particular, contingent social arrangements without introducing (neoclassical) economic notions of equilibrium. In recent years, this approach has been championed by proponents of the French *économie des conventions* school, with particular emphasis on the forms of coordination that result from the operation of radical uncertainty.

Cooperation, Cultural Evolution of

This entry presents an account of the indispensable social phenomenon of cooperation from the viewpoint of modern theories of evolution. In particular, the entry sketches the outline of a process in which cultural evolution, or the transmission of behaviors and beliefs among individuals via social learning, can explain the full range of human cooperation.

Cooperative Behavior and Kin Selection

Cooperative acts, those that provide a benefit to others at a cost to the individual performing them, are common across all cultures. Consider food sharing in hunter-gatherer societies, voting in modern societies, or fighters willingly dying in battle for their tribe or country. From an evolutionary perspective, that any individuals cooperate at all is puzzling, because we expect evolution by natural selection to result in behaviors that benefit the individual performing them. Human cooperation, furthermore, is particularly vexing, because unlike in other organisms, in human societies, cooperation involves hundreds, thousands, or even millions of *unrelated* individuals engaging in *unrepeated* interactions. The common

explanations for cooperative behavior in other organisms are kin selection and reciprocity. Kin selection involves the evolution of a genetic propensity to provide benefits to related individuals because they are more likely than average to share your cooperative genetic heritage. Reciprocity involves the evolution of a propensity to provide benefits to others, regardless of relationship, if they are likely to return the favor in the future. Kin selection and reciprocity have undoubtedly played an important role in the evolution of human cooperation; nepotism and reciprocal favors are ubiquitous. Still, these two mechanisms alone are unable to explain cooperation among unrelated individuals in unrepeated encounters.

Learning

Social learning, or the acquisition of behaviors and beliefs from another individual through teaching or direct imitation, is one way an individual can acquire useful information about the environment. When information is costly and environments are variable, it can be adaptive to rely on social learning to shape behavior (rather than learning individually by trial and error, or using a relatively inflexible set of innate behaviors). Because it is not always clear whom to learn from in a complex social environment, social learning can often take the form of simple general strategies, such as "copy the majority" or "copy the most successful other individual." Such strategies allow individuals to efficiently acquire appropriate behavior in a complicated world and thus are a likely product of evolution by natural selection under a range of conditions. Over longer periods of time, transmission of information among individuals via social learning results in a process of cultural evolution in the sense that behaviors become more or less common in the population based on whether or not they are transmitted successfully. As individuals reshape and retransmit information they acquire from others, cultural complexity accumulates such that no single individual, in his or her own lifetime, can reinvent the complete body of knowledge stored in the entire population. Cumulative cultural evolution, a human hallmark, is therefore an important emergent property of the evolution of the capacity to learn socially.

Norms and "Cultural Group Selection"

One characteristic of cumulative cultural evolution particularly relevant to cooperation is that it has the capacity to create different norms, or stable, shared behavioral standards, among different groups of individuals. For example, if many individuals follow the behavior of the single most successful or prestigious founder of a society, then the group at large will tend to develop a specific norm. If individuals also have a tendency to copy the majority, then a norm can be maintained within a group, even if new people or ideas migrate into the group at high rates, because new arrivals will quickly conform to the preexisting norm in the group. Via such processes, different groups will evolve different norms of behavior; some groups will be more cooperative, while other groups will be less cooperative. The emergence of variation in cooperative norms among groups establishes the conditions for intergroup competition, in which norms from successful groups spread to other, less successful groups. This process, known as "cultural group selection," can occur when cooperative groups outcompete other groups in direct conflict or war, when they produce more individuals who subsequently migrate to other groups, or when they are preferentially imitated by individuals in less successful groups. While genetic group selection is generally thought to be an unimportant evolutionary process in genetically well-mixed species, such as humans, cultural group selection is plausible because the culture-specific evolutionary processes outlined above work to maintain cultural variation *between* groups while reducing cultural variation *within* groups.

Stable Environments and "Gene–Culture Coevolution"

The cultural evolution of cooperation as described above thus results in the creation of novel and stable environments, which can then influence the further genetic evolution of cooperative tendencies. In an environment of stable cooperation, genes that predispose individuals to identify and follow local, cooperative norms will be favored. For example, moral norms lead cooperators to collaborate to reduce the genetic fitness of norm violators. This can lead to the evolution of innate propensities to follow norms, as well as impulses, such as guilt and shame, that compel people to behave cooperatively. Ultimately, then, human cooperation is the result of a complicated coevolutionary process of selection on cultural variation and selection on genes. In summary, the evolution of a capacity for social learning leads to

cumulative cultural evolution and the emergence of stable, between-group behavioral variation. This variation then potentiates cultural group selection and the spread of cooperative norms across groups, which in turn leads to the evolution of innate psychological tendencies adapted to a world of cooperative norms. This "gene–culture coevolutionary" process complements our understanding of the evolution of cooperation via kin selection and reciprocity and can help explain how and why humans are unique in cooperating in large, ephemeral groups of unrelated individuals.

Cooperation/Coordination

Adam Smith pointed out in *The Wealth of Nations* that man is unique among God's creatures in that he stands at all times in need of the cooperation of a great multitude of his fellow men for his very survival. Nature is red in tooth and claw, and the human being is not physically well provided to survive. So we must cooperate with our fellow humans. But such cooperation is usually the realm of intimate friends and those in kinship relationships with us. The mystery of modern life is that the individual has the time and opportunity to make but a few close personal friends in his or her lifetime but requires the cooperation of hundreds, thousands, and even millions of others to be able to survive.

Smith's reasoning was that since one is relying on the cooperation of others but these others are unknown to one and perhaps will always remain unknown, the puzzle is how to achieve cooperation among strangers. He argued that one cannot rely on an appeal to their benevolence but instead must make an appeal to their self-interest. It is not from the benevolence of the butcher, the baker, and the brewer that we secure our dinner but through their self-interest.

In marshaling the self-interest of some to meet the demands of others, social cooperation under the division of labor is achieved. But Smith, in passages in the first book of *The Wealth of Nations,* delves into the complex coordination of economic activities that is required to realize the gains from trade. As he puts it at one point, the number of exchanges would exceed all computation, yet it is through the market mechanism that the complex coordination of the activities that constitute the division of labor in any society is achieved. Cooperation is realized because coordination is achieved.

This is the most important meaning of the terms *cooperation* and *coordination* in economics as historically contemplated. But in more contemporary treatments, these terms often take on different meanings—usually associated with behavior within a model. For example, businessmen might cooperate with one another to set the price in a model about cartel behavior. Or in a model of market equilibrium the production plans of some are meshed with the consumption demands of others, such that a full coordination of economic plans occurs. Cooperation and coordination are important attributes of a variety of game-theoretic models in the social sciences. The question remains as to how the attribute of the model dovetails with the more real-world notion of cooperation and coordination that Smith was talking about.

A canonical game-theoretic model is that of the Prisoner's Dilemma. In that model, the possibility of cooperation among the players is precluded by design, and each is compelled by the logic of the situation to choose a suboptimal path of defect–defect, rather than the collectively preferred option of cooperate–cooperate. This model has been utilized to illuminate a surprising number of complex problem situations in the real world—from the instability of cartel agreements to the escalating arms race during the Cold War.

A more recent vein of research tried to demonstrate how through small adjustments social cooperation could actually be achieved even in similar Prisoner's Dilemma situations. The possibility of cooperation arising out of situations of conflict has tended to highlight various mechanisms of reputation, and other punishment strategies that shift the payoffs that agents face when they don't cooperate and instead cheat. Robert Axelrod's *The Evolution of Cooperation* demonstrated that in iterative interactions, players benefited more from cooperation than from cheating, even in situations such as a one-shot game, where the rational strategy would have been to defect. In experimental economics, as Vernon Smith has shown, the results of the vast majority of experiments reveal that more cooperation is possible than the standard model would predict.

The existence of common-pool resources has also raised issues related to the interests of individuals and groups. A common-pool resource is defined by two fundamental characteristics: (1) one person's use of a unit of common-pool resource makes that same unit unavailable to anybody else and (2) it is costly to exclude potential users of a common-pool resource. Some classic examples of common-pool resources include fisheries, forests, underwater basins, and grazing lands. In a 1968 article, "The Tragedy of the Commons," Garrett Hardin argued that because of the unique characteristic of the commons, its users were in a situation that ultimately led to the destruction of the very resources they depended on—when, for example, individuals overfished or overgrazed resources for immediate individual gain. To avoid the tragedy from playing out, Hardin suggested that the commons should be either privatized or managed by the government, so that the right to entry and use could be controlled. However, Elinor Ostrom showed through a variety of field case studies across time and place that cooperation is indeed possible as communities evolve rules of self-governance to protect common-pool resources. In the Ostrom study, as long as rules come to limit access, assign accountability for use, and introduce graduated penalties for inappropriate use of the resource, cooperation through self-governance is indeed possible.

In fact, one way to reconcile the insights of Scottish Enlightenment thinkers such as Smith on cooperation and coordination, and the modern game-theoretic literature in political economy is to draw inspiration from Ostrom's work on institutional analysis. The self-interest postulate is squared with the invisible-hand postulate through institutional analysis. Or to put it another way, Ostrom has provided a multitude of evidence from the field and in the lab to show that out of a Hobbesian problem situation (after Thomas Hobbes's description of the state of nature as a war of all against all) a Smithian solution concerning social cooperation under the division of labor can be achieved provided the rules of governance are in operation.

Cost–Benefit Analysis

Cost–benefit reasoning has been a central idea not only in economics but also in several social-scientific disciplines and in philosophy as well, especially in certain approaches to moral and political theory. Reasoning according to a cost–benefit analysis (CBA) is seen as a crucial element of rationality in action and is therefore important for any philosophical understanding of social action.

This entry introduces the notion, shows the key role it plays in policy making, and gives a critical overview of the various approaches on offer.

Overview

CBA is a tool for evaluating governmental policies. It is widely employed by applied economists and, increasingly, by governments. CBA ranks policies by summing willingness-to-pay/accept (WTP/WTA) amounts (as estimated from behavioral evidence or surveys). Consider two policies, *a* and *b*. For simplicity, assume that *a* leads for sure to outcome *x* and that *b* leads for sure to outcome *y*. Imagine that Joe prefers *y* to *x*. Joe's WTP for *y*, taking *x* as baseline, is the reduction in his monetary income in *y* that just suffices to make him indifferent between the outcomes. Similarly, if Sue prefers *x* to *y*, then her WTA for *y*, taking *x* as baseline, is the increase in her income in *y* that just suffices to make her indifferent between the outcomes.

CBA then compares policies *a* and *b* by seeing whether *x* (the outcome of *a*) has net positive monetized benefits as compared with *y* (the outcome of *b*). Take the aggregate WTP amounts of the individuals who prefer *y*, and subtract the aggregate WTA amounts of the individuals who prefer *x*. Call this value for short the "WTP/WTA aggregate" for *y* relative to *x*. CBA ranks *a* over *b* just in case this value is positive.

The definition of CBA just provided smoothly generalizes to the more realistic case where policy outcomes are uncertain—in that case, each policy corresponds to a probability distribution over outcomes—but to ease presentation, this entry will focus on the simpler case and will frame the discussion directly in terms of outcomes rather than the policies giving rise to them.

Approaches and Critiques

CBA has been criticized on numerous grounds, and the most important are the following.

Ordering Failure

CBA can actually fail to rank outcomes in a minimally rational manner. It turns out to be possible that the WTP/WTA aggregate for *y*, relative to *x*, is positive (so that CBA says *y* is a better outcome) but that the WTP/WTA aggregate for *x*, relative to *y*, is also positive. It is also possible that everyone prefers *z* to *y* but that the WTP/WTA aggregate for *z*, relative to *x*, is less than the WTP/WTA aggregate for *y*, relative to *x*.

These ordering failures, however, can be solved via a refinement of the CBA test. Given a set of outcomes, arbitrarily choose one (*x*) as baseline. For every other outcome *y*, assign it an overall amount equaling the *negative* WTP/WTA aggregate for *x*, relative to *y*. (Assign *x* an overall amount of 0.) Rank outcomes according to these overall amounts. This ranking will be transitive; there will never be reversals, with each of a pair of outcomes ranked better than the other; and if everyone prefers one outcome, it will be ranked better.

Kaldor-Hicks Efficiency and the Justification of CBA

One outcome is *Pareto superior* to a second if everyone prefers the first. The CBA test does not, of course, guarantee Pareto superiority. The WTP/WTA aggregate for *x*, relative to *y*, can be positive, even though some prefer *x* and others, *y*.

However, CBA is often defended by invoking the idea of *potential* Pareto superiority or, equivalently, Kaldor-Hicks efficiency. Outcome *x* is Kaldor-Hicks efficient, relative to *y*, if there is a hypothetical, costless redistribution of resources—converting *x* into *x** such that *x** is Pareto superior to *y*. Leaving aside some technical issues, it is roughly true that if the WTP/WTA aggregate for *x*, relative to *y*, is positive, then *x* is Kaldor-Hicks efficient relative to *y*.

Less formally, one outcome passes the CBA test, relative to a second, if those who gain from the first outcome could, in principle, fully compensate those who lose, via a scheme of compensation payments with no administrative costs—leaving everyone better off.

However, the nexus between CBA and *hypothetical* compensation does not really furnish much of a justification. If *x* is Kaldor-Hicks efficient relative to *y*, but not Pareto superior, there are some individuals who prefer *y*. Why do the premises that (a) everyone prefers *x** to *y* and (b) *x* is transformable into *x** warrant the conclusion that (c) *x* (and not just *x**) is better than *y*? To tell those made worse off by some governmental policy that they *could* be compensated hardly answers their complaints about the policy if compensation is not, in fact, forthcoming.

A better justification for CBA sees it as a rough proxy for overall well-being. The fact that the WTP/

WTA aggregate for *x*, relative to *y*, is positive indicates (albeit fallibly so) that the aggregate well-being gain of those who benefit from *x* exceeds the aggregate well-being loss of those who are worse off. This argument assumes that we can make interpersonal comparisons of well-being: If Jim is better off in *x* and Sheila in *y*, then the change in Jim's well-being can be compared with the change in Sheila's. The argument also presupposes that money has roughly the same "utility" for Jim as for Sheila—that money in Jim's hands is transformed into well-being at roughly the same "rate" as money in Sheila's hands. If Jim is much richer than Sheila, then it is quite possible that some policy produces a small welfare benefit for Jim (relative to some baseline) and a larger welfare loss for Sheila, and yet Jim's WTP for the policy relative to baseline is greater than Sheila's WTA.

CBA's reliability as a proxy for overall well-being can be improved by "distributional" weights. Each person's WTP/WTA is multiplied by a weighting factor, inversely proportional to her wealth. Some academic work, and even governmental practice, takes this approach.

Preferences and Well-Being

CBA understands well-being as preference satisfaction. Such a view is standard in economics but still quite problematic. Someone's preferences might be hasty and unreflective. She might be insensitive to relevant facts. More subtly, her preferences might incorporate moral considerations. For example, if Sue on balance prefers *x* to *y*, even though her income is lower, because she judges the distribution of income in *x* to be fairer, Sue herself might quite possibly be worse off in *x*.

A more plausible view analyzes well-being in terms of idealized (fully informed, fully rational) and self-interested preferences and refines CBA by aggregating WTP/WTA amounts relative to such preferences. To be sure, specifying "full information," "full rationality," and "self-interest" poses major challenges.

Welfarism, Consequentialism, and Inequality

CBA (whether understood as an indicator of Kaldor-Hicks efficiency or, instead, of overall welfare) is consequentialist and welfarist in ranking outcomes. Welfarism says that if each person is equally well-off in two outcomes, the two are equally good. CBA satisfies this constraint (with well-being defined as preference satisfaction or as idealized and self-interested preferences with a matching refinement of the CBA test).

Consequentialism, at the level of governmental choice, says that government should evaluate policies in light of the goodness of their outcomes. CBA takes this route, and thus it is insensitive to deontological side constraints that arguably constrain the maximization of good consequences—side constraints barring torture, killing, deception, and so on.

Finally, CBA (even as corrected to incorporate distributive weights counterbalancing the variable "utility" of money) is an indicator of overall (total) well-being and does not take account of whether the distribution of well-being is more or less equal.

Challenges to CBA based on these concerns raise many complex issues. One response is to see overall welfare as *one* normative factor relevant to government choice, along with others: non-welfare goods, deontological side constraints, and fair distribution. CBA, on this view, is not a "superprocedure" but instead a rough proxy for *one* of the items (overall welfare) that government should care about.

Incommensurability

Many find it problematic that CBA employs money as a universal metric. CBA supposes that *whatever* the qualitative differences between two outcomes bearing on some individual's well-being, there is a single WTP/WTA amount for her that perfectly equilibrates those differences. Is this really true? For example, suppose that Fred has more friends in one outcome. Is the welfare value of these additional friends precisely equal to the value of any specific change in Fred's monetary assets? Isn't friendship valuable just because we resist thinking about its value in monetary terms? Suppose, tragically, that Fred loses a child. Can any sum of money compensate him for his loss?

The "incommensurability" critique of CBA subsumes these various challenges: (a) *incomparability* (that someone might be incomparably well-off in two outcomes rather than better off in one or equally well-off in both), (b) *constitutive incommensurability* (that the welfare value of certain goods consists in refusing to consciously monetize them), and (c) *lexical orderings* (that some losses are too great to be compensated by dollars).

CBA can be refined to deal with the incomparability challenge (although at the cost of additional complexity). CBA does require individuals to consciously monetize goods—but only occasionally, when posed a monetization question as part of a "stated preference" survey, designed to estimate WTP/WTA amounts. Nothing in CBA requires that individuals engage in ongoing monetary thinking throughout day-to-day life; and to insist that some goods are damaged if *ever* consciously monetized would seem to understate the resilience of these goods. Finally, CBA handles lexical orderings by shifting from the valuation of a good to the valuation of the risk of gaining or losing it. This is the approach used to arrive at WTP/WTA values for policies that save lives or cause deaths.

Covering-Law Model

The covering-law model is an early and influential model of scientific explanation that suggests that to explain a phenomenon is to show how a statement of that phenomenon can be derived using an argument that includes laws. Its chief advocate was the philosopher Carl Hempel. While the model was originally developed in the context of the natural sciences, Hempel and others attempted to extend it to the social sciences. A number of varieties of covering-law models have been developed, the most important of which are the *deductive-nomological* (DN) model and the *inductive-statistical* (IS) model. The DN model features deductive arguments and deterministic laws, while the IS model features inductive arguments and statistical laws.

As a simple example of a covering-law explanation, consider this explanation of why a helium-filled balloon will rise:

> The weight of the helium balloon is less than the weight of the volume of air the balloon displaces.
>
> Whenever an object weighs less than the air it displaces, *it will rise when released*.
>
> This balloon rises when released.

The explanation is in the form of an argument. The premises of an explanatory argument are called the *explanans,* while the conclusion is called the *explanandum*. What makes this argument a covering-law explanation is that the explanans contains a *general law*—here the claim that whenever an object weighs less than the air that it displaces, it will rise when released.

The following section presents a review of the requirements for and difficulties with the DN and IS variants of the covering-law model. The entry concludes with a discussion of some special difficulties with the application of these models to the social sciences.

The Deductive-Nomological Model

The DN model is the earliest and most widely discussed version of the covering-law model. According to this model, a DN explanation is an argument that meets the following four conditions:

1. The argument must be deductively valid.
2. The explanans must contain at least one law.
3. The explanans must have empirical content.
4. The statements comprising the explanans must all be true.

To say that the explanatory argument must be deductively valid is just to say that the explanandum is the logical consequence of the explanans—in other words, that it is impossible for all the premises in the explanans to be true and the conclusion to be false.

To clarify the requirement that the explanans must contain one law, one must be able to say just what counts as a law, and this has been a major challenge. As a starting point, philosophers of science

take laws to be certain kinds of universal generalizations, for example, "All metals conduct electricity." However, not all universal generalizations are laws. Laws must be distinguished from generalizations that are only accidentally true—for instance, the generalization that all the students in the philosophy class are less than 25 years old. One typical way of distinguishing laws from accidental generalizations is to say that the former, but not the latter, support counterfactual conditionals. Advocates of the DN model typically accept a Humean analysis of laws, understanding laws to be generalizations of unrestricted scope, whose terms do not refer explicitly or implicitly to particular objects, places, or times. This criterion rules out many obviously accidental generalizations, like the one about the age of students in the philosophy class, but it also rules out generalizations that one might consider laws. For instance, the generalization in the explanation of the balloon's rising is non-accidental, but it makes reference to the weight of an object, and thus implicitly to particular objects, namely, the earth and its gravitational field. The Logical Empiricists hoped that generalizations such as this might ultimately be derived from purely general laws, but this program of reduction has proved intractable. Moreover, there remains much debate about how many laws there are, if indeed there are any at all, and about what is an appropriate criterion for lawfulness.

The requirement that the explanans have empirical content is meant to rule out pseudoscientific explanations, in which the supposed laws or explanatory facts are not empirically testable. For instance, a Freudian explanation of a neurosis derived from laws concerning the interaction of the id and the superego would only meet this standard if it were possible to submit these supposed laws to at least an indirect empirical test.

Hempel's fourth condition, that the statements in the explanans must be true, may seem obvious, but it poses certain problems. For instance, because Newtonian mechanics have been superseded by relativistic mechanics, putative DN explanations of, for example, the motion of balls rolling down inclined planes will, according to this criterion, not be genuine. More generally, idealization and approximation are increasingly recognized as central to the explanatory practices of both the natural and the social sciences—and this is not apparently permitted within the DN model.

One consequence of the DN model (and covering-law models generally) is the structural identity of explanation and prediction. Hempel suggested that explanations and arguments share the same structure, with the difference only depending on contextual factors, such as whether the state of affairs described in the conclusion of the predictive/explanatory argument has yet occurred. For instance, the argument at the beginning of this entry can be viewed both as an explanation of why the balloon will rise and as a prediction that it will rise. However, critics of the DN model have argued that there are many instances where explanations do not predict and predictions do not explain. It is possible, for instance, to construct a DN argument inferring the height of a flagpole from the length of the shadow it casts and the angle of the sun. This argument can predict the height of the flagpole, but clearly it does not explain it. Conversely, it seems possible to explain events (especially low-probability events) after the fact even if it is not possible to predict them. A probable diagnosis of the difficulties with the structural identity thesis is that explanations must appeal to causes where predictions do not. The height of the flagpole is causally relevant to the length of the shadow, so it both predicts and explains that length, but since the length of the shadow is not causally relevant to the height of the flagpole, it predicts but does not explain it.

Another well-known counterexample to the DN model is this: Whenever a magician hexes a bit of salt and throws it into water, the salt dissolves. If the DN model is correct, an argument using this "law" will explain the salt's dissolving by reference to its having been hexed. As in the case of the flagpole and the shadow, what this counterexample seems to show is that the DN model has failed to capture the explanatorily essential concept of causal relevance.

The Inductive-Statistical Model

The IS model is Hempel's attempt to extend the covering-law model to the realm of statistical generalizations (or laws). Consider the following example:

> A patient with breast cancer who receives chemotherapy with drug A has a 95% two-year survival rate.
>
> *Smith received chemotherapy with drug A.*
>
> Probably, Smith survives two years.

This argument exemplifies the IS model of explanation, and the statistical generalization both predicts and explains Smith's survival. Formally, the requirements for IS explanations are identical to those for DN explanations, except that the laws involved are statistical and, accordingly, the arguments are inductive. Instead of requiring that the argument be deductively valid, the IS model requires that the argument be inductively strong—in other words, that it is improbable that the premises will be true while the conclusion false.

The IS model suffers from difficulties similar to those encountered in the DN model but with some added complications due to the addition of statistical premises. The argument above looks initially explanatory. But suppose it is the case that the two-year survival rate for breast cancer victims not taking the drug is also 95%; then, like the hexing of the salt, the taking of the drug is causally and explanatorily irrelevant.

An additional problem with statistical generalizations is that the probabilities involved often represent ignorance of relevant facts, so that with the addition of further facts, seemingly legitimate explanations turn out to be not explanatory. Suppose, in the above example, it is discovered that Smith's cancer is of a rare type that has a very low survival rate when treated with drug A. In that case, the argument would not explain Smith's survival.

A final problem has to do with Hempel's requirement that an IS explanation must show that the explanandum is probable in light of the explanans. Suppose, for instance, that Smith suffered from a virulent cancer strain with almost certain mortality. An experimental treatment promises a 5% chance of two-year survival, whereas in the absence of the treatment, the survival rate is near 0%. Even if Smith took the treatment she would be unlikely to survive. But even so, if she did survive, one would think that the treatment explained it. This example shows that in the IS model, as in the DN model, there turns out to be a breakdown of the structural identity between explanation and prediction.

Applications of the Covering-Law Model to the Social Sciences

The attempt to apply covering-law models to the social sciences is part of a larger project of metaphysically and methodologically unifying the natural and the social sciences. This project—often called *naturalism*—assumes that, at least ideally, social-scientific theories, like the theories of natural science, should consist of laws and that these theories can explain by showing how the laws cover the phenomena described by social science. Accordingly, much of the debate has been concerned with whether social-scientific phenomena are law governed or not.

It is sometimes held that there are no laws in the social sciences because the phenomena studied are too complex. Such laws as one does find in fields such as economics are ceteris paribus (all things being equal) laws—laws that hold only under idealized conditions, which are never realized and can seldom, if ever, be used to derive concrete predictions. One possible conclusion to draw from the ceteris paribus character of social-scientific laws is that naturalism is false, but increasingly, philosophers of natural science are inclined to think that laws in natural science are also ceteris paribus laws. Nancy Cartwright, in particular, has emphasized the parallels between explanations in physics and economics, arguing that in both cases there is a trade-off between truth and explanatory power. If Cartwright is correct, these cases reveal a defect in the covering-law model.

A second obstacle to the application of covering-law explanations is the supposed interpretive or hermeneutic character of explanation in the social sciences, whereby human actions in the social world are "understood," not explained, by subsumption under covering laws. Advocates of the interpretive approach suggest that it is impossible to explain human behavior and social institutions in purely empirical terms or to characterize the reasons that explain human action in terms of law-governed causes.

The difficulties in applying the covering-law model to the social sciences have led philosophers to seek other models more appropriate to actual explanatory practices. Two important alternatives are functional and mechanistic explanations. Functional explanations explain the existence of a social phenomenon by reference to its causal role or consequences. Mechanistic explanations seek to explain a phenomenon by describing the causal mechanism that produces it. Both of these forms of explanation seem to be important to social scientists, and neither appears to be reducible to covering-law explanation.

Criminology, Epistemological Critique of

This entry brings to light a cluster of epistemological and methodological issues regarding the scientific status and practice of criminology. These issues are related to methodological concerns in the philosophy of the social sciences as well as to issues in the cognitive sciences.

Criminology is the scientific study of crime and criminal justice systems. The field exists because some actions have been deemed "crimes," which merit a public response such as incarceration or rehabilitation. Because criminology adopts a scientific perspective on crime, it is distinct from theories of justice, which may examine what acts *should* be considered criminal. The basic schools of thought include the classical school, the positivists, the Chicago school, and the (newly evolving) modern schools of criminology.

Origins

The first text in criminology is generally considered to be Cesare Beccaria's 1764 work *On Crimes and Punishments* (*Dei delitti e delle pene*), which opposed torture and proposed that punishment be proportionate to the crime. Lawrence W. Sherman has noted, however, that Henry Fielding published an essay in 1751 calling for the rationalization of criminal justice, a state-run police force, and professional prosecutors. The "classical" school of Beccaria, along with the utilitarian philosopher and legal reformist Jeremy Bentham in the late 18th century, as well as others, saw crime as a rational choice responsive to incentives. The individual makes a simple calculation of whether the expected pain is greater than the expected pleasure. The solution from a society's standpoint is to create deterrence by providing swift and sure punishment.

The positivist school of criminology was founded in 1876 by Cesare Lombroso, who spoke of the "born criminal," whose "atavistic" (biologically "primitive") character was revealed by physical traits such as a sloping brow. The school emphasized empiricism and the scientific method to discover those aspects outside an individual's control that made the individual indulge in criminal behavior. Various researchers focused on the biological, social, demographic, or psychological causes of criminal behavior.

In the 1920s, theorists of the Chicago school shifted attention from the supposed biological or psychological causes of crime, adopting a "sociological ecology" approach that emphasized "social disorganization" as a cause of crime. This school sought to solve the problem of criminal behavior by changing the social environment in which the individual functioned.

Modern Developments and Epistemological Issues

Modern criminologists have begun to reject these more simplistic theories and have sought to create a more complex, cross-disciplinary view of crime in the context of modern society. Criminologists have adopted empirical methods, but there is some disagreement over what particular methods are the most appropriate to the subject. In particular, Lawrence Sherman and others extol an "experimental" approach as a necessary complement to the more "analytical" methods that may dominate the field today. Some writers take a critical stance and suggest that criminological theory and methods may be a function of class interest, political power, or similar considerations that are generally viewed as illegitimate in standard views of science.

An epistemological critique of criminology may be directed to criminal justice studies, asking questions such as "How do we know that our theories are right?" It may also be directed at criminal justice systems, asking questions such as "How do we know whether the suspect committed the crime?" At both these levels, the methodological and the scientific, relatively little has been written about the epistemology of criminology. At the methodological level, however, epistemological critiques of criminology can draw on the vast existing literature on the methodology of the social sciences. The epistemic properties of criminal justice systems have been less thoroughly explored in spite of evidence of error in both common law and civil law countries. The "reliabilist" or "veritistic" social epistemology described in Alvin Goldman's *Knowledge in a Social World* emphasizes truth conductivity and gives us a good foundation for the epistemological critique of criminology.

Cognitive biases cause persistent, recurrent, and systematic errors in criminal justice systems. Both criminal justice personnel and nonprofessional participants in the system are subject to cognitive biases that may lead to errors such as false convictions. Police officials are subject to confirmation bias, tunnel vision, and *us versus them* thinking. Forensic scientists are subject to cognitive biases that may encourage errors favoring the police theory of a case, as are prosecutors and judges. Suspects themselves may contribute to false convictions through false confessions, which are more likely in more vulnerable populations.

It seems clear that jurors are no less subject to cognitive bias than others. We do not know, however, whether deliberation improves outcomes. The infirmities of eyewitness testimony are probably better understood. Police lineups, for example, invite error if not properly structured. Eyewitnesses are more likely to misidentify a person perceived to be of a different "race."

Individual cognitive bias is not the only cause of error in criminal justice systems. The organization of a criminal justice system may influence the chance of error even when individuals are "rational" in some strong sense, such as that of economic theory. Police and prosecutors may have an incentive to maximize convictions rather than to separate the guilty from the innocent. Such incentives run afoul of the "multitask problem" of organizational economics, whereby unobserved aspects of the job are sacrificed to increase measured values of the observed dimensions. Police agencies may sometimes act to increase case clearings, without adequate regard for crime reduction or avoidance of false conviction.

The police interest in clearing cases may spread to the crime lab if it is organized under the police, as is typical in the United States. Lab fundings may depend in part on case clearing. In some cases, a lab may receive a payment for each guilty plea or guilty verdict involving lab testing or, perhaps, in certain categories such as drug use or drunk driving. Individual forensic scientists have sometimes been led into error in part because of a feeling of identification with the police.

The risk of forensic science error is increased by a twofold monopoly in forensic science. First, evidence is typically examined by one crime lab only. In this sense, the crime lab receiving a bit of evidence has a monopoly on examination of that evidence. Second, that same lab will normally be the only one to offer an interpretation of the results of the examination it performs. The monopoly structure of forensic science contrasts with the relatively open competition in research science, where any one lab may challenge the results of any other lab.

The monopoly structure of forensic science interacts with the architecture of the human mind. Even if the individual scientist's objective is to provide unbiased information, he or she is still an agent of the police and the prosecution. Moreover, standard practice gives the examiner context information about the crime, the victim, and the suspect. These conditions create conscious or unconscious bias that may induce error.

Different lines of evidence, such as eyewitness testimony, confessions, and different types of forensic evidence, will often emerge from one investigation and one team of investigators. This unity of the evidence-generation process creates the risk that errors will be correlated across evidence classes. Police investigators may induce a false confession from a suspect, employ a snitch to testify against the suspect, consciously or unconsciously influence eyewitnesses to testify against the suspect, and provide the crime lab with context information that may induce an incriminating forensic science error. In such cases, errors are correlated across seemingly independent evidence channels. Jurors, who implicitly assume

that errors are independent across types of evidence, may underestimate the probability of innocence.

If the epistemic infirmities of criminal justice systems are greater than is generally recognized by affected citizens, there may be cause to consider reform measures such as taping suspect interviews, enhancing the defense's right to expertise, separating crime labs from law enforcement, and eliminating the snitch system. The relatively unambiguous distinction between guilt and innocence may also help make criminal justice systems a good area for further research in social epistemology.

Critical Rationalism

Critical rationalism is a term sometimes used to refer to Karl Popper's philosophical system, or a large part thereof. But it more precisely refers to a critical *attitude* that Popper advocated, and derivatively to the claim that we ought to adopt this attitude (in a significant class of contexts, e.g., when doing science).

In *The Open Society and Its Enemies,* Popper contrasts critical rationalism with comprehensive rationalism. Each position involves the view that we should employ argument and experience in order to assess statements; this is the *rationalist* component. (Do not be confused by the fact that "rationalism" is typically used in a different sense in contemporary philosophy, to refer to the view that pure reason, unaided by experience, is a source of knowledge—standardly taken as the opposite of "empiricism.")

This entry presents the position of critical rationalism by distinguishing it from other kindred rationalist stances, presents critiques of it, and ends by showing the relevance as well as the limitations of rationalist stances, both in the case of an individual versus a group she or he is a member of and as regards how scientists should be expected to proceed rationally, or not, in benefiting science.

Comprehensive Rationalism

The comprehensive rationalist follows (or strives to follow), implicitly or explicitly, the rule that *any statement that cannot be supported by argument or experience should be abandoned.* And there is scope to understand "abandoned" in several different fashions, such as "classified as false," "believed to be false," "not classified as true," and "not believed to be true." (Failing to believe that a given statement is true is not equivalent to believing that it is false; one might suspend judgment as to its truth or be unaware of the statement and thus be unable to form an opinion on its veracity.) So the classical epistemological position that one should not believe in something without support from reason or experience is a form of comprehensive rationalism.

The problem with comprehensive rationalism, however, is that it appears to be self-refuting. Consider the aforementioned statement: "Any statement that cannot be supported by argument or experience should be abandoned." As *this* statement cannot be supported by argument or experience—this is typically uncontested in the literature—it should be abandoned even if it is true! And while it would be easy to achieve a quick fix by changing "any statement" to "any statement except this one," it would be ad hoc. To foreshadow the subsequent discussion, the comprehensive rationalist

would have difficulty in explaining why one should not instead adopt a foundational rule, such as "Any statement that cannot be supported by appeal to the King James Bible—except this one—should be abandoned."

Critical Rationalism

In light of the problem with comprehensive rationalism, Popper suggests that the rationalist attitude must ultimately rest on faith (or irrational commitment). And he suggests that it is therefore appropriate to adopt a more modest stance, a *critical rationalism,* where this is frankly admitted. As part of this, Popper advocates a critical attitude of accepting that one might be wrong and that those with whom one disagrees may be right. He also suggests that we should work together to eliminate errors.

However, critical rationalism, and more particularly the view that it is acceptable for rationalism to be based on faith, is criticized in turn by William Warren Bartley. The problem is that if the rationalist embraces faith as her starting point, then she concedes a priority to faith. So anyone who does not want to be a rationalist is excused, and there is no loss of "intellectual integrity" in opting for a form of irrationalism instead. Imagine, for example, that a critical rationalist were to criticize a religious person for summarily dismissing the results of a well-developed special science, such as physics. This person could simply respond with "But you, too, start with faith. And my alternative faith leads me to believe that these results are false." In fact, Bartley's *The Retreat to Commitment* pays particular attention to how this tu quoque move could be employed by Christians.

Pancritical Rationalism

Bartley therefore suggests that critical rationalism may be replaced with *pancritical* rationalism (which is also known as *comprehensively critical rationalism*). The simple idea is that the rationalist may forswear any reliance on faith whatsoever by holding all her positions open to criticism and by being willing to give any of them up under the right circumstances. Crucially, this goes for pancritical rationalism *itself;* in essence, the idea is that argument and experience might be used, in principle, to show that we require faith instead.

A radical component of Bartley's view is that it can be perfectly rational to believe in something—or to hold some position—even in the absence of any justification (in the sense of a reason) for doing so. On the contrary, the rationality in holding a position consists precisely in the willingness to subject it to criticism and to abandon it if it fails to stand up under fire. This fits nicely with the emphasis on testing in Popper's philosophy of science and with the idea that it's what we do with our theories, when we have them, that really matters.

It should be noted that simply avoiding susceptibility to the tu quoque move does not provide an argument *for* being a pancritical rationalist. Such an argument is supplementary and might be made on either ethical or epistemic grounds; in particular, it may be urged that being a pancritical rationalist (or as close to the ideal as one can be) is virtuous. Nonetheless, there is a gap between what is best for an individual and best for the group of which she is a part. And there is reason to think that science benefits from having some dogmatic scientists and does rather better in virtue of their presence than it would if *all* scientists were pancritical rationalists.

Critical Realism in Economics

The central claim of the project of critical realism in economics is that the discipline would benefit from a more explicit, systematic, and sustained concern with *ontology*—that is, with the philosophical analysis of the nature of what exists in the social world—than its practitioners have hitherto displayed. Underpinning this claim is the belief that social research is most likely to bear fruit if it uses tools that are tailored to suit the nature of the material under investigation. To that end, critical realists style themselves as adopting an underlabor role, whereby they develop an account of the ontology of the social world that is used to inform an analysis of the research methods that are most likely to bear fruit in social research.

Main Tenets

Holism, Structures, and Openness

Critical realists argue that many commonly acknowledged general features of the social world—such as the possibility of genuine human choice, the often routinized nature of (much of) social life, the segmented and other-directed nature of many social practices, and the fact that the practices followed in particular settings often remain the same even when the specific individual carrying them out changes—can be rendered intelligible only if it is acknowledged that the social world has certain broad features. These features show that the social world is structured, consisting not only of people but also of social structures—social rules and institutions—that are ontologically irreducible to social practices. The social world is therefore in large part holistic, with the aforementioned structures consisting of networks of internally related positions (e.g., those of capitalist and worker, buyer and seller, and creditor and debtor) through the occupancy of which people and social structures come together. Furthermore, the social world is shown to be inherently dynamic or processual—with people drawing on social structures in order to act and, in acting, either reproducing or transforming both those structures and their own capacities and personalities—and open, being characterized by a paucity of sharp, stable event regularities of the form "Whenever this event or state of affairs *x*, then that event or state of affairs *y*."

On this view, socioeconomic phenomena are to be explained as the outcome of the causal interplay over historical time between (antecedent) social structure and (subsequent) human agency. More specifically, the initial stage of an explanation involves the identification of the practices responsible for the phenomenon under investigation, after which it is necessary to uncover the social structures and tacit skills that facilitate those practices, together with any conscious and unconscious psychological factors that motivate them. Within this general view, the distinctive role of the discipline of economics is that of being the branch of social science that focuses on the social structures and processes governing the production, distribution, and use of the material conditions of well-being.

Causal Mechanisms

Epistemic access to these underlying causal mechanisms can often be obtained by focusing on what critical realists term "contrastives"—that is, situations where there are two or more comparable groups or populations with similar histories and shared conditions and where our background knowledge leads us to expect a specific relationship (often, though not always, one of similarity) between the outcomes experienced by those groups but where we are surprised ex post facto by the relation actually discovered. For instance, the contrast in question might stem from the observation that since World War II productivity growth has often been lower in the United Kingdom than in the economies of other major industrialized nations. The existence of such contrasts provides prima facie evidence that there is an unidentified causal mechanism at work, whose influence accounts for the unexpected relation between the outcomes displayed by the populations or groups in question. And, having been alerted to the (potential) existence of a hitherto unknown causal mechanism in this way, the task of the researcher is then to identify and illuminate it—perhaps by investigating the hypothesis that the ill-understood mechanism in question is analogous to some other, better-known mechanism in a different field of inquiry—thereby explaining the contrast in question.

Critical Realism Against Mainstream Economics

One key implication of their social ontology, critical realists contend, is that mainstream economics is unlikely to yield insights into the social world. For critical realists, the hallmark of mainstream economics lies in its commitment to formal mathematical modeling and to a mode of explanation according to which social phenomena of interest are explained when a description of them is deduced from sets of axioms and assumptions expressing regularities of the following form, as we have seen: "Whenever this event or state of affairs (x), then that event or state of affairs (y)." However, the a posteriori observation—in particular, of the fragility of many of the results obtained by econometricians—reveals that the socioeconomic world displays few sharp, stable event regularities of the kind required for such deductivist explanations. What this implies is that the construction of the orthodoxy's mathematical-deductivist models requires that economists make assumptions—for example, that people always and everywhere maximize their expected utility or that the economy consists only of one "representative" agent—designed to ensure that under given conditions (x) the homunculi who inhabit the model economic worlds in question always act in the same way and produce the same (probability distribution of) outcome(s) (y) as the deducibility of theoretical results requires. The problem with such assumptions is that they are not descriptive of most of the social world; designed as they are to eliminate various sources of indeterminacy from models of a social world that is in large part open, such assumptions portray people as passive atoms who inhabit isolated or self-contained worlds, when in fact they are nothing of the sort. The scope for such fictional models to advance our understanding of real economic issues is, Tony Lawson argues, far from obvious and certainly insufficiently well established to warrant the way in which their use dominates the economics profession.

Relation of Critical Realism With Heterodox Economics

On the other hand, there is a good deal of common ground between critical realism and the views held by various heterodox schools of economic thought. Many Austrian, feminist, old-institutionalist, Marxist, and post-Keynesian economists make the case for their own preferred style of economic analysis by using arguments that presuppose, if only implicitly, a social ontology closely akin to that espoused by critical realists. The value of critical realism for heterodox economists lies in the way it affords them philosophical resources that can help them make explicit, clarify, systematize, and so realize the full potential of their insights into the nature of the socioeconomic being and its implications for an appropriate methodology for economics, in particular by facilitating the clarification and refinement of various important substantive concepts, including *social order, probability, money, markets,* and *capabilities.*

Cultural Evolution

Culture involves the social transmission of novel behavior, such as gestures, songs, or tool-making skills, among individuals who are generally members of the same species. Elements of culture spread both vertically, from one generation to another, and horizontally, among members of a generation. Thus, two key components of culture are (1) a means of *generating* novel behavior and (2) a means of *spreading* it, such as imitation and other forms of social learning. This entry outlines efforts to develop a scientific

framework for understanding the dynamics of cultural change.

It is widely believed that nonhuman species such as chimpanzees possess culture, but human culture is noteworthy because it is *cumulative*. Individuals build on each other's ideas, not just in a random manner that reflects mere copying errors, individual differences, and limitations in physique or differences in the materials at hand, but in a way that is *adaptive*. We strategically modify the ideas of others to suit our own needs and tastes, such that cultural products become more useful, expressive, or aesthetically pleasing. Anthropologists usually place the origins of human culture approximately 2 million years ago, during the transition from *Homo habilis* to the upright walking *Homo erectus*. Our earliest stone tools date back to this time. However, there is little evidence of *cumulative* cultural change until approximately 100,000 to 50,000 years ago, during the Middle-Upper Paleolithic Era. This period constitutes a dramatic transition in human culture, as it marks the beginning of many kinds of cultural artifacts, including task-specific tools, art, ornamental jewelry, and indications of ritualized religion.

Thus, not only does adaptive cultural change accumulate over time, but it *diversifies,* becomes increasingly complex, and exhibits phenomena observed in biological evolution, such as niches, and punctuated equilibrium. Like biological evolution, culture is *open-ended*; there is no apparent limit to the variety of new forms it can give rise to. For these reasons, it has been argued that culture constitutes a second evolutionary process, one that, though it grew out of biological evolution, exhibits an evolutionary dynamic in its own right that cannot be reduced to biology. Some of what is considered cultural behavior *can* be explained by biology. Most, however, would probably concede that, much as principles of physics do not go far toward an explanation of, say, the vertebrate body plan (though things like gravity play some role), biology does not go far toward an explanation of, say, the form and content of a sonnet (though factors like selective pressure for intelligence play some role). Most would concede that to explain how and why such forms arise, accumulate, and adapt over time, one must look to culture. Nevertheless, the attempt to establish an evolutionary framework for culture remains a struggle.

One theory is that culture evolves through natural selection. What necessitated Charles Darwin's theory of how species evolve through natural selection is that traits that are *acquired* by an organism over its lifetime are not transmitted to the offspring and thus not passed down through time. Thus, whereas a rock that smashes stays smashed, if a rat loses its tail, the rat's offspring are *not* born tail-less; the "bitten-off tail" trait is lost from the rat lineage. The paradox Darwin faced was this: If change is not retained from parent to offspring, then how does change *accumulate?* His solution was as follows: He proposed that part of an organism *is* retained (the part we now call DNA). It is responsible for traits shared by relatives, and it undergoes random change from one generation to the next. Since random changes that are beneficial cause their bearers to have more offspring, or be selected, over generations, such traits proliferate at the expense of detrimental ones and become more widely represented in a population.

John von Neumann determined the minimal algorithmic structure capable of evolving through natural selection, which he termed a *self-replicating automaton*. It consists of self-assembly instructions that are both *copied* to make offspring and *interpreted* to develop them into adults. However, it was the simpler notion of a *replicator,* something that merely makes copies of itself, that inspired the *Darwinian theory of culture*. According to this theory, culture evolves through the variation and selection of replicators, sometimes referred to as *memes*. Darwinian anthropologists apply phylogenetic methods, developed for classifying biological organisms into lineages, to cultural artifacts. This works well for highly conserved assemblages but falsely classifies similarity due to horizontal exchange of ideas as similarity originating from a common ancestor. *Dual-inheritance theory* is a version of the Darwinian view that posits that humans have two inheritance systems—biological and cultural—and focuses on processes that bias the transmission of cultural information, such as the tendency to preferentially imitate high-prestige individuals. However, since the theory of natural selection assumes that variation is randomly generated and acquired change is not transmitted, to the extent that transmission is biased from the random, and ideas acquire change between transmission events as we contemplate them, the Darwinian approach gives a distorted model.

Another theory of cultural evolution was inspired by recent evidence that the earliest forms of life were

self-organized metabolic networks that evolved through a non-Darwinian process involving transmission of acquired traits, sometimes referred to as *communal exchange*. It has been proposed that what evolves through culture is *worldviews*—the integrated webs of ideas, beliefs, and so forth, that constitute our internal models of the world—and they evolve, as did early life, not through competition and survival of the *fittest* but through communal transformation of *all*. In other words, the assemblage of human worldviews changes over time not because some replicate at the expense of others, as in natural selection, but because of ongoing mutual interaction and modification. Elements of culture, such as rituals, customs, and artifacts, reflect the states of the worldviews that generate them. The theory is consistent with network-based approaches to modeling trade, artifact lineages, and the social exchange of knowledge and beliefs and with the unexpectedly high degree of cooperativity in human culture.

Cultural Studies

Cultural studies can be seen as an extension of and, at the same time, a challenge to the social sciences. This is because it has a highly ambiguous relation to them, with some practitioners of cultural studies seeing themselves as social scientists (or akin to them) but many being wary of the scientific claims made by them. This relation is also complicated by the broad and multidisciplinary (or sometimes antidisciplinary) character of cultural studies, which is highly dispersed geographically and not easy to define in terms of either its objects of study or its methodologies. Of course, this does not mean that it does not have dominant themes and common ways of thinking, but it does mean that it does not have a simple definition.

The most convenient way of understanding cultural studies and its theoretical evolution is to refer to one of its key founding institutions in terms of its later development and expansion—the Birmingham Centre for Contemporary Cultural Studies in England, which was founded by Richard Hoggart in 1964, a key early figure in the area, who distinguished himself in 1957 by publishing his *The Uses of Literacy.* Although Hoggart did not make any claims to being a social scientist, this publication has often been seen as an ethnographic approach to the description, analysis, and understanding of working-class life. This work, along with E. P. Thompson's 1963 work, *The Making of the English Working Class,* and a whole series of studies by one of the major early scholars associated with the field, Raymond Williams, helped establish one of the main thematic areas that would be explored in what would become known as cultural studies—the study and analysis of working-class life and the values, beliefs, language, tastes, institutions, leisure interests, and social and political struggles that characterize it (although some critics now question the value of using a term like *the working class*). Nevertheless, these writers, and especially Raymond Williams (who theorized culture "as a whole way of life" from a materialist point of view), have become founders of the area.

This tradition of analysis would help stimulate many studies centered on popular culture and the understanding of youth subcultures, which would sometimes involve borrowing ideas from sociology (particularly the Chicago school). It might be noted here that early interest in working-class culture in Britain was not restricted to the Birmingham Centre; many extramural courses were taught outside the mainstream university system, and there were other centers in other parts of Britain (and sociology departments in many parts of the world). Also, the early stimulus for interest in popular forms of working-class culture came about as a challenge to what was often considered elitist views about "high/minority" versus "low/mass/popular" culture,

promulgated in what has become known as the Culture and Civilization tradition, associated with 19th-century writers such as Matthew Arnold and his influence on 20th-century critics including F. R. and Queenie Leavis and Denys Thompson. It was Raymond Williams who helped promulgate the anthropological idea that culture, far from being the preserve of cultural elites, was "ordinary" and would include everything from Dostoyevsky, Picasso, and Beethoven to sports, social clubs, family life, and entertainment.

The directorship of the Birmingham Centre was taken over in 1969 by Stuart Hall, a key figure in the New Left in Britain, and this was the moment when the Centre began to consider its relation to theory in very self-conscious ways. One of the key currents of thought (which can be broadly defined as philosophical) that has structured much writing in cultural studies is the Marxist tradition. However, in Birmingham, and beyond, the Marxist legacy has been complex and conflicted. Thompson was a Marxist who stressed working-class agency through its radical history; however, this was only one way of applying Marxist-inflected thought. One early way in which Marxist thought was mobilized was through the Frankfurt school's fusion of Marxist and Freudian thinking (referred to as "critical theory") to show how the culture industry dehumanized, disempowered, and depoliticized the working class, but this way of thinking (mainly associated with Theodor Adorno and Max Horkheimer) was complemented and challenged by other Marxist approaches.

The work of the French Marxist philosopher Louis Althusser exercised considerable influence over cultural studies' practitioners in the 1970s and 1980s, helping scholars theorize ideology with relation to what he called "state apparatuses" but particularly with his notion of "interpellation," which described how people actually become subjects of ideology. This had a particular influence on film theory as practiced by many writers who contributed to the journal *Screen,* which explored how audiovisual forms situated (or interpellated) the public as viewing subjects. One of the most enduring essays written during this period was the feminist film critic Laura Mulvey's "Visual Pleasure and Narrative Cinema" (first published in 1973), which argued that classic Hollywood cinema was biased toward the male gaze insofar as most of the protagonists were male, and women actors were reduced to their role of objects of male desire. In this way, the audience was interpellated in a thoroughly sexist way. Althusser also introduced the term *problematic,* which helped critics explore not only what a text says but also what lurks in the gaps and silences of *what it does not say,* so as to be able to unearth and explore the hidden ideological background as a kind of Freudian symptom.

One of the most important theoretical developments in the Birmingham Centre (and beyond) was the use of Antonio Gramsci's notion of *hegemony,* which describes the exercise of power within democracies as not only a question of the use of force (in relation to the police, the army, the courts, etc.) but also in relation to the role of how groups gain power through alliances, negotiation, and compromise in order to gain intellectual, cultural, and political leadership. This approach takes the emphasis off the more simplistic Marxist notion of the dominant class exercising power over the dominated in a more or less determined way and helps critics consider how power blocs are *themselves* subject to internal conflict and alliances. Here, culture is understood as the site of struggle where dominant values and ideas are subject to counterhegemonic strategies. This was linked to Gramsci's idea of the "organic" intellectual, a member of a repressed but revolutionary class who would create and propagate counterhegemonic ideas and values to challenge those of the dominant political order (something Stuart Hall felt was part of the role of scholars at the Birmingham Centre). These ideas, together with the application of hegemony to describe how official high forms of culture are established, became so important that historians of cultural studies often refer to it as *the turn to Gramsci.* Here, it is possible to see that the use of Marxist theory provided paradigms for analysis and helped forge politically motivated scholars who not only analyzed the world but also wished to change it (an important inheritance passed on to many [but not all] practitioners of cultural studies).

Other important theoretical currents that were explored in Birmingham and many other centers from around the 1980s (when cultural studies' institutional expansion began in earnest not only in Britain but, principally, in the United States and Australia and then in many other parts of the world) were related to what are referred to as structuralism, poststructuralism, and postmodernism. The turn to structuralism in the humanities, which was inspired by the work of linguists like Ferdinand de

Saussure, Charles Peirce, Roman Jakobson, and Émile Benveniste and the anthropologist Claude Lévi-Strauss, led to many attempts at what were considered "scientific" analyses of culture that put the emphasis on the way cultures could be explained with relation to the way complex social rules provided a "grammar" that explained all kinds of social phenomena with relation to codes and signs (Saussure provided a key theory of the sign, which would have enduring influence).

These ideas were developed by writers such as Roland Barthes and Umberto Eco and, in the case of Barthes's early work, were often linked to efforts to show how capitalist cultures were dominated by bourgeois values and interests (Althusser would draw on structuralist ideas as well as on Freud and Marx). After the first wave of structuralism, writers became more skeptical of the so-called objectivity of structuralist science and many turned to the later Barthes and the deconstructive philosophy of Jacques Derrida. Derrida's philosophy, known as *deconstruction,* undermined structuralism (and just about all forms of thought with claims to scientific truth) by careful readings that showed how all texts were ultimately structured on oppositions and rhetorical devices that were vulnerable to the destabilizing tactics of close reading. In this way meaning, while possible, is constantly differed and plural. Like many areas in the humanities, cultural studies began to draw on these ideas not in order to forward deconstructive philosophy *as such* but in order to question the discourses that had structured Western thinking. This interest in poststructuralist reading (as it became known) coincided with other theoretical and thematic interests that extended an interest in class to include subordination on the grounds of gender, race/ethnicity, and, later, sexuality.

This very broad interest in subordinated groups led to complex readings that also combined with Marxism, psychoanalysis, and theories and approaches developed within feminism, postcolonial theory, and queer theory. The ideas of the poststructuralist psychoanalyst Jacques Lacan have also been enormously influential in terms of the construction of identity. The Lacanian tradition does not assume that identity is the unique essence of the self found in much thinking in the Western philosophical tradition, including Christian notions of the soul, but instead it depends on symbolic cultural constructions. This means that the self does not precede culture and language as an essence but is actually a product of them. This idea, very reminiscent of structuralist approaches, has been applied to all kinds of identities whether they be personal, cultural, national, or historical.

Another major influence has been the work of Michel Foucault and his theories and methods concerning the construction of the lunatic, the criminal, and the homosexual in the human sciences. His insistence on the importance of "discourse" to the understanding of identity has often provided an alternative to the Marxist-Freudian traditions of thought. The work of Derrida, Lacan, and Foucault has often been associated with the idea of postmodernism, which generally questions, or complicates, the fixed meanings associated with philosophical and scientific traditions that seek absolute, stable truths and meanings. Two key thinkers in this context are Jean-François Lyotard and Jean Baudrillard. One of Lyotard's central claims was that from around the 1970s all the old certainties in thought were no longer credible and these were being replaced by "little narratives" that made no universalizing claims to truth and that truth was being replaced by *performativity* (a pragmatic approach to knowledge that only insists on utility rather than on notions of truth). This was part of what Lyotard referred to as "the postmodern condition." One of the most influential claims that Baudrillard made was that societies dominated by contemporary capitalism had lost contact with a sense of the real—they were "hyperreal," meaning that signs were no longer taken as referring to any kind of reality but were empty copies of copies.

Since the later part of the 20th century, there have been a number of shifts in the theoretical emphasis in cultural studies, with major contributions coming from critics who have placed the emphasis on empirically based audience studies that, in a loose philosophical sense, are related to phenomenology and reception theory. Furthermore, prominent critics like Stuart Hall and Lawrence Grossberg have suggested that cultural critics put less emphasis on identity politics and on questions of ideology, which tended to dominate cultural studies in the 1980s and 1990s. This has led to some innovative, if tentative, explorations of the work of philosophers like Gilles Deleuze and Félix Guattari, Giorgio Agamben, Slavoj Žižek, and Alain Badiou, and these explorations have been complemented by a thematic broadening that has seen studies focused on new media, anticapitalism,

the transnational, celebrity cultures, and digital and convergence cultures (among many others).

The field of cultural studies, then, continues to remain enormously eclectic from both the theoretical and the methodological points of view, challenging mainstream social sciences, erasing disciplinary boundaries, and drawing on all the writers mentioned above and many others, on a very broad-ranging and ever-expanding area.

Death and Immortality, Philosophical Perspectives

This entry provides a brief account of how philosophy looks at death by sketching some views about the nature of life, persons, death, and the implications for immortality.

Being *immortal* is not the same thing as being indestructible. Something is immortal if it *will* merely remain alive forever, which is not to say that it *could* not perish. What death is and whether immortality is possible, whether for us or for other sorts of beings, depends on what we are and what it is to be alive.

Life

To define "alive," we want to identify some capacity that is distinctive of living things. However, there are many candidates. On Aristotle's list, we find nutrition, appetite, growth, reproduction, perception, motion, and thought; later, biologists added responsiveness to the environment, homeostasis, and metabolism. It is not easy to define "alive" because it is difficult to find one characteristic that all and only living things exemplify. Aristotle's solution was to equate being alive with possessing *one or more* of the capacities on his list; unlike him, however, we know how to build mechanisms that possess some of these features yet are not alive.

Although no definition of life has achieved consensus, the only living things we know of are organisms and perhaps some of their components (e.g., organs), and there is wide agreement that an organism is alive only if it has the capacity to develop or maintain itself in a suitable environment. The processes by which it does this are called *vital processes*.

Persons

But it is not clear that you and I *are* organisms. Suppose that, as René Descartes said, we are essentially thinking things. The existence of thinking things need not depend on vital processes. If it is possible to build mechanisms capable of thought, such as the fictional android Data, then thinking beings need not be organisms and their persistence may not require that they be alive.

Some contemporary theorists, such as Peter Van Inwagen, Paul Snowdon, and Eric Olson, say we are organisms, but many others disagree. According to Derek Parfit and Jeff McMahan, we are minds, with psychological persistence conditions. Parfit has argued that we remain in existence over time if our psychological attributes do not suddenly change drastically and we do not undergo fission like an amoeba. Given his view, we need not be organisms to survive; in theory, we could transfer our psychological features to machines and continue our existence indefinitely. But this gives us the potential for immortality only if the notion of immortality is extended to embrace eternal existence (as opposed to eternal life).

Death

The term *death* is ambiguous. Death might be a *state*—the state we are in once we perish. Alternatively, it might be the *process* of extinction.

It could also be equated with one of two *events*: the point when the dying process reaches irreversibility or when it completes itself. The process of death can be compared to a race, which begins at some time, continues a while, and then ends; so it is not instantaneous (it takes time to complete itself).

It seems clear that only organisms and some of their components can die and also that an organism dies only when its vital processes cease. But many questions remain: (1) How is dying related to ceasing to exist? (2) Vital processes can be suspended, or even reversed; is an organism alive whose vital processes are suspended? (3) Is it possible to resurrect an organism that has died? (4) Is there some other way to avoid ceasing to exist?

Question 1 arises since it is conceivable that thinking beings (such as Data, from the TV series *Star Trek: The Next Generation*) could exist that are not alive at all. Such beings cannot die, but they could cease to exist; their ending would be deathless. Some theorists would add that dying does not entail ceasing to exist. Fred Feldman argues that we are organisms, but organisms do not cease to exist when they die. They remain in existence for a time—as corpses. On this view, we could continue our existence indefinitely, if not forever, as frozen corpses. However, many other theorists reject this position on the grounds that an organism ceases to exist when it dies.

Seeds, spores, some small creatures, and even human embryos can be frozen indefinitely yet remain viable; thereby, their vital processes are suspended. In time, it may become possible to freeze adult human beings. If so, it seems plausible to say that we could remain in existence indefinitely, in suspended animation. However, it remains controversial whether an organism is alive while in suspended animation.

The possibility of resurrection, raised by the third question, can seem straightforward: If we take a car completely apart, it ceases to exist; but if we reassemble the parts, the car's existence continues. Why should the same not be true of us? According to some theorists, it would. Typically, the molecules of which we are made disperse at death, but if they were later reassembled, just as they were when we died, our existence would continue.

There may be another way to survive death: Perhaps, contrary to appearances, we are immortal souls, as Descartes claimed—things distinct from, and capable of existing separately from, the bodies we inhabit. While the coherence of this suggestion has been challenged, the chief objection to it is that there is no evidence for the existence of souls.

Death in the Social Sciences

The interdisciplinary study of the concept of death has paralleled the interest this topic has evoked among the general population. Although some early interest is known to have existed during the early 1920s, a much greater interest emerges in the aftermath of World War II and, more particularly, during the latter half of the 20th century and well into the second decade of the 21st century. Since the 1950s, interest in identifying cultural meanings and the social correlates of death has become an established area of inquiry among academics and practitioners alike.

This entry provides an overview of the concept of death, which is shown to be a continuous, evolving area of interest within the social sciences, not unlike that found in the behavioral and biological sciences.

Definition of Death and Application of the Death Concept

Defined by *Webster's New World Dictionary* as the "act or fact of dying," death is more than a biological concept; indeed, death has legal as well as medical consequences. In the former instance, death occurs when bodily functions close down and vital signs cease to be recorded. This legal definition is promoted as brain death, or the cessation of brain function. In the latter, medical perspective, death is described as the shutdown of circulatory and respiratory functions and of all the functions of the brain. Medically, death is the irreversible end of or absence of life; the end of life is the fact of brain death. But whether scholarly or applied, from a social science perspective, death is often defined through *metaphors,* demonstrated, for example, through the meaning attributed to cultural artifacts such as the law and medicine.

The historical and contemporary social-scientific analyses of mortality emerge from the four official categories of death: namely, *natural death, accidental death, homicide,* and *suicide*. Instances of death other than natural death, certifiable by an attending physician, must be documented by either a medical pathologist or a physician coroner. The need for such expert certification has long been a matter of contention in the science research literature as well as social policy assessment of this issue.

During the past 70 years, death has been found to be a *fluid* concept, as is noted in the vast social science literature. Indeed, death may be one of the most researched interdisciplinary topics, and for this reason, the analyses of specific types of biological death may be motivated by political and economic interests, especially within the medical research arena, wherein lies a great dependence upon government research funding.

The Early Emphases

The study of culture offers insights into the symbolic rituals that serve the need of a society to communicate the meaning of dying and death. The early emphasis on mortality focused on cultural practices specific to death, and this led to the establishment of subareas of interest within individual social sciences. Later, this research would take on an identity of its own, namely interdisciplinary death studies.

The data-gathering effort of the early-19th-century moral statisticians serves as the precursor for the social-scientific study of death. First published in 1897, Émile Durkheim's classic study *Suicide: A Study in Sociology* portrayed the correlates and causes of suicide, thereby setting the path for future concern with methodology in social science. At the same time, the cultural anthropological analyses of death-related cultural values, social rituals, and ceremonial rites also were to prove important to the evolution of this concept. Moreover, the development of probability theory and statistics in Europe during the latter part of the 19th century and the adoption of these methods by U.S. scholars were to have a profound effect on the study of death, especially in the application of actuarial tables to age-specific calculation of life insurance policies.

The 1920s brought a significant gain in the role of death-related research and the beginning of the death awareness movement. Three decades later, accounts of death camps and the reported annihilation of millions of civilians focused the public's attention on the reality of death, a reality that was introduced into homes and vividly portrayed through television. Finally, the writings of the displaced European intellectuals in the aftermath of World War II enhanced scholarly interest in the social aspects of death.

Death and Dying Movement

During the 1960s, 1970s, and 1980s, the mortality concept became a focal point of the death and dying movement. This movement transcended specific discipline boundaries to spawn a large and varied cultural and social structural dying and death literature. Each decade was to witness a few publications of special importance among the general population and a community of scholars.

Important examples include the 1959 work edited by Herman Feifel and titled *The Meaning of Death,* a book that arguably established the requisite foundation for the study of death; the exposé of the funeral industry, especially the high cost of funerals noted in the popular report *The American Way of Death,*

published in 1963; and, 10 years later, an assessment of the public perspective in *The Denial of Death,* a book by Ernest Becker. Furthermore, these research efforts included the assessment of the respective roles of the general physician and elected officials/medical examiners, such as coroners, and the evolving role of highly trained medical pathologists.

Exponential Growth of Higher Education and a New Academic Discipline

Early thematic social science books and edited anthologies underscore the topics that capture the attention of the public and members of academe. As the sociologist Robert Fulton declared in a personal communiqué, the 1960s was (to be) the decade for the study of one aspect of death, namely, suicide.

Soon, classes in death and dying were introduced into the growing North American and Western European college and university curricula. The emphasis that began in the late 1950s became more accepted throughout the following decades, as the study of death and dying became an important component of university and college course offerings. By the mid-1970s, interdisciplinary academic departments were formed, and thousands of classes that related to death and dying and other aspects of the human condition were offered.

The cross-cultural research proliferated to include topics such as bereavement and grieving; the respective roles of the dying patient and loved ones; the effects of tobacco; intimacy/sexuality; methods of death; the demography of death; the death care industry; religion and death; funerals and funeral facilities; the meaning of death, hospice, suicide, criminal homicide, drug-related deaths, art of death, fear of death, the role of religion; and age-related views of death. During the next several decades, other areas of research and clinical interest emerged.

The Application of New Knowledge

More recent insights into death and the human condition extend far beyond the earlier considerations. Noteworthy are euthanasia, rational suicide, reevaluations of fear and the social recognition of death, religion and death perceptions, and esoteric topics such as cryonics. Included also in this assessment are the laws relating to funeral and burial practices.

Important research also focuses on child and adolescent bereavement and short- and long-term consequences of the death of a parent. Other noteworthy areas include issues relating to the dying process and topics focusing on the living. All enhance the need to understand the complex litigious and social issues that heretofore were taboo topics, such as medical mistakes and wrongful death. Additional topics include pet cemeteries, drive-through funerals, and perpetual memorials.

In sum, death studies emerged as an interdisciplinary entity, and social scientists continue their quest to learn more about the macro- and microsocial organization of death-related activity. It is expected that future death-related insights will be gleaned from the multicultural aspects of death. Among these areas of interest will be a continuing focus on organ transplants; the funeral process; cyberspace memorialization; cremation; social control and death; the demographics of death; quality of life among an increasing aged, worldwide population; the respective changed roles of the clergy, funeral directors, and grief counselors; hospice; and a changed infrastructure for the expected incapacity of a growing number of the terminally ill.

Questions continue to be raised. These include issues relating to organ transplants, death notification, the need to conduct autopsies, community responses to death, and survival in the aftermath of natural disasters, such as tornados, hurricanes, and flooding, and megadeaths resulting from disasters of human origin.

Debunking Social Science

To say that a subject has been "debunked" is to imply that despite its pretensions toward fulfilling some grandiose standard, it has fallen so radically short that its claims are revealed as not merely false but in some sense fraudulent. When one speaks of debunking social science, the customary argument is between those who contend that social science is on par with natural science—in theory if not quite yet in practice—and those who assert that the social sciences are just too soft in their methodology and too shot through with ideology to be taken seriously as sciences.

It is important to realize that apart from the question of whether the social sciences have actually succeeded in meeting scientific standards, there is a prior debate about whether they should even be trying to be scientific. One can, that is, attempt to debunk not only the idea of whether the social sciences have succeeded in fulfilling the scientific ideal but also whether the emulation of scientific standards is an appropriate ideal in the study of human behavior in the first place.

The claim that social science should (and could) meet scientific standards goes back at least to the Enlightenment, when the fruits of the Scientific Revolution began to shape our understanding of the natural world and held out the prospect that similar success might be enjoyed by those inquiries that emulated scientific methodology. If the foundation for social science is the desire to get to the truth about what causes human action, some have felt, what better way to get there than to embrace the empirical and experimental method that has given us the best basis for objective knowledge in human history?

Others have held, however, that this is a false ideal and that the problem is with the standard itself, since not even the natural sciences can live up to the logic of science that has been limned by philosophers. The idea here is that one needs to debunk not only social science but natural science as well, given recent philosophical work that purport to show that rampant sexism and racism pervade the allegedly "objective" investigation of the natural world, as well as other speculations having to do with the relativity and social construction of human knowledge.

Many have disagreed with such claims, however, and have held that they are belied not only by the internal problems within postmodern theory but also by the practical success of natural science. On this view, the problem is more specific to the social sciences. In the natural sciences, some have argued, we have done the best job that we can of eschewing ideology and making empirical compensations for human fallibility. But in the social sciences, the underlying problem exists not just in the alleged foibles of the investigator but in the very subject under inquiry. Humans are conscious; they may even have free will. As such, their behavior is subject to such a complicated set of self-referring influences and spontaneous causes that any piece of behavior must be accepted as open-ended. Science is just not possible, they claim, when one has a subject matter that is capable of such constant and unpredictable change.

There inevitably follows the question of whether social science *can* be more scientific. Until recently, many people on both sides of the debate about *whether* social science should be more scientific believed that it had done a poor job of living up to the standards set by natural-scientific investigation. Over and above the theoretical problems of how to contend with explanation in an open system, many felt that there are intractable practical problems in devising a better methodology for the social sciences, due to the corrupting influence of political ideology, cherry picking favorable results, failure to change one's theory in the face of falsifying instances, and ethical barriers to human experimentation, which had conspired to hobble the success of human inquiry. Recent work in the field of behavioral economics, however, has shown that it is possible to use better methodological techniques to contend with such problems, even if one cannot use them to decide questions such as free will.

Whether it is possible for the social sciences to build on this success and continue to make human behavior more predictable (and explicable) in the rest of the social sciences, however, must be seen as separate from the truth or falsity of any single theory. For one must recognize that all scientific theories—even well-accepted ones from natural science—are subject to empirical refutation. Isaac Newton's theory of gravity, for instance, is technically speaking false, but few would be so rash as to dismiss it as unscientific. To say that a theory is refuted by the evidence is not, therefore, to say that it has been debunked, for to debunk a claim is to show that it never had any business pretending to

the status that it had claimed for itself, which is different from saying (as in "refutation") that although the theory might have been true if the world had turned out to be a different place, it simply wasn't true given the way the world happens to be.

In this way, as more and more social-scientific theories are assessed not on their conformity with some abstract philosophical ideal but rather by their empirical success, one may discover that it is possible for the study of human behavior to hew more closely to the standards of scientific explanation. For even if this standard is still subject to the claim that it should be debunked, it is significant to note that this would amount to more than a mere debunking of social science, as it would require us also to recognize that all scientific theories—whether they are true or not—are trying to live up to the same ideal of finding true causal explanations.

Decision Theory

Decision Theory is the theoretical study of decision making. Sometimes the term *Decision Theory* is used in a broad sense. It then includes game theory and Social Choice Theory. However, in many contexts, Decision Theory refers to the theoretical study of decisions taken by a single agent in which the outcome is independent of what other agents do. This entry follows that convention and discusses Decision Theory from this more restricted point of view, which is widely accepted in the literature.

Theories of decision making are commonly divided into *normative* theories and *descriptive* ones. The aim of normative decision theories is to formulate a coherent view about what we ought to do given the information about the world available to us at the point of making the decision. Descriptive decision theories on the other hand seek to describe—that is, explain and predict—how people actually make decisions. Numerous empirical studies have shown that people frequently violate the recommendations of the most well-established normative theories.

Maximizing Expected Value

The history of normative Decision Theory began in 1654, as Blaise Pascal and Pierre de Fermat developed the concept of probability, which they used for analyzing which bets or gambles a rational player would accept. A few years later, in a book by Antoine Arnauld and Pierre Nicole (1662/1996) commonly known as the *Port Royal Logic,* we find the first precise formulation of what is still the most widely accepted decision rule among decision theorists, namely, the principle of maximizing expected value:

> In order to judge of what we ought to do in order to obtain a good and to avoid an evil, it is necessary to consider not only the good and evil in themselves, but also the probability of their happening and not happening, and to regard geometrically the proportion which all these things have, taken together. (p. 274)

Let us illustrate this decision rule in a concrete example. Imagine, for instance, that you wish to figure out whether it is worth paying £30 for travel insurance that would cover your medical expenses if you were to get ill when visiting a foreign country. Whether it is rational to buy this insurance arguably depends on how likely it is that you will get ill, as well as on the cost of medical treatment in the country you plan to visit. Suppose that you find out, in one way or another, that one person per 1,000 travelers gets ill in the country you plan to visit and that the typical cost for medical treatment is £5,000. This means that if you pay £30 you can avoid a probability of .001 of having to pay £5,000. Would it be rational to take out such an insurance policy?

The principle of maximizing expected value prescribes that an act is rational if and only if its

expected monetary value is at least as high as that of every other alternative act. The expected value of an act is defined as the sum total of the values of all possible outcomes, weighted by the probability of each outcome. In our example, there are two alternative acts: buy insurance or do not. Each act will result in exactly one of two possible outcomes: You either get ill or you do not. This entails that the expected monetary value of buying the insurance is –£30 + .001 × £5,000 = –£25, whereas the expected monetary value of not buying it is .001 × £5,000 = –£5. It therefore seems that we have to conclude that it would not be rational to buy the insurance.

The Concept of Utility

Throughout the history of Decision Theory, scholars have discussed how to exactly formulate the principle of maximizing expected value. In 1738, Daniel Bernoulli pointed out that it is not an act's expected *monetary* value that matters but rather what we nowadays call its expected *utility.* The concept of utility is much broader and includes all aspects of an outcome that decision makers may care about, such as the fact that one would perhaps feel safer if one buys travel insurance before visiting a foreign country. Moreover, as pointed out already by Bernoulli, many people have a decreasing marginal utility for money. This means that a large amount of money is not worth twice as much to you as half of the large amount. The first million you earn typically matters more to you than the second. Therefore, decision theorists seeking to apply the principle of maximizing expected value need to find ways of replacing the monetary values of all the possible outcomes with some linear representation of value, and the concept of utility is designed to do exactly that. By definition, the difference in utility between 2 million units of utility and 1 million is exactly as large as the difference in utility between 1 million and 0 units.

Modern research in Decision Theory has been dominated by attempts to construct axiomatic arguments for the principle of maximizing expected utility. The agenda for this endeavor was set by Frank Ramsey's paper "Truth and Probability," written in 1926 but published posthumously in 1931. In this paper, Ramsey proposed a set of eight axioms for how rational decision makers ought to choose among uncertain prospects. He noted that a decision maker who acts in ways that are compatible with his axioms will always perform acts that are *compatible* with the principle of maximizing expected utility, by *implicitly* assigning numerical probabilities and utilities to outcomes. However, Ramsey did not claim that the decision maker's choices were *actually triggered* by these implicit probabilities and utilities.

Another important point of departure for modern work in Decision Theory is John von Neumann and Oscar Morgenstern's book *Theory of Games and Economic Behavior,* in particular the second edition published in 1947. In that edition, they presented a set of axioms for how rational decision makers ought to choose among lotteries. The term *lottery* is used here in a broad sense. Imagine, for example, that you prefer a BMW to a Volvo, and a Volvo to a Ford, and that you are indifferent between getting a Volvo for certain and a 50:50 chance of getting a BMW or a Ford. Then, a BMW is worth 1, a Volvo 0.5, and a Ford 0 (or any positive linear transformation of these numbers) on your personal utility scale. Why? Because given that you evaluate lotteries in coherent ways, your preferences have revealed how much value (utility) you place on the three cars. This means that your utility function for cars is *defined* in terms of preferences over lotteries.

Von Neumann and Morgenstern showed that every decision maker who acts in accordance with their axioms implicitly behaves in accordance with the principle of maximizing expected utility. This means that we can assign numerical utilities to outcomes that help us explain and predict how the decision maker will behave in the future. The main difference between von Neumann and Morgenstern's work and that of Ramsey is that Ramsey also presented a novel (subjective) theory of probability. In his 1954 book *The Foundations of Statistics,* Leonard Savage presented a somewhat different but also very influential axiomatic analysis of the principle of maximizing expected utility. Many of Savage's ideas can be found in Ramsey's paper.

Bayesian Decision Theory

Explicit discussions of which act to perform in a given situation are only a minor part of what Decision Theory is about. The key issue in the contemporary debate is, rather, how basic concepts such as preference, utility, probability, and expected utility should be defined and interpreted. For many years, the dominating view has been something called

Bayesian Decision Theory—after Thomas Bayes, the English mathematician and Presbyterian minister (1701–1761). Bayesians claim that probabilities are subjective degrees of belief that should be updated in light of new evidence by applying Bayes's theorem. This theorem, also known as the *reversed probability law,* says in its simplest form that the probability of event A given event B is equal to the probability of A multiplied by the probability of B given A, divided by the probability of B. (Note that Bayes's theorem follows deductively from the axioms of the probability calculus, so its truth is not open to any fruitful criticism or disagreement, but its scope and relevance are.) Bayesians furthermore maintain that probabilities are subjective degrees that should be defined, together with utilities, in terms of preferences over risky gambles, which can in turn be used for indirectly justifying the principle of maximizing expected utility.

The assumption that preferences are revealed in choices can be criticized. One objection is that we sometimes seem to *be,* and *feel,* uncertain about our own preferences. Suppose, for instance, that Anne is about to vote in an upcoming election. She knows for certain that she prefers both the Liberal Party candidate (L) and the Conservative Party candidate (C) over the candidate representing the Communist Party. But she is uncertain about her preference between the Liberal candidate and the Conservative candidate. In a traditional theory of preference, all one can say about this situation is that Anne's preference ordering is incomplete; that is, all of the following are false: L is preferred to C, C is preferred to L, and L and C are indifferent. However, such an analysis overlooks significant aspects. Suppose, for example, that Anne is almost sure that she prefers the Liberal candidate and feels that she would vote for that candidate 9 times out of 10 (not changing any of her mental dispositions). If this is the case, it is not reasonable to maintain that Anne, at each point of time, has a certain preference and that this preference wobbles between L and C; the concept of uncertain preference models the situation better.

Another objection to Bayesian Decision Theory is that from a linguistic point of view it seems rather odd to say that the *meaning* of utility has something to do with preferences among uncertain prospects. Even a decision maker who believes that she lives in a deterministic world—that is, a world in which every act has a well-determined outcome—can meaningfully say that the utility of some certain outcome is higher than the utility of another certain outcome. Although orthodox Bayesians never assign probability 1 or 0 to any outcomes, it seems that this inability to account for our considered intuitions in this type of case is a serious problem.

Objections to the Expected Utility Principle

A lot of recent work in Decision Theory aims to cast doubt on the principle of maximizing expected utility, as both a normative principle as well as a descriptive claim. The starting point for much of this criticism is a famous example discussed by Maurice Allais in the 1950s. Consider the following lotteries, in which exactly one winning ticket will be drawn at random.

Empirical studies by Daniel Kahneman and Amos Tversky and others show that in a choice between Lottery 1 and Lottery 2 about 80% of ordinary people prefer Lottery 1. From a normative point of view, this seems very reasonable, since Lottery 1 gives the decision maker £10 million for sure. Moreover, the same empirical studies also show that in a choice between Lottery 3 and Lottery 4 about 80% feel that it is rational sense to trade a ten-in-hundred chance of getting £50 million against a 1 in 100 risk of getting nothing, and consequently, they prefer Lottery 4. However, the point of the example is that no matter what utility one assigns to money, the principle of maximizing expected utility recommends that the decision maker prefer Lottery 1 to Lottery 2 *if and only if* Lottery 3 is preferred to Lottery 4. There is simply no utility function such that the principle of maximizing utility is consistent with a preference for Lottery 1 to Lottery 2 *and* a preference for Lottery 4 to Lottery 3. In order to prove this, we calculate the *difference* in expected utility between the two pairs of lotteries. The probability that Ticket 1 will be drawn is .01, and the probability that one of the tickets numbered 2 to 11 will be drawn is .1; hence, the probability that one

	Ticket No. 1	*Ticket No. 2–11*	*Ticket No. 12–100*
Lottery 1	£10 million	£10 million	£10 million
Lottery 2	£0	£50 million	£10 million
Lottery 3	£10 million	£10 million	£0
Lottery 4	£0	£50 million	£0

of the tickets numbered 12 to 100 will be drawn is .89. We, thus, have the following equations:

$$u(\mathrm{L1}) - (u(\mathrm{L2}) = u(1\mathrm{M}) - [.01u(0\mathrm{M}) + .1u(5\mathrm{M}) + 0.89u(1\mathrm{M})] = .11u(1\mathrm{M}) - [.01u(0) + .1u(5\mathrm{M})] \quad (1)$$

$$u(\mathrm{L3}) - u(\mathrm{L4}) = [.11u(1\mathrm{M}) + .89u(0)] - [.9u(0\mathrm{M}) + .1u(5\mathrm{M})] = .11u(1\mathrm{M}) - [.01u(0) + .1u(5\mathrm{M})], \quad (2)$$

where L represents Lottery and M represents million.

By looking at Equations 1 and 2, we see that the difference in expected utility between L1 and L2 is the same as the difference between L3 and L4. We can therefore conclude that no matter what the decision maker's utility of money is, it is impossible to simultaneously prefer L1 to L2 *and* to prefer L4 to L3 without violating the expected utility principle. However, since many people still think it would be rational to stick to the preference pattern described above, it seems that there is something wrong with the expected utility principle.

Decisions Under Ignorance

Scholars who reject subjective theories of probabilities (according to which probabilities are subjective degrees of belief) think that there are decision problems in which it would be meaningless to ascribe probabilities to outcomes. Imagine, for instance, that you are thinking about getting married to your fiancé. What is the (objective) probability that your particular marriage would be a happy one? It would obviously make little sense to study other marriages, since every marriage is unique. Decision theorists call this type of decision, in which you do not know the probabilities of the possible outcomes, "decisions, under *ignorance*" (or under *uncertainty*). Two of the most influential decision rules for dealing with decisions under ignorance are the *maximin* rule and the *principle of insufficient reason*. The maximin rule was famously discussed by John Rawls in his work on justice. The key idea behind this rule is that the decision maker should *maximize* the *minimal* value obtainable with each alternative act. If the worst possible outcome of getting married is worse than the worst possible outcome of remaining unmarried, then it is rational to refuse marriage.

The principle of insufficient reason, as proposed by Bernoulli and Pierre-Simon Laplace, urges us to transform our ignorance about the relevant probabilities into a decision under risk by assigning *equal* probabilities to all possible outcomes of an act. That is, if one has *no* reason to think that one outcome is more probable than another, then all outcomes should be assigned equal probability. It is sometimes objected that it seems completely arbitrary to infer that all outcomes are equally probable if one has no reason to think that one outcome is more probable than another. In such a case, it seems strange to conclude anything at all about probabilities.

Some Contemporary Problems in Decision Theory

An important debate in contemporary Decision Theory concerns the controversy over *causal* and *evidential* Decision Theory. In many decision problems, the decision maker's beliefs about causal processes play a significant role. However, it is very difficult to give a convincing explanation of what role beliefs about causal process should be allowed to play, as illustrated in an example known as the *smoking lesion*. We know that smoking is strongly correlated with lung cancer; but imagine that in some remote world, lung cancer and the urge to smoke have a common, perhaps genetic, cause. In that world, smoking does not cause cancer; the two are rather effects of a common cause. Now imagine that you prefer smoking without cancer to not smoking without cancer and that you also prefer smoking with cancer to not smoking with cancer. Given these assumptions, would it be rational to smoke? Although you may have a strong intuition about what it would be rational to do in this case, there are other, structurally similar cases that are much harder to analyze.

Another major subfield of modern Decision Theory is multi-attribute Decision Theory. While in a single-attribute approach all outcomes are compared on a single utility scale, multi-attribute approaches seek to evaluate the outcomes along the scale deemed to be the most appropriate for the type of value at stake. Imagine, for instance, that we have to decide whether it is worth spending £10 million on a program that aims to increase road safety by saving one extra statistical life per year or whether it would be better to spend the money on reducing the number of nonlethal accidents aboard fishing

vessels. Many people think that such direct comparisons between the value of a human life, money, and other types of accidents are impossible, meaning that these entities are incomparable values. Now, multi-attribute Decision Theory seeks to avoid the criticism that, for example, money and human welfare are incomparable values by relaxing the assumption that all outcomes have to be compared on a common scale. In multi-attribute Decision Theory, each type of value is measured in the unit considered to be the most suitable for that value. While money appears to be the right unit to use for measuring financial costs, the number of quality-adjusted life-years might be the unit we should use for measuring human welfare. The total value of an alternative act is then calculated by aggregating the different values into an overall ranking of the available alternatives.

DEDUCTION

In ordinary language, the term *deduction* vaguely refers to a kind of activity in which we all are involved when we try to solve theoretical or practical problems: drawing conclusions from given premises. In logical theory, the term has a more precise meaning and refers to the special case in which the conclusion is *indisputably* justified on the basis of the premises. Deductive reasoning plays a pervasive role in philosophical and scientific practice as well as in everyday problem solving and decision making, and the ability of a "rational agent" to perform deductive inferences (no matter how complex) is an idealized assumption of some economical, political, and ethical theories.

This entry offers an informal overview of the general concept of deduction. A rigorous treatment is the subject of formal logic.

From a linguistic viewpoint, an *inference* consists of a list of sentences (premises) followed by words like *hence, thus,* or *therefore* and then by another sentence (the "conclusion"). Consider the following two examples:

A:	B:
1. All ravens are black.	1. All ravens observed so far are black.
2. Mr. Poe is a raven.	2. Mr. Poe is a raven.
Therefore: Mr. Poe is black.	Therefore: Mr. Poe is black.

In both examples, the premises provide some justification for asserting the conclusion. However, in Inference A, the justification is as strong as it gets: No rational agent can fail to recognize that its conclusion must *certainly* be true in all situations in which the premises are true. This is what we mean by saying that A is *deductively sound*. In contrast, it is perfectly conceivable that the premises of B are true while its conclusion is false. So B is not deductively sound and (much) harder to justify. According to some authors—most eminently Karl

Popper in his *Logic of Scientific Discovery*—it cannot be justified at all. According to others—most eminently Bertrand Russell in his *The Problems of Philosophy*—it may be justified by a general "principle of induction" and thereby regarded as *inductively* sound.

In order to recognize that A is sound, we do not need to understand the meaning of "raven" and "black," or the denotation of "Mr. Poe." Indeed, all these words could be substituted by other words, such as *whales, white,* and *Moby Dick,* without affecting the soundness of the inference. However, substituting "all" with "some" would yield an obviously unsound inference. Hence, the soundness of A depends only on the meaning of "all." A word whose meaning is essential for recognizing the soundness of an inference is called a *logical word* or *logical constant*. The other words are called *extralogical* and can be replaced by schematic letters. So the general form of A is as follows:

A*:

1. All *U* are *V*.

2. *x* is *U*.

Therefore: *x* is *V*.

A schematic inference such as A* is called an *inference rule*. The soundness of all its instances can be immediately recognized by any agent who understands the meaning of "all." (Indeed, some authors maintain that the meaning of a logical word can be completely defined by exhibiting simple inference rules, such as A*, showing how the logical word can be legitimately used in inference.) So, recognizing that an inference is deductively sound, in the simplest cases, is just part of our linguistic competence. This is why deductive reasoning has often been described as "analytic," and it has been maintained, especially by logical neopositivists, that it conveys no new information. (This claim, however, is intuitively implausible, and Jaakko Hintikka has called it a true "scandal of deduction.")

When the inference is not an instance of any basic inference rule, and so its soundness is not immediately obvious, we may still be able to fill the gap between premises and conclusion by constructing a *deduction*—that is, a sequence of "steps" each of which is an instance of some obviously sound rule. If we fail, we can try to show that the inference is *not* sound by exhibiting a counterexample, namely, a possible situation in which the premises are true but the conclusion is not.

This is, however, only the skeleton of a suitable notion of deduction. Specific notions are obtained by specifying which words are to be regarded as logical and the basic inference rules that capture their meaning. In classical logic—whose modern roots can be found in the works of George Boole, Gottlob Frege, Ludwig Wittgenstein, Bertrand Russell, David Hilbert, and Alfred Tarski—the logical words are the Boolean operators "and," "or" (in its inclusive sense), and "not," plus the quantifiers "all" and "some." These logical words allow also for an approximation of the conditional "if *P*, then *Q*"—defined as "not-(*P* and not-*Q*)"—which works reasonably well in mathematical contexts but is quite removed from ordinary usage in most of the others. (This meaning of the conditional operator was proposed by Philo of Megara in antiquity and was already criticized by the Stoic Chrysippus, who proposed an alternative definition that can be related to C. I. Lewis's *strict conditional*.)

The classical meaning of the logical words is intertwined with the Aristotelian "Principle of Bivalence," according to which a sentence is determinately either true or false, independently of our epistemic means for recognizing its truth or falsity. This hidden metaphysical assumption provided the *intuitionists* a strong motivation for rejecting the soundness of all inferences depending on it—such as the rule of proof *ex absurdo,* by which means one shows that the conclusion follows from the premises by showing that its negation is inconsistent with them—on the grounds of their mathematical anti-realism. Other nonclassical logics that have been proposed in the 20th century depart from the classical paradigm either because, like intuitionistic logic, they reject some classical inferences as unsound (this is the case of Relevance Logic) or because they extend the stock of logical words (this is the case of modal and epistemic logics). As a result of recent developments, especially in the areas of nonmonotonic, substructural, paraconsistent, and quantum logics, the classical paradigm has been replaced by a proliferation of logical theories that are perceived as fulfilling different application needs rather than competing with each other, and the very concept of deduction has been considerably stretched far beyond its standard meaning discussed in this entry.

Deontic Logic and Agency

Deontic Logic is the branch of formal logic that aims to model the reasoning of agents who are subject to obligations, prohibitions, and permissions relative to a normative system. *Agency* is the philosophical term for an agent's capacity to influence the possible courses of history our world can take. For a thorough understanding of both, Deontic Logic and theories of agency are often studied in combination.

Obligations, permissions, and prohibitions are always defined relative to a normative system. These normative systems come in various forms. They can be private and determine an agent's response to personal attitudes, such as when an agent believes she has the duty to do something with her talents. Or they may live in what John Searle calls *social reality,* such as when agents have to adhere to the norms, conventions, or unwritten rules of conduct their membership in a society, culture, or religion brings with it. Or normative systems may be formalized and made explicit in law books, contracts, product user guides, cookbooks, and so on. Deontic Logic aims to mathematically model the reasoning with deontic modalities explicitly or implicitly defined relative to such normative systems.

Although there were earlier attempts at formalizing deontic reasoning, it is generally agreed upon that modern Deontic Logic started with Georg Henrik von Wright's article "Deontic Logic" in 1951. In this work, the three central deontic modalities—obligation, prohibition, and permission—are formalized as the operators of what later came to be known as *Standard Deontic Logic* (SDL), a formalism that logicians nowadays classify as a modal logic of the type KD. Roughly, von Wright's SDL drew two main lines of criticism. The first concerned the fact that its logical operators could not faithfully model conditional obligations, such as "If you help, you have to tell that you will," and so-called contrary-to-duty obligations, such as "You have to help, but if you do not, you should not tell that you will." This led to the study of dyadic Deontic Logic operators for conditional obligations, with dyadic operators O(p|q) read as "Given that q, it is obliged that p." Based on the philosophical viewpoint that if (dyadic) deontic operators represent norms—in other words, think of them as the rules in a law book—they cannot bear truth-values (since they are prescriptive and not descriptive, i.e., they express an "ought" not an "is"), David Makinson transformed the dyadic approach to what he referred to as developing systems of *iterative detachment*. Together with the work of Leon van der Torre, this new approach led to the study of *input–output logics*.

The second type of criticism toward von Wright's SDL concerned the fact that it aims to study deontic modalities in isolation, while in any concrete example of deontic reasoning, modalities of time, action, intention, belief, and so on interfere. It was suggested then that the many counterexamples to the modeling power of SDL that were found—the so-called deontic paradoxes—could be accommodated by extending Deontic Logic with suitable operators for action, time, and knowledge.

In line with this second type of criticism, the concept of *agency* also was observed as missing from the conceptual repertoire of SDL. Agency, as we have seen, is the philosophical term for any agent's apparent capacity to influence the course of history our world can take. Philosophers distinguish here between events and actions. Events might occur without agentive involvement. Actions, though, are always the result of decisions by agents and of the agentive effort to exert these choices. That the phenomenon of agency provokes deep philosophical questions becomes evident right away if one realizes that prima facie it is not clear how to reconcile it

with either causal determinism or indeterminism—namely, with the question of whether human agents are free to choose their action, that is, whether they have free will or, in contrast, are subject to causes they cannot control.

The questions of agency and of Deontic Logic were brought together for the first time in the work of Stig Kanger and further developed by, among others, his student Ingmar Pörn. The intimate relation between normative reasoning and agency becomes clear if we look at the notion of excuse. An agent can be (partially) excused for violating a prohibition if there are reasons for not holding him (completely) responsible for what he did. And an agent can be (partially) excused for not meeting an obligation if there are reasons for not holding him (completely) responsible for what he refrained from doing. It might be, for instance, that another agent was complicit in the wrongdoing or that an act was forced upon an agent by some other agent or that an agent was influenced by other external circumstances beyond her control. Early attempts at formalizing the type of agency that in the context of a normative system and a violation implies culpability focused on the counterfactual condition that an agent can only be held responsible if she could have chosen or acted otherwise. In the early works of Kanger and Pörn, this counterfactual condition was left implicit in the abstract semantics of the agency operators of the logic. Later, Nuel Belnap and John Horty further developed this line of work by adding the branching-time dimension to the models and the language of the logic. This resulted in logics where the central modality for "seeing to it that" (*stit,* for short) equates agency with selecting certain histories (timelines) and excluding others. The formalism enabled them to be more precise about the counterfactual side conditions involved in deliberative agency. This line of work culminated in Horty's influential book on agency and Deontic Logic, which studies different forms of agency, such as individual agency, group agency, strategic agency, and so on, in interaction with different types of normative modalities, such as ought-to-be, ought-to-do, or conditional obligation.

Recent developments in the theory of Deontic Logic and agency have acknowledged the role of epistemic and motivational modalities in the kind of agency that can be classified as nonexcusable culpable conduct. For instance, we might want a logic to reflect that only intentional action can lead to wrongdoing. Or we might want to incorporate that an agent is only responsible for acts he knows he does. By extending the framework of *stit* logic with operators for "knowingly doing," Jan Broersen showed recently how we can formally characterize several levels of *mens rea* (guilty mind) found in the legal literature. To date, many questions in this area are still open. For instance, it is not clear how to formalize group agency of the type where agents collectively know what they are bringing about. Also, it is not clear yet how exactly examples of moral luck can be modeled. Finally, more research will have to be devoted to questions concerning the formalization of partial responsibility, attempt, unsuccessful action, and probabilistic action.

Determinism

The entry reviews some of the core philosophical issues about determinism and forges the links with the social sciences.

Determinism is the philosophical notion not only that every event has a cause but also that every event is the inevitable result of a causal chain that stretches backward in time to infinity. If true, this would mean that there are no random, uncaused events. This notion is controversial enough when applied to the natural world, where it quickly leads to some of the most complex (and unsettled) debates in subatomic physics. But when the notion of determinism is applied to human events, it is perhaps even more controversial, since its truth here would seem to imply that human beings are not in control of their own destinies, because many have felt that determinism is incompatible with free will.

In social science, claims about determinism concern two matters: First, that every piece of human behavior must be caused (which is problematic enough in some circles, since it would seem to imply that a scientific study of human behavior is possible) and, second, that these causes originate outside the person whose behavior we are studying, since each cause was itself presumably the result of some earlier cause that led up to it. In tracing such a line of causation to its origin, we inevitably arrive at a point before the person's birth. And how can one be responsible for this?

All the plans, passions, decisions, and motivations of human life would therefore threaten to be mere epiphenomena; if we are not the author of the events in our lives, but merely the mechanism through which the inevitable chain of events determined before our birth plays itself out, then what is the point of human cognition or accountability? Is the point of human life merely to feel that our actions are meaningful, even if we do not in fact cause them?

Debates about determinism in the social sciences thus quickly involve us in questions about free will, predictability, and moral responsibility for our actions.

Free Will

Is human behavior part of an open system? Are we capable of choosing to do whatever we like? If so, one wonders why we keep seeing the same sorts of tragedies repeat themselves in human affairs over the ages. But if not, some have felt that it is even more of a tragedy because there is nothing that we can do to ameliorate human suffering. Whether human systems are open or not, it seems important to try to square our feeling of freedom with the reality that human behavior seems at times to be highly regular.

Free will cannot mean that human events are totally capricious, for if it did, we could not hope to understand them. Surely, one cannot have a science where there is no regularity. But it also seems true that even a subjective understanding of human events would fail if there were not some close correlation between our inner awareness and the behavior that we (and others) exhibit.

Perhaps, some have argued, such a subjective understanding is consistent with the idea that free will originates in the beliefs and desires that influence human action. Yes, these beliefs and desires may cause our actions, but they also presumably come from us, thus locating the causal origin of human behavior in a place over which we seem to have some degree of control. This idea, however, suffers from the reality that our beliefs and desires at times seem heavily influenced—perhaps unbeknownst to us—by outside events. Even if our beliefs and desires are ours, have we been caused to have them?

This raises the specter that there might be some degree of causal force behind human events, over which we have no control. Would this conflict with free will? Not necessarily, for some might claim here that we are merely ignorant of the reasons behind our actions, even if we are the author of them, and when we someday become enlightened (perhaps through the social sciences), we will be better able to change our behavior simply by changing the beliefs and desires that govern it.

Either way, we would be wise to embark on a more systematic understanding of the causes of human action. Whether our behavior is completely determined or we are, in fact, free but merely ignorant of the ways in which our beliefs and desires have been manipulated by outside forces, it seems important to have a good deal more foreknowledge of how particular decisions on our part can lead to certain outcomes.

Prediction

The prediction of human action has been a goal of the social sciences since their inception. Based on the successful model of Newtonian mechanics, which views prediction and explanation as flip sides

of the same coin, one wonders whether the same could be true for human behavior. Specifically, if human action is determined, there would seem to be, in principle, no barrier to predicting human action with the same degree of precision one might use to predict an eclipse. With deterministic systems, if we understand the causes, then we understand the outcome. But there is a problem, for the types of systems that one is able to predict in Newtonian physics are not conscious and do not intentionally try to defy the predictions that are made about their actions once they become aware of them.

The problem of "reflexive prediction" seems unique to human affairs. But it is not, since natural science does have examples whereby a prediction made about a system comes to foul the very thing that one is trying to predict. (Examples abound, from the mundane, the prediction of an avalanche in a loud voice, to the subtle, the prediction of the momentum of a subatomic particle once we have already discerned its position, as per Heisenberg's Uncertainty Principle.) But given the degree to which such self-awareness is embedded in human consciousness, understanding a prediction being made about us does seem to present a special challenge to forecasting human behavior. If the chairman of the Federal Reserve predicts a rally in the stock market, it may very well happen. Likewise, if one predicts to a chronically tardy friend that he will be late for a movie, one should not be surprised to find him tapping his foot on the sidewalk in defiance when we arrive to find him 5 minutes early. Whether the prediction is "self-fulfilling" or "self-defeating," the complexity of human affairs seems to all but guarantee that any prediction about human action will itself become a link in the causal chain that influences the action in question.

It is important to note, however, that this tendency does not necessarily defeat the determinism of human events, nor does it prove that we have free will. The very fact that humans are regular in their behavioral response to predictions seems significant and may suggest that predictions can at times be used to manipulate human action even when we are trying our best to act freely. Did we predict that our friend would be late precisely because we wanted him to arrive on time for once? But surely, the advocate for free will points out, if he had known this, he could have acted differently, but then so would we, and so on, ad infinitum.

Still, the underlying problem here is one that is endemic to predictions across both the natural and the social sciences, whether determinism is true or not, which is that prediction is practically difficult when dealing with complex systems. Even if human affairs are not actually "open" (as one assumes they would be if we had free will) but are in fact merely "complex" (as they might be if our behavior were determined by multiple factors), it might still prove impractical to predict human affairs. As one sees in meteorology, extremely small influences can be amplified and thus confound a prediction, even when a system is completely causally closed. Whether or not human behavior is, in fact, predictable, therefore, would seem a poor proxy for discerning whether it is determined.

Moral Responsibility

There is yet another area of contrast between human and natural events, and this is that in studying inanimate matter we do not face the question of moral responsibility. If human behavior is determined, some philosophers have argued, then we are not morally responsible for it. If something is outside our control, how can we be praised or blamed for it? Others have claimed, however, that this reasoning does not hold, for even if an event is determined there still might be grounds for assessing moral responsibility; note that we tolerate complete prediction as compatible with moral responsibility in other realms. The classic example is the existence of an omniscient God. If God sees everything, then He can predict our behavior. But if He also gave us free will, then presumably we are nonetheless responsible for our actions, even if God foresaw them. Such "compatibalist" arguments are the source of widespread debate among determinist philosophers.

But there is another side to this paradox that is highlighted by those who reject determinism. If determinism is not true, then there are at least some uncaused human events. But if they are not caused, then they are not caused by me, so how can I be held responsible for them? Here, some philosophers have constructed a causal model to rescue the notion of moral responsibility, even in the face of indeterminism, whereby one has just enough causation to seat the event in the "agent" who is making the decision, but not so much causation that the agent is "caused to cause" her decision. This model too remains a source of controversy among philosophers.

Thus, the notion of human responsibility would seem to hang either on the thread of the success of compatibalist arguments in the face of determinism

or the claim that human free will is the very seat of causal efficacy that lies behind human action.

Epistemological Limits

Should the absence of resolution in the debate over human determinism be a barrier to the social sciences? In particular, should it obstruct the claim that we may pursue a scientific study of human behavior?

It seems inconsistent to argue that the debate over determinism in social science must be resolved in order to move forward in the study of human affairs when we have not yet resolved the issue of determinism in natural science. If anomalous results, like the possibility of violating causal laws at the subatomic level, are possible in physics, then surely this gives us some latitude in the face of insistence that the issue of human determinism must be resolved before we can make progress in the social sciences? After all, there has been plenty of progress in the natural sciences, notwithstanding their own controversies over determinism—witness the continued dispute over quantum mechanics.

Whether determinism is true—either in the social sciences or in some more ultimate sense—the question of whether we can pursue an empirical program of study in the social sciences would seem to rest less on the metaphysical question of whether human action is completely determined than on the epistemological question of how we may come to know the causes that underlie human behavior, whatever be their origin.

Developmental Psychology

This entry looks into the social science of developmental psychology, traces the changes through which it has gone, focuses on its various epistemic aspects, such as research design or the theoretical issues associated with the nature/nurture debate, and goes on to introduce recent developments known as *neuroconstructivism* along with other new directions in the field.

All living organisms change over time. Developmental psychology is the scientific study of change in the perceptual, motor, social, emotional, linguistic, and cognitive capacities of humans. The field used to be mainly restricted to developmental change in the early years, from infancy to childhood; more recently, it has expanded to embrace atypical development (including genetic disorders such as Down syndrome, Williams syndrome, Autism Spectrum Disorder) and development throughout the entire life span (including the prenatal period and old age).

Human development is particularly slow compared with that of other species, and many scientists believe that this is an evolutionary advantage as it allows the human brain to adapt to environmental stimuli, to fine-tune learning, and to become progressively specialized over a lengthy developmental period. From a theoretical perspective, developmental psychology addresses numerous questions, two of which are crucial to understanding change over developmental time: (1) Are developmental changes gradual, or do they emerge rapidly with spurts of new forms of thought and behavior? (2) How do gene expression, brain function, cognitive processes, behavior, and environmental factors interact? The first question addresses the issue of continuity, that is, whether changes occur through progressive accumulation of knowledge or by developmental stages and through critical learning periods. The second question addresses the issue of the weighting of the

contribution of different factors to developmental change.

Developmental Research Design

Research in developmental psychology uses a wide range of different experimental and observational methods and covers both prenatal and postnatal participants. Modern neuroimaging techniques, such as functional magnetic resonance imaging (fMRI) or event-related potentials (ERP), allow researchers to study brain activity associated with a specific cognitive task in vivo. The use of powerful statistical procedures also enables developmental scientists to draw predictions and build models, or trajectories, of both typical and atypical development.

An ideal way to investigate development would be through longitudinal studies, in which researchers study the same individuals throughout a certain period of time. Due to time and cost constraints, cross-sectional designs are often preferred. This allows scientists to test people from different groups who share a similar history. The study of their families and environment also adds crucial information. Increasingly, a focus on individual differences rather than group differences is coming to the fore in developmental research.

Theoretical Issues: The Nature/Nurture Debate

One of the major issues of concern to developmental scientists is the way in which biological predispositions interact with the social environment. What is the relative contribution of nature and nurture to development? Two opposing theoretical perspectives address this relationship: the *biological maturation* and the *environmental learning* frameworks. Theorists of the biological maturation framework share the view that developmental changes are predominantly *endogenous*; that is, they arise from inside the organism in a sequence of genetically predetermined phases. Theories within the environmental learning framework see developmental changes predominantly as the product of *exogenous* causes: that is, they are shaped by environmental factors.

Interactionist Frameworks: Piaget and Vygotsky

The Swiss epistemologist Jean Piaget went beyond the long-standing nature versus nurture debate, addressing the issue of the dynamic of interaction between genes and the environment throughout development. He proposed the *constructivist* theory, according to which children construct sequentially higher levels of knowledge by actively engaging with their environment.

The Russian psychologist Lev Vygotsky also focused on interaction and the dynamic roles of nature and nurture. However, he introduced another factor: culture. In the cultural context framework, the interaction between genes and the environment is mediated by the knowledge transmitted from one generation to another through language, traditions, values, and beliefs.

Beyond Piaget

Piaget's theory of cognitive development was heavily criticized by Neo-Piagetians, in particular for not explaining individual differences in speed of processing and working memory, which regulate the child's ability to solve problems at different levels of complexity. Neo-Piagetian theories also integrate Vygotsky's social-cognitive principles to account for cultural and socioeconomic differences.

Neuroconstructivism

More recent approaches, such as *neuroconstructivism,* incorporate changes in brain circuitry over developmental time. Developmental scientists embracing this framework emphasize the importance of a multidisciplinary approach exploring developmental changes in gene expression, brain, cognition, and environment.

Developmental Change at the Genetic Level

Many studies attempt to map specific genes to specific behaviors. However, gene expression (where in the brain, and how much, protein is expressed) changes over time as a function of environmental influences. These epigenetic changes are becoming increasingly important for understanding development.

Developmental Change at the Neural Level

The structure and function of the human brain change significantly after birth. This is known as *neuroplasticity.* Using modern neuroimaging techniques, studies have shown that brain structure changes as a function of experience, for example, in learning a second language or developing specific skills even in adulthood.

Developmental Change at the Cognitive Level

To better understand cognitive development in normal conditions, modern research has also focused on neurodevelopmental disorders. Within the neuroconstructivist approach, cross-syndrome comparisons of cognitive abilities, such as language acquisition, number processing, and face processing, focus on tracing deficits at the cognitive level back to basic-level impairments in infancy, whose effects cascade over time on the developmental outcome.

Developmental Change at the Environmental Level

The environment is not static either. There are many factors that may affect development in both typical and atypical populations. Socioeconomic status and parental education are two of the most important factors, but modern developmental research also takes into account subtle differences in environmental factors, like the dynamics of interaction between children and caregivers.

New Directions

The nature/nurture debate continues to rage. Modern developmental psychology research has a renewed multidisciplinary focus on individual differences and also on important areas like bilingualism and multiculturalism. New brain imaging methodologies are constantly being developed and adapted to developmental populations, such as functional near-infrared spectroscopy, which provides better spatial resolution than ERP and better temporal resolution than fMRI. This noninvasive method measures neural activity in ways that are suitable for studying changes in brain development during early infancy.

The convergence of multiple methods as well as new experimental and statistical techniques should contribute to resolving the fascinating factors that make human development both similar to and different from that of other species.

Dialectic, in the History of Philosophy

Dialectic is a method or set of methods that is meant to provide a definition of a thing or a concept, which it achieves by reference to opposites in a discursive, step-by-step process of reasoning, through a number of questions and answers. Dialectic first appeared in ancient Greek philosophy and was rethought in its meaning and in its use throughout the history of philosophy, often in critical response to other thinkers. This entry traces the history of the notion of dialectic, and its role in philosophy from ancient times to our own.

Early History

The term *dialectic* (διαλεκτικής) comes from the Greek word *dialegomai,* "to converse with," and is used by Plato throughout his dialogues in order to establish the essence of any item whatsoever. As a set of argumentative methods, dialectic itself comes out of the live oral debates practiced by the Sophists, and most notably by Socrates, intended to demonstrate what a thing is. In Plato's early dialogues, dialectic is often an imitation of the Socratic questioning or discourse, *Sōkratikos logos,* or *elenchus,* which became an established literary genre also used by Socrates's other disciples, including Aeschines and Antisthenes.

Such dialectic is *negative* in that it leads to an apparent dead end or *aporia* in an *elenchic* or refutative dialogue, which, through a number of questions and answers, demonstrates the untenability of the initial thesis or definition. Taken at its extreme, negative dialectic may seem to suggest that any thesis and its antithesis can be equally refuted.

This notion of negative dialectic gives rise to the skepticism of the Middle and New Academy under Arcesilaus and the Stoic Carneades. It is in this sense that one needs to take Aristotle's ascription of the invention of dialectic to the Eleatic Zeno, who argued for the logical impossibility of the existence of the many, since one *can* demonstrate that "many" should be both finite and infinite at the same time. Yet in his later dialogues, Plato also uses dialectic as a positive method for achieving the "unalloyed knowledge" of the being of the forms (in the *Republic*) or of the one and the many (in the *Sophist* and *Parmenides*). As such, dialectic is a "coping stone" of all particular sciences, including mathematical sciences. The later Neo-Platonic philosopher Plotinus radicalizes this understanding of dialectic. For him, dialectic uses ordered reasoning to overcome and abandon discursive thinking, thus achieving Plato's "good beyond being," which is the source and condition of being yet itself is not being.

Dialectic in Plato does not appear as one single method but embraces a number of related logical methods. An example of such a method is *diairesis* ("division"), which establishes the sought-after definition through a number of consequent subdivisions of a concept (e.g., art) into several parts (principally in the later dialogues: *Sophist* or *Statesman*). One can distinguish other dialectical methods (analysis and synthesis, collection, definition, induction, *mesotēs,* i.e., searching for a middle between the extremes of more and less, etc.). Every such method is then only *a* method, a logical tool for achieving the knowledge of the essence of a thing. Since there is no prescribed way to obtain such knowledge, dialectic can be considered an *art, dialektikē tekhnē* (as in Plato's dialogue *Phaedrus*). However, the later tradition takes dialectic as a constitutive, logical part of philosophy, along with practical and theoretical philosophy (as in Alcinous's *Didaskalikos*). This division corresponds to Xenocrates's threefold division of philosophy into logic, ethics, and physics.

As a critique of Plato, Aristotle contrasts dialectic with syllogistic, the proper philosophical method, which alone is capable of understanding being as such, *to ontōs on*. Aristotelian dialectic is based on a seemingly correct opinion and considers only accidental properties; the premises of a dialectical syllogism are only plausible. For Aristotle, dialectic has much in common with rhetoric, insofar as neither considers a particular subject matter but provides logical form and strategies for argumentation.

In the Middle Ages, this led to the inclusion of dialectic, together with grammar, in the *trivium* (the tripartite core of standard medieval liberal studies: grammar, logic, rhetoric) and to the rethinking of dialectic as formal logic, for example, in Abelard's *Dialectica*.

Modern History

Early modern philosophy assimilates the logical subject that has predicates to subjectivity of the *ego* as the autonomous center of theoretical and moral activity. Such subjectivity should be equipped with a universal method of cognition that is seen in a logical method based on exhaustive enumerations arranged in a precise order. The ideal of the method is largely drawn from dialectic and developed in the work of Raimundus Lullus, Rudolph Agricola, and Petrus Ramus, and later in the work of René Descartes and G. W. Leibniz.

In the work of Immanuel Kant, *dialectic* becomes an integral part of his system of theoretical philosophy, but the term is employed with a significantly altered—negative in its connotation—meaning. The Transcendental Dialectic is a critique of reason that attempts in vain to go beyond the limits of possible experience, where reason aspires to achieve complete and absolute knowledge by unduly extending the use of the categories of understanding in an extra-empirical way, which leads to a transcendental illusion. After Kant, the search for a universal method for philosophy and science led German idealism to adopt dialectic as a method allowing for movement from one category to another within the edifice of a systematic philosophy. J. W. Fichte applies dialectic to producing categories out of the "I" and F. W. J. Schelling applies it to understanding nature.

In the work of G. W. F. Hegel, dialectic is given pride of place for becoming the method of building a grand synthesis of all logical, natural, and social phenomena within a philosophical system. Hegel's dialectical method describes the passage from one philosophical determination to another, from logic (being–essence–concept) to the philosophy

of nature to the philosophy of spirit (subjective spirit–objective spirit of institutions–absolute spirit of art, religion, and philosophy). Such development repeatedly occurs in the triadic structure of thesis–antithesis–synthesis (not his own terminology), where the synthetic member is sublated (in Hegel's terminology)—in other words both overcoming and preserving the content of the two previous opposite terms. Central to Hegelian dialectic are (a) postulating the dialectical motion by way of opposites not allowing for mediation, which creates a productive tension for the passage from one term to another, and (b) the distinction between reason (*Vernunft*) and understanding (*Verstand*), where speculative reason is a completed totality and alone is capable of grasping the opposites in their unity, inaccessible to understanding. Both principles are Platonic in origin. Before Hegel, these principles had been used by Nicholas of Cusa, who also accepted the coincidence of opposites in actual infinity or the "absolute maximum," which, due to the suspension of the principle of noncontradiction, can only be grasped nondiscursively by reason and is not accessible to discursive understanding.

In subsequent philosophy and social theory, dialectic often comes as a critical appropriation and rethinking of Hegelian dialectic. Thus, Friedrich Schleiermacher, who originally had construed dialectic as a theory of scientific construction that makes knowledge into an "absolute science," later turned to the Platonic dialogical understanding of dialectic as the art of conversation in the realm of pure thinking. Karl Marx applies Hegel's dialectic to the materialistic understanding of history, where opposites are taken as antagonistic classes whose conflict results in social, economic, and political progress.

Recent History

In his *Negative Dialectics,* Theodor Adorno speaks against the Hegelian totalization, stressing nonidentity and difference that cannot be dialectically overcome and subsumed under the universal. Similarly, in *Truth and Method,* Hans-Georg Gadamer rejects dialectic as a logical system-building method and instead accepts dialectic as the art of leading a genuine conversation and of questioning ever further, thereby returning to the Socratic conversational origin of the Platonic dialectic.

Dialectic, in the Social Sciences

This entry introduces the notion of dialectic and its use in social science, tracing its history with special emphasis on Marx's thought and the Marxist tradition, where the notion loomed large, and concludes by mentioning contemporary developments.

Historical Antecedents

Dialectic is a term from ancient Greek philosophy, denoting a style of argument used by Socrates in the works of Plato (and further specified by him as a certain methodological procedure for discovering definitions, as demonstrated in some of his later dialogues, e.g., *The Statesman*). It refers to a search for truth that proceeds successively through statement and refutation. The method uses logic and rationality rather than entrenched opposition or persuasive rhetoric. It is also described by Plato as a highly

abstract mode of thought accessible only to trained philosophers, because only they can release their minds from the concerns of the phenomenal world and thus know a realm of timeless truth.

This general method was subsequently formalized as positing hypotheses or theses (positive statements), antitheses (negating or contradicting statements), and—through the identification of error or inconsistency—syntheses (new positive statements arising from this process). The concept was revived in 18th-century German philosophical idealism by J. G. Fichte and G. W. F. Hegel. Hegel's own formulation of dialectic purported to grasp opposites in their unity or the positive in the negative. His particular contribution was to claim that in the movement of successive contradictions nothing was ever fully negated but rather was sublated, that is, retained and transcended (*Aufhebung*). Neither used the now famous but overly simplistic triadic formula, thesis–antithesis–synthesis, which originated in contemporary commentary. This triad has been erroneously attributed to Karl Marx and Friedrich Engels, who made the most famous use of dialectic or dialectics in modern times.

Marx's Critique of Hegel's Dialectic

The Hegelian dialectic was a *political* matter for Marx, because the interpretation of Hegel's philosophical legacy was itself a political issue in the German states of the 1830s and 1840s. Hegelian philosophy posited a historically evolving unity between the thought-world of concepts and the world of material experience, rather than a unity existing merely in the perceptions of a conscious individual. By incorporating history, social life, and an overtly political goal of human freedom into his thought, Hegel politicized philosophy.

In Marx's early years, overt political activity was not permitted in what were then aristocratic, monarchical, and highly authoritarian systems. Academic versions of political controversy were somewhat tolerated but were also manipulated for political ends. From 1842, Marx's engagement with Hegel was thus not that of an academic philosopher but rather a political engagement with philosophical issues as a matter of democratic and class-conscious radicalism. Marx's substantial quarrel with Hegel and Hegelians was to do with their politically debilitating view that dialectical motion in thought was somehow the origin of all motion in the world, human and otherwise. Marx referred to this disparagingly as a demiurge.

Marx rarely mentioned dialectic after 1844, when German Hegelians faded from his political horizon. Subsequently, he produced scathing critiques of other would-be Hegelians, such as P. J. Proudhon, author of a dialectical system of economic contradictions. Marx's major writings after that either do not mention dialectic at all or refer to it only briefly.

The Marxist Tradition

After 1859, Marx's friend and occasional collaborator Friedrich Engels undertook a lengthy series of popularizations and commentaries on his work. In these writings, dialectic was claimed to be a central concept in Marx's unique method, which Engels ultimately claimed was equal to, and a synthesis of, the methods of Hegel and Charles Darwin. Engels's clearest definition emerged in a manuscript work, published in Soviet Russia in 1925, in which he formulated three *materialist laws,* purporting to explain nature, history, and thought:

- Transformation of quantity into quality
- Interpenetration of opposites
- Negation of the negation

In that light Marx's occasional comments many years earlier have assumed an importance within this particular interpretive framework.

Marx's later comments on dialectic are in correspondence or in response to reviewers. In one of his most famous remarks, Marx simply said that his dialectic had a rational and political form, including in its comprehension and affirmation of existing conditions a critical recognition of their inevitable negation. In connection with his critical work on political economy, he commented that he had found Hegel's *Logic* very useful in analyzing and presenting conceptual relationships. However, he seldom identified as a materialist, having criticized traditional materialism for its reduction of human activities to timeless and history-less material factors. His new materialism, briefly identified as such, was founded instead on human social activities as they have evolved historically. He focused particularly on developments in industrial production and in corresponding social structures and forms of thought.

From selective interpretations of Marx's and Engels's works, the 20th-century philosophy of *dialectical materialism* evolved within communist and Soviet circles, but this was never accepted in the Western academy. Dissident Marxists influenced by Hegel, such as those in the Frankfurt School, promoted a nontriadic and nonmaterialist form of political criticism and social science in the 1920s and 1930s, using dialectic as a metaphor for their historicism and antipositivism.

Revivals and Developments

From the 1970s, there have been noncommunist revivals of dialectical thinking as a philosophy. These works link the polyvalent interrelatedness of concepts with the critical understanding of social phenomena, particularly capitalism. Dialectical approaches to society and politics have been somewhat overtaken since the 1990s by the "linguistic turn," in which Hegel and other German idealists and phenomenologists represent a major influence. However, this successor tradition also owes a considerable debt to the linguistic philosophy of J. L. Austin and the "language-games" of the later Ludwig Wittgenstein, so it cannot be considered dialectical in any straightforward way.

Dialogical Logic

Dialogical logic (DL) is a novel field that aims at recovering the philosophical and technical links between argumentation, logic (logic as *Agon*), and epistemology, via the development of a pragmatist semantics. This semantics, inspired by both Ludwig Wittgenstein's *language-games* and game-theoretic concepts, provides the basis for the notion of formal strategy by means of which inference is understood dynamically—that is, as a kind of a rational interaction of agents.

The link between argumentation and logic, particularly in the context of the social sciences, may seem self-evident. Moreover, in the writings of modern thinkers, argumentation and argumentation practice have maintained the importance they gained in the time of the ancient Sophists. However, after the decline of formal axiomatics, the aforementioned tie with logic has declined.

This entry presents an overview of the new field of DL and its implications for the social sciences.

Background

In the late 1950s, Paul Lorenzen was the first to introduce a game-based theory of meaning for intuitionistic and classical logic, and it was further developed by Kuno Lorenz—somewhat resembling Socratic dialogues, Arabic theories of debate, and the medieval theory of *Obligationes*. At almost the same time as Lorenzen, Jaakko Hintikka developed a model-theoretical approach known in the literature as *GTS* (Game-Theoretical Semantics). Since then, a number of different game semantics have been studied in logic. Shahid Rahman and collaborators developed what they called *Dialogic* into a general framework for the study of logics such as connexive logic, epistemic logic, free logic, IF logic, linear logic, logic of belief revision, modal logic, nonmonotonic logic, paraconsistent logic, public announcement logic, and relevant logic.

This novel philosophical impulse experienced a parallel renewal in the fields of theoretical computer science and its interface with the social sciences, triggered by the work of Johan van Benthem and collaborators in Amsterdam, who explore thoroughly the interaction between logic and games. New results in linear logic by J.-Y. Girard in the interfaces between

mathematical game theory and logic, on the one hand, and argumentation theory and logic, on the other, resulted in the work of many others, including S. Abramsky, A. Blass, T. Coquand, D. Gabbay, M. Hyland, R. Jagadessan, G. Japaridze, E. Krabbe, H. Prakken, G. Sandu, T. Tulenheimo, D. Walton, and J. Woods, who placed game semantics in the center of a new approach in which logic is understood as a dynamic instrument of inference.

The point underlying dialogical-approach semantics is that those rules that fix meaning may be of more than one type and they determine the kind of reconstruction of an argumentative and/or linguistic practice that a certain sort of language-games called *dialogues* provide. The dialogical approach is not a logic but a *semantic rule–based framework* where different logics could be developed, combined, or compared.

More precisely, in a dialogue, two parties argue about a thesis respecting certain fixed rules. The player who states the thesis is called the Proponent (**P**); the rival is called the Opponent (**O**). Dialogues are designed in such a way that each of the plays ends after a finite number of moves, with one player winning while the other loses. Actions or moves in a dialogue are often understood as *utterances* or as *speech acts*. The point is that the rules of the dialogue do not operate on expressions or sentences isolated from the act of uttering them. The rules are divided into particle rules or rules for logical constants (*Partikelregeln*) and structural rules (*Rahmenregeln*). The structural rules determine the general course of a dialogue game, whereas the particle rules regulate those moves (or utterances) that are requests (to the moves of a rival) and those moves that are answers (to the requests).

Crucial for the dialogical approach and what distinguishes it from all other approaches are the following points (which will be elucidated later in the entry):

- The distinction between local (rules that determine how to challenge and defend a logical constant) and global meaning (general rules on how to play)
- The player independence of local meaning
- The distinction between the play level (winning of a play) and the strategic level (existence of a winning strategy)
- The notion of formal play

Dialogical Logic and Meaning

Local Meaning

Particle Rules: In dialogical logic, the particle rules are said to state the local semantics: What is at stake is only the request and the answer corresponding to the utterance of a given logical constant, rather than the whole context where the logical constant is embedded.

The following displays the particle rules, where X and Y stand for any of the players **O** or **P**:

Utterance:	**X:** $\alpha\vee\beta$ (X utters α *and/or* β//I////I//).
Challenge:	**Y:** ?-$\vee$ (Y requests X to utter one of both sides of the disjunction).
Defense:	**X:** α or **X:** β (X chooses).
Utterance:	**X:** $\alpha\wedge\beta$ (X utters α *and* β//I////I//).
Challenge:	**Y:** ?- $\wedge$L or **Y:** ?- $\wedge$R (Y requests X to utter the left or the right side of the conjunction).
Defense:	**X:** α or **X:** β (X chooses).
Utterance:	**X:** $\alpha\rightarrow\beta$ (X utters *If* α, *then* β).
Challenge:	**Y:** α (Y challenges the conditional by uttering α and requesting X to utter β).
Defense:	X: β.
Utterance:	**X:** $\sim\alpha$ (X utters *It is not the case that* α).
Challenge:	**Y:** α (Y challenges the negation by uttering himself α//I//).
Defense:	—(No defense is available; however, during the game, counterattacks on — might be possible).
Utterance:	**X:** $\forall x\alpha$ (X utters *For every x it is the case that* α).
Challenge:	**Y:** ?- $\forall$x/k (Y challenges the quantifier by choosing k and requesting X to utter αk//I//).
Defense:	**X:** α [x/k].
Utterance:	**X:** $\exists x\alpha$ (X utters *For some x it is the case that* α).
Challenge:	**Y:** ?- $\exists$ (Y requests X to choose one k for which α is the case).
Defense:	**X:** α [x/k].

Local meaning distinguishes between the following types of actions:

a. Choice of declarative utterances (=: disjunction and conjunction)

b. Choice of interrogative utterances involving individual constants (=: quantifiers)

c. Switch of the roles of defender and challenger (=: conditional and negation)

Player Independence: The particle rules are symmetric in the sense that they are player independent. If they were not, the logical constant would mean something for Player X and something else for Player Y. Take the case of chess as analogy: The rules that determine how, say, the knight moves, must hold for both players, the one playing with the white pieces as well as the one playing with the black pieces.

Global Meaning

Structural Rules

(SR 0) (Starting Rule): The initial formula is uttered by **P**. It provides the topic of the argumentation. Moves are alternately uttered by **P** and **O**. Each move that follows the initial formula is either a request or an answer.

(SR 1) (No-Delaying-Tactics Rule): After the move that sets the thesis players **O** and **P**, each chooses a natural number *n* and *m,* respectively (termed their *repetition ranks*). Thereafter, the players move alternately, each move being a request or an answer.

In the course of the dialogue, **O** (**P**) may attack or defend any single (token of an) utterance at most *n* (or *m*) times.

(SR 2) (Formal Rule): **P** may not utter an atomic formula unless **O** uttered it first. Atomic formulae cannot be challenged.

This rule allows us to formulate a notion of validity that does not amount to true in any model but is true *independently* of any model.

The dialogical framework is flexible enough to define what is known as *material dialogues:*

*(SR *2) (Rule for Material Dialogues):* Only atomic formulae standing for true propositions may be uttered. Atomic formulae standing for false propositions cannot be uttered.

(SR 3) (Winning Rule): X wins if it is Y's turn, but he cannot move (either challenge or defend).

Global Meaning

These rules determine the meaning of a formula where a particle occurs as a main operator in every possible play.

(SR 4i) (Intuitionist Rule): In any move, each player may challenge a (complex) formula uttered by his or her partner, or he or she may defend himself or herself against the last challenge that has not yet been defended.

(SR 4c) (Classical Rule): In any move, each player may challenge a (complex) formula uttered by his or her partner, or he or she may defend herself or himself against any challenge (including those challenges that have already been defended once).

Notice that the dialogical framework offers a fine-grained answer to the question: Are intuitionist and classical negation the same negations? Namely, the particle rules are the same, but it is the global meaning that changes.

In the dialogical approach, *validity* is defined via the notion of *winning strategy,* where winning strategy for X means that for any choice of moves by Y, X has at least one possible move at his or her disposal such that he or she (X) wins:

Validity (definition): A formula is "valid" in a certain dialogical system if **P** has a formal winning strategy for this formula.

Thus,

A is classically valid if there is a winning strategy for **P** in the formal dialogue Dc(*A*).

A is intuitionistically valid if there is a winning strategy for **P** in the formal dialogue Dint (*A*).

The main point of the dialogical approach is that dialogues are built from the bottom up, from local semantics (rules on how to challenge and defend a logical constant) to global semantics (rules on how to play) and from global semantics to validity via the notion of strategy (rules on how to win). This establishes the priority of the play level over the winning-strategy level. The levels are to be thought of as defining an order. From the dialogical point of view, to set the meaning of the logical constants via validity is like trying to define the (meaning) moves of the king in the game of chess by the strategic rules of how to win a play. Within the dialogical approach, the more basic step of meaning at the play level is the setting of player-independent particle rules.

Conclusion

One of the main objectives of DL is to motivate—overcoming the boundaries separating analytic

and continental conceptions of philosophy—a cross-fertilization between both computer-assisted approaches (including artificial intelligence) and formal approaches to the logic of argumentation, on the one hand, and informal approaches to reasoning, on the other. Furthermore, the dynamic approach to inference provided by DL should offer a theoretical framework that forges links between the humanities and social sciences in the central areas of concern to public life: informed debate, lucid decision making, and action based on reflection.

Disagreement

Disagreement is of interest to philosophers because it may seem to undermine the possibility of attaining knowledge, or rational, confident opinions, on controversial matters. This entry surveys the main lines of approach to this epistemological problem. Disagreement is, of course, a central feature of social life.

Disagreement is to be expected when different people have different information or when there is a clear disparity in cognitive skills. But difficult issues arise when disagreement occurs between "epistemic peers": people who seem to possess (roughly) equal cognitive skills and who are familiar with (roughly) the same information and/or arguments relevant to the disputed issue.

The intractability of certain kinds of disagreements—for example, ones about what tastes good and perhaps those involving artistic or moral judgments—are sometimes taken to indicate that the relevant subject matters are not really matters of objective fact. But epistemological problems arise from peer disagreement on questions that would seem to be straightforwardly factual. Persistent widespread disagreements of this type arise in history, economics, psychology, and philosophy—even among experts in the relevant fields. Peer disagreements over factual questions also occur in everyday social interactions, as when people disagree over who will win an election or about what their shares of an equally divided restaurant bill come to.

The main question raised by these disagreements is a *normative* one: How should knowing about disagreements by one's peers affect what one believes? Or, alternatively, what is the rational response to learning about peer disagreement? (Related questions also apply to disagreement by one's epistemic

superiors or inferiors, but to make it simpler, most of the discussion focuses on peer disagreement.)

Some have argued that persistent disagreement among experts in fields such as philosophy indicates that whatever methods the experts are using cannot be very reliable (if they were, the experts would tend to converge on the true answer). They have argued that recognizing this unreliability should preclude a person from having confidence in answers to controversial questions in these fields—even when some particular answer seems to her to be strongly supported by the evidence and arguments.

A similar position has been taken with respect to the local disagreements that crop up in ordinary social interactions. If a person finds herself disagreeing with someone she has good reason to regard as an epistemic peer, it is argued that she should realize that one of them has made a mistake, and she should take the possibility that she made the mistake as being at least roughly as likely as the possibility that her peer made the mistake. If she reasons this way, it seems that she should lose confidence in her original belief.

Positions of this sort—which claim that one should often lose confidence in the face of peer disagreement—are sometimes termed "conciliatory." An opposing sort of position holds that one may often rationally retain confidence in one's beliefs, even in the face of peer disagreement; positions of this sort are sometimes called "steadfast." (These labels, of course, refer to opposite directions on a spectrum of possible positions.)

Advocates of steadfast responses to peer disagreement point to the reasons one might have for privileging one's own initial belief over that of one's peer. The most prominent strand of steadfast argument points out that one's initial belief might in fact be well supported by one's initial evidence and arguments; that is, one's peer might have made the mistake. In that case, it is argued, the original evidence and arguments should tilt the balance in favor of one's original belief, and one needn't lose much (or, in the radically steadfast view, any) confidence in one's original belief.

Advocates of conciliatory views argue that this sort of steadfast response begs the question: One cannot rationally rely on one's own initial reasoning—the very reasoning apparently called into question by the peer's disagreement—to support the conclusion that one's peer was the one who made the mistake. On the other hand, advocates of steadfast views argue that conciliatory reactions to disagreement amount to irrationally ignoring or throwing away one's original evidence. Some also worry that conciliatory views lead to an unacceptable degree of skepticism.

It may be a source of worry that inquiry might suffer if people in general lost confidence in their views on controversial topics; perhaps, scientific research goes best when different investigators are committed to different lines of research. But this is compatible with seeing the individual investigator's confidence as irrational; it could be that certain patterns of individual irrationality are conducive to collective scientific progress.

Another avenue of approach to disagreement involves asking whether inquirers (or communities) who follow conciliatory policies do better or worse than inquirers who follow steadfast policies, when it comes to forming accurate beliefs. Some have explored this using mathematical models and computer simulations. This approach often takes beliefs to come in degrees of confidence and takes the aims of inquiry to include having high confidence in truths and low confidence in falsehoods. Different approaches to modeling may involve different assumptions about inquirers and different ways of measuring accuracy. The results of these exercises in modeling are mixed, with no general policy appearing clearly the best.

A more traditionally philosophical approach to the question relates it to other questions about rationally accommodating evidence that one has made a cognitive error. The disagreement of others is one source of such evidence, but one may also get evidence that one is biased, overtired, oxygen deprived, or under the influence of judgment-distorting drugs or psychological manipulation. In reacting to these bits of evidence, the same sort of question arises: If a thinker has initially reasoned correctly, can her rational confidence in her conclusion be undermined by her getting evidence that he's made a cognitive mistake? Again, arguments turn on whether particular responses beg the question, or disregard the original evidence.

Disciplinarity

Disciplinarity may be taken to denote the presence of distinct and well-circumscribed modes of knowledge systematically organized into authoritative bodies of discrete specializations representing different "sciences" or "disciplines" cognitively and institutionally separated from each other. This entry presents aspects of disciplinarity, or lack thereof, dividing "disciplines" within the social sciences into different kinds along that line, and charts the possible historical and political causes behind the genesis of distinct disciplines in the social sciences.

Disciplinarity is less widely discussed than its nominal opposite, interdisciplinarity. For some social scientists, interdisciplinarity is a virtue, albeit one whose philosophical basis is difficult to specify, while disciplinarity is a vice, one whose meaning is clear. For others, adherence to disciplinary norms and methods is a mark of intellectual integrity, while interdisciplinarity is a byword for the inexact study of transient matters. Given the proliferation of (postmodernist) notions that celebrate approaches that favor the "multi-," "trans-," "inter-," "intra-," and so on, methodological routes of study privileging all sorts of "interface," to talk of or defend rigid disciplinarity—independent and self-bounded disciplines, especially in the social science—may sound outmoded to some critics. They claim that disciplinarity is an invention.

A disciplinary attitude is more likely in some social sciences than in others; in economics, political science, or some branches of psychology, a belief that confident generalizations—including causal laws—about social phenomena can be attained using intradisciplinary resources is still common. By contrast, sociology and anthropology have traditionally been more porous, less clearly specialized disciplines, not the least because they have often taken on the task of reflecting on the nature of the social sciences themselves. This distinction between degrees of disciplinarity is related to further distinctions between the degrees of rigidity with which social science disciplines define their object domain and methods, and the ease with which different object domains lend themselves or are claimed to lend themselves to firm intradisciplinary generalizations. Although internal disagreement is endemic to all social sciences, economists and political scientists have traditionally subscribed more readily to claims about the *laws* of the market or the perennial rules of political conflict (e.g., the German sociologist Robert Michel laid down what is known as his "iron law of oligarchy" in 1911) than sociologists or anthropologists have done to claims about the existence of social rules or historical laws.

One common claim in the philosophy of the social sciences is that if this is the case it is because the former disciplines (economics and political science) have an identity based upon an institutionalized body of theory and method, a stable corpus of empirical findings, a clearly bounded object domain, and a "core research program." The originator of the latter term, Imre Lakatos, believed that none of the social sciences were capable of generating one, and curiously enough, many such claims to disciplinary robustness in the social sciences have themselves depended on an appeal to models and modes of data processing taken from the natural sciences. Such models and procedures have occupied an intermediate and in some ways genuinely interdisciplinary zone, being available to a series of individual disciplines that have sought to import them with varying degrees of enthusiasm. Sociology and anthropology have remained the most internally divided social sciences in this respect, with structuralist, structural-functionalist, and systems theory sitting uneasily alongside hermeneutic or interpretive approaches; the sense of disciplinarity here is maintained by an uneasy agreement about the existence of "society" or "culture."

This raises the question of what holds disciplines together, how they maintain their sense of disciplinarity, and how they survive or adapt to historical change. The modern social science disciplines emerged during a particular historical period, adding to or replacing older disciplines, and there is no obvious reason why they should survive in their present form. "The light of cultural problems moves on," Max Weber said, and new object domains emerge, along with new disciplines to study them. Thus, it might be said that economics emerged with the growth of market capitalism; psychology with the growth of more interiorized understandings of the person, attendant on the rise of "bourgeois society"; and sociology with the making of the working class

and the rise of the "social question" in 19th-century Europe. On the other hand, there is much to the claim that those disciplines themselves emerged when they did as part of an internal development within a more strictly discursive field and that, moreover, they helped shape the emergence of those very objects of inquiry. In that case, disciplinarity—and the hard to specify relationship between modern disciplines and modern states—is a driving force of modern history as much as it is a response to it. The question of the precise weight to accord material and ideal factors in intellectual history is a perennial one, and it is illustrated when one considers the recently voiced claims that at the start of the 21st century market capitalism (object of economics) remains stronger than ever while "society" (object of sociology) is disappearing; these claims have been made not by economists but by sociologists themselves.

A final question is whether disciplinarity itself might one day disappear. There are indications that in some areas of the social sciences, disciplines defined by an institutionalized body of theory and method are not only being added to but also supplanted by new types of research activities. These activities both appeal to overtly non–natural-scientific models, notably those found in the humanities, and increasingly identify themselves according to substantive interests or concerns, defined tightly enough to suggest a research field but loosely enough to foster collaborative or interdisciplinary research efforts. University research centers, and sometimes whole departments named after such a substantive area—often going under the title of "X studies"—or the amalgamation of discipline-based departments into "schools," are an indicator of this trend.

The consequences for the social sciences of the increasing popularity of non–natural science methods are variable; the use of hermeneutic methods can appear incongruous in economics or political science or can be seen as an opportunity for innovation. By contrast, it may push disciplines such as sociology or anthropology toward the substantive agendas to be found in cultural studies or take them back to their early-20th-century classics, which still occupied an ill-defined zone between literature and science. It remains an open question whether this proves or disproves the maxim that a discipline that is afraid to forget its founders is doomed.

Discourse Analysis

This entry presents an overview of the field of discourse analysis and all its ramifications, charts its multidisciplinary nature, shows how it has been intricately related to a number of social sciences, and shows its importance both for the humanities and the social sciences.

The Emergence of Discourse Studies Between 1964 and 1974

Discourse analysis, or discourse studies, is a cross-discipline that emerged between 1964 and 1974 in most of the disciplines of the humanities and the social sciences.

In anthropology, arguably the first discipline explicitly focusing on discourse (besides traditional literary studies and classical rhetoric), the ethnography of speaking, most notably represented in the work of Dell Hymes, examined "communicative events"—before the recent development of linguistic anthropology as such.

In linguistics, its main aim was to go beyond the sentence boundaries of structural and generative grammars, with the argument that real language use

takes place in the form of text and talk and not as isolated sentences.

The sociology of everyday life, and especially ethnomethodology, developed the very successful study of conversational interaction, soon also broadly represented in neighboring disciplines.

At the same time, in the early 1970s, cognitive psychology began its first experimental studies of discourse comprehension, while in the field of artificial intelligence, automatic processing of discourse began to be explored together with the representation of knowledge, crucially necessary in all production and comprehension of discourse.

Finally, in the 1980s, social psychology, especially in the United Kingdom, developed its own constructivist "discursive psychology." More recent are developments in communication studies, for instance, of media discourse analysis as well as the study of organizational discourse. Strangely, besides its traditional accounts of political rhetoric, political science has been among the few disciplines in the social sciences in which the explicit and systematic study of text and talk has not yet been introduced successfully. Parallel to these widespread empirical and concrete studies of text and talk in various disciplines, philosophy in the 1960s also knew various (obviously more conceptual) approaches to discourse, most notably represented in the work of Michel Foucault.

Neighboring Developments

It is interesting to observe that in the same period other inter- or cross-disciplines also emerged from within the humanities and the social sciences, often overlapping with discourse studies. Thus, *semiotics,* at first especially in literature, films, and the arts, was one of the developments in structural linguistics and related disciplines, later more broadly concerned with sign systems and semiosis, especially of nonverbal, multimodal messages. Whereas traditional, structural, and generative grammars and linguistics were limited to phonology, syntax, and (later) semantics, the *philosophy of language* proposed the study of *speech acts* and illocution, in what soon would be called *pragmatics*—closely related to discourse and conversation analysis, as was the case with the work of the philosophers John Austin, John Searle, and Paul Grice. The more empirical social and cognitive approaches to language use were the object of studies in the quickly developing interdisciplinary fields of sociolinguistics and psycholinguistics. Even formal (logical, etc.) grammars finally turned to the study of some properties of discourse, such as coherence and coreference, influenced, for example, by the work of the logician Richard Montague on grammar.

Methods and Dimensions of Discourse Studies

Today, the study of discourse has become a major area in virtually all disciplines of the humanities and the social sciences. Whereas earlier grammars hardly offered much more than an abstract and formal approach to some linguistic phenomena (e.g., language learning), multidisciplinary discourse studies offered a very broad and widely applied and applicable approach to the study of text and talk in many aspects of human and social life.

In the social sciences, the label "discourse analysis" is often understood as referring to a *method* of analysis, comparable with traditional *content analysis,* instead of to a (cross-)discipline with many different methods. This is also why the term *discourse studies* is currently preferred to refer to that discipline.

The study of discourse makes use of a variety of methods, many of these also common in the social sciences, such as (various types of) ethnography, participant observation, interviews, life histories, focus groups, document analysis, historiography, action and interaction analysis, laboratory and field experiments, and so on, represented elsewhere in this encyclopedia. It bears to be stressed what is usually forgotten in the application of these methods elsewhere in the social sciences—namely, that the means and products of these methods are mostly forms of text and talk, whose qualitative analysis again would require some kind of discourse analysis.

More typical of qualitative discourse studies is the systematic and explicit analysis of the structures or strategies of spoken or written discourse, for instance, at the following levels of description.

Grammar

Various types of structural, generative, and functional grammars are still dominant in the detailed description of the phonological, syntactic, and semantic structures of sentences. Discourse grammars have gone beyond the scope of the sentence and specifically

focus on local and global coherence, discourse topics (semantic macrostructures), the description of actors and agents, implications, presuppositions, and so on. This remains also the most systematic and explicit approach to discourse, as much of it can be based on quite sophisticated formal approaches. For the social sciences, a detailed *semantic analysis* of text or talk is one of the most interesting linguistic methods to be used in many forms of research, for instance, for the analysis of the ways polarized (Us vs. Them) ideologies are expressed and reproduced by discourse, for instance, by emphasizing Our Good Things and Their Bad Things (and mitigating Our Bad Things and Their Good Things).

Conversation Analysis

No doubt the most popular application of sociological discourse analysis has been the focus on everyday interaction in *conversation analysis*, initially interested in the study of turn-taking of everyday talk but later expanding to many other properties of situated conversation, also in organizational and institutional contexts, such as starting and ending conversations, topic change, storytelling, agreeing and disagreeing, and much more.

Narrative Analysis

Among the various genres and formats of discourse organization and function, narrative has probably been studied the most—besides conversation—beginning with traditional literary studies of narrative. Later, in sociolinguistics as well as in the other social sciences, the focus turned to everyday informal storytelling, for example, as a method of life history analysis.

Argumentation Analysis

Developing from classical rhetoric and dialectics, contemporary argumentation analysis also has found application in many other disciplines, for instance, in law (courtroom interaction) and science (scientific argument). Such analyses study the ways explicit and implicit arguments are formulated in support of a thesis or standpoint, according to the rules and moves of appropriate reasoning and argumentation, that is, avoiding the usual fallacies.

Genre Analysis

Discourse comes in many types or genres, basically defined in terms of the *context* of text and talk, consisting of *setting* (time, place), *participants* (and their *social and communicative identities, roles, and relations*), a *social action* being accomplished by the discourse (e.g., giving a lecture, consulting a doctor), and the *goals and knowledge* of the participants. Such genre analyses systematically study the linguistic and other formal and functional properties of the many kinds of text and talk used in the domains of politics (e.g., parliamentary debates), the mass media (e.g., news, editorials, or soap operas), education (e.g., textbooks and classroom interaction), the bureaucracy (e.g., forms, interaction with clients), the law (e.g., laws, interrogations, testimony), and science (e.g., scholarly articles, reviews), among many others.

Multimodal (Semiotic) Analysis

Discourse is not just verbal but, with the introduction of the computer and the Internet, increasingly multimodal, combining verbal structures with images, sound, and so on. Contemporary social semiotics is developing sophisticated theories for the systematic analysis of such multimodal messages.

Stylistics and Rhetoric

Traditionally associated with literary studies, the study of style and rhetoric also has developed more broadly across disciplinary boundaries, for instance, for the study of the linguistic variation of the syntax and lexicon of text and talk and for the classical ways discourse can be made more persuasive with rhetorical structures ("figures of speech") such as rhyme, repetition, hyperbole, euphemism, metaphor, and metonymy, among many others, functioning to enhance or mitigate the meaning of discourse. The polarized (Us vs. Them) structures of ideological discourse typically use various forms of rhetorical "figures," such as hyperboles and euphemisms, to emphasize or mitigate assumed in-group and out-group properties.

Corpus Analysis

Computers and databases have enabled the storage of vast corpora of text and talk. These corpora allow quantitative and qualitative analyses of thousands of discourses and many millions of words, word combinations and collocations, keywords, syntactic structures, and so on. Especially for the study of large numbers of texts, such analyses have become indispensable in much contemporary discourse studies.

Conclusion

Since its striking emergence in the humanities and social sciences half a century ago, the cross-discipline of discourse studies has come a long way. There is virtually no form of human conduct, interaction, and communication that does not involve the use of language as it is manifested in a vast number of types of text or talk. Multidisciplinary theories and increasingly sophisticated methods of *quantitative* and especially *qualitative* discourse analysis have been developed. These have found widespread application in the study of a large number of social problems, such as the discursive nature of the acquisition and reproduction of ethnic prejudice and racism. More than any other development in the humanities and social sciences, the study of discourse has established multidisciplinary relationships among these disciplines. Discourse is at the same time a form of language use, communication, interaction, social cognition, and power—and hence the interface between micro- and macrostructures of society.

Distributed Cognition and Extended-Mind Theory

It may seem natural to think of the mind as a stream of conscious experience occurring squarely behind the eyes or perhaps as some single, persisting subject of these experiences, hovering in the center of the skull. The past 100 years of scientific thinking about the mind have challenged this view in a variety of ways. The most recent challenge, and the most striking to date, rests partly on the distributed nature of cognition—the fact that intelligent behavior emerges from the interaction of a variety of elements, some of which may be spatially removed from the locus of behavior. From such distributed models of cognition, many authors have inferred the extended-mind thesis, the claim that the mind itself spreads into the world beyond the boundary of the human organism.

Distributed cognitive models have had a direct impact on, and to some extent have been inspired by, research in the social sciences. Studies of insect behavior, for instance, form a bridge between the interests of cognitive scientists and matters to do with group-level behavior: Large numbers of social insects, each of which "mindlessly" follows simple information-processing rules such as "Drop my ball of mud where the pheromonal concentration is the strongest," design elaborate nests. This illustrates both how intelligent-looking results can arise from a distributed—and one might think fairly unintelligent—process and also how their emergence might be social in nature: Environmental conditions induce various subpopulations to play different roles in the life of the insect colony. Some robustly cognitive, human social processes also seem amenable to distributed theorizing: Contemporary scientific results, in particle physics, for example, often involve the contribution of hundreds, or even thousands, of individuals and instruments; here, each individual exercises a rich set of her own cognitive resources while playing a role in a much larger, highly structured enterprise. An intermediate case might be the modeling of traffic patterns: Individual humans can reason in flexible

and complex ways about driving and routes of travel, but constrained by the presence of other automobiles and the surrounding infrastructure, drivers' contributions to traffic flow, and the resulting traffic patterns, have much in common with the large-scale behavioral patterns of social insects.

The remainder of this entry consists of three sections. The first describes distributed cognitive modeling and the extended-mind thesis in more detail. The next section reviews critical reactions to the extended-mind thesis. The final section briefly discusses fruitful areas of ongoing research on distributed cognition and the extended mind.

From Distributed Cognition to the Extended Mind

In the early 20th century, Sigmund Freud proposed that subconscious mental states sometimes drive human behavior, thereby taking a significant step away from the commonsense view of the mind bruited at the outset. Given that the Freudian subconscious deals primarily in emotions and desires, however, Freudian innovations might seem to have little to do with intelligence or rationality per se. In contrast, the cognitivist revolution and its computer model of the mind marked a wholesale departure from the Cartesian view, at least with regard to the role of introspection in the life of reason. The new cognitive science set out to model the mechanisms the operation of which accounts for central aspects of human intelligence—memory, reading, means–end reasoning, perception, speech processing, and so on—with no particular emphasis on consciousness. The overriding goal was to model behavioral data or produce simulations of human-grade performance; it mattered not whether the details of such models jibe with the revelations of introspection. From the standpoint of the new cognitive science, all that matters is that a series of mathematically defined states, causally connected by precisely defined operations, produces intelligent behavior.

The demotion of consciousness together with the focus on mechanisms paved the way for distributed accounts of cognition. If one need not ground one's models in a conscious, first-person perspective, one is free to look for cognitive mechanisms wherever the causal contributors to human behavior might be. Think again of the historical context. The computer model of the mind enjoyed substantial empirical success, but much of this was in artificially limited domains or in the solution of narrowly circumscribed problems. Special-purpose systems can diagnose patients when given lists of symptoms, but such systems do not exhibit human-like intelligence, flexibly and smoothly navigating their way through the real world, in real time.

In response, a new breed of cognitive scientists began searching for a richer—or at least different—set of causal contributors to intelligent behavior—influences that might help produce human behavior without requiring that their contributions take the form of computer code. Much of this research focused on the entire, interactive system of brain, body, and world and, in doing so, cast the constraining influence of environmental structure in a new light. In addition to being a source of input, the environment appears to work together with bodily processes to guide intelligent behavior—both literally, as in navigation, and metaphorically, as when it limits a decision maker's options. The child does not learn to walk via the maturation-based appearance of an innate, internally stored motor program, for example; rather, walking emerges as the joint activity of the child's musculoskeletal system, the solid floor, and gravitational fields, all interacting as physical contributors to a stable cycle of movement through space. The visual system does not explicitly encode the proposition that objects in the environment are likely to be relatively rigid. Instead, the visual system computes the layout of the environment in a way that works effectively only in environments in which most of the objects are rigid. The rigidity assumption is left implicit, and thus, when the visual system functions properly, it does so by pooling its own contributions together with those of an environment that contains rigid objects. Philosophers took notice of, and sometimes contributed to, this developing trend in cognitive science, arguing, for example, that from an evolutionary perspective, we should expect environment-dependent cognitive processing to be widespread.

Into this intellectual foment, Andy Clark and David Chalmers cast "The Extended Mind" and, in doing so, crystallized the vanguard's vision. This vision draws heavily on empirical work related to distributed cognition. For example, a central notion from the literature on distributed cognition is that of an epistemic action. Such actions do not bring the physical world any closer to a state in which the subject's goal has been achieved; instead, epistemic

actions divulge information about how the subject might best pursue her goal. The rearranging of Scrabble tiles on one's rack, for instance, does not change the state of the game board so that it is any closer to having a new, completed word on it; rearranging the letters adds nothing to the board itself. Rather, this epistemic action provides information to the player's cognitive mechanisms so that she might more readily identify a word among her set of letters. Such actions take place partly in the environment, and thus we can see how elements of the problem-solving process itself might be outside the organism. What matters with regard to cognitive-scientific explanation is the role these contributors play in the production of intelligent behavior, not whether the contributors happen to appear within the boundary of skin and skull. Given the plausible additional premise that at least part of one's mind is physically located where one's cognitive processes are located, empirical work on distributed cognitive processing supports the extended-mind thesis.

The preceding style of reasoning also applies to pedestrian mental states such as belief. Perhaps the contents of most of a typical individual's beliefs are neurally encoded. Nevertheless, such contents could be encoded externally—in a trusty notebook, for example—and if these external encodings were to interact with the organism in the right way, they would constitute part of the material basis of human mental states. So long as (a) the subject carries the notebook with her—the information in it reliably available—(b) she trusts what's written in the notebook, and (c) she can fluidly deploy the information stored there, the notebook does not differ relevantly from internal resources, at least with regard to its role in the production of intelligent behavior. Thus, mental states recognized by our traditional, commonsense understanding of ourselves—beliefs, memories, perceptions—can reside, at least partly, beyond the boundary of the human organism. Moreover, new cognition-enhancing technological devices appear almost daily, and thus we can expect this phenomenon to become ever more pervasive.

Critical Reaction

Sometimes proponents of the extended-mind thesis press a merely prejudice-removing agenda; they hope to neutralize readers' internalist biases by showing how cognition and mind *could* comprise environmental states or processes. Illustrative examples (such as the Scrabble example given above) play an indispensable role in this project, but these illustrations often lead double-lives, being meant also to suggest that extended cognition surrounds us in the actual world. Here is where the more substantial question lies: Do cognition and mind actually extend into the environment in deep and substantial ways, extensively enough to ground a revolution in cognitive science and a reconception of ourselves as persons?

Advocates for the extended view typically claim that (a) it constitutes the best interpretation of existing cognitive-scientific results, (b) it offers the most promising framework for future research in cognitive science (even if the existing results don't conclusively support the extended view over its rivals), or (c) it captures the deep nature of the mind—where the plausibility of (c) derives from the plausibility of (a) or (b). It is no surprise, then, that critics often attack the cognitive-scientific basis of the extended-mind thesis.

In this vein, some critics have charged that an extension-friendly cognitive science is bound to lack scientific unity. External objects and states, and the processes in which they participate, differ significantly from the internal ones heretofore fruitfully studied in cognitive science. The behaviorally relevant causal profile of neurally encoded memories, for instance, differs enormously from the causal profile of, say, graphite scratches in a notebook. It may well be useful to study the complex ways in which humans interact with and exploit the environment during problem solving, but the external processes so studied will almost certainly differ in substantive ways from internal ones—at least if attention is directed to real-life cases involving paradigmatic cognitive capacities. As a result, there will be no reason to treat the entire run of states and processes, internal and external, as cognitive—as being of essentially the same kind. This thought is closely related to another: Even when the organism enters into an ongoing causal relation with portions of the environment, that does not by itself extend cognition or mind into the environment. Reasoning to the contrary commits the so-called causal-constitution (or coupling-constitution) fallacy.

Thus, it is demanded that philosophers of cognitive science produce a mark of the cognitive or at the very least some cluster of central traits that tend to qualify a state or process as genuinely cognitive. By adverting to such a mark, proponents of the

extended view might explain what unifies internal and external processes during extended cognitive processing and also make clear the conditions under which an ongoing causal connection brings into existence a fully cognitive process.

Critics themselves have proposed various marks of the cognitive—or at least necessary conditions on something's being genuinely cognitive—to ground their arguments against the extended-mind hypothesis or to undercut arguments in support of the extended view. Mental representations, for example, have played a central theoretical role in cognitive science. Perhaps, then, for a process to be genuinely cognitive, it must consist of the manipulation of representational states—that is, states that picture, refer to, or describe parts of the world. Even if some external units are representational, their representational status derives from our interpretation of them, which is believed to show that external processes are not cognitive in their own right.

A further critical approach contrasts the extended view with others that fall under the general rubric of *situated cognition*. According to one of these, the embodied view, nonneural bodily states or processes constitute significant parts of human cognition. According to another one, the embedded view, human cognitive processing is highly interactive and exploits structure in the environment, even though the external materials don't become proper parts of cognition itself. The critic claims, though, that data thought to support the extended view should be taken to support the embodied or embedded view instead. Once we have established the utility of a persisting cognitive system located in the body and have explained how it interacts with the passing parade of external stimuli and materials, it appears gratuitous to say that when the integrated, persisting cognitive system—typically housed within the body—interacts with the external materials, a new, fully cognitive system comes into being.

For all that's been said, this critical approach might seem to be a washout: The relevant data cohere well enough with either an extended or an embedded–embodied view. But this would be to ignore the central theoretical role of the relatively integrated, persisting *system*. It is the core construct in cognitive-scientific modeling and, as such, seems to offer the most promising basis on which to distinguish merely causal contributors to intelligent behavior from those processes the location of which bears on the location of the mind. All forms of cognitive modeling—computationalist, connectionist, dynamicist, as well as the brute-biological—specify a set of integrated elements and operations governing their interaction; the functioning of this system explains intelligent behavior as the result of interaction between the system and whatever materials or stimuli it happens to come across. On this view, then, being a state of a part of the integrated, relatively persisting system serves as a necessary condition for something's being a genuinely cognitive state. This constitutes a criticism of the extended view only because, and to the extent that, for humans, the integrated, relatively persisting cognitive system appears within the organism.

The consideration of a final critical perspective will bring more clearly into focus the relation between cognition and mind. One might accept that cognition is distributed but think that our enduring and stable conception of the mind should play a winnowing role when we evaluate the implications of distributed models of cognition. It is arguably a central feature of our concept of the mind that it be the locus of control of intelligent behavior. Thus, even if we bracket the demand for a mark of the cognitive and even if the persisting cognitive system stands as merely one element of many in cognitive-scientific modeling, this system has privileged status: It serves as the locus of control of the various forms of behavior cognitive scientists hope to explain; therefore, where we find it, we find the mind. If the integrated, relatively persisting cognitive system appears within the human organism—as seems likely to be the case for most humans, most of the time—then so does the human mind.

Future Directions

Debate about distributed cognition and its philosophical implications remains lively, as does the development and testing of distributed models. Among others, the following areas of research—of particular note in connection with the social sciences—flourish.

Some authors have attempted to characterize mathematically the relevant structural properties of integrated intelligent systems. According to one suggestion, a wide range of networks—including the brain and well-functioning computer networks—exhibit a distinctive trade-off between the specialization of

their components and the sharing of information among those components.

Along similar lines, structural properties have been sought at the level of social groups. For example, memory researchers have found that people who work together to solve problems often take on specialized roles within the group (e.g., with regard to what sort of information they're responsible for remembering); the distribution of such roles facilitates some efforts but may hinder others. This sort of investigation might help us decide whether group minds appear among the extended minds. It also has the potential to contribute substantially to research in the social sciences—from the analysis of voting behavior to the study of the dynamics of online communities.

Last, it's worth emphasizing the contribution dynamical-systems–based approaches have made to the discussion of distributed cognition and the extended-mind thesis. Computer-based and neural-network–based metaphors have dominated research in cognitive science. Nevertheless, a significant minority of cognitive scientists instead view the mind as something more like a physical system in motion, one best described using differential equations that express dependence relations among various continuously interacting quantities. On this view, cognition occurs when the organism enters, even for a short time, into an interdependent relation with physical systems beyond the boundary of the organism—with each component in the system constraining the other in a relationship of ongoing mutual determination. Proponents of such dynamical modeling often claim that cognition and mind permeate the entire system: the organism and the external materials to which it is coupled. It remains to be seen whether the dynamical-systems approach can be used to model paradigmatically cognitive activities such as long-term planning and theoretical reasoning. Nevertheless, exploration of dynamical processes should help us better understand at least some cognition-related interaction between thinkers and their environments.

Duhem-Quine Thesis and the Social Sciences

The so-called Duhem-Quine thesis emerged in the context of Willard Van Orman Quine's challenge to logical positivism/empiricism, first published in his famous "Two Dogmas of Empiricism" in 1951. This challenging thesis is called the Duhem-Quine thesis, not the Quine thesis, because Quine in footnotes attributes it to Pierre Duhem (1861–1916), a French theorist of thermodynamics with an in-depth knowledge of the history of science, who popularized the idea behind the thesis in the memorable phrase "saving

the phenomena"; that is, any body of observable facts can be sustained by suitably adjusted rival explanations against possible counterexamples. Duhem distinguished the physical sciences from metaphysics. Metaphysics, not science, explains the observable world. Thus, contrary to scientific realism, which claims that science explains the empirical world, Duhem argues that physical theory is merely a system of mathematical equations that sums up experimental laws. Despite Quine, it should be noted that the consensus among Duhemian scholars is that Duhem's views should not be conflated with those of Quine. Nonetheless, the term *Duhem-Quine thesis* remains standard terminology for Quine's thesis.

Centrally, the Duhem-Quine thesis concerns the experimental testing of scientific hypotheses. The thesis challenges two widespread claims: (1) the Baconian view of crucial experiments and (2) Popperian falsifiability. Contrary to the Baconian view, there are no crucial experiments. The experimental confirmation of a crucial prediction, such as the experimental confirmation that light rays are deflected by a gravitational field—a result crucial to the acceptance of Einstein's general theory of relativity—does not constitute a telling proof of that theory. Second, contrary to what the naive Popperians believed, the experimental disconfirmation of the logical consequence of an individual hypothesis does not necessarily falsify that hypothesis. Both Baconians and Popperians assume that a hypothesis can be tested on its own. This is not so: Hypotheses do not face the tribunal of experience individually; rather, they face it as part of a complex network including auxiliary hypotheses and theoretical presuppositions regarding the working of instruments, and so on. Hence, any hypothesis can he held true, irrespective of what may happen experimentally, provided scientists make appropriate adjustments, however drastic, elsewhere in the system.

In this entry, the Duhem-Quine thesis is examined within the context of Quine's philosophy of science, in particular his holism, and its interpretation within the social sciences is addressed.

Quine's Holistic Empiricism

The Duhem-Quine thesis is a consequence of Quine's innovative, holist linguistic approach to empiricism, which differs from classical Humean empiricism (after David Hume, with his separation of matters of fact from relations of ideas and consequently the epistemic revisability of the former but not of the latter—underpinning the rigid distinction between the analytic/synthetic distinction) and its 20th-century reformulation in logical positivism. Contrary to Humeans, the first Quinean step shifts the epistemological focus away from ideas and other mental entities onto words. The second step is the shift from words to sentences. The basic unit of communication is not the word; rather, it is the sentence. For example, if one does not know how to use the word *doctor* in a range of sentences, then one does not properly understand that term. Third, sentences are not atomistic units. A sentence is embedded in a system of sentences. For instance, to understand the sentence "The doctor prescribed ampicillin," one has to grasp a network of sentences about medicine. The next two steps are Quine's rejection of the "two dogmas" of classical empiricism: the analytic/synthetic distinction and the doctrine of reductionism. The former divides all significant discourse into logical truths (analytic sentences or relations of ideas, in Hume's language) and observational-empirical truths (synthetic sentences or sentences reporting matters of fact). Reductionism requires that complex synthetic sentences be translatable into basic sentences about the final elements of experience.

Quine's holistic philosophy implies that the totality of human knowledge, from, say, geography or history to pure mathematics and quantum physics, is an intricate, humanly constructed network of sentences that impinges on experience only along its edges—that is, a web of beliefs. This vast system is so underdetermined by sensory experience that rational beings have a genuine choice as to what sentences to reevaluate in light of a single piece of contrary evidence (so revisability is no longer constrained by the Humean distinction—followed by the logical empiricists too—between revisable, contingent knowledge of matters of fact and unrevisable, necessary, analytic sentences expressing relations of ideas). Thus, the rational standard for evaluating basic changes to a system is not the realist standard of correspondence to reality (of synthetic statements expressing matters of fact); rather, the standard is a pragmatic one and, thus, can touch even the so-called core of what were erstwhile thought of as necessarily true analytic statements (expressing unrevisable relations of ideas).

Interpretations of the Duhem-Quine Thesis and the Social Sciences

In general, by challenging the hegemony of logical positivism from within, the Duhem-Quine thesis contributed to opening up the methodology of the social sciences to what Bruce Caldwell and others call *methodological pluralism*. However, its most direct influence perhaps is evident in one of the major social sciences, namely, economics. A central concern in the philosophy of economics is the issue of the testing of economic theory, especially what is called neoclassical or orthodox theory. Following the marginalist revolution, neoclassical theory has proved to be very robust throughout the 20th century and into the next, despite its critics. Defenders of neoclassical theory, such as the American philosopher of economics Daniel Hausman, argue that the robustness of neoclassical theory is justifiable on the grounds of the Duhem-Quine thesis: The core of neoclassical theory is privileged by making adjustments in noncore areas. This defensive reading of the Duhem-Quine thesis is challenged by others using the more nuanced reading of the Duhem-Quine thesis provided by the British philosopher of science Mary Hesse. In light of Quine's own commitment to an empiricism without the dogmas of logical positivism, in Hesse's nuanced empiricist reading, no scientific, theoretical core is privileged—that is, immune from rejection. The core of a scientific theory is rejected if the totality of evidence, ranging from the empirical end to the analytico-conceptual end of the spectrum of evidence, tells against it. While no one single piece of empirical evidence taken on its own is capable of bringing down the core, the totality of evidence has this capability: Otherwise, the theory is not an empirical science. In this nuanced reading, the core of neoclassical economics is not privileged. Clearly, the Duhem-Quine thesis, given the range of interpretations from the defensive reading to the nuanced empiricist reading, continues to present challenges to philosophers of social science in their efforts at understanding the role of experience in the scientific endeavor.

Durkheim's Philosophy of Social Science

Émile Durkheim's philosophy of social science defines the goals and methods of his sociology. He sought to explain *social facts* in terms of social causes, which were to be discovered through testing causal hypotheses against the facts. His sociology was an inspiration for a variety of social sciences, including the French ethnological tradition of Claude Lévi-Strauss, the British social anthropology of Alfred Radcliffe-Brown, and the American structural functionalist sociology of Talcott Parsons. Social scientists have interpreted Durkheim's methodology each in their own way to suit their particular intellectual agendas.

Rather than investigate all the ways in which Durkheim's thought has been used or abused, this entry explains his philosophy of social science on its own terms. It considers the relationships among his methodology, sociological realism, and model of explanation against the background provided by the methods he actually used in his empirical sociological works.

Background

Durkheim (1858–1917) was a humanistically educated philosopher who sought to transform sociology into an empirical science that could provide answers to many of the questions that have traditionally been the domain of philosophy. He and his collaborators helped establish sociology as an academic discipline, drawing on works in philosophy, history, comparative law, economics, criminology, political geography, and ethnography. Although he had little first-hand knowledge of the natural sciences, he took them as his model for the social sciences, supplementing what he learned about scientific method in his philosophy classes with a critical study of the works of Auguste Comte, John Stuart Mill, and Charles Renouvier.

Recently discovered student notes taken in Durkheim's Lycée philosophy classes reveal that from the very beginning of his career he taught that *hypotheses* are absolutely necessary to scientific inquiry. Laws do not leap to the eye, he said. Drawing on examples from the work of scientists such as Galileo, Isaac Newton, and Blaise Pascal, he argued that creative imagination is needed to find explanatory hypotheses. However, there must be some constraints on imaginative hypotheses: They must be simple and precise, explain the known facts, and lead to successful predictions of new facts. He cautioned that scientific laws never lose their hypothetical status no matter how many supporting facts are found, but they can be refuted by a single contradictory phenomenon.

Durkheim's Goals and Methods

Durkheim's philosophy of sociology, which has been called *social realism,* is summed up in his slogan "Treat social facts as things." That is, social facts are real entities with their own underlying causes, not reducible to individual psychological facts. For Durkheim, social reality ultimately consists of collective representations that are shared by members of society, make up the collective or social consciousness, and give rise to social forces and currents. He regarded these social forces as just as real as physical forces.

Social forces cannot be studied through introspection, which reveals only effects and not their causes. One must instead use the experimental method of the natural sciences, which consists of testing hypotheses by comparing their implications with observable facts. In sociology, these included phenomena such as crime statistics, codes of law, religious rites, and various social constraints on ways of thinking and acting. Durkheim's methodology does not quite conform to our contemporary notion of hypothetico-deductivism. He seemed to think that effects could be deduced solely from their causes and that logical relationships were the same as causal relationships. There is no discussion of the distinction between general laws and statements of initial conditions or of the role of auxiliary assumptions in drawing test implications. Nevertheless, he made such assumptions in drawing implications from both his own hypotheses and those against which he was comparing them.

In *The Rules of Sociological Method* (1895), Durkheim championed the use of induction in the social sciences, criticizing economists and others for relying on the abstract, deductive methods of mathematics and philosophy. The method of induction he recommended was not the simple one of enumerating particular observations and then generalizing a conclusion from them. Durkheim was opposed to the mere accumulation of facts, such as one often finds in ethnographies, arguing that science is interested only in what Francis Bacon called "decisive" or "crucial facts," that is, facts that are critical for choosing between competing hypotheses. He thought J. S. Mill's methods of eliminative induction, so called because they are methods for eliminating causal hypotheses that disagree with observations, captured the logic of these crucial experiments.

According to Durkheim, the most useful of Mill's methods for the social sciences is the method of concomitant variation, in which a connection is shown between changes in two different phenomena. For instance, in *The Division of Labor in Society* (1893), Durkheim sought to show that changes in the relative proportions of restitutive and repressive laws vary with the level of complexity of social organization. Although the presence of a concomitance will not alone prove a causal relationship, Durkheim's arguments in *Suicide* (1897) reveal that he thought the *absence* of a concomitance could disprove a causal hypothesis. When there is a concomitance that agrees with our hypothesis, we must still make further comparisons, preferably with other societies, to make sure that it was not just an accident. For example, if we were to find an inverse relationship between the size of families and suicide rates,

we should investigate whether this also holds in countries other than our own. *Suicide* adds two further conditions on the acceptability of a causal hypothesis: The facts must not allow for some alternative explanation, and the hypothesis must not be contradicted by other facts.

Durkheim's Working Method

Durkheim's working method begins with formulating a provisional *definition* of some class of social facts, such as crime, suicide, or religion, in terms of their observable characteristics. This definition is then analyzed into its simplest parts, which often involves tracing what he took to be the historical development of this social phenomenon from its most primitive beginnings. He would then seek the underlying *causes* that would explain these observable characteristics, comparing his own hypothesis with those of others and arguing that his had the greater explanatory scope.

The best example of his use of this method is provided by *The Elementary Forms of Religious Life* (1912). This book begins with a provisional definition of religion, expressed in terms of a distinction between the sacred and the profane, which is maintained by an institution such as a church. It then turns to what Durkheim regarded as the simplest, earliest form of religion: totemism, particularly as it is practiced by the indigenous peoples of Australia. He defended the hypothesis that totemism is the earliest form of religion against the alternatives that either animism or naturism were, arguing that only the totemistic hypothesis could explain the origins of the distinction between the sacred and the profane, as well as the ideas of souls, sacred beings, and religious forces. The totemistic hypothesis explains the sacred character attached to certain totemic objects in terms of the "social forces" that are experienced in periods of collective effervescence that are produced during religious rites. Durkheim then generalized his conclusion to include contemporary religion, maintaining that the feelings of well-being to which it gives rise are but the result of social forces. He held that there is no more reason to think that the reality underlying our religious experiences resembles these experiences than that the reality underlying our experiences of heat, light, and color resembles them in any way.

Durkheim also expanded the concept of a *crucial experiment,* which he also called a "well-made experiment," in *The Elementary Forms*. Anticipating the objection that he had generalized from too few cases, he argued that his study of Australian religions is a well-made experiment. It constituted a crucial test between his totemistic hypothesis, according to which religion rests on social causes, and the animistic and naturistic hypotheses, according to which religion rests on individual, psychological experiences. Although Durkheim generally placed more trust in disconfirmation than in confirmation, here he added that a disconfirming instance must allow for only one possible interpretation and that it cannot be explained without rejecting the hypothesis it seems to disconfirm. He also included among "decisive facts" not only those that contradict a hypothesis but those that a hypothesis fails to explain, either at all or without generating additional problems or making ad hoc assumptions. In short, he included nonrefuting anomalies in the method of crucial experiments.

Durkheim argued that when a law has been established by a well-made experiment, it may be considered a universal law, since he thought that the same effect could not result from different causes. Nevertheless, he maintained that the results achieved by science are always provisional and that the best that science can achieve is probabilities, not certainties.

Explanation

Durkheim sought *causal explanations* of social or collective phenomena, rather than interpretations of the actions of individual social agents. For instance, he was more interested in why suicide rates varied with one's religion or nation than with any individual person's reasons for killing herself or himself. His concept of causal explanation combines the traditional idea of finding the *underlying real essences* behind the appearances with the more modern notion of discovering the laws that govern the phenomena. For Durkheim, the hidden essences of social phenomena both logically entail and causally explain them.

In Durkheim's mind, causes were not simply the antecedents of a general expression in conditional form. He rejected Mill's doctrine of the plurality of causes for the same effect, as well as the plurality of effects for the same cause, at least in the normal state of affairs. Causes for Durkheim are both necessary

and sufficient for their effects, and vice versa. Thus, causes can easily be confused with effects when interpreting some of his claims in his empirical works. Also, since the *functions* of social facts are to be found among their effects, causes can easily be confused with functions, in spite of his warnings in *The Rules* about keeping causal explanations distinct from functional explanations.

For instance, in *Division,* Durkheim presented the rise of cities and towns as both a necessary and a sufficient condition for the increase in social or moral density, a measure of the quantity of interpersonal relationships. Thus, it is unclear whether he meant that an increase in the density of interpersonal relationships is caused by urbanization and thus by population density or whether an increase in social density leads to the creation of towns and villages. Also, it is not clear whether he claimed that specialization is caused by an increase in population density or that specialization is an adaptation to conditions in the social and physical environment. The latter interpretation gains support from Durkheim's making an analogy with Charles Darwin's principle of the divergence of character in *On the Origin of Species* (1859), according to which specialization in nature is not *caused* by the struggle for existence but is rather a solution to it that decreases the competition for resources. In this analogy, the specialization of human labor would be a solution to the Darwinian struggle for existence in a dense population. Durkheim explained that population density alone could simply lead people to emigrate. Specialization allows more people to survive in the same environment, so they do not have to break social bonds that are important to them by emigrating. However, this Darwinian account is a functional, not a causal, explanation of the division of labor. It is not clear whether Durkheim ever did provide a *cause* for the division of labor, leaving himself open to the interpretation that it is caused by physical population density.

Durkheim introduced the distinction between "normal" and "pathological" cases in *Division* in order to deal with anomalies in his theory that labor specialization in turn gives rise to organic solidarity, and thus with exceptions to his one cause/one effect rule. He also made use of this distinction in his attempts to provide a naturalized, sociological basis for ethics, identifying the normal with the average. But, of course, the average is not necessarily morally good, and deviations from the norm in this sense are not necessarily bad.

Durkheim's Antireductionism

According to Durkheim, any time one gives a psychological explanation of a social phenomenon, the explanation is false. Social causes are distinct from psychological causes, and social functions are distinct from individual goals and purposes. He was particularly opposed to intentional explanations, arguing that the fact that some individual or presumably even a group of individuals desired some state of affairs cannot explain what brought it about.

An important goal for Durkheim in writing *Suicide* was to demonstrate that sociology is an autonomous science that does not depend on psychology. According to Durkheim, *societal facts,* such as the varying rates of suicide, dependent on things such as one's country, region, religion, and marital status, cannot be explained simply by summing up individual factors. This is not to deny that there are psychological mechanisms that mediate the effects of society on the individual. For instance, Durkheim maintained that men with large families were more socially integrated and thus less likely to commit suicide than bachelors. Assuming this were true, it would be because people *know* about their familial relations and obligations. But again, explaining the actions of individuals was not Durkheim's concern.

Objections to Durkheim's methodological collectivism (or holism) have often turned on the assumption that it must entail the existence of some sort of entity that exists over and above the individual members of society. Because many of his critics understood his term *collective consciousness* to refer to some such "group mind," he eventually dropped this term and simply referred to a culture's "collective representations" instead. He nevertheless continued to insist that collective representations constituted a realm of real entities distinct from individual mental representations and gave that as the reason why sociological explanations could not be reduced to psychological explanations.

Durkheim did not quite see that the view that sociology does not reduce to psychology no more entails a metaphysical position than any other antireductionist stance in the philosophy of science. For instance, to say that biology does not entirely reduce to chemistry is not to assert the existence of vital spirits. It is simply

to say that there are concepts in biology, such as adaptation, that cannot be defined in chemical terms and generalizations in biology, such as Darwin's theory of evolution through natural selection, that cannot be derived from chemical laws. Similarly, to say that there are concepts, such as social density or social solidarity, that cannot be defined in psychological terms or that cultural preferences for types of suicide or murder weapons cannot be explained psychologically is not to commit oneself to any particular metaphysics.

Lectures on Pragmatism

Durkheim's nephew and collaborator Marcel Mauss regarded Durkheim's series of lectures on pragmatism, which he gave toward the end of his life, as his most important philosophical work. In them, Durkheim defended a realist stance against William James's pragmatist theory of truth. But perhaps his more philosophically interesting argument is his critique of Jamesian pragmatism for being too individualistic. Durkheim argued that truth and reason as well as morality are normative concepts and that one cannot explain normativity from an individualistic perspective, maintaining that it could not be constructed in the life experiences of a single individual. Durkheim's position here calls to mind the Wittgensteinian argument that unless an individual is embedded in society, there is no one to tell her that she is going about things the wrong way, that is, that she is transgressing a norm. However, to say that normativity is a collective or social phenomenon is only to provide a necessary condition for it. Durkheim struggled during his entire career to give a sufficient account of *normativity,* leaving behind the unfinished *La Morale* when he passed away.

Conclusion

Durkheim's works provide an exemplar of the methodological collectivist (holist) position in the philosophy of social science. He argued that *there are social facts that are distinct from individual psychological facts,* such as crime rates, and that require uniquely *sociological* explanations. The social character of normativity comes out most clearly in his critique of the work of William James.

He also maintained some rather sophisticated views concerning comparative theory evaluation, expanding the concept of a crucial experiment to include a role for nonrefuting anomalies as well as for conceptual problems, such as a failure to explain the phenomena without making ad hoc hypotheses.

ECONOMETRICS: METHODOLOGICAL ISSUES

This entry reviews the major methodological debates that shaped the field of econometrics by unifying statistics and economics and explains the roles of causality (and probability) and of modeling in econometrics.

In the 1920s, Ragnar Frisch coined the term *econometrics* as the unification of statistics, economic theory, and mathematics to turn economics into a science. Because most current economic theories are expressed in a mathematical language, the constituent mathematics is not considered anymore to be part of modern econometrics. The aim of econometrics is generally conceived as Trygve Haavelmo defined it to be, namely, *a conjunction of economic theory and measurement,* using the theory and technique of *statistical inference* as a bridge pier. But current econometricians emphasize that economies are so highly dimensional, nonstationary, and complicated that economic theory can never precisely specify the underlying process. So a commonly held view today is that econometrics is synonymous with economic statistics.

Methodological Debates

Since its origin in the 1930s, subsequent debates shaped the ideas of what econometrics entails, or is supposed to entail.

The Keynes-Tinbergen Debate

The first two macroeconometric models were constructed by Jan Tinbergen in the late 1930s. The second model was built when Tinbergen was commissioned by the League of Nations to perform statistical tests on business-cycle theories. Tinbergen's new method of econometric testing provoked a great deal of controversy. It was John Maynard Keynes's critique of "Tinbergen's method" that sparked off the debate about the role of econometrics and what it might be able to achieve.

According to Keynes, the technique of multiple correlation analysis that had been adopted by Tinbergen was solely a method for measurement. It contributed nothing in terms of either discovery or criticism. The implication was that if the economic theorist does not provide the modeler with a complete set of causal factors, then the measurement of the other causal factors will be biased. Moreover, Keynes argued that some significant factors in any economy are not capable of measurement or may be interdependent.

The "Measurement Without Theory" Debate

Another early econometric debate in the 1940s started with Tjalling C. Koopmans's book review of *Measuring Business Cycles,* by Arthur F. Burns and Wesley C. Mitchell, published by the National Bureau of Economic Research (NBER). Koopmans's critique was based on Haavelmo's "Probability Approach." In fact, he was defending the Cowles Commission's (CC) structural equation approach

against the NBER's "empiricist position." He accused Burns and Mitchell of trying to measure economic cycles in the absence of any economic theory about the workings of such cycles. According to the CC approach, economic variables are determined by the simultaneous validity of a large number of structural equations describing behavior and technology. Any observed empirical regularity between a number of variables may be the result of the working of several simultaneous structural relations. Because so many empirical relations are valid simultaneously, it may be difficult—or even impossible—to uncover the more fundamental structural relationships. In the absence of experimentation, the identification of these structural relations is possible only if the set of variables involved in each equation, and the manner in which they are combined, is specified by economic theory.

The "Science or Statistical Alchemy" Debate

After 1950, econometrics became a mature field, and the CC approach was the dominant practice. But after two decades (the 1950s and 1960s) of high expectations of econometrics as a producer of reliable predictions and policy advice, in the 1970s, these expectations were increasingly doubted. In the early 1980s, David F. Hendry revisited the Keynes-Tinbergen debate as a backdrop to reiterating the scientific possibilities of econometrics. The ease with which a mechanical application of the econometric method produced spurious correlations suggests alchemy, but according to Hendry, the scientific status of econometrics can be regained by showing that such deceptions are testable. He, therefore, came up with the following simple methodology: "The three golden rules of econometrics are test, test and test."

Edward Leamer's article "Let's Take the Con Out of Econometrics," also written in the early 1980s, is very much about the "myth" of science that empirical research is (randomized controlled) experimentation and scientific inference is objective and free of personal prejudice. The problem of nonexperimental settings (usually the case in economics) compared with experimental settings (common in science) is that the specification uncertainty in many experimental settings may be very small, but this hardly is the case in nonexperimental settings. The often used image that econometrics is like agricultural experimentation (randomized controlled experimentation) is, according to Leamer, grossly misleading.

Econometrics and Causality

Econometrics is a discipline that has paid much attention to how laws, probabilities, and causes fit together. See, for example, the works of T. Haavelmo and Herbert Simon and, more recently, those of Clive Granger and James Heckman. Moreover, it is with econometrics that probabilities entered economics. So econometrics, particularly the CC structural approach, is for some philosophers of science, like Nancy Cartwright and Kevin Hoover, a good starting place for a study of the relationship between causes and regularities.

Econometrics and Empirical Modeling

Tinbergen's econometric models originated a new practice of empirical research in economics, namely, that of *empirical modeling*. Studies of this empirical practice have had an important influence on the development of alternative accounts of models to the more dominant, semantic view. The semantic view is that a model is an interpretation of a theory in which all the axioms of that theory are true. The problem with this view is that econometric models are representations of economic systems of such complexity that these representations cannot be reduced to a small set of axioms. It appeared that models in econometrics function more like instruments, mediating between theories and data in a much more autonomous way.

Economic Anthropology

Economic anthropology arose where the disciplines of anthropology and economics meet. The Greek *oikonomia* meant household management with the aim of self-sufficiency through thrift, careful budgeting, and the avoidance of trade. This ideal persisted in Europe up to around 1800. Adam Smith's revolution focused on the division of labor and the functioning of markets in the wider society. *Economy* has since come to refer primarily to market exchange, although the old meaning of making ends meet persists. Economy could still mean "putting one's house in order," both practically and figuratively. Everyone should feel "at home" in a world made by markets, but we cannot survive on the basis of market economy alone.

Two Pioneers

The sociologist Marcel Mauss asked, "What rule compels the gift to be reciprocated?" People find the personal character of the gift compelling, since it evokes diffuse social and spiritual ties. Human institutions everywhere are founded on the unity of the individual and society, freedom and obligation, and self-interest and concern for others. Modern capitalism and economics rest on an unsustainable attachment to one extreme. Mauss held that markets and money are universal, though not in their current impersonal form, while advocating a pragmatic approach to the human economy of relevance to people's daily lives.

The political economist and philosopher Karl Polanyi's *The Great Transformation* showed how a free-wage labor market in Victorian England led to the economy becoming "disembedded." The 20th century's crises and World Wars were the result. He later argued that the "formal" and "substantive" meanings of the word *economy* had been conflated. The first refers to economizing, a means–end relationship, whereas the second is concerned with the provisioning of material wants. The economic institutions of preindustrial societies guarantee social survival, whereas the abstract market principles that drive the economy of industrial societies do not. This led him to abandon the study of modern economies to the economists.

For both these thinkers, society is founded on a limited number of economic principles that are distributed widely in history but combined variably. Like Karl Marx, they rejected the reduction of society to capitalist markets. They saw the economy as being pulled in two directions at once: inward to secure local guarantees of a community's rights and interests and outward to make good deficiencies of local supply by engaging with foreigners through money and markets. An economic anthropology for the 21st century would perhaps do well to build on their example.

The History of Economic Anthropology

The field's origins lie in the democratic revolutions of the 18th century. Philosophers like Jean-Jacques Rousseau offered a revolutionary critique of the

premise of inequality and constructive proposals for a more equal future. Karl Marx and Friedrich Engels subsequently made fertile use of this precedent in their own critique of the state and capitalism. Few writers have come close to matching Marx's vision of economic history as a whole.

Modern anthropologists asked whether the economic behavior of "savages" was as efficient and rational as the Western equivalent. Ethnographers sought to engage the general propositions of "neoclassical" economics with their particular findings about "primitive societies." They failed mainly because they misunderstood the economists' premises.

In midcentury, anthropologists argued about the theories and methods needed to study tribesmen and peasants. "Formalists," who saw an abstract individualism everywhere, held that the tools of mainstream economics were adequate to the task, while "substantivists" claimed that institutional approaches were more appropriate. This "formalist versus substantivist" debate ended in a stalemate, opening the way for Marxists and feminists to exercise a brief dominance, but they too at first drew mainly on exotic subject matter.

Developments From the 1980s

Anthropologists now address the full range of economic organization, but so far, they have preferred to stick with ethnographic observation. Formalism lives on as the "new institutional economics." This consists in extending market models and rational choice approaches into new areas, while relying on the concept of *transaction costs*. Many economic anthropologists have tried to open up the black box of "culture." The best combine an ethnographic sensitivity to the "social life of things" with the recognition that cultural valuation is itself shaped by inequalities of wealth, power, and status. This "cultural turn" has extended the substantivists' critique of the bourgeois economic categories by showing that they offer just another local model and an unattractive one at that.

We all seem to be living in a world unified by capitalism, so economic anthropologists now investigate that. A significant strand studies the material culture of consumption at home. There has been some excellent ethnography of industrial work, and anthropologists have engaged critically with the great questions of modern history: unequal development, socialism, and global capitalism. The aim of humanizing the anonymous forces governing our lives has produced a fashion for the anthropology of money and financial institutions. This field has exploded since 2008. It is hard to argue now that economies prosper only if markets are freed from political bondage. So there may be more scope for alternative approaches to the economy.

The basic issue remains whether the forms of market economy that have dominated for two centuries rest on principles of universal human validity. A new synthesis of anthropology, world history, and economics might provide some answers.

Economic Sociology

Economic sociology can be defined as the sociological analysis of economic phenomena. It was created during the 19th century and is currently one of the most popular subfields of sociology in the United States and elsewhere. Its two most important founders are Karl Marx and Max Weber. The field revived in the 1980s and operates today with concepts such as *embeddedness, social capital,* and *field*.

The Classics and Onward

Karl Marx created his own kind of analysis that does not fit very well into any modern social science discipline. Max Weber, in contrast, helped make sociology accepted as a university subject and was extremely interested in *Wirtschaftssoziologie*. Like Marx, Weber was very well versed in economic theory as well as economic history, and both of these disciplines helped him formulate a powerful program in economic sociology. This program can be found in Chapter 3 of his *Economy and Society,* titled "Sociological Categories of Economic Action."

Like all of Weber's sociology, his economic sociology was part of what he called "interpretive sociology." In this type of sociology, it is imperative that the actor's view of things is part of the analysis. This perspective also informs Weber's earlier works, written before he decided to call himself a sociologist. This is, for example, true for the classic *The Protestant Ethic and the Spirit of Capitalism.*

Weber died in 1920, and during the period from 1920 to the 1980s, economic sociology more or less disappeared from the universities. Very few courses were taught in this field, and very few studies were carried out. Despite this fact, three major economic sociologists were active during this period. They are Joseph Schumpeter, Karl Polanyi, and Talcott Parsons.

Schumpeter wrote a series of essays in economic sociology but was mainly seen as an economist. His most important essay in economic sociology is on the role of taxation in society and can be described as an early and vigorous argument for a fiscal sociology. Many people also think that Schumpeter's economic analysis was quite sociological in nature. This is especially true of *Capitalism, Socialism and Democracy.*

Karl Polanyi can be described as an interdisciplinary and normatively engaged scholar. His work has had a great impact on economic sociology, not the least on people critical of the existing economic order. According to Polanyi, the economy had originally been subordinate to religion and politics but was set free from all restraints in 19th-century England. This resulted in huge and destructive changes in human society, analyzed and recorded in Polanyi's masterpiece *The Great Transformation*. Polanyi was also a skillful theoretician, and his notion that all economic acts can be characterized as a form of reciprocity, redistribution, or exchange is generally accepted in modern economic sociology.

Talcott Parsons had (like Weber) been educated as an economist, and he later put this knowledge into use when he became a sociologist. Together with his student Neil Smelser, Parsons published a famous study centered on the idea that the economy can be seen as a social system. Just like any social system, Parsons and Smelser argued, an economy has to deal with issues such as adaptation, setting goals, and so on.

Modern Economic Sociology

The birth of modern economic sociology is usually associated with the publication in 1985 of a famous article by Mark Granovetter on *embeddedness*. In contrast to Polanyi, who used this term in a vague sense, Granovetter specified that embeddedness means that economic action is always embedded in ongoing *networks* of social relations. The idea of "homo economicus" is not so much wrong from this perspective because economic man is seen as exclusively driven by profit or wealth but because it ignores the role of social structure.

In the two to three decades after Granovetter's article, "new economic sociology" (as it is sometimes called) has advanced very quickly. Today, the subject is totally institutionalized in the sense that most major sociology departments routinely teach courses in economic sociology, there are several textbooks and handbooks on economic sociology, and most national sociological associations have sections on economic sociology.

Economic sociologists have made important contributions to a number of areas. They have, for example, closely followed the transition from the traditional firm to the so-called shareholding view of the firm. The role that networks play in people getting

jobs and in firms collaborating with one another has similarly been carefully studied. Another important area has to do with the role of gender differences in the economy. More generally, there exist today studies on pretty much everything, from how to buy a house in France to how the global financial services firm Lehman Brothers collapsed in the fall of 2008.

In carrying out their studies, economic sociologists draw on a wide variety of methods. Some economic sociologists conduct surveys or work with huge data sets. Others conduct participant observation studies, apply a cultural approach to what they study, or use a historical and comparative perspective. Like modern sociology, modern economic sociology is pluralistic. There exist economic sociologists who are very close to economists and also those who refuse to accept anything that economists do.

When economic sociology was revived in the mid-1980s, it was hoped that economic sociology would one day be strong enough to take on economists. Alternatively, it was hoped that economists would become interested in the sociological analysis of the economy. To date, none of these things have happened. Nonetheless, today's economic sociology does constitute a lively and interesting area of study.

Economics of Scientific Knowledge

This entry introduces a blossoming research field in the philosophy of science in which certain tools used by economists are applied to the analysis of the production and evaluation of scientific knowledge. On this view, scientists are seen as economic agents. The entry reviews the different approaches this field has taken. The special interest of this field lies in the way philosophy makes use of the tools and models of a particular social science, economics, in analyzing scientific knowledge and the way scientists act in evaluating their theory production.

Background

The term *economics of scientific knowledge* (hereafter ESK) was coined in the 1990s as a reaction to the field known from the 1970s as the sociology of scientific knowledge. The latter had been defined by the members of the so-called Strong Program in contraposition to the classical notion of a sociology of science, referring to the distinction between the sociological explanation of the institutional, political, and cultural aspects of science, on the one hand, and the sociological explanation of the *cognitive* aspects of science, on the other. The sociology of science would be devoted to the external (nonepistemic) aspects of science, whereas the sociology of scientific knowledge would study the *internal* content of science, that is, why certain theories, facts, or paradigms are accepted or rejected. Sociologists in the Strong Program derived some radically relativist conclusions from this starting point, in opposition to most traditional views about scientific knowledge.

As a result of this, an open question remained, namely, whether the application of analytical instruments drawn from the economist's toolkit to the understanding of the process of knowledge generation —that is, the view of scientists as agents within an economic model—would support the relativist claims of radical sociologists. Or, on the contrary, it would serve to "save" the intuitive character of scientific knowledge as a paradigm of "objectivity." As this entry will show, most contributions to ESK fall under the second of these options.

In retrospect, we can realize that many prior works can be identified under the ESK label, though the main production of papers and books on the topic has occurred in the past two decades. One possible way of classifying all these works is according to the type of economic models or metaphors they attempt to apply to the study of the creation of scientific knowledge. From this point of view, we can distinguish *formal* (or "mathematical") from *nonformal* (or "institutional") approaches.

Formal Approaches

One of the most important contributions in the first group is Philip Kitcher's 1990 article titled "The Division of Cognitive Labor," later reprinted in an extended form as the last chapter of his 1993 book *The Advancement of Science,* in which he develops a set of models based on the assumption of interacting, rational, self-interested scientists. According to Kitcher, the aim of his models is to "identify the properties of epistemically well-designed social systems," that is, to study how a group of individuals, by interacting with each other, manage to reach a consensus gradually, working under certain rules. Other interesting mathematical models of scientific activity that have been developed during the past decades refer to a tit-for-tat "game" between researchers and journal editors, to the way in which researchers try to change the subjective probabilities of their colleagues, or to the decision whether to replicate another researcher's experiments, or the decision of accepting a more "popular" theory or defending a more heterodox one, on the basis of the different information about both theories each individual scientist has. The last two cases show the possible existence of more than one equilibrium in the "cognitive state" of the scientific community—which can lead to phenomena of path dependence, inefficiency, and sudden "revolutions." Some more recent contributions have analyzed the properties of the priority rule and the choice of methodological rules, while Jesús Zamora-Bonilla has studied the negotiation taking place with regard to the interpretation of empirical findings. More recently, due to the availability of more powerful software, the use of simulation models to study Kitcherian "division of epistemic labor" problems has become relatively common, especially in cases where complexity is relevant. Many of these articles are grounded on the simulation models of Reiner Hegselmann and Urich Krause, which in turn are inspired by the work of Keith Lehrer and Carl Wagner on "rational" belief aggregation.

A brief review of the formal approach to ESK would be incomplete without mention of Samir Okasha's 2011 article, "Theory Choice and Social Choice." Here, an analogy is suggested between the aggregation of individual preference functions, to which the famous Arrow impossibility theorem was originally applied (showing that there is no way of constructing a "social" preference function that respects certain minimal and reasonable requirements), and the combination of different "scientific values" that would result in something like an objective "epistemic preference function." Okasha argues that this analogy justifies in a way Thomas Kuhn's thesis that there is no algorithm allowing us to determine in an objective sense when one theory is epistemically better than another; the difference would be that whereas Kuhn's original intuition, and almost all of the subsequent interpretations, has held that the problem is that there are an indefinite number of possible ways of aggregating the different scientific values, none of them being justifiably better than the others, Arrow's theorem would imply that the problem is that there is simply no "rational' way of performing such an aggregation. It can be argued, however, that even if it is true that several scientific values cannot be algorithmically combined, scientists might agree in employing a common epistemic scale that is nonoptimal for each one but that is an equilibrium in a negotiation (or "social contract") about how to evaluate research.

We must not forget what is very likely the first contribution to ESK. The 19th-century American pragmatist philosopher Charles S. Peirce made an amazing application of the then just-invented marginal analysis of economic functions to the process of deciding how much effort to expend in alternative

research projects. This "cost–benefit" approach has been further explored by other authors, such as Nicholas Rescher and Gerhard Radnitzky.

Most of the works referred to in the previous paragraphs support the conclusion that, in spite of being motivated by "personal" goals like recognition, power, or "credit" (to use the concept coined by Pierre Bourdieu, whose sociological insights have been decisively influential and inspiring in the development of ESK), we can reasonably expect that, under certain circumstances and mechanisms of interaction, a group of scientists could attain results that will score high on an epistemic scale.

Nonformal Approaches

With respect to the nonformal approaches to ESK, this entry identifies them as "institutional," in line with the tradition in institutional economics, which is basically qualitative in the sense of grounding its conclusions not on logico-mathematical theorems or models but on mere commonsense reflection on our knowledge of the situations and of the available data. In this area, the basic motivation has been to discuss whether science can be legitimately understood as a "marketplace of ideas," very likely having in mind the conclusion that if science is a kind of free market, then it can be led, "as if by an invisible hand," toward the truth, in spite of the base motivation of single scientists. A pioneering work on this idea was Michael Polanyi's article "The Republic of Science." Some more recent works that share in some way the "Austrian economics flavor" of Polanyi's are that of the philosopher of biology David Hull (though this is hardly classifiable as belonging to any "economic" approach, being more biologically inspired) and those of Yanfei Shi and Alan Walstad. Christoph Lütge offers a similar view but one that is based on James Buchanan's constitutional political economy (or "public choice" theory), which has also influenced the work of Shi.

There are also authors who have employed the market metaphor but in a critical sense, either trying to illuminate in what respects science is not a market or trying to show that science's being something like a market makes it inefficient in the pursuit of truth. In the second group, we can include the work of some sociologists of science, such as Bruno Latour and Steve Woolgar, who employ a Marxist notion of "market" and also some works in which it is argued that economic science, in particular, does not function as if guided by an invisible hand toward the truth but is governed by other forces and social mechanisms that do not warrant that epistemically efficient theories are unanimously accepted.

Econophysics

Econophysics (a term coined in 1995 in a conference on statistical physics held at Kolkata, India) views the problems in economics in a physical way and attempts to solve them employing the techniques of physics. Indeed, viewed more generally, econophysics holds that the dynamical aspects of societies, and markets in particular, are purely physical in origin and nature, in contrast to the received view of economics as a typical social science.

Methods of obtaining knowledge toward the truth can be either deductive or inductive. Mathematics is a standard example of deductive knowledge (though not all of it can be deduced from axiomatic logic), not requiring laboratory or natural observation to validate its truths. In contrast, all the natural sciences are essentially inductive in origin, based on observations. The tools of mathematics and logic are only employed in these sciences subsequently in order to find and establish relationships among the observations. These quantifiable links between often seemingly unrelated observations help identify the basic truths of nature. Physicists, chemists, biologists, economists, or sociologists all tend to do the same. In all its various manifestations, inanimate, biological, or sociological, reality perhaps employs the same elegant truth code expressed differently in its various parts. Scientists having different perspectives in mind perceive them differently. The basic truth established, therefore, in one branch of natural science (say physics) should not be seen as invalid in another (say chemistry or biology), and the same should hold true for economics if viewed as another branch of natural science.

Social sciences like economics can be empirical or inductive, like physics or the other natural sciences, where deductions or logical derivations, correlating various empirical observations, play the role indicated above. But that need not be mistaken to be an indication for an essentially deductive science. Just like biophysics or biochemistry (each borrowing established knowledge, i.e., truths from the parent sciences of physics or chemistry, to develop biology), econophysics can help develop economics by utilizing the knowledge borrowed from physics, the most developed branch of natural science. If physics can offer such a helping hand, the indispensability of econophysics can be acknowledged.

Econophysicists' observations that the fluctuation in the size of a company decreases with the size itself, following a power-law, and that the network of companies in the market shrinks in a crisis period have given major insights into market dynamics. On another front, the problem of repetitive games of collective choices within a community of agents, each trying to belong to the minority group (the payoff being greater for those choosing the less crowded option), has been successfully modeled following the dynamical multi-attractor learning models in statistical physics of frustrated many-body systems. Observations regarding the precise nature of the fluctuations (over averages) of stock prices have been extensively analyzed recently and have provided the initial motivation for the formulations of minority game models: the El Farol Bar problem or its generalization, called the Kolkata Paise Restaurant problem. In both cases, the aforementioned techniques provided quite successful solutions.

Among the major research themes in econophysics today, one is to characterize the "natural" forms of economic inequality in society. With the identification of money or wealth exchange dynamics between any two traders as the two-body scattering or collision processes in a gas, considerable progress has recently been made. In particular, the entropy-maximizing stochastic kinetic exchange dynamics, studied extensively in the context of statistical mechanics of gases for more than 100 years, are seen to be equivalent to the (microeconomic) utility maximization problem of the agents in the market (subject to budget constraints). Utilizing this equivalence and the well-established physical models of kinetics in gases, considerable progress has been made. It shows how the socialist norm of zero-dispersion (absolute equality) distribution gets quickly destabilized to the entropy-maximizing, Gibbs-like distribution of money or wealth in such exchange markets. Incorporation of the saving propensity of the traders immediately gives the nonmonotonic, Gamma-like distribution for the bulk of society, with the Pareto power-law decay distribution of the number of superrich in the market with their money holdings or wealth. These studies indicate that inevitable economic inequalities follow, modeled on the analogy with the natural laws of entropy maximization in such dynamical processes. They also indicate ways to control such dispersions in the distribution.

However, the social dynamics of a large collection of individuals with (possibly finite) intelligence placed in a market cannot be trivially identical to the many-body dynamics of inane material particles in a gas or to similar simplistic physical systems. Hence, the approach has attracted criticism and the despair of some about the ultimate future of econophysics. This is not quite unexpected. However, proper improvisations can easily overcome many such problems. Also, current limitations need not pose any fundamental problem to econophysicists: Even intelligent learning models developed in physics or computer science, though immature, are already in use in medical applications and in designing new generations of computers, among other things. Applications of such learning models in multi-agent repetitive games are already leading to intriguing success. Prospects therefore look quite healthy. Though rather young as a discipline (formally started only in 1995) and not quite developed or established yet, econophysics has already infused economic science with a unique natural-scientific spirit and guiding philosophy.

Ego

The notion of ego is central to psychoanalysis and has been a significant concept in psychology too, more generally. It has been a significant notion originating from social science, as opposed to that of the "self" in its predominantly philosophical use. This entry starts by presenting the varying conceptions of the ego put forward by Sigmund Freud, goes on to explain its functions, considers different post-Freudian developments (some anticipating "functionalism" in recent philosophy of mind), and ends by contrasting philosophy with psychoanalysis in this regard. The latter has important implications for the analysis of agency.

Definitions

Some use the term *ego* to refer to the self as a whole; others use it to designate a part of the mind. Freud uses it both ways.

In some of his writings, particularly on narcissism, Freud identifies the ego with the self. He makes this equation explicit in the fourth paragraph of *Civilization and Its Discontents,* where he says that

normally there is nothing of which we are more certain than the feeling of our own self, of our own ego.

In other works, Freud thinks of the ego as just part of the mind. In *The Ego and the Id,* he says that in each individual there is a coherent organization of mental processes, which he calls "the ego." Psychoanalysts sometimes call this concept the "agency concept" because Freud describes this mental organization as the mental agency that supervises its own constituent processes. He also attributes to it special attributes, especially consciousness, and special functions.

In his early writings, Freud theorized that the ego was entirely conscious, but he indicated a change of mind in 1922, when he read a paper at the Seventh International Psycho-Analytical Congress. In the abstract of his paper, Freud notes that previously he had regarded the repressed as coinciding with the unconscious, whereas the ego was identified with the preconscious and conscious, but, later, two facts mandated a change in view. The two facts are (1) resistance proceeding from the ego during analysis and (2) an unconscious sense of guilt. Because of these two facts, Freud argues, the correct view is that the ego is not only partly conscious or preconscious but is also partly unconscious.

Functions

As to the functions of the ego, Freud held that one important function is to deal with the perception of dangers emanating from both the external and the internal world. The internal threats come partly from the id, the totally unconscious part of the human mind that is present at birth, out of which the ego develops and which seeks only the satisfaction of instinctual needs.

The id threatens the ego in two ways, according to Freud. First, an excessive instinctual demand can threaten the dynamic relationship between the id and the ego and change the ego back into being a portion of the id. Second, experience may have taught the ego that satisfaction of some instinctual demand that is not in itself intolerable might nevertheless involve dangers in the external world, so that an instinctual demand of that kind is perceived to be dangerous. The ego, then, is fighting on two fronts: It has to defend its existence against an external world threatening its annihilation, and it must cope with excessive instinctual demands from the id.

There is a third front as well. Prior to age 5, the ego mediates between the id and the external world, guided at all times by the injunctions of a modified pleasure principle. At the end of the fifth year, Freudian theory holds, an important change takes place. A new psychic agency develops out of the ego as people in the external world, mainly the parents, are abandoned as objects and the new agency carries on the functions of the abandoned objects. This agency, which Freud calls the "superego," observes the ego, gives it orders, and judges it, just like the parents whose place it has taken. The superego at times also threatens the ego with punishment, just as the parents have, but, Freud notes, it often displays a severity for which no model has been provided by the real parents. In addition, it calls the ego to account not only for its deeds but also for its thoughts and unexecuted intentions.

When the ego is threatened by the world, the id, or the superego, often reacts by using defense mechanisms, the most important of which is repression. Freud described the essence of repression as simply turning something away and keeping it at a distance from consciousness. The concept of repression plays a key role in Freud's theory of dreams, his theory of neuroses, as well as in his theory of treatment. He called the theory of repression the cornerstone of psychoanalysis.

Other ego defense mechanisms include sublimation, denial, reaction formation, projection, and regression. They operate at an unconscious level, leaving the subject unaware of the true purpose of the defensive behavior.

Another important function of the ego is dream censorship. In one of his best-known works, *The Interpretation of Dreams,* Freud describes how the ego is weakened when it goes to sleep and reacts to the id's forcing upon it infantile repressed wishes. The ego reacts by censoring the unconscious material emanating from the id, allowing the material to enter the preconscious only in a disguised form. If, upon waking, a person remembers a dream, then it is always the manifest content of the dream that is remembered; it is the product of the ego's distortion of the latent and unconscious dream thoughts and images. Some features of the manifest dream, the dream as remembered by the dreamer, may be due not to distortion of infantile repressed wishes but to urges from waking life, which Freud calls the day residue.

Post-Freudian Psychoanalytic Developments

Freud's ambiguous use of the term *ego* is reflected in successor psychoanalytic theories. One of these is the theory of ego psychology, developed by Heinz Hartmann, David Rappaport, Ernst Kris, Merton Gill, and others. The ego psychologists generally follow the view of *The Ego and the Id,* characterizing the ego as an agent having specific functions, including those described by Freud.

In contrast, those in the object relations tradition, developed by Melanie Klein, R. D. Fairbairn, and D. W. Winnicott, follow Freud in his writings on narcissism, identifying the ego with the self and often using the two concepts interchangeably.

One leading object relations theorist, R. D. Fairbairn, speaks of the splitting of the ego, whereas others in the same paradigm talk about the splitting of the self. How can an ego or a self split? The answer lies in how Fairbairn and others use the idea of the internalization of objects.

The term *object* in object relation theories is often, but not consistently, used to refer to persons in an infant's environment, such as the mother or father, or to parts of persons, such as the mother's breast, but when object relation theorists turn to internalized objects, they refer not to external things but to something mental, such as an experience or representation. At some point, the infant "internalizes" the objects in its environment, or more precisely, it internalizes or makes part of itself an *experience* or *representation* of the mother or father, or some other external object. The internalized object, on Fairbairn's account, is divided into a good and a bad object, with the ego repressing the latter. Because part of the ego is thought to remain attached to the repressed object and part of the ego is not so attached, Fairbairn speaks of a splitting of the ego. Others appear to be expressing the same thought when they speak of a splitting of the self.

In still another variant of psychoanalysis, self-psychology, the psychology associated with Heinz Kohut and Otto Kernberg, the ego is generally identified with the entire self, as it is in object relations theory.

Postulation of an ego can give rise to certain mysteries depending on what is postulated. As noted earlier, in *The Ego and the Id,* Freud conceives the ego to be only a part of the mind, yet he also speaks of it as a mental agency that supervises its own processes, discharges excitations into the external world, goes to sleep at night, and censors dreams. To philosophers and psychologists who think of an agent as a person, it is puzzling how a part of a person can also be an agent, something that decides, acts, and goes to sleep.

Another mystery concerns the nature of the ego. Some ego psychologists claim to sidestep questions about its essence by identifying it with its functions, as Freud himself did. The ego, they say, is just that part of the mind that censors dreams and deals with perceived dangers coming from the external world, the id, and the superego by using repression and other defense mechanisms. Here, Freud and the ego psychologists anticipate a widely held view in the philosophy of mind, known as *functionalism.* Mental states, such as beliefs and desires, are said by functionalists in philosophy to be kinds of internal states that stand in certain functional relationships with the agent's behavior and other mental states.

Philosophy Versus Psychoanalysis

There is this difference between the philosophical and the psychoanalytic view. Philosophers characterize functional states in causal terms. A belief is said to be that sort of mental state that causes certain types of behavior and other mental states. Psychoanalysts, however, are referring not to causes but to what the ego does, such as censoring dream content and triggering defense mechanisms, although what it does has certain significant effects.

Psychoanalysts who identify the ego with the self might appear to spare themselves the problems of dealing with the agency concept. After all, as Freud pointed out, there is nothing of which we are more certain than the feeling of our own self. Of course, if Freud is right about one of his central contentions, that there exists in each of us a deep unconscious, there is much about our own self that we know nothing, unless we undergo a successful psychoanalysis; for without psychoanalytic treatment, we have no access to that part of the self that is unconscious.

There is also a philosophical problem about the self, and hence about the ego if we identify the two. As David Hume noted, whenever we introspect, we come across a particular mental state, such as a feeling or thought or sensation, but never the self. How,

then, do we know it even exists in ourselves, let alone in others? Ego psychologists and object relations theorists have various answers to this query, but whether or not their answers are satisfactory, the problem of proving the existence of an unobservable ego arises generally, whether the ego is conceived of as the entire self or as an agent that is just a part of the mind. The problems diminish for nonpsychoanalytic theories when the self is said to be not an entity within a person but the entire person or when it is identified with a collection of mental states and processes.

Embodied Cognition

This entry discusses the recent major turn in the study of cognition that has brought to center stage a view of cognition as fundamentally embodied; explains how it arose in reaction to the received view of cognition dominant so far, in which the body played at best a secondary role; shows its precursors and sources of inspiration; and underlines some of the recent evidence in its favor offered by cognitive neuroscience. What is important is that this new conception of cognition as embodied brings in its wake a wider concept of what cognition is, linking it inexorably to its environment, which is not just physical but also interpersonal and social. Brain, body, and environment thus form a multidimensional dynamic reality in which meanings, value, and culture are present.

Historical Background

The term *embodied cognition* did not come into common usage until the beginning of the 21st century. Throughout most of the 20th century, mainstream Anglo-American "analytic" philosophy gave almost no attention to embodiment, focusing instead primarily on conceptual and linguistic analysis and conditions of epistemic justification. The body was regarded as nothing more than a repository for the brain and a conduit for sense perception, and it was therefore deemed not to be constitutive of processes of understanding and reasoning. The dramatic reversal of this neglect of the body began partly in phenomenology, gained momentum in some parts of feminist philosophy, and came to fruition with the recent meteoric rise of the cognitive sciences over the past three decades. In particular, the biological and cognitive sciences have come to recognize how our embodiment gives rise to mind, thought, language, and other forms of symbolic human interaction. What was once the most peripheral of topics has now moved to center stage in virtually every discipline concerned with any aspect of human existence.

Fundamental Tenets

"Embodied cognition" does not define a single monolithic perspective, but most of those who align with this orientation would agree with two fundamental claims: (1) there is no mind or mental activity

(and hence no perception, feeling, thought, communication, valuing, or action) without a body and (2) the body plays an indispensable role both in *what* has meaning for us and in *how* we experience and make that meaning. In other words, the body does not just provide representational content for mental operations. Rather, it shapes the ways we conceptualize, reason, and communicate.

According to the first tenet, to say that cognition is embodied is to say that the body actively functioning within its environments is indispensably necessary for any kind of cognitive activity. The American pragmatist philosopher John Dewey argued that the locus of all experience, thought, and communication is a human organism in ongoing engagement with an environment that has physical (biological), interpersonal, and cultural dimensions intricately interwoven. Dewey coined the term *body-mind* to capture this continuous transaction between what we term the *physical* and *mental* aspects of our existence. In short, no body, never mind. Moreover, Dewey correctly insisted that we cannot adequately address the nature of "mind," experience, or thought without paying attention to the environments in which the mind emerges and operates. In short, no world, never mind. Today, the preferred term for this ongoing embodied experiential process is *enaction,* which is meant to capture the dynamic, active, purposive engagement of an organism with its ever-changing environments.

Embodied cognition views emerged as a criticism of, and a major alternative to, theories in the 1960s and 1970s that regarded the mind as a unified set of computational programs that take input and generate output. These early computational ("functionalist") theories of mind meshed nicely with the then-dominant Chomskyan generative linguistics paradigm, which focused on an allegedly innate mechanism for generating formal structures (syntax) for possible natural languages. Chomsky claimed that syntax is independent from anything having to do with our bodies, and so he incisively described his project as a "Cartesian linguistics." Functionalist theories tend to ignore the body, claiming only that some embodied "wetware" is needed, but only to run the programs that constitute mind, thought, and language processing.

By the 1970s, it was becoming clear that these functionalist approaches were incompatible with the newly developing sciences of mind that began to show how our bodily capacities and actions provide the basis for human meaning, reasoning, and symbolic interaction. According to this new body of empirical research, our bodies are the primary source of meaning, values, and the very patterns and qualities of our so-called mental operations.

This developing research generates the second tenet above, which is that the body in large measure determines both *what* we can experience, conceptualize, reason about, and communicate and *how* we perform these cognitive activities. The body plays an indispensable role in the possibility and nature of all aspects of cognition.

Sources

Evidence for the embodiment of mind, thought, and language comes primarily from three sources: (1) phenomenological descriptions of our bodily situatedness in the world, (2) studies of the conceptual systems that underlie language and other forms of symbolic interaction, and (3) the cognitive science and neuroscience of the body and brain. Taken together, these bodies of research make a compelling case for the central role of the body in every aspect of human cognition.

Phenomenology

Although the forefathers of phenomenology—Edmund Husserl, Martin Heidegger, and other existential phenomenologists—recognized the body's role in shaping what they called our *lifeworld,* it was the French phenomenologist Maurice Merleau-Ponty who did the most to remind us that our body is never merely a physical object in space but rather a "lived" or "phenomenal" body that provides the very possibility of our inhabiting a meaningful world and is the source of our meaning and thought. All of the dichotomous distinctions we make, such as mind/body, subject/object, cognition/emotion, are abstractions from the bodily processes out of which our world emerges. They mark real aspects of our experience, but they have no substantial independent existence. Merleau-Ponty, thus, put the lived body center stage by recognizing it as the corporeal and interpersonal processes that give rise to all the meaning and significance of which we are capable, including gesture, language, science, and all the arts. A good example of this type of approach is Maxine Sheets-Johnstone's exploration of the role of bodily

movement in our ability to make sense of our world. She shows how this "primal animateness" both situates us and generates the qualities, properties, and relations that define how we dwell meaningfully in our world.

Empirical Studies of Embodied Conceptual Systems and Language

If "body" and "mind" are not distinct, separable *things* but are instead dimensions, aspects, or patterns abstracted from the primordial give-and-take of an organism and its environment, then what we call conceptualization is a fundamentally bodily process. Lawrence Barsalou's exploration of perceptual symbol systems reveals how our concepts and reasoning are inherently rooted in perceptual and motor activities. He emphasizes the key role of sensory-motor simulation in our ability to experience and make meaning. George Lakoff and Mark Johnson have identified a number of basic body-based "image schemas"—such as up/down (verticality), containment, source–path–goal, iteration, front/back, scalar intensity, and so forth—that structure our perception, action, and spatial relations concepts (and their linguistic expressions). For instance, the English word *in* activates a container schema with its own distinctive logic of in–out relations, based on our bodily experience of how physical containers (e.g., boxes, cups, bowls) give rise to a bodily logic of containment (e.g., *if Container A is in Container B, and Container B is in Container C, then A is in C*—known as the Transitivity relation in logic).

The bodily grounding of concepts for concrete objects, spatial relations, and actions is perhaps not such a surprising hypothesis, since our sensory-motor experience is so basic to our ability to understand, act within, and transform aspects of our physical environment. What is more striking is the role of embodiment in creating and understanding abstract concepts (e.g., mind, thought, causation, values, institutions, mathematics, and logic). One of the most productive strategies for explaining abstraction has come from Conceptual Metaphor Theory, which argues that virtually all our abstract concepts are defined by metaphorical mappings of structure from a typically body-based source domain onto a target domain, so that the image-schematic spatial or corporeal logic of the source domain is used to reason about the target. For instance, the metaphor "Knowing is seeing" conceptualizes acts of knowing as body-based visual processes, as in "I *see* what you mean" and "Could you *shed some light* on relativity theory?"

Cognitive Neuroscience

The development of sophisticated neuroimaging technologies has recently made it possible to supplement traditional phenomenological description, conceptual analysis, and cognitive linguistic research by revealing some of the bodily systems underlying these conceptual systems and thought processes. By means of lesion studies and brain-imaging experiments, we are beginning to understand some of the general conditions for certain types of cognitive activity, such as perception, conception, feeling, emotion, reasoning, communication, and willing. One of the more striking recent findings is about the key role played by sensory-motor processes, emotions, and feelings in reasoning. In contrast to disembodied views of cognition, neuroscientists like Antonio Damasio and Gerald Edelman present extensive research showing that what we traditionally have thought of as purely "mental" cognition actually recruits neural clusters responsible primarily for perception and action. It appears that a functional emotional apparatus is necessary for practical and social reasoning.

Recent exciting developments in cognitive neuroscience have also made it possible to give the basics of an embodied cognition approach to language and symbolic interaction. Based on the joint tenets that (a) thought is structured neural activity and (b) language is inextricable from thought and experience, Jerome Feldman and several others have explored what are known as structured or constrained connectionist neural models for various aspects of syntax, semantics, and pragmatics of natural languages. George Lakoff and his coauthors have provided the basics of similar neural models for certain types of concrete concepts, image schemas, and conceptual metaphors. The cognitive neuroscience of language and symbolic interaction is still in its infancy, but it is making major strides in uncovering the neural bases of our capacities for language comprehension and production. Most promisingly, it is beginning to offer experimental methods for determining whether sensory and motor areas are actually activated in the processing of various kinds of concepts and in our reasoning about abstract notions.

In only a few decades of research, we have thus moved from an almost total neglect of embodiment to a deep appreciation of the role of the body in mind, thought, and language. First, what we call "mind" and "mental activity" are intrinsically embodied. Second, as Gerald Edelman has insisted, it is now evident that neither is the brain completely modular nor is all cognition processed in a global, whole-brain fashion. There exist both modularity and complex reciprocal parallel interactions of multiple brain regions for most of our cognition. Third, thought and feeling are intimately intertwined, so much so that an intact emotional system is a requisite for all forms of practical and social reasoning. The traditional rigid and exclusive alignment of the mind with thought (conceptualization and reasoning) and the body with feeling and emotion is a nonstarter from a neural perspective. The body shapes all aspects of our higher cognitive activities. Fourth, the mind is not the brain. As William Bechtel has argued, although there is a tendency toward reductionist explanation in cognitive science, reductionist accounts of cognition often recognize the necessity of multiple irreducible explanatory levels that require multiple methods of inquiry and theorizing. None of this reduces the mind to neural activation alone.

We, thus, return to our earlier insistence that the locus of experience and cognition is not just a brain, not just a body, and not just a system of cultural practices but rather a functioning brain in a functioning body engaged with environments—physical, interpersonal, and cultural. The "body" of embodied cognition is a complex, multidimensional dynamic reality that gives us meaning, understanding, thought, and value.

Emergence

An emergent phenomenon is one that is novel, develops from other (usually more basic) phenomena, has some degree of autonomy from those phenomena, and often has a holistic aspect.

Because social phenomena are often significantly different from psychological and biological phenomena, can frequently be given a functional characterization, and often appear to possess holistic features, the first, third, and fourth of these properties tend to be present in social systems. The constructive task is then to provide an account of how the second feature is satisfied. In earlier times, emergent phenomena were viewed with suspicion, in part because of a bias toward reductionist methods, including methodological individualism, and in part because early writers on the topic restricted themselves to problematic cases such as consciousness and vital forces. The suspicion has lessened as a result of an increased understanding of what the concept of emergence entails and with the realization that emergence may be quite common, allowing more transparent examples.

Taxonomy of Emergence

What counts as an example of emergence is, nevertheless, currently a matter of significant dispute. One can divide positions on emergence into two broad kinds.

Emergence Resulting From Lack of Knowledge of a System

From the perspective of the first kind, emergence results from our lack of knowledge of a system. With systems of a sufficient degree of complexity, features can appear as a result of interactions between the components of the system, and those features will strike the observer as "novel" and "irreducible" because they lie far beyond our capacity to predict their appearance. For example, it is quite easy to construct computer simulations that effectively mimic the emergence of conventional standards in society, such as the almost universal adoption of the relatively inefficient QWERTY keyboard as a standard for typewriters. In the actual historical situation, the number and complexity of the choices made by typists, typewriter manufacturers, and businesses precluded both prediction of the emergence of this standard and its explanation via the decomposition strategies that are often successful in giving us understanding in less complex systems. Some versions of this unpredictability approach suggest that it is impossible in principle to predict emergent features, although because predictability is relative to the theory used for prediction and an unpredictability claim can be trivially undermined by adding the sentence to be predicted, such claims are rarely both precise and convincing. One reasonable interpretation of what is intended, however, is that the novel state of affairs could have been known only by waiting until it first appeared, even in the simulation model. These approaches using unpredictability fall into the category of what is often called *weak emergence*—weak because there is no commitment to downward causation, only to the existence of certain stable patterns in society.

What is, in contrast, often called *strong emergence* has a robustly ontological commitment; something genuinely new has emerged in the social world, beyond what was in the elements from which the whole was constructed. It is strong emergence that has traditionally been the source of disputes in the social sciences. Those who subscribe to some form of individualism—the position that only individuals and their properties exist—hold that not only do individuals preexist social arrangements, both temporally and ontologically, but that there is nothing over and above individuals, their properties, and the relations between individuals. Strong emergentists deny this and argue that there is more to the systems than individuals and their properties but tend to differ on what more there is. Some allow that there are social properties in addition to individual properties; others allow that higher-order entities such as corporations and universities exist in addition to their members; some others allow that individuals play no essential role in social processes and that all identifiably social causation occurs at the social level; and still others hold that there are emergent social laws that govern the development of social units or individuals. Within the individualist camp, the status of social relations is the subject of discussion. For some, such relations can be completely reduced to, or supervene on, intrinsic properties; in the latter case, once the intrinsic properties have been fixed, the social relations are automatically determined. For others, these social relations are sui generis and constrain the individuals they relate, often by influencing the agents' beliefs.

It is widely believed that the supervenience position precludes downward causation and hence strong emergence, because any influence from downward causation would be redundant given the causal processes at the level of individuals. But there is less reason to think that the realm of intentional action by individuals is causally closed in the way the physical realm might be closed, and so this application of the causal exclusion argument is not completely convincing.

Many anti-individualist positions can sensibly be called emergentist positions, and even individualist positions allow for weakly emergent features. Despite this, one must be aware that much talk of emergence in the social science literature is a *façon de parler* and does not reflect the existence of emergence in the strong sense.

It is commonly held among weak emergentists that emergence occurs when a threshold of complexity is crossed in a system. Investigations of this sort of emergence have been aided by the development of agent-based models. The constituent elements of these models are individuals, but in virtue of allowing multiple iterations of usually pairwise and often

nonlinear interactions between large numbers of agents, the emergence of novel structures or equilibria is sometimes observed. A well-known early example of this type of model was Thomas Schelling's toy model of social segregation, which demonstrated that small preferences about the type of one's neighbor can lead to structures of segregation in the society as a whole. These models have great potential in sociology, anthropology, and microeconomics, although they have not been welcomed by all, especially those who work in traditional economics. Such simulations support one version of weak emergence in which the only way to know how the system will evolve is to let the system run its course or to simulate its micro-states. This computational incompressibility gives some precision to unpredictability, but it is important to maintain a separation between emergent phenomena occurring in computer simulations of societies and the related phenomena occurring in the societies themselves. One consequence of our inability to predict the dynamics of complex systems on the basis of micro-information alone is the introduction of a macro-level vocabulary that is conceptually different from the micro-level descriptions and that facilitates prediction and description by virtue of erasing many of the details of the micro-states. This is why the vocabularies of microeconomics and of macroeconomics differ, as do the vocabularies of cognitive psychology and sociology and those of sociobiology and anthropology.

A common position holds that emergence entails the impossibility of reduction, although this incompatibility is occasionally resisted. This tradition requires that a hierarchy of levels or domains be identified for one level or domain to be reduced to or emerge from another. The usual ordering of levels based on composition, in which a necessary condition for one entity to exist at a higher level than another is that the latter be a constituent of the former, breaks down for the social sciences. Prima facie, one could argue that a particular type of economic system emerged from a set of cultural norms in a society, but neither economic processes nor cultural norms are constituents of one another. A possible source of confusion also needs to be addressed. It is sometimes claimed that *B*'s being explained in terms of *A* entails that *B* has been reduced to *A*. In certain cases, such as theoretical explanation, this makes sense, but in other cases, such as ontological explanations, this is straightforwardly false, as can be seen in the case when *A* is the cause of *B,* and the claim relating explanation and reduction seems to presuppose the presence of inter-level explanations.

Synchronic Versus Diachronic Emergence

A second broad division in emergence is that between synchronic and diachronic emergence. Although the majority of the philosophical literature on emergence addresses the synchronic case, the role of history in social institutions suggests the need to examine diachronic emergence more closely. Path dependence is a common phenomenon in the development of societies and social institutions, and synchronic emergence is unable to address this feature. It is the ability to computationally model the dynamics of social systems that has led to an increased acceptance of the existence of dynamically emergent social features.

Social Facts

The taxonomy given above makes no reference to rationality, intentionality, cultural norms, or other special features of human agency, whereas the existence of some emergent features of social groups seems to depend on the specifically social and normative aspects of social systems. The most prominent of these types of claims is Émile Durkheim's view that social facts exist, either as concrete institutions or as social norms, but social cooperation, group intentionality, and collective agency have been the focus of research in recent years. A core topic in this area is the emergence of cooperative behavior in societies, in particular the problem of how self-interested individuals can maintain a stable, cohesive, and efficient society. In this and other cases, normative criteria, especially those related to rationality, must frequently be taken into account. Some approaches in this area are reductive and neither require nor entail emergent features, but many are committed, via an irreducible appeal to first-person plural perspectives—"We endorse the candidate" can be true even if some individuals in the group voted against that candidate—to, at least, representations of collective social phenomena. Social interaction often involves representations, hence it presents the difficult philosophical problem of intentionality in ways that examples of physical emergence do not. To this end, John Searle has argued that collective intentionality resulting in linguistic declarations can

lead to social facts such as the establishment of a corporation, which may or may not be followed by the existence of an entity, the concrete corporation.

Although much of this literature concerns group agency, and hence the question of whether the group acts rationally on at least some occasions, there is an ontological aspect to this issue, which is whether social agents emerge from the interactions of individuals and exist autonomously from those individuals. For example, there is a long tradition within U.S. law of treating corporations as individuals. Whether or not this is legally or morally correct, one reason to think that some organizations are autonomous is the fact that group agents, such as corporations and universities, can retain their identities and ability to act despite complete replacement of the individuals who work in them. Mechanisms of self-organization can help us understand how certain types of groups can act cooperatively, and in Niklaus Luhmann's work, it is this combination of self-organization (*autopoiesis*) and the independence of features such as economic patterns from the individuals who instantiate them that is characteristic of social systems.

Despite the increased availability of tools to represent emergent features in social systems, it is important to maintain reductive individualism as the default position and to postulate emergent phenomena only when there is no convincing alternative position available. Unless one adopts this methodological position, introducing emergent entities becomes an escape route that is too easily available to avoid the difficult work of constructing a plausible individualist explanation.

Emergence and Social Collectivism

Emergence refers to the processes whereby the global behavior of a system results from the actions and interactions of agents. There is no central controller or plan; a higher-level order emerges from the interaction of the individual components. Such systems are self-organizing, with control distributed throughout the system. Emergent systems are often complex in that they manifest order at the global-system level, which is difficult to explain by analyzing the individual components of the system in isolation. In this sense, sociological theories of emergence have been used to argue in support of social collectivism: the position that social collectives cannot be understood by reduction to properties of the participating individuals—a contrasting stance known as *methodological individualism*.

This entry summarizes emergence theories, and their connections to complexity theory and systems theory, and shows their relevance for the study of social systems, in particular social entities that are irreducible social collectivities.

Emergence, Complexity, and Systems Theory

Emergence is generally associated with complex systems—systems that reside between simplicity and randomness. When the laws governing a system are relatively simple, the system's behavior is easy to understand, explain, and predict. These systems are often most easily explained by reduction to an understanding of their components and their interactions. At the other extreme, some systems seem to behave randomly. There may be laws governing

their behavior, but the system is highly nonlinear, such that small variations in the state of the system at one time could result in very large changes to later states of the system. Such systems are often said to be *chaotic*. Complex systems are somewhere in between these two extremes: The system is not easy to explain by reduction to an analysis of its components, but it is not so chaotic that understanding it is completely impossible.

Examples of emergence include traffic jams, the colonies of social insects, and bird flocks. To illustrate, the V shape of the bird flock does not result from one bird being selected as the leader and the other birds lining up behind the leader. Instead, each bird's behavior is based on its position relative to the birds nearby. The V shape is not planned or centrally determined in top-down fashion. Rather, it emerges out of simple pair-interaction rules, that is, from the bottom up. The bird flock demonstrates one of the most striking features of emergent phenomena: Higher-level regularities are often the result of quite simple rules and local interactions at the lower level.

Mental states, such as conscious awareness, memories, or intentions, are often said to emerge from the biological brain. Complex systems that manifest emergence tend to have a large number of units, with each unit connected to a moderate number of other units, and frequent, repeated interactions among the connected units, which occur simultaneously throughout the system. Continuing our example of the mind–brain relation, the brain is a complex system composed of more than 100 billion neurons, with each connected to between 1,000 and 10,000 other neurons at synapses. Complex physical and biological systems tend to have relatively simple interactions between components. For example, neurons communicate by changing the rate of firing across a synapse. In contrast, the units in complex social systems are individuals who communicate using the full richness of natural language.

Emergence and Society

In the social sciences, a comparable example of an emergent phenomenon is language shift. Historians of language have documented that languages have changed frequently throughout history, with vocabulary and even grammar changing over the centuries. Yet until the rise of the modern nation-state, such changes were not consciously selected by any official body, nor were they imposed by force on a population. Rather, language shift is an emergent phenomenon, arising out of the nearly infinite number of everyday conversations in small groups scattered throughout the society. In this social system, successive conversations among speakers result in the emergence over time of a collective social fact: language as a property of a social group. The study of social emergence requires a focus on multiple levels of analysis—individuals, interactions, and groups—and a dynamic focus on how social group phenomena emerge from communication processes among individual members.

Societies have often been compared with other complex systems that manifest emergence. Just after World War II, Talcott Parsons's influential structural functional theory was inspired by cybernetics, a field centrally concerned with developing models of the computational and communication technologies that were emerging in the postwar period. In the 1960s and 1970s, general systems theory continued in this interdisciplinary fashion. It was grounded in the premise that complex systems at all levels of analysis—from the smallest unicellular organisms up to modern industrial societies—could be understood using the same set of theories and methodologies.

Common to all of these metaphors is the basic insight that societies gain their effectiveness and functions from a complex configuration of many people engaged in overlapping and interlocking patterns of relationships with one another. Some key questions raised by these "society as system" metaphors are as follows: What do these relations and configurations look like? Which systems are the most effective, and which are stable and long lasting? How could a stable complex system ever change and evolve, as societies often do? What is the role of the individual in the system? Such questions have long been central to sociology.

Theories of emergence have the potential to provide several new insights into these central sociological questions. Beginning in the mid-1990s, several scientific developments converged to create a qualitatively more advanced approach to emergence, and theories of emergence (often drawn from complexity theory) began to influence a wide range of disciplines from biology to economics. This influential new approach has begun to filter into

sociology. The study of emergence can provide new perspectives on important unresolved issues facing the social sciences—the relations between individuals and groups, the emergence of unintended effects from collective action, and the relation between the disciplines of economics and sociology.

Parsons's structural functional theory represented the first wave of systems theories in sociology, drawing on systems concepts from cybernetics to describe human societies as complex self-maintaining systems. The general systems theories of the 1960s and 1970s represented a second wave. General systems theories were always more successful at explaining natural systems than social systems. In spite of the universalist ambitions of such theorists, social scientists generally ignored them. In contrast, the latest work in complexity theory—the *third wave* of systems theory—is particularly well suited to sociological explanation because it focuses more squarely on emergence. Third-wave sociological systems theory grew out of developments in computer technology. In the 1990s, computer power advanced to the point where societies could be simulated using a distinct computational agent for every individual in the society, using a computational technique known as *multi-agent systems*. A multi-agent system contains hundreds or thousands of agents, each engaged in communication with at least some of the others. The researcher can use these simulations to create *artificial societies*. The researcher defines and implements a model of the individual agent, creates a communication language for the agents to interact, and then observes the overall macro-behavior of the system that emerges over time.

Whether or not a global-system property is emergent, and what this means both theoretically and methodologically, has been defined in many different ways. For example, in some accounts, system properties are said to be emergent when they are *unpredictable* even given complete knowledge of the lower-level description of the system—a complete knowledge of the state of each component and of their interactions. In other accounts, system properties are said to be emergent when they are *irreducible,* in any lawful and regular fashion, to properties of the system components. In yet other accounts, system properties are said to be emergent when they are *novel,* when they are not held by any of the components of the system. Philosophers of science began debating such properties early in the 20th century. Social scientists have applied widely different definitions of emergence, resulting in some conceptual confusion.

Emergence Versus Reductionism: Social Collectivism

Sociological theorists and philosophers of science have argued that the emergent higher level may have autonomous laws and properties that cannot be easily reduced to lower-level, more basic sciences. Thus, the paradigm of complexity is often opposed to the paradigm of reductionism. For example, cognitive scientists generally agree that mental properties may not be easily reduced to neurobiological properties, because of the complex dynamical nature of the brain. In an analogous fashion, several sociological theorists have used complexity theory to argue against attempts to explain societies in terms of individuals, a reductionist approach known as *methodological individualism*. Because many socially emergent phenomena are difficult to explain in terms of the system's components and their interactions, these theorists have claimed that emergentist thinking supports social collectivism or holism and that individualist approaches will have limited success as a potential explanation for many social phenomena.

For example, due to complexity and emergence, there may be potential limitations of individualist methodologies such as neoclassical microeconomics and evolutionary psychology. Emergence and social collectivism suggest that both psychology and microeconomics are likely to be severely limited in their ability to explain human behavior in groups. As currently conceived, psychology is the study of system-independent properties of individuals (e.g., variables, traits, mental models, cognitive capacities). Microeconomics is the study of how collective phenomena emerge from aggregations of individual preferences and actions. Both are individualist in that they reject explanations that propose that group properties could lawfully influence individual action. Many contemporary paradigms are based on such reductionist assumptions—evolutionary psychology, cognitive neuroscience, behavioral genetics, and social cognition. Yet an emergentist perspective suggests that many social systems may not be explainable in terms of individuals and that neither

psychology nor microeconomics can fully explain the socially contextualized nature of human behavior.

Because societies are complex systems, individualists cannot assume that a given social system will be reducible to explanations in terms of individuals. Inversely, social collectivists cannot assume that a given social system will not be so reducible. Whether or not a social system can be understood solely in terms of its component individuals and their interactions is an empirical question, to be resolved anew with respect to each social system. Theories of emergence show why some social properties cannot be explained in terms of individuals. Thus, one cannot assume that methodological individualism can exhaustively explain human behavior in social groups. However, not all social systems are irreducibly complex, and some social properties can be explained by identifying their processes of emergence from individuals in interaction. Complexity approaches can help determine which approach will be the most appropriate for which social system.

Conclusion

Studies of social groups must be fundamentally interdisciplinary, because a focus on emergence requires a simultaneous consideration of multiple levels of analysis: the individual, the communication language, and the group. A complete explanation of the most complex social systems may require interdisciplinary teams composed of psychologists, sociologists, communication scholars, and economists.

Emotions

Emotions have been one of the subject matters of philosophy from ancient times to the present. This entry presents two of the main ways of analyzing the essential features of emotional states and concludes by delineating how emotions relate to morality.

Emotions are probably the most complex mental phenomena, as they involve all types of mental entities and states that belong to various ontological levels. In order to capture the complexities and subtleties of emotions, a few complementary methods may be used. One major way is to describe a typical emotion; another is to attempt to define the essence of emotions.

What Is a "Typical" Emotion?

Typical emotions are generated by perceived significant changes, and their focus of concern is personal and comparative. Typical emotional characteristics are instability, great intensity, partiality, and brief duration. Basic components are cognition, evaluation, motivation, and feelings.

Emotions typically occur when we perceive positive or negative significant changes in our personal situation or in the situation of those related to us. Like burglar alarms going off when an intruder appears, emotions signal that something needs attention.

Emotions occur when a change is evaluated as relevant to our personal concerns. Emotions serve to monitor and safeguard our personal concerns; they give the eliciting event its significance. Emotional meaning is mainly comparative. The comparison underlying emotional significance encompasses the mental construction of the availability of an alternative situation. The more available the

alternative—that is, the closer the imagined alternative is to reality—the more intense the emotion.

Instability, great intensity, a partial perspective, and relative brevity can be considered as the basic characteristics of typical emotions. This characterization refers to "hot emotions," which are the typical intense emotions. The more moderate emotions lack some of the characteristics associated with typical emotions.

In light of the crucial role that changes play in generating emotions, instability of the mental (as well as the physiological) system is a basic characteristic of emotions. Emotions indicate a transition in which the preceding context has changed but no new context has yet stabilized. Emotions are like storms and fire—they are intense, occasional, and limited in duration.

Emotions are intense reactions. In emotions, the mental system has not yet adapted to the given change, and due to its significance, the change requires the mobilization of many resources. No wonder that emotions are associated with urgency and heat. A typical characteristic of emotions is their magnifying nature: Everything looms larger when we are emotional.

Emotions are partial in two basic senses: They are focused on a narrow target, such as one person or very few people, and they express a personal and interested perspective. Emotions direct and color our attention by addressing practical concerns from a personal perspective.

Typical emotions are relatively brief. The mobilization of all resources to focus on one event cannot last forever. A system cannot be unstable for a long period and still function normally; it could explode due to the continuous increase in emotional intensity.

In addition to these typical characteristics, we can also divide emotions into four basic components: cognition, evaluation, motivation, and feeling. Cognition contains descriptive information about the object; evaluation assigns value to the information included in the cognitive component and, consequently, in many cases generates great motivation and desire to act in a certain manner toward the emotional object. The feeling component expresses the subject's state.

Emotional intensity is determined by several variables that can be divided into two major groups: one referring to the perceived impact of the event eliciting the emotional state and the other to the background circumstances of the agents involved in the emotional state. The major variables constituting the event's impact are the strength, reality, and relevance of the event; the major variables constituting the agent's background circumstances are accountability, readiness, and deservingness.

Kindred Types of Affective States

Together with the emotions, the affective realm includes other phenomena such as sentiments, moods, affective traits, and affective disorders. Emotions and sentiments have a specific object, whereas the object of moods, affective disorders, and affective traits is general and diffuse. Emotions and moods are essentially occurrent states; sentiments and affective traits are dispositional in nature. These differences are expressed in temporal differences. Emotions and moods are relatively short, whereas sentiments and affective traits last for a longer period.

The Common Essence of Emotions

In addition to explaining emotions by describing their typical features, emotions can be explained by defining the essence common to all those features. This method is problematic because emotions are so complex that it is difficult to find such a single definition.

One such possible definition is that emotions are a general mode (or style) of the mental system. Such a general mode is a complex arrangement that functions over time. It is a dynamic, structured experience. The kinds of elements involved in a certain mode and the particular arrangement of these elements constitute the uniqueness of each mode. Other possible modes are the perceptual, imaginative, and intellectual modes. The emotional mode is more complex, comprehensive, and dynamic than the other mental modes.

The relationship between emotional and intellectual modes has been at the center of many disputes. There is a long tradition that criticizes emotions as being irrational and nonfunctional. It seems that this tradition is fundamentally wrong. Emotions are rational in the normative sense of being an appropriate response in the given circumstances. Although emotions are not functional in all circumstances, they are tremendously important when facing urgent situations involving a significant change. In these situations, emotions might be the optimal response.

Three major functions of emotions are (1) an initial indication of the proper direction in which to respond, (2) quick mobilization of resources, and (3) social communication. Emotional excess might be harmful, but so are all types of excess. Thus, it is advisable neither to suppress our emotions nor to have an excess of them; ideally, we should strive for emotional balance.

Emotional intelligence is the optimal integration of the emotional and intellectual systems; it consists of recognizing and regulating emotions in an optimal manner. In light of the differences between the two systems, we can speak of "emotional reasoning" as different from intellectual reasoning.

Emotions and Morality

The role of emotions in the moral domain has been frequently disputed. The partial nature of emotions seems to contradict the more general and egalitarian nature of basic moral evaluations. Emotions are nevertheless morally valuable. They are especially so in our relationships with those near and dear to us. In such circumstances, which constitute the bulk of our daily life, discriminatory emotional attitudes are not only possible but morally commendable as well. Particular emotional attention to the specific needs of those close to us is of crucial moral importance. Emotional attitudes are also a moral barrier against many crimes. The crucial role of emotions in moral life does not imply their exclusivity; the intellectual capacity is important as well.

Emotions in Economic Behavior

Emotions can influence economically relevant decisions in at least two ways. First, emotions expected to occur as the result of a particular course of action (e.g., happiness that might result from taking a vacation or regret that might result from not taking it) can be components of that action's desirability or "utility." Second, emotions experienced at the moment of choice may influence expected utility or override deliberate consideration of expected utility. These "immediate emotions" can either be integral to the decision at hand (e.g., the anxiety experienced when deciding whether to make an indulgent purchase) or incidental to the decision (e.g., lingering anxiety about an upcoming medical exam). Economists have made good progress toward understanding the influence of "expected emotions" on decision making but have only recently explored the role of immediate emotions.

Insights From Behavioral Economics

For most of the past century, economists largely ignored emotions. Economists typically assumed that decisions reveal stable preferences. Because choice presumably conveys such rich information, expected emotions, which may merely be one component of stable preferences, required little attention. Emotions experienced at the moment of choice were of even less interest, since decision makers should be forward looking, forming their decisions purely on the basis of potential outcomes. Other properties of emotions such as their fleeting nature and the difficulty involved in measuring them precisely likely contributed to their absence from economic analyses.

This situation began to change in the 1980s with the emergence of behavioral economics, a subfield of economics that incorporates insights from psychology and neighboring disciplines to increase the descriptive accuracy and predictive power of economic theory. Findings from behavioral decision research, a subfield of psychology, increasingly suggested that

decision makers rarely act on preferences that are stable and well formed but rather on preferences that are constructed on the spot. Contextual factors that influence the construction of preferences (e.g., whether outcomes are framed as gains or losses) generated much interest among behavioral economists. Emotions were less central to behavioral economists but did begin to receive attention.

Behavioral economists appealed to emotions to help explain phenomena that were anomalous from the standard economic perspective. Consider, for example, typical behavior in the "ultimatum game." In the game, there is an amount of money to be divided between a proposer and a responder. The proposer proposes a division, and the responder can either accept the proposal or reject it, leaving both players with nothing. If players are strictly self-interested (the standard economic assumption), the responder should accept any positive amount of money, and the proposer should therefore offer the responder the smallest positive amount of money possible. In reality, proposers often offer to split the money equally, and responders often reject lopsided offers that would leave them with far less than the proposer. The results suggest that anger over being treated unfairly can swamp self-interest (and proposers largely expect this). Indeed, Sally Blount found that responders were significantly more likely to accept lopsided proposals when those proposals were generated by chance than when those proposals were actually made by human proposers, suggesting that anger played a significant role in the high rejection rate of intentionally lopsided proposals.

Other research demonstrated that incidental emotions, unrelated to the task at hand, could predictably influence economically relevant decisions. For example, David Hirshleifer and Tyler Shumway found that the amount of morning sunshine correlated positively with daily stock returns, possibly because investors misattributed their good mood to positive economic prospects. Laboratory research by Jennifer Lerner and colleagues also demonstrated that discrete incidental emotions can influence economic valuations (e.g., willingness to pay), further challenging standard economic theory.

Enter Neuroeconomics

Interest among economists in the role of immediate emotions has increased markedly since the advent of neuroeconomics, a subfield of behavioral economics that examines the neural processes that underlie economic decision making. Early foundational work in this area by Antoine Bechara, Antonio Damasio, and colleagues focused on the role of *somatic markers,* feelings that encode the consequences of alternative courses of action, in guiding decision making. They demonstrated that people with damage to the ventromedial prefrontal cortex, a brain region that plays a critical role in this affective encoding process, were unable to execute what they cognitively realized was the optimal strategy in an economic game, thus costing themselves money. While the extent to which emotional deficits actually harm decision making depends on the situation, this work demonstrates that immediate integral emotions can play a central role in decision making.

Interest in emotions further accelerated as neuroeconomists began to investigate the neural underpinnings of economic decision making with functional magnetic resonance imaging. Economists, chronically skeptical of the "cheap talk" possible when experimental participants are asked to report their feelings or why they behaved in a particular way, are increasingly willing to listen to the brain rather than the person. There are limitations to neuroeconomic data, however (e.g., they are largely correlational; inferring an emotion from activation in a particular region is difficult when that region is not selectively activated by that emotion), and the subfield is certainly not without its critics within economics, who argue that economics should remain focused on predicting behavior rather than the processes underlying behavior (e.g., neural activation). Nevertheless, a spate of models inspired by neuroeconomic research, attempting to characterize the interactions between affect and deliberation, has recently emerged in behavioral economics.

Open Questions

Ongoing debates center on whether there are separate emotional and deliberative neural systems that interact to influence decision making, whether emotions help or hurt decision makers, and whether societal problems are more attributable to intense or insufficient emotions.

Empathy

The British psychologist Edward Titchener introduced the term *empathy* in 1909 as an English translation of the German word *einfühlung* ("feeling into"). *Einfühlung* is rooted in philosophical aesthetics. It was used by German philosophers toward the end of the 19th century to describe our ability to imaginatively "feel into" works of art and nature. However, it was the German philosopher Theodor Lipps who broadened the term to encompass our experience of other people. Lipps transformed empathy from a predominantly aesthetic concept into a concept at the center of philosophical and psychological analyses of sociality. This emphasis on the social-scientific significance of empathy continues to inform current discussions.

This entry looks at empathy within the context of social cognition. It considers empathy in relation to the philosophical problem of other minds, the mechanisms of social cognition, and the relation between empathy and affectivity.

Empathy and the Epistemology of Other Minds

Empathy has been summoned to deal with the philosophical problem of other minds. This problem arises from the question "How do we know that other people have minds like ours?" That others *do* have minds like ours seems fairly certain. Yet one might think that we cannot see other minds or experience them via some other perceptual modality. The only mind we can directly experience is our own. Given this lack of experiential access to any mind but our own, how is knowledge of other minds possible?

This is an epistemological puzzle: the question of how we are justified in believing that others have minds like ours. One answer is that we rely on inference from analogy. This inference explains how we attribute minds to others. It begins with a Cartesian assumption: We enjoy direct, infallible access to our own mind; in contrast, our access to other minds is indirect and fallible. Moreover, we know that when we experience certain mental states (anger, sadness, etc.), those states characteristically cause certain patterns of behavior (frowning and fist shaking, weeping, etc.). Accordingly, when we observe this behavior in others, we infer the existence of the relevant mental state causally responsible for that type of behavior. We assume the other to be psychologically similar to us and infer that his behavior is animated by the same type of mental state(s) animating our own behavior.

Many have not found this answer satisfactory. Lipps is one such philosopher. In his 1907 article "Das Wissen von fremden Ichen" (The knowledge of other "I"s), Lipps argues that analogy cannot account for our basic openness to others. It is unclear, Lipps argues, how analogical inference can simultaneously allow us to think about another's mental states as both similar to our own and yet radically different, that is, as *that person's* mental states. Lipps argues that empathy can better explain this openness. For Lipps, this "instinct of empathy" consists of my imitating the gestures or expressions I see in others. When I see another's expression of anger,

say, I reproduce this anger—I experience the feeling of anger myself—but I then project this feeling onto the person who first evoked it. Empathy is therefore a process of simulation and projection. It is, Lipps argues, at the root of interpersonal understanding.

Phenomenologists such as Edmund Husserl, Max Scheler, and Edith Stein offer an alternative picture. They agree that analogical inference is not the way to understand our basic experience of other minds. Yet, although they differ in the details, they reject Lipps's "simulation plus projection" alternative. Instead, they argue that empathy is what Stein terms an "experiential act sui generis": a primitive, irreducible form of intentionality that, prior to inference or simulation, presents other human beings to me *as* "minded" *in* my experience of them. Empathy is a form of direct perception, not simulation. From the start, I perceive others differently than I do rocks, tables, or trees. I see them as a locus of unique thoughts, feelings, and intentions: a psycho-physical "expressive unity," as Scheler puts it. This is because the actions, gestures, and facial expressions of others present me with the experience of a concretely embodied mind. The phenomenological model of empathy thus rejects the Cartesian assumption that minds are entirely in the head, hidden from others. In perceiving expressive behavior, I see the mental life of others play out *in* that behavior. Perception of others in their concrete expressiveness is thus sufficient to justify our belief that others are likewise minded.

Empathy and the Psychology of Other Minds

There remains another puzzle. We might term this the psychological problem of other minds: the question concerning the mechanisms ultimately responsible for interpersonal understanding. Here, empathy is often framed as a kind of "mind reading," or the ability to detect and respond to the mental life of others and to interpret and predict their behavior.

This is an empirical question. It is distinct from the epistemological question of other minds. Independently of whether or not we are justified in believing in other minds, there remains the question of how we come to know what another person is thinking, feeling, or intending, or how to interpret his or her behavior. This issue is the focus of most current empathy research in the cognitive and social sciences. However, there is little agreement on the proposed candidate mechanisms enabling empathy. There is even disagreement over the nature of empathy itself.

We have already encountered some of the mechanisms said to be responsible for empathy: inference, simulation, and perception. *Theory Theorists* argue that we use our lay theories about how minds work ("folk psychology") to infer the existence of mental states in others and to interpret their emotional expressions and behavior. These lay theories are the basic mechanisms of empathy. They are sometimes said to emerge from innate 'mind reading' modules in the brain; others claim that they develop as we age and gain social experience. When we deploy our lay theories, we use inference from perceived behavior (including utterances) to hidden internal states. This theory-driven knowledge of another's internal state(s) is sometimes called "cognitive empathy" or "empathic accuracy."

Simulation theorists, on the other hand, argue that we use our own emotional and imaginative resources to put ourselves in others' mental shoes and read their internal states through observing their behavior. We use imagination as well as the knowledge of how we would feel in their situation to take their perspective and come to understand what they are thinking and feeling. This is sometimes called "projective empathy" or "perspective taking."

Other simulation theorists argue that a different sort of simulation is responsible for empathy: *mimicry*. I mimic another person's posture or expression —think of two friends speaking closely while leaning on a bar or a newborn imitating the facial expressions of her caregiver—and come to understand what this other person is thinking and feeling. This is an example of behavioral mimicry. It has been called "facial empathy," "imitation," or more commonly "motor mimicry." Other simulation theorists argue that the relevant mimicry occurs at the neural level. Brain studies indicate that when we observe someone perform an intentional action, such as swinging a baseball bat or reaching for a cup of coffee, the same neurons in our own brain are activated as if we had performed the action. These "mirror neurons" allow us to interpret the actions of others; we read their minds by (neurally) mimicking their actions and discerning their intentions. This is sometimes called a "perception–action" model of empathy because perception and action—perceiving another's action and performing the action ourselves—rely on similar neural circuits.

Other researchers return to phenomenological characterizations of empathy and argue that *perception* is the primary mechanism for empathy. They

argue that our interactions with others are simply too fast, automatic, and flexible to involve the conscious use of either lay theories or imaginative simulations. There is no phenomenological evidence that we deliberately employ either of these mechanisms to understand others, except in unusual circumstances. Rather, we directly see mental phenomena in ongoing patterns of expressive behavior and respond accordingly. This behavior, as well as an appreciation of the different situations that contextualize it, provides sufficiently rich information to discern others' thoughts, emotions, and intentions. Even if mirror neuron activity is part of this story, it is not the exclusive locus of empathy; rather, it is an aspect of a more complex, temporally extended pattern of social perception. This approach, with its emphasis on face-to-face encounters, is sometimes called a "direct perception," "enactive," or "interactionist" approach to empathy.

Empathy and Affectivity

Another area of disagreement concerns the relation between empathy and affectivity. When we see another's facial expressions and behavior, we often *feel* something in response. A remaining issue concerns the extent to which empathy involves feeling—specifically, feeling *what* another person is going through or minimally feeling a response *to* what he or she is going through. There are two questions here. The first is the extent to which affectivity is necessary for empathy. The second is the question of what compels us to consider and respond with care to the suffering of others. Although the second question deals with important issues concerning motivation and moral psychology, these issues are beyond the scope of this entry.

With respect to the first question, some theorists mark a distinction between empathy and *sympathy*. The former is our basic ability to detect and interpret another's emotions and behavior; the latter is our ability to feel with another person, to either replicate her or his emotion or feel something similar. Empathy—whatever its mechanistic basis—thus proceeds independently of other-oriented affectivity. For example, I can attain knowledge of my friend's suffering via her facial expressions, behavior, utterances, and so on, as well as understand the source of her suffering and how it will guide her behavior, while failing to feel congruent suffering myself. Indeed, becoming highly emotionally aroused can actually impede one's ability to read another's behavior and respond appropriately. So it's not clear that other-directed feeling is necessary for empathy.

Nevertheless, affectivity might be an important part of empathy's ontogenesis. Evidence from developmental psychology suggests that emotional intimacy in early infant–caregiver interactions may provide the developmental context for basic social-cognitive abilities. From birth, the emotional character of these interactions has a motivational effect on infants, compelling them to engage with others. It also guides the infant's attention toward socially salient phenomena such as facial expressions and gestures. *Affect attunement*—the ability to coordinate one's affective states with those of another—thus appears to be the basis from which various individualistic capacities (e.g., self-consciousness, language, self-regulation, self-representation) arise. Since an individualized sense of self and subjectivity is necessary for empathy—that is, to appreciate another's experience *as another's*—affectivity in social relations might be thought of as the ground of empathy, even if affectivity need not be present for empathy to occur.

Judging from the state of current research, the term *empathy* serves as an umbrella term for a relatively heterogeneous group of structures and processes that facilitates different facets of sociality and interpersonal understanding. As such, it is not clear that any single paradigm or disciplinary perspective will adequately capture all of its aspects.

Empiricism

The term *empiricism* is often taken to be a vague term for a cluster of doctrines held by the classic modern empiricist philosophers John Locke (1632–1704), George Berkeley (1685–1753), and David Hume (1711–1776), in opposition to the "rationalist" tradition of René Descartes, Baruch Spinoza, and G. W. Leibniz. This takes the terms to be similar to labels for certain tendencies with no clear issue to distinguish them. The result is that many philosophers think these terms are best avoided in serious discussion. But this is premature. There are two clear issues that separate empiricists from rationalists: (1) whether there are innate ideas and (2) whether any propositions can be rationally justified independently of experience. *Conceptual empiricism* is the doctrine that there are no innate ideas but all concepts are acquired through experience, either by introspection or by sense experience, while *justificatory empiricism* holds that all knowledge that something exists independently of experience must be justified on the basis of experience, that is, it must have an empirical justification. The first is a psychological claim about the origin of ideas, while the second is a thesis about evidence and is thus an epistemological claim. The negations of them are conceptual and justificatory rationalism, respectively.

This entry focuses on the British empiricists, in relation to these two issues, innateness and justification. Concept innateness, or *nativism* as it is now called, has come back as one of the central issues debated in contemporary philosophy of mind (this issue is discussed in another entry but indicated here in some items in the Further Readings).

The Two Issues

Concepts

The psychological issue arises in the work of René Descartes (1595–1650). He holds that certain basic concepts such as those of God, infinity, extension, and the mathematical entities cannot be derived from experience and so must be innate. The concept of a line, for instance, cannot come from sense experience, since the lines we experience are only imperfect copies of the lines studied by geometry. Seeing lines on a piece of paper triggers our innate ability to form the concept of the ideal line of geometry, but it does not give us the *idea.* It is an idea of reason or intellect distinct from an image or any idea we can acquire by perception. John Locke, however, denied this and held that the concept derives from experience by abstraction, where experience includes reflection and sense perception, or "inner" and "outer" sense as he calls it. We see lines and leave out their particular characteristics, and by abstraction, we form the notion of a line as an extended series of points with no width. Philosophers discussed this question in the 19th century, but interest in it waned in the early 20th century, when psychology became experimental. The work of the linguist Noam Chomsky reawakened interest in the issue in the later part of the century. Before turning to this, let us look at the question raised by the second issue, that of justification.

Justification

Since Plato, it has seemed clear that knowledge cannot be reduced to true belief. As Socrates argues in Plato's dialogue *Meno,* one might have a true belief about the road to Larissa but be right by accident. He says that beliefs are like the statues of Daedalus, which are so real that they move around. Like them, beliefs need to be "tied down" so they do not "roam about," and the way to do this is to support them with a *logos* or "account." Without this, they cannot qualify as knowledge even if they are true. The modern term for this third element is that the believer must have some reason for thinking that the belief is true, that is, it must be "justified."

The justificatory empiricist holds that if the belief is about a real existent—that is, an entity that exists independently of what is thought about it—it must be justified by sense experience or introspection, while the rationalist holds that claims about real entities can be justified a priori, that is, on grounds independent of experience. Taking *empirical* to mean that the proposition is justified by appeal to experience, we may sum this up by saying that the justificatory empiricist holds that *all knowledge of real existence is empirical,* while the rationalist holds that not all of it is but some is a priori or justified independently of experience.

By "knowledge of real existence" here is meant knowledge that an object or class of objects has real existence, that is, knowledge of truths of the form "There are Xs." Propositions of the form "There are no Xs" may be known empirically (e.g., "There are no two-headed snakes") or a priori (e.g., "There are no round squares"). Experience is not necessary to be justified in believing that there are no round squares, since they are contradictory. The empiricist holds that for us to know that objects have real existence, experience is necessary, but we may know a priori that an object, at least one of a certain special kind (e.g., an impossible object, like a round square), does not exist.

This point is important for understanding George Berkeley. It is sometimes thought that he is not an empiricist since he claims to know that there are no material objects by means of a purely conceptual argument —that is, a priori. Briefly, his argument is that it is inconceivable for something to exist unperceived, since in thinking about it we are perceiving it; that is, he holds that "Material objects exist" is contradictory. For material objects, Berkeley says, "*esse est percipi*" ("to be is to be perceived"). Whether this argument succeeds is a question for metaphysics and need not concern us here (since we are confined to the epistemological side). The important point is that giving an a priori argument for the impossibility of material objects is not inconsistent with his being an empiricist.

More generally, it should be noted that the justificatory empiricist (or just "empiricist" from now on) need not deny that we have a priori knowledge. He might hold that propositions such as that triangles are three-sided figures and 2 + 3 = 5 are a priori but are about useful fictions that have no existence independently of what is thought about them. Locke, Berkeley, and Hume all accepted a priori knowledge, but since they were nominalists (repudiating the reality of universals), this was consistent with their claiming that knowledge of real existence is empirical. Locke, for instance, holds that "The angles of a triangle equal 180 degrees" is a priori (although he never uses the word) and that it is about triangles in nature only if we also know empirically that there are triangular objects. The result is that pure mathematics is a priori but not about real existence, while applied mathematics is about reality but is empirical. Other empiricists, such as J. S. Mill in the 19th century and Willard Quine in the 20th century, go further and reject a priori knowledge altogether, but this does not make Locke any less an empiricist.

Several other points should be noted about this characterization of the issues. First, on this account, empiricism and rationalism on both issues are contradictories. One cannot consistently be both (an empiricist and a rationalist) on either the psychological or the justificatory issue. Second, the justificatory empiricist need not have any opinion on the psychological issue since justification is a matter of evidence and is independent of the genesis of our ideas. Hume appears to be a case in point. He is clearly an empiricist since he holds that all existence claims are empirical, but he also seems to think that the debate over innate ideas is frivolous (*Enquiry Concerning Human Understanding,* sec. II). A third point is that anyone who accepts the ontological argument for God—in other words, the argument that God's existence is known by a priori examining the concept of God—is a justificatory rationalist, while all empiricists must reject it. Finally, these definitions have implications that startle (and perhaps offend) some philosophers. One is that Immanuel Kant is a rationalist since he holds that Newton's law of universal gravitation is a *synthetic* a priori truth about reality. Another is that the early Bertrand Russell is also a rationalist. Russell (1912) says the empiricists were right that all knowledge of existence is empirical, but he also holds that we have a priori knowledge of "subsistent" entities that "have being" timelessly in a Platonic world divorced from ours (*Problems of Philosophy,* chaps. VII and IX).

Criticism and Rejoinders

Empiricism and Innate Ideas

Let us first look at Locke's criticisms of the doctrine of innate ideas and then turn to the issue of

justification. Descartes did not hold that we are always thinking of our innate ideas but that they exist as mental dispositions and need experience only to bring them to consciousness. As he says, children have these ideas in the same way as adult humans have ideas "when they are not attending to them" (letter to Hyperaspistes, 1641). Unlike other mental dispositions (e.g., the ability to speak a language or to play chess), experience is not necessary to first shape them. Let us call them innate *abilities* as opposed to *capacities* (i.e., *dispositions to acquire abilities*). More generally, innate ideas are unstructured powers. An iron bar has the unstructured power to attract iron filings, but it must first be magnetized (or "structured"), perhaps by hitting it with a hammer or passing it through an electrical field. Descartes's view is that our idea of God and the "simple natures" of mathematics are unstructured, innate powers to think of their objects. Experience is only necessary to bring them to consciousness.

One of Descartes's arguments derives from Plato. As we saw, he holds that we cannot acquire the ideas of pure geometry from sense experience since the lines and figures we perceive are not perfectly straight, circular, or triangular. Locke argues that the more plausible theory is that we arrive at them by noting similarities between sensed objects and abstracting from them. They are "perfect" because we ignore the imperfections in our images. Furthermore, the results of this process are fictions or ideal entities (*entia rationis*) that have no real existence outside of thought. Leibniz offered several arguments against Locke in the preface to his *New Essays Concerning Human Understanding,* but most of them rest on misunderstandings of Locke, although this is not generally recognized. First, Leibniz ignores Locke's distinction between inner and outer sense and discounts the role of abstraction. The result is that he merely repeats the traditional arguments that ignore Locke's innovation. Second, Leibniz does not recognize Locke's argument that the innateness doctrine makes all ideas innate if it claims only that we have an innate power to create innate ideas, since every idea we have presupposes an innate power to have it. That is, he ignores what I have called the distinction between capacities and abilities. He bases his criticism on Locke's claim that the mind is a blank tablet at birth (*tabula rasa*), claiming that it is more like a marble block with veins in it. But all Locke meant was that there are no ideas in the mind at birth; he was not denying that we have innate capacities. As Quine was later to put it, the empiricist is "up to his neck in innate mechanisms." The issue is whether abstraction and experience in Locke's expanded sense offer a more plausible explanation of mathematical and logical concepts than innateness, and Leibniz does not address this question.

Historically, conceptual empiricism spurred psychological research in the 19th century through the work of Johann Herbart and Hermann von Helmholtz in Germany and the Mills (John and John Stuart) and Alexander Bain in Britain. Most of this work was speculative or "literary" psychology until Wilhelm Wundt discovered experimentally that the recognition of symbols rests on learning and unconscious processing. In one experiment, subjects were asked to guess three-letter words flashed on a screen too briefly for them to be recognized consciously. He found that native speakers of the language of the target words guessed correctly far beyond what chance would predict, while speakers of other languages performed according to chance. The upshot of this research was that introspection cannot determine when a conceptual ability is innate or derived from experience.

Recently, the linguist Noam Chomsky has revived the debate by arguing that something like the Cartesian doctrine is necessary to explain the fact that humans are only capable of learning a limited range of natural languages. Once again, empiricist critics have argued that this only means that we have an innate capacity to learn only these languages; it does not mean that we have an unstructured innate ability to learn them. It is in this context that Quine remarked that empiricists have always recognized innate capacities. Chomsky has also argued that behaviorism cannot explain language learning since we cannot learn it by generalizing by induction from what we hear. Some behaviorists might overemphasize induction in this connection, but the empiricist is not committed to induction alone. He can argue that children learn language by hearing certain patterns, forming hypotheses, then rejecting them on further experience until they acquire one of the small number of natural grammars the human brain is innately capable of learning. These debates cannot be pursued here, but it seems clear that further progress rests on recognizing the distinction between innate capacities, which need to be shaped by experience,

and innate abilities, which are ready to go without assembly by experience.

Empiricism and Justification

This issue is obscured by the difficulty of getting a clear explanation of a priori justification. Descartes holds that propositions such as "Nothing can be *F* and not be *F* at the same time" and "2 + 3 = 5" are immediately known independently of any sense experience and so must be justified by some other faculty, which he calls "the light of reason" or "pure intellect." But this merely puts a name to the source without explaining it. All we know about it is what it does, not what it is or how it operates. This is similar to saying that opium causes sleep because of its soporific power. By contrast, we have some understanding of experience as a source of evidence from common sense and our knowledge of our sense organs and how they work.

Ironically, when rationalists try to characterize the a priori positively, they always end up comparing it with sense experience. Russell, for instance, says that experience may make us think of the proposition that 2 + 2 = 4 but "it does not suffice to prove it"; it merely directs our attention so that "we see its truth without requiring any proof from experience" (*Problems of Philosophy,* chap. VII). "Seeing" here means seeing with the mind and is a metaphor. Our conviction about the proposition resembles what we have when we see with our eyes that there is an apple on the table, but it is intellectual perception. The problem is that nonsensory seeing does not provide a mark to distinguish it from intense conviction that is not in itself evidential. It may appear to Russell to be an act of insight on par with seeing an apple, but it may also be just a firm belief. It is surely not uncommon to confuse conviction with insight. It is sometimes said that we "grasp" the truth of propositions like "2 + 2 = 4" as soon as we understand them, but this is another metaphor. These metaphors can be traced to the ancient Stoic doctrine of the *kateleptic* (from the Greek word *kataleipsis,* meaning "taking hold of," "grasping," or "seizing"), that is, the grasping cognition that certainty is like a clenched fist that holds its object tightly so it cannot escape, but conviction is also a clenched fist. Sometimes the issue reduces to name-calling. In the phenomenological tradition, Edmund Husserl (1907/1999) says, for instance, that a priori cognition is directed at "general essences" and is a "luminous intuition." The skeptic who denies such cognition is like a blind man who denies that there is such a thing as seeing. "How could we convince him, assuming that he has no other mode of perception?" (*The Idea of Phenomenology,* Lecture IV). But this is not helpful; the skeptic will reply that arguing with Husserl is like talking to a madman who is prone to hallucinations. The empiricist's conclusion from this is that a priori justification is hopelessly obscure.

One curious feature of this debate is that the concept of an innate idea seems clearer than that of the a priori itself. As we saw, Descartes thinks that the idea of a triangle is in the mind from birth in the same way in which the ideas of familiar objects are in the mind when we are not actually thinking of them. We can bring an innate idea to consciousness by attention alone and form judgments about it without prior experience. He may be mistaken that we have such ideas, but at least it is clear what he means by them.

The obscurity of the a priori also affects moderate empiricists, like Locke, Berkeley, and Hume, who accept a priori knowledge but deny that it informs us about real existence. But there is also a difference. Moderate empiricists are willing to accept the a priori since it only covers propositions that are true according to the meanings of their terms (e.g., analytic sentences), and these are based on convention alone, while substantive claims about reality can be known only on the basis of experience. The rationalist, on the other hand, wants the a priori to give knowledge about real existence. Sometimes he claims that essences do not exist but subsist, but whatever he calls them, they are not *entia rationis* but have an independent existence, and this is what the empiricist finds suspect.

The main argument for the a priori is that it is needed in order to answer the skeptic about the general principles of knowledge. This can be illustrated by the problem of induction. Hume (1748/2007) holds that we know generalizations such as that bread nourishes because it has nourished us in the past and we believe that "like causes will be followed by like effects" (*An Enquiry Concerning Human Understanding*). But this principle is itself a matter of fact, and his empiricism commits him to holding that all knowledge of matters of fact must be justified by experience. Hence, any attempt to justify it by experience would be circular. This is known as the problem of induction. Hume thinks that the problem is unsolvable but that we cannot

help accepting induction; we believe the principle by instinct, or what he calls custom, and "nature is too strong for principle." The rationalist argues that the problem shows empiricism to imply that we have no knowledge by induction. For an inferential practice to yield justified beliefs, we must be able to justify the principles on which it operates, and the only way to do this in this case is by appealing to the a priori.

This debate is ongoing, but two points might be ventured here in closing. First, it is not clear how appealing to the a priori will solve the problem, given its obscurity. Second, and more interestingly, it is not clear that we must justify induction in order to have inductive knowledge. All reasoning must rest on premises that are either accepted as ultimate or justified immediately by something like Husserl's "luminous intuition," which, as we saw, cannot be clearly distinguished from strong conviction. The result is that perhaps the most we can hope is that Hume's principle is true. Not being able to justify it noncircularly is just one facet of the human condition. To show that not being able to justify it noncircularly leads to skepticism, the rationalist must give a convincing argument that it does, and this is not promising given the obscurity of the a priori.

Encyclopedia

Encyclopedia has been an important and enduring form of the human endeavor toward an exhaustive, universal exposition of knowledge, to which both scientific knowledge and philosophical knowledge have aspired.

This entry introduces the origin of the word *encyclopedia* and presents the formal elements that make up the genus "encyclopedia" as well as its more specific typology. The entry discusses these features, first generally and then more specifically, in their philosophical dimension. The entry also includes a brief reference to the more significant historical moments of *encyclopedism* as well as to the actual developments of encyclopedia, namely, electronic and online encyclopedias, hypertext, and the Internet as its actual realization.

The Word

The word "encyclopedia" (Greek ἐγκυκλοπαίδεια) comes from the Hellenistic expression *enkuklios paideia* (ἐγκύκλιος παιδεία) meaning "perfect or regular cycle of studies"—in other words, an instituted general course (or cycle) of studies. It is taken up again in Roman culture, appearing in the dedication to Emperor Titus in the *Historia Naturalis* of Plinius. In early-modern times, the word was first used in English by Sir Thomas Elyot (*Boke of the Governour,* 1531) and in French by Rabelais (*Pantagruel,* 1532).

There are many works that may be retroactively considered as belonging to the genus encyclopedia, although they had not carried that designation in their title (e.g., Vincent de Beauvais's *Speculum Majus,* ca. 1260). In fact, it is only in the 17th century that the word *encyclopedia* comes close to its current meaning. It is also about then that as a literary product encyclopedia becomes a kind of its own, bearing its distinctive identity and characteristic procedures.

The Elements of an Encyclopedia

Encyclopedia aims, ideally, to be the exposition of *all* knowledge conquered by mankind. Sometimes such aims toward an exhaustive inclusion of everything known may lead encyclopedias to a teratological dimension, as in the case of the immense Chinese encyclopedias. However, in the West, encyclopedias are of a rather contained or relatively limited kind, combining comprehensiveness with selectivity.

Encyclopedia is also a *historical production* reflecting specific cultural and scientific conditions. Never complete, always destined to be surpassed by ongoing progress in knowledge, it requires constant reworking or renewal. Such an updating consists of not only including new entries according to recent developments (e.g., "Cloning") but also diminishing the weight of some entries or altogether deleting others (e.g., "Phlogiston") and raising the importance of yet other entries (e.g., "Globalization").

Encyclopedia is *not a dictionary.* Dictionaries aspire to be a full, consistent codification of language—that is, they are contained within linguistic meanings. On the contrary, encyclopedia is semantically open, beyond mere meanings, to the actual things, events, theories, or concepts to which the terms it contains refer, that is, to what is known. Although many encyclopedias have been designed as dictionaries, an encyclopedia is never concerned with words but with what specific terms or concepts mean or refer to: the world behind the words.

Like dictionaries, encyclopedias are a discontinuous text made of independent entries, which, however, never present well-defined borders. Each entry opens (explicitly or implicitly) to other entries (cross-references or "See also"), which in turn open to others, in such a way that each entry is virtually connected with all the others. Thus, encyclopedia is not so much a mereological aggregate of all items of knowledge placed, in a disconnected fashion, in one enclosed *topos* but rather a circulation (*navigation*) throughout the vast net of its multidimensional elements.

Thus, the material objectivity of encyclopedia has an *unlimited and combinatory condition*. Behind the additive synthesis of all its entries, encyclopedia points to the exhaustion of all the possible combinations of its entries, which can be articulated in an undetermined number of combinations—a kind of combinatory without rule.

This situation has important consequences for the *reading regime* of encyclopedia. The readers of an encyclopedia are offered the possibility of making their own journey of reading according to their interests and preferences (surfing). It is the reader (navigator) who selects, by successive choice, which semantic field she or he will read further on. In fact, encyclopedia affords this possibility, proposing several resources that invite the reader to actualize one of the many possibilities it offers (indexes, thesaurus, internal references, reader's guide, cross-connections, articulations, and instantaneous electronic *links,* which today characterize hypertext and the Internet as its extension).

Encyclopedias extensively use *nonlinear materials* such as maps, drawings, illustrations, statistic schemata, plans, and tables of all types (see the 11 complementary volumes of tables published by Diderot or the wide number of imaging resources in electronic encyclopedias, in hypertexts, and on the Internet). That is to say, all encyclopedias point to the semantic exploration of the diagrammatic resources of language, putting them in the service of the iconic, imagistic, cartographic description of the world.

Encyclopedia is a *collective work*. Some encyclopedias were made by only one author (e.g., Pierre Bayle's *Dictionnaire Linguistique et Critique,* 1647–1706). However, encyclopedia inevitably presupposes the collaboration of different competencies:

celebrated scientists, appointed experts, identified authors, as well as anonymous, unidentified, and even unknown collaborators (as in today's *Wikipedia*).

Implicitly or explicitly, encyclopedia is always an *ordered, organized structure*. It is that ordered structure that determines the quantity and quality of entries, the inclusion or exclusion of certain topics, and the relative importance of some entries compared with others. This does not mean that encyclopedias should be endowed with a unique, constraining point of view. What it means is that encyclopedias have an undeniable synthesizing and structuring task.

Encyclopedia always has a *prospective role*. By promoting terminological unification, local systematizations, and interdisciplinary connections, encyclopedia favors the establishment of bridges from one domain to another. By synthesizing what is already known, encyclopedia constitutes a kind of mnemonic prosthesis, which liberates or unburdens natural memory for what really matters: the unknown. It intends to reduce the opposition between memory and invention. That is why encyclopedia is such a strong anti-Cartesian device. It does not make a *tabula rasa* of previous achievements.

Typology of Encyclopedia

Encyclopedias are essentially *general in kind*, offering an (as much as possible) exhaustive yet concise and selective exposition of the empirical, scientific, or philosophical knowledge acquired by humankind until a given point in time. They may be *disciplinary* in kind (based on a classification of sciences), *alphabetic* (operating by definition of a huge set of concepts alphabetically ordered), *thematic* (constituted by large entries covering a set of selected subjects or whole fields), or *mixed* (aiming to safeguard the combined benefits of disciplinary and thematic encyclopedias with the practical advantages of the alphabetic ordering).

However, confronted with the development of scientific knowledge and its compartmentalization as well as with a growing cultural complexity, encyclopedias were forced, mostly during the 19th century, to become *specialized*, focusing on a single or specific human activity or domain of knowledge.

Philosophical encyclopedias are such a type of specialized encyclopedias, aiming to cover a certain philosophical tradition or branch. Nevertheless, they may be considered to coincide with the very philosophical project as such. The case of Gottfried Leibniz in the 17th and 18th centuries and of Otto Neurath in our own times will serve to illustrate this. For both philosophers, it is through encyclopedia that philosophy reaches its aim of a *unified* knowledge of the world.

It is true that Leibniz did not provide any actual encyclopedia. He did, however, formulate with extreme rigor the theoretical presuppositions and problems associated with such an enterprise. He clearly understood the need and heuristic significance of constructing, in parallel, both the encyclopedia and the *characteristica universalis*. If the construction of the scientific language presupposes the analysis of all fundamental concepts and their definitions—that is, the encyclopedia—then, on the other hand, the symbolic transposition of the cognitive conceptual contents of the linguistic system that is already constituted allows for the discovery of new possible meanings, thus favoring the accomplishment of encyclopedia. By revealing the diverse regions of science, encyclopedia facilitates the analytical decomposition of terms. But, inversely, the use of a symbolic system capable of expressing the various ideas and their relationships leads to the full analysis of those ideas and, thus, to their definition and systematic articulation; that is, it helps the construction of encyclopedia.

As for Neurath, he refused the need of both a foundationalist basis for encyclopedia and its unique, total, a priori systematic organization. He emphasized the cooperative, historical, and unfinished nature of encyclopedia, which he considered to be the symbol of the scientific fraternity and a living intellectual force in the service of mankind. Like Leibniz, Neurath gave great emphasis to the heuristic role of encyclopedia, which he considered to be a kind of *organon* for scientific progress. In doing so, he fully identified encyclopedia as the "model" of human knowledge and as the main task for the *unity* of science. Such unity, like encyclopedia itself, should be plural, heterogeneous, always provisory, and incomplete while open to further cooperative contributions.

Historical Summary

From the *Historia Naturalis* of Plinius (Caius Plinius Secundus or Plinius the Elder, 23–79 CE) to the *Etimologies* of Isidorus (St. Isidore of Sevilla, ca.

560–636) or the *Eruditionis Didascalicae* of Hugh (Hugh of Saint Victor, ca. 1096–1141), it is possible to talk of a medieval and even Roman encyclopedia. However, in a more precise sense, encyclopedia is a product of the 18th century. Facing the intense scientific activity of modern times, encyclopedia appears as the *topos* where new forms of disciplinary and systematic arrangement of knowledge and new schemes of intelligibility are intended (e.g., Bacon's *Instauratio Magna,* 1620; Alsted's *Encyclopaedia Omnium Scientiarum,* 1630; Comenius's *Pansofia Prodomus,* 1639; as well as Leibniz's "Mathesis Universalis"—dispersed in many fragments and texts of Leibniz's).

The 18th century is the golden age of *encyclopedism*. Projects turned into successful, actualized outputs. Having reached its classical form, science offered itself the luxury of its own monumentality. Encyclopedias started playing the role of a medieval cathedral, a monument in which human beings face what is more important: not God anymore but the created World. The major realization is undoubtedly the *Encyclopédie ou Diccionaire Raisonné des Sciences, des Arts et des Métiers* (1751–1765), by Denis Diderot and Jean D'Alembert, a kind of laboratory where it is possible to grasp not only all the positive qualities but also the difficulties of the encyclopedic project. Diderot and D'Alembert were able to assemble many of the most eminent intellectuals of the century as well as humble artisans of all areas of human activity. They were able to construct a kind of a cartographic overview not of the secrets of the world (of which God was until then the first and final cause) but of the heterogeneous, contingent, and precarious achievements of human knowledge. The Enlightenment encyclopedia of Diderot and D'Alembert is in fact a singular moment in the history of Western culture in which, for the first time, a secular world was envisaged, that is, a reality with its own autonomy and intelligibility was opened to the human intelligence and industry as the background to a further, infinite cognitive conquest.

In the 19th century, two divergent lines of encyclopedism were put forward. Under the positivist regime proposed by Auguste Comte, encyclopedia became the instrument for the coordination of particular sciences. It had to consider the achievements of each discipline and point to the logical law of their development (e.g., *Grande Encyclopédie: inventaire raisonné des sciences, des lettres, et des arts,* by André Berthelot and Ferdinand-Camille Dreyfus, 1886–1903). On the other side, German romantic encyclopedism aimed to construct a "total science" on the basis of the deep analogies among the particular sciences (see Novalis's *Fragmente,* 1802) or to expose their organic unity while being necessary parts of the philosophical whole (as in Hegel's *Enzyklopädie der Philosophischen Wissenschaften im Grundrisse,* 1817).

In the first decades of the 20th century, and in the context of Logical Positivism, Otto Neurath, whom we encountered above, had the merit of having conceived the original plan and of having effectively taken charge of the organization of the *International Encyclopedia of Unified Science,* of which the part called *Foundations of the Unity of Science* was published in 1938 to 1969 in two volumes (comprising in total 19 monographs, among which was Thomas Kuhn's celebrated *The Structure of Scientific Revolutions,* which appeared in 1962 as the second monograph of Volume II).

The decades between 1940 and 1960 were characterized by a generalized disillusion with the very idea of encyclopedia. Above all, in literature, scholars like Alberto Savinio, Georges Perec, Italo Calvino, or Jorge Luis Borges came to explore the paradoxes of any such totalizing attempt and to announce the end of any encyclopedic effort.

However, a surprising renewal was to take place in the 1970s. Contrary to what might have been expected, encyclopedia took up a new integrative format intended to critically prevail over the huge fragmentation of scientific knowledge and information. The most innovative encyclopedias—namely the *Encyclopedia Universalis* (1968–1975) and the *Encyclopedia Einaudi* (1977–1984)—put into practice thematic, interdisciplinary structures dealing with controversial matters, pioneering concepts, current debates, and unexpected articulations.

Current Developments

In the last decades of the 20th century, another decisive development took place. Hypertext, devised by Ted Nelson (1965), and the World Wide Web, developed by Tim Berners-Lee (1991), can directly be inscribed in the history of encyclopedia. That is why, as soon as the necessary technical conditions were in place, the classical form of encyclopedia promptly adhered to its own informatization (*Britannica's* first

CD-ROM and *online* editions appeared in 1993 and 1994, respectively). This development can be seen as if the electronic encyclopedia and, further, the hypertext and the Internet, all came to realize the primordial aspirations of encyclopedia itself.

Of course, in the case of hypertext—which can be taken as an actual apex of the encyclopedia proper—there are enormous difficulties, terrible noise, a dangerous lack of cartographic references, serious deficiency of selectivity and credibility of contents, and so forth. But there are enormous advantages as well. Like encyclopedia, the hypertext is a generalist technology of knowledge operating by a regime of multiple choices among always growing yet never fully actualized, virtual contents. And the access to all those possibilities is effectuated by the simple activation of a mouse's click.

Occupying the privileged place of the unity of science, encyclopedia and today's hypertext are a powerful form of resistance against the effects of specialization. Encyclopedia and hypertext are the only attempts toward unification of knowledge that can claim success in being effectively accomplished. They are the only forms of a material realization of the goal of the unity of science that condense and present to the eyes of all of us a large part of that information that could never be seen, grasped, and confronted otherwise.

Enlightenment, Critique of

This entry presents the critical voices the Enlightenment attracted against itself both during its heyday and more recently, when what is known as "the Enlightenment project" became the subject of critical controversy. The tenets of Enlightenment have been vital both to political philosophy and to the rise of modern social sciences. Thus, a critical turning against the Enlightenment signals a critical turning, too, against received views about the nature of social science.

Origins

The Enlightenment and its critics were born together, like twins, in the middle of the 18th century. It was then that a group of thinkers in Europe and the United States first began to view themselves as part of a very broad, loose movement of reform committed to reason, science, and religious toleration. In France, where this movement was most self-conscious, they were referred to, and referred to themselves as, *philosophes,* a word for which there is no precise English equivalent. In French, it means both philosophers in the narrow sense and, more broadly, public intellectuals and thinkers, including natural scientists, clerics, politicians, public officials, novelists, and journalists. They also sometimes referred to themselves collectively as a "society of

men of letters" who owed allegiance to a cosmopolitan "republic of letters" devoted to reform and the popular dissemination of enlightenment. While the best-known *philosophes* were French—men such as Voltaire, Denis Diderot, Jean d'Alembert, the Comte de Buffon, Étienne de Condillac, and Baron de Montesquieu—they had counterparts across Europe and the United States, most notably Adam Smith and David Hume in Scotland, Immanuel Kant and Gotthold Lessing in Germany, Thomas Jefferson and Benjamin Franklin in the United States, and Cesare Beccaria in Italy. Virtually all the *philosophes* in France contributed to the *Encyclopédie,* a vast compendium of knowledge that comprised 28 large volumes with more than 70,000 articles and illustrations that served as a *machine de guerre* of the Enlightenment designed to "change the way people think," in the words of its editor, Diderot.

Early Phase

Perhaps the first significant opponent of this movement was one of its own members, the Swiss writer Jean-Jacques Rousseau, a defector from within its own ranks who had been a friend and ally of the *philosophes*. Yet in his *Discourse of the Sciences and the Arts* (1750), he praises ignorance and associates the acquisition of knowledge of the arts and sciences (modern "civilization") with decadence and moral depravity. Many *philosophes* were shocked by this argument, including the coeditor of the *Encyclopédie,* d'Alembert, who rebuked Rousseau in his *Preliminary Discourse to the Encyclopédie* (1751), which became the movement's unofficial manifesto in France. This early skirmish soon escalated into a major clash between Rousseau and the *philosophes* and launched a war between the Enlightenment and its opponents that has raged ever since.

In Germany, Johann Georg Hamann launched a crusade against the German Enlightenment—(*die Aufklärung*)—and its institutional embodiment there, the Prussian state of Frederick II, based in Berlin. Beginning in 1758, he wrote a series of essays attacking the enlightened despotism of Frederick in the name of his own mystical conception of faith, denouncing the pedantic "lettered men of our enlightened century" as dogmatists of a new secular religion whose "bible," the *Encyclopédie,* is a barren substitute for the Holy Bible. His enlightened friend Kant was dismayed and puzzled by Hamann's turn against the *Aufklärung,* just as d'Alembert felt betrayed by Rousseau's attack on the values of the Enlightenment a few years earlier.

In 18th-century France, where the church was formally allied to the state and retained considerable power and influence, many of the earliest opponents of the *philosophes* were conservative Catholic *dévots,* such as Nicolas-Sylvestre Bergier and Guillaume François Berthier, who attacked the *encyclopédistes* in periodicals like the *Journal de Trévoux* for undermining Christianity and for the alleged corrosion of popular morals. Many of these early religious critics of the *philosophes* portrayed them as dangerous atheists blind to the potentially nihilistic consequences of disbelief. This was a convenient caricature, since very few *philosophes* actually denied the existence of God. While some, such as Claude Adrien Helvétius and the Baron d'Holbach, were indeed atheists (and philosophical materialists), they were rare exceptions; most *philosophes* were moderate deists, like Voltaire, who were as critical of atheism as they were of religious fanaticism. When the Faculty of Theology at the University of Paris unanimously passed the heterodox thesis of the Abbé de Prades in 1751, it sparked enormous controversy and opposition (the so-called Prades affair), setting religious traditionalists against anticlerical reformers in France during the decades that followed. The *Encyclopédie* was eventually suppressed in France in 1759, although it continued to be published unofficially with the support of some very high-placed officials, including Guillaume-Chrétien Malesherbes, the director of censorship and publication.

It was not until the French Revolution that criticism of the Enlightenment really took off. Many blamed the violent excesses of the Revolution on the Enlightenment, which it was widely believed had systematically destroyed the legitimacy of the ancien régime and plunged Europe into violent chaos for a generation. Among the most eloquent proponents of this view was the ultramontane Savoyard Joseph de Maistre (subsequently an early icon of conservatism in political thought), whose *Considerations on France* (1796) depicts the events of the 1790s as divine punishment for the sins of the Enlightenment. Its most popular proponent was the Abbé Augustin Barruel, whose bestselling *Memoirs Illustrating the History of Jacobinism* was published in 1797. In it, he makes the case that a deliberate conspiracy

of *philosophes,* Freemasons, and the international Order of the Illuminati plotted to overthrow the ancien régime in Europe with a violent revolution. Edmund Burke, who read and admired Barruel's *Memoirs* shortly before his death, had already traced the origins of the Revolution to the *philosophes* in his enormously successful and influential *Reflections on the Revolution in France* (1790), which indicts Condorcet, Voltaire, Rousseau, d'Alembert, Diderot, and Helvétius by name for destroying the foundations of social and political order in France with their corrosive skepticism.

Many early romantic writers at the end of the 18th and early 19th centuries in France, Germany, and Britain shared in the criticism that the Enlightenment was both politically dangerous and spiritually empty. Many of these writers were very critical of the Enlightenment's allegedly narrow emphasis on reason at the expense of emotion and the passions, which, they claimed, had made the 18th century an age devoid of beauty, imagination, and spirit. This is the central theme of François-René Chateaubriand's *The Genius of Christianity* (1802), a popular aesthetic defense of Christianity, which gives the beauty and mystery of faith a centrality absent in the rationalistic natural religion that was popular among the *encyclopédistes*. He condemns the "atheistic sect" of the *philosophes,* led by Voltaire, for promoting a disenchanted view of the universe that is sterile, ugly, and reductionistic. Similar views were expressed by the German nobleman Georg Friedrich Philip von Hardenberg (who used the nom de plume Novalis). In *Christendom or Europe* (1826), he paints a very unflattering picture of the Enlightenment as a sterile secular age made up of "rigid seas, dead cliffs, fog instead of starry heavens," in stark contrast to the beauty and enchantment of medieval Catholicism, which he depicts as a time of simple beauty and deep piety.

Later Phase

Not all of the Enlightenment's critics were religious conservatives or traditionalists. The Enlightenment became a key organizing concept in much of social and political thought after World War II, in the process attracting large numbers of critics from all points of the ideological compass, including some liberals, socialists, feminists, environmentalists, and postmodernists. For example, the Enlightenment played a central role in the understanding of 20th-century totalitarianism for many intellectuals, such as the Neo-Marxists Max Horkheimer and Theodor Adorno, whose influential 1947 work *Dialectic of Enlightenment* depicts Western enlightenment in all its forms as linked to a narrowly instrumental conception of reason that is inimical to decent human life. Cold War liberals such as Jacob Talmon and Isaiah Berlin also identified the legacy of the Enlightenment as one that was perversely connected to destructive political pathologies in the 20th century, particularly communism. Some "poststructuralists" have echoed these ideas. Michel Foucault, whose views were influenced by Horkheimer and Adorno, wrote several books in the 1960s and 1970s chronicling the emergence in the late 17th and 18th centuries of a deeply sinister "disciplinary society" that was masked and justified by a deceptively liberal and humane rhetoric. The feminist writer Jane Flax has attacked the Enlightenment for its supposedly "pure" conception of reason, which is a form of "androcentrism" that suppresses key gender differences in the interests of men.

One of the most common and consistent themes among the Enlightenment's critics since the 18th century is what can be called its *perversion of reason*—distorted conceptions of reason that many associate with the Enlightenment. It plays an important (in many cases central) part in almost every depiction of the Enlightenment by its critics, from the mid 18th century to the present and from the far left to the far right. Some, like Rousseau and de Maistre, have accused the *philosophes* of greatly exaggerating the power and influence of reason and underestimating the importance of nonrational influences on human behavior, such as conscience, in Rousseau's case, or sin, in de Maistre's. Others, such as Horkheimer and Adorno, have alleged that the Enlightenment had a narrowly instrumental conception of reason, incapable of providing insight into objective truths about morality, justice, beauty, or the proper ends of life and that this conception has turned the West into an "iron cage." Finally, writers such as Hamann and Flax have accused the *philosophes* of propounding a view of reason as "pure," when in fact it is inextricably mixed with power and interests. In each of these cases, the proper role, character, and importance of reason have allegedly been grossly distorted by the Enlightenment, usually with disastrous consequences.

It is important not to misrepresent this conflict as one between friends and enemies of reason, even though many of the Enlightenment's critics have tried to do so. Although objections have consistently been raised against what has been taken to be the "typical" Enlightenment view of reason by its critics, this has almost never been generalized to reason as such. None of the critics of the Enlightenment have been prepared to abandon reason entirely. And most 18th-century *philosophes* were keenly aware of both the power of the passions and the limitations of reason. Very few agreed with Descartes that reason is, or ever could be, absolutely sovereign, and some (e.g., Diderot) defended the passions from the proponents of both Christian dogma and Cartesian rationalism. The battle between the Enlightenment and its critics has really been over the scope, meaning, and application of reason, not over whether it is good or bad, desirable or undesirable, essential or inessential per se.

The history of Enlightenment criticism is as much a history of constructions of "the Enlightenment" as it is of criticisms of it. Although the philosophers of the Enlightenment used the terms *éclaircissement* in French and *Aufklärung* in German to refer to the general process of replacing ignorance with knowledge or insight, just as *enlightenment* was used in English, they did not have a term comparable with "the Enlightenment" (definite article, capital *E*) to refer to a particular historical period. The latter was a retrospective invention, just as "the Renaissance" and "the Reformation" were. "*Die Aufklärung*" was used from the late 18th and early 19th centuries in German to refer to the period we now call "the Enlightenment," not the least by Hegel, whereas "the Enlightenment" did not appear in English until the late 19th century and was not widely used until after World War II. The French term *le siècle des Lumières* (the century of lights) is even more recent. This is significant because it suggests that many later writers have projected back onto the 18th century a unity and self-consciousness that it lacked at the time, often to set up a straw man that could easily be knocked down, attributing a degree of coherence and purpose to the *philosophes* that never really existed. As our view of the internal complexity and diversity of the Enlightenment has become increasingly sophisticated in the past 40 years, many scholars have become wary of referring too casually to "the Enlightenment," let alone to a single "Enlightenment project." Some have even argued that the term should be abandoned as a straightforward anachronism. We have already seen, for example, that very few of the Enlightenment's 18th-century proponents were atheists, even though many of their critics have accused them of being just that and blamed them for the supposed consequences of disbelief.

Another common belief attributed to the Enlightenment is that its advocates were naive optimists who believed in the inevitability of progress, even though Voltaire, in many ways the quintessential Enlightenment figure, openly mocked this view in his popular novel *Candide* (1759). At best, they were very cautiously optimistic about the prospects for improvement, with a keen sense of how slow and uncertain it could be. Even so, most believed that things had improved and would likely continue to do so as reason, toleration, and science gradually displaced religion, intolerance, and superstition.

Not all of the Enlightenment's critics wished to undermine it, let alone destroy it. There are friendly critics sympathetic to its basic values and goals who have rejected some of its assumptions and prescriptions in order to save it, just as some 20th-century Marxists have revised some of Marx's original claims in order to strengthen the general theory in light of our knowledge and experience of the world since the 19th century. For example, Berlin thought that the German philosopher Johann Georg Herder was an early example of this, describing him as not an enemy but a critic of the French Enlightenment. Recently, the philosopher Jürgen Habermas has criticized some aspects of the Enlightenment in order to improve it rather than to undermine it. Such friendly critics should be clearly distinguished from more extreme critics or "enemies" of the Enlightenment, like Hamann and de Maistre.

Epistemic Approaches to Democracy

This entry introduces the idea of establishing the value of democracy on the basis of epistemic merits expected to accrue from certain democratic procedures. The discussion of such *epistemic approaches* to democracy blends epistemological issues (including those of rational choice and probability) with political philosophy and political science. The entry critically reviews various approaches and ends by discussing what is known as *Condorcet's jury theorem.*

Epistemic approaches to democracy argue that its value consists at least partly in the tendency of some democratic arrangements to make good political decisions. The name, based on the Greek word for knowledge or wisdom, *epistêmê,* was coined only recently by Jules Coleman and John Ferejohn, though the approach appears throughout the tradition—as far back as in the work of Jean-Jacques Rousseau or more recently in the work of Alexander Meiklejohn. Epistemic approaches are not committed to moral consequentialism, since they might be combined with noninstrumental moral principles of justice or justification.

Democracy has long been burdened by the charge that it is absurd to decide such important matters by neglecting the differences between those who have relevant knowledge or abilities and those who do not. There are two alternative responses to the *epistemic critique of democracy.* First, in a nonepistemic approach to democracy, one devises an account of the value of democracy that does not depend on its having any particular epistemic virtues—any particular tendency to make good decisions. Second, in an epistemic approach to democracy, one accepts the epistemic demands and argues that democracy *can* meet them.

Some theories argue that (properly arranged) democratic procedures are epistemically the best methods possible. The losing voter is expected to take the outcome of the vote as her best evidence on the question and, presumably, to change her mind (a classic example of such a thesis being Rousseau's theory). An alternative view, espoused by David Estlund, denies that greater wisdom gives anyone the right to rule unless their expertise is itself beyond reasonable denial.

Many advocates of democracy have preferred a *nonepistemic* approach. One reason is that the idea of a fair political procedure by which the people rule themselves might account for our democratic convictions even without any appeal to good decisions. Casting democracy as a right to self-rule, however, threatens to neglect the obvious fact that voters decide the rules for others as well as for themselves. Emphasizing fair procedure rather than self-rule prompts a distinct worry. The thin idea of an equal procedure does not justify voting procedures for choosing policies rather than random procedures

such as flipping a coin. If voting is to be preferred to random methods, it is evidently not on grounds of fair procedure alone and might even be on unstated epistemic grounds.

An important mathematical result that derives from Marquis de Condorcet (in his *Essay on the Application of Analysis to the Probability of Majority Decisions,* 1775) shows that a group of voters, each of whom is better than random, using majority rule, can perform better even than the best of the individual voters. Performance improves as the group gets larger, approaching infallibility. Applying this "jury theorem" to the case of democratic voting is problematic for at least the following three reasons: (1) the mathematical results are far less impressive if the choice is between more than two alternatives; (2) voters who are influenced by other voters in certain ways do not allow for the full mathematical effect, and so deep structures of influence can dampen the results significantly; and (3) voters who, as most humans do, have various prejudices, blind spots, or rational defects might be worse than random, in which case the jury theorem drives the group's competence just as impressively toward certain error.

The jury theorem approach doesn't rely on any epistemic benefits of communication, as other epistemic approaches do. In some contexts, interpersonal communication clearly improves a group's epistemic competence, and public deliberation about political decisions may have some of these epistemically beneficial features. Critics of "deliberative democracy" (a family of views that only sometimes takes this epistemic form), however, argue that interpersonal deliberation is often distorted by power dynamics, by tendencies to follow the herd, and so on.

On some views, the standards of correctness for decisions are independent of the deliberative process, just as a sum of two numbers is independent of the method used to find it. On other views, including several "pragmatist" epistemic approaches to democracy influenced by Dewey and others, a just or correct political decision *is* one that was (or would have been) produced by properly arranged public political deliberation. A closely related family of views also holds that the standards are constituted by actual or hypothetical deliberative processes, not (as in the pragmatist variant) processes of inquiry but processes of individual pursuit of interests in a morally appropriate framework.

Epistemic approaches do not assume that actually existing democracies make good decisions, or even that greatly improved arrangements would lead to predominantly good decisions. What makes them count as epistemic approaches is their holding that an adequate normative theory of democracy's legitimacy, authority, or justification depends partly on some tendency of (some) democratic arrangements to make good political decisions by aiming to do so.

EPISTEMOLOGY

Epistemology is the philosophical subdiscipline that studies the evaluative dimensions of cognition, their metaphysical bases, and, increasingly nowadays, the language we use to ascribe cognitive achievements. The nature and scope of knowledge is the central focus of epistemology.

Knowledge and Assertion

Assertion is a speech act whereby we communicate to our audience that a certain proposition is true, and it is the main way we communicate information to one another. Given that we rely so pervasively on assertions, it is natural to wonder what the standards ought to be for our assertions and whether we as assertors live up to them? Research into the epistemic norms of assertion is one of the most exciting and rapidly growing fields within philosophy. Within this field, the leading proposal is that knowledge is the norm of assertion, a view known as *the knowledge account of assertion.*

The knowledge account of assertion says that knowledge sets the standard for permissible assertion: You may assert *P* only if you know that *P* is true. The primary evidence for the knowledge account is an explanatory inference from linguistic data, in particular conversational patterns surrounding the give-and-take of assertion. For example, typically, when you make an assertion, even when the content of your assertion has nothing to do with you or what you know, it is appropriate to ask you "How do you know that?" The knowledge account explains the appropriateness of the question as follows: In making the assertion, you represent yourself as having the authority to do so, and knowledge is what gives you the authority, rendering it sensible to ask how you know that. Similarly, if someone makes an assertion, the response "You don't know that" is taken as an outright rejection of his or her authority to make the assertion, which the knowledge account easily explains. Also, when someone asks you a question, even when the question has nothing to do with you or what you know, it is typically appropriate for you to respond, "I don't know." The knowledge account explains why it is appropriate: By saying "I don't know," you inform the questioner that you lack the authority to answer the question.

Those attracted to the knowledge account of assertion are often attracted to related views about practical reasoning, action, and belief, namely, that knowledge is the norm of these too. These other three accounts are also supported by linguistic data and patterns of appraisal, though the overall case for them is generally regarded as weaker than the case for the knowledge account of assertion.

Furthermore, investigation into the epistemic norms of assertion, reasoning, action, and belief presents opportunities for collaboration among epistemologists and social and cognitive scientists.

Contextualism

Skepticism perennially fascinates philosophers. It is almost unanimously accepted that skepticism is false, so one main question is "Why do skeptical challenges nevertheless seem so formidable?" For example, it usually seems obvious that when you say, for instance, "I know that I have hands," you speak truthfully. But do you know that you are not a handless brain in a vat (BIV) being perfectly deceived into thinking that you have hands? Most people hesitate at this question, and many go so far as to say, "No, I don't know that I'm not a handless BIV." Yet if you know that you have *hands,* then you seem to be in an ideal position to simply deduce, and thereby know, that you are not a *handless* BIV. So why are we tempted to say "I don't know" in such a situation?

Setting aside extravagant skeptical scenarios featuring BIVs, we see a similar effect when speakers move from an ordinary context to a high-stakes context. If a fellow traveler in an airport looks up from his magazine and nonchalantly asks, "I'm bored. Do you know whether this flight we're about to board goes directly to Chicago?" You might check the board, see that it says "Direct flight to Chicago" and respond, "Yes, I happen to know that it does." But suppose that instead of being asked by a nonchalant fellow traveler, you are asked the same question by an organ courier transporting an organ to a patient in Chicago, which will spoil unless she takes a direct flight to Chicago. Now, even if the board says "Direct flight to Chicago," it would be natural for you to respond by saying, "No, sorry, I don't know. Maybe you should go ask the captain." Again, why are we tempted to say "I don't know" in such a situation?

In recent years, some epistemologists have proposed a *semantic* solution to the apparent conflict in what we are willing to say about knowledge in ordinary contexts versus what we say when confronted with skeptical hypotheses or high-stakes decisions. *Epistemic contextualism* is the view that the cognitive verb *knows,* as it features in propositional knowledge ascriptions such as "I know that *P*" and "You don't know that *P,*" is a context-sensitive term. The truth conditions of "I know that this is a direct flight" are different in an ordinary context from those in a high-stakes context; in an ordinary context, less evidence is required for you to truly say "I know that this is a direct flight" or "I have hands" than is required in a context where the stakes are high or where serious skeptical hypotheses have been raised. Thus, the contextualist can maintain *both* that we typically speak truthfully when we say "I know this" or "I know that" *and* that the skeptic speaks truthfully when he says "You don't know this" or "You don't know that." Despite appearances, what the skeptic says does not contradict what we ordinarily say, just as I do not contradict you when I say (in Vancouver) "It's raining here" and you say (in Paris) "It's not raining here."

Contextualists disagree over the correct semantic model for "knows." Some contextualists say that "knows" is an indexical expression, similar to the pronoun *I* or the adverb *yesterday.* Others liken it to gradable adjectives, such as *tall* and *flat.* But both of those semantic models have been severely criticized. A more recent suggestion is that knowledge ascriptions are context-sensitive not because "knows" is context-sensitive but because *in general* the propositional content of speech acts is context-sensitive and knowledge ascriptions are no exception. The semantics of "knows" and knowledge ascriptions is ripe for interdisciplinary collaboration between epistemologists and linguists. Research into the psychology of judgments made in high-stakes contexts or in the context of skeptical challenges could also be highly relevant to sorting out the linguistic data. And anthropological data on the linguistic behavior of humans in other cultures could highlight further important data and theoretical possibilities.

The Value of Knowledge

It is a virtual platitude that knowledge is intellectually better than mere true belief. Going all the way back to Plato's dialogue *Meno,* philosophers have asked why this is so. One deceptively simple answer is that knowledge is better because it has greater practical value than true belief. But Plato ruled this out when he first raised the question, noting, for example, that merely truly believing this is the road to Larissa will get you to Larissa just as well as knowing that this is the road to Larissa will. So not only does it seem correct that knowledge is better than mere true belief, it also seems that knowledge's added value is not merely practical. Some epistemologists contend furthermore that knowledge is better than mere true belief not only in degree but also in kind: Knowledge has a kind of intellectual value that mere true belief lacks.

It is widely accepted that an adequate theory of knowledge must explain knowledge's special value, though this is not entirely uncontroversial. There is a consensus, however, that it is at least a good thing for a theory to explain knowledge's value.

Several theories have been proposed to explain knowledge's value. On one view, knowledge is valuable because it is the most general factive propositional attitude. Factive propositional attitudes are attitudes that you can have only toward a true proposition; this class of attitudes includes *remembering that P, perceiving that P,* and *being aware that P.* To say that knowledge is the most general factive propositional attitude is to say that the following is a necessarily true generalization: If you bear any factive propositional attitude toward the proposition *P,* then you know that *P.* We value a match between mind and world, and knowing is the most general attitude in which the mind must match the world, which according to this view explains why knowledge is specially valuable.

A different proposal begins by pointing out that while it is, of course, good to have good things, it is even better to *merit* or *earn* the good things you have. For example, other things being equal, it is better to earn your fortune than to win it through the lottery. Put otherwise, it is better to succeed through skill and effort than through luck. So if knowledge were true belief for which you earn credit or if knowledge were true belief manifesting intellectual skill, then that would explain why knowledge is better than mere true belief. For then the superiority of knowledge would just be a special case of the superiority of earning something good or achieving it through skill, as opposed to just getting lucky. This

explanation of knowledge's value is distinctive of an increasingly popular approach in epistemology called *virtue epistemology.*

The Gettier Problem

Perhaps the most important development in epistemology over the past 50 years was the research program ignited by Edmund Gettier's three-page article published in 1963, "Is Justified True Belief Knowledge?" Many philosophers at the time thought that knowledge could be defined as justified true belief (JTB for short). Gettier presented what most philosophers took to be decisive counterexamples to the JTB account of knowledge. These examples were taken to show that JTB is not sufficient for knowledge—that something more than JTB is required.

Gettier cases follow a recipe. Start with a belief sufficiently justified to meet the justification requirement on knowledge. Then, add an element of bad luck that would normally prevent the justified belief from being true. Last, add a dose of good luck that counteracts the bad luck, so that the belief ends up true anyhow. It has proven difficult to explain why this "double-luck" structure prevents knowledge.

Philosophers have proposed dozens of hypotheses to handle these "Gettier cases," as they came to be called. It is widely assumed that an acceptable theory of knowledge must explain what goes wrong in Gettier cases. No-false-basis theorists argued that knowledge is JTB, which is not essentially based on a falsehood, but Gettier cases all involve beliefs essentially based on a falsehood. Defeasibility theorists argued that knowledge is JTB, for which there is no further fact such that it would defeat the subject's justification if she learned of it, but Gettier cases all involve facts that defeat justification. Reliabilists argued that knowledge is reliably produced true belief, but Gettier cases are examples of unreliably produced belief. Causal theorists argued that knowledge is true belief nondeviantly caused by the fact believed to be true, but the right kind of causal link is missing in Gettier cases. Counterfactual theorists argued that knowledge is true belief that has the right counterfactual relationship to the truth believed (the believer would get it right across a relevant class of counterfactual scenarios), but in Gettier cases, the relevant counterfactual relation is missing. Virtue epistemologists argue that knowledge is true belief manifesting intellectual virtue, but in Gettier cases, the subject's true belief fails to manifest her virtue.

None of these solutions has been widely accepted. At least a few epistemologists claim that the entire literature on the Gettier problem is mistaken because it falsely presupposes that the subject in a Gettier case lacks knowledge. On one such view, knowledge is merely true belief, though this view is almost universally rejected.

Epistemology and Experimental Philosophy

Experimental philosophers have made a very interesting and potentially significant sociological observation: People from East Asian cultures have a greater tendency than people from Western cultures to judge that the subject in a Gettier case has knowledge. More generally, results from experimental philosophy demonstrate that differences in gender, age, socioeconomic status, and culture are often associated with statistically significant differences in intuitive judgments about thought experiments of the sort Gettier used and that philosophers routinely rely on in the course of debate and inquiry. Uncovering these often very surprising differences and understanding their significance is an area of extremely fruitful and rapidly increasing collaboration among philosophers and psychologists.

Epistemology of Mass Collaboration

People usually work together to get things done. In particular, they often team up to find things out. New information technologies now allow large numbers of people to collaborate in order to discover and to disseminate knowledge. A notable example is Wikipedia, the "free online encyclopedia that anyone can edit."

The *epistemology of mass collaboration* is the study of when, and why, such large collaborative efforts can be effective at producing knowledge. In particular, when, and why, is the information produced by large groups of people reliable?

This entry looks at how this topic relates to epistemology in general, provides some examples of mass collaboration, and discusses what is known about the reliability of large groups.

Connections With Epistemology

Roughly speaking, epistemology is the study of (a) what knowledge is; (b) what sorts of things, if any, people can know; and (c) how people can come to know these sorts of things. Epistemology has traditionally focused on how people can come to know things working on their own (e.g., using perception or reasoning). However, most people acquire most of their knowledge from other people. The prototypical case is where one person tells another person something. But the ultimate source of our information about the world is often a group of people who have worked together to make a discovery. Thus, the epistemology of mass collaboration falls within the domain of *social epistemology* and the *epistemology of testimony.*

Examples of Mass Collaboration

It is fairly common for scientists to work together in teams to discover facts about the physical world. Although such scientific research teams are usually fairly small, they have steadily been getting larger. In fact, papers in high-energy physics with hundreds of coauthors are not uncommon.

New information technologies now allow even larger numbers of people, separated by very large distances, to work together on a single project. For instance, thousands of programmers from around the world have collaborated on open-source software projects, such as the GNU/Linux operating system. *Yahoo! Answers* is a social networking project that allows people to get answers to just about any question by leveraging the collective wisdom of many other Internet users. The *Iowa Electronic Markets* allow people to buy and sell contracts about future events, and the value of each contract can be used to predict whether the event in question will actually occur.

There are two main ways to leverage large groups to discover and to disseminate knowledge: (1) the project can involve actual collaboration, as when many people make contributions to an entry in Wikipedia and/or (2) the project can involve simply aggregating the separate opinions of the members of the group, as with prediction markets.

It seems plausible that a large group of experts would be more reliable than a single expert. For instance, scientific research teams are usually made up of people whose areas of expertise complement each other. But many large collaborative projects are open to anyone who is interested in participating. So, for example, there is no guarantee that the person writing or editing the Wikipedia article on bioethics has any training or expertise in bioethics. This lack of expertise has led to worries about the reliability of such large collaborative projects.

The Wisdom of Crowds

Researchers such as James Surowiecki and Scott Page have found that *sufficiently large* groups of nonexperts can be surprisingly reliable. For instance, on the television show *Who Wants to Be a Millionaire?* when a contestant is stumped by a question, she can poll the studio audience or phone a friend for help. It turns out that consulting the collective wisdom of the audience is a much more reliable "lifeline" than consulting your smartest friend. This phenomenon is typically referred to as the *wisdom of crowds*.

A notable result in game theory, known as the *Condorcet Jury Theorem,* helps explain this phenomenon (from Marquis de Condorcet's *Essay on the Application of Analysis to the Probability of Majority Decisions,* 1775). Suppose that we ask the members of a large group to vote on a factual yes-or-no question. According to the theorem, even if the individual members are not all that reliable on this question, the group as a whole is very reliable. Moreover, the bigger the group is, the more reliable it is. In fact, if the group is big enough, the majority vote is almost certainly correct.

This phenomenon also seems to apply to social networking projects such as Wikipedia. A study published in the journal *Nature* found that Wikipedia is only slightly less reliable on scientific topics than *Encyclopedia Britannica*. A partial explanation for Wikipedia's reliability is suggested by the saying in the software industry that "given enough eyeballs, all bugs are shallow." Any errors in Wikipedia can be corrected very quickly because any of the millions of people reading the encyclopedia can make corrections.

The Properties of Wise Groups

But not just any large group of people is going to be reliable on just any question. For instance, a large group of nonexperts could *introduce* errors into Wikipedia just as easily as they could correct errors. To be wise, a large group must have certain properties.

Indeed, the Condorcet Jury Theorem does not simply assume that there are a lot of voters. It also assumes each voter is at least slightly more likely to give a correct answer than an incorrect answer. In addition, the theorem assumes that their votes are *independent*. In other words, there is no correlation between the probability that one voter will vote a certain way and the probability that another voter will vote that same way.

Surowiecki hypothesizes that wise groups must be diverse, independent, and decentralized. Independence is a very strong requirement. Fortuitously, as Page has discovered, it is actually diversity rather than independence that makes a group wise. Independence is just a good way to ensure that there is a reasonable degree of diversity in a group.

Equilibrium in Economics and Game Theory

At the core of modern economics lies the notion of *equilibrium*. The possibility of identifying how the actions of different agents eventually define a resting point provides the economic analysis with a powerful instrument to foresee some of the consequences of different economic policies. At the same time, the notion of equilibrium is central to game theory.

This entry discusses the most widely used definitions of equilibrium and their relation to game theory, applied especially to the domain of economic behavior. Critical philosophical issues are shown to be raised by such an equilibrium methodology in economics.

The Walrasian Equilibrium

Adam Smith's notion of the invisible hand is perhaps the first description of an economic equilibrium. One century later, the French mathematical economist Léon Walras provided a rigorous definition:

The equilibrium is achieved when the plans of both sellers and buyers are compatible with each other in a precise, mathematical way. However, although Walras's theory gives a compelling characterization of the equilibrium point, it fails to explain how the economy gets there in the first place.

Walras himself postulated a "*tatonnement* process" to solve the problem. If there is an excess supply, the price falls; if there is an excess demand, it rises. Theoretically, this process is simple, but it is not entirely satisfactory because it relies on an ad hoc behavioral hypothesis and is not specific enough to guarantee that, out of equilibrium, the economic system will converge to it. The process is not without merit, either, as the ad hoc hypotheses are not too demanding, and the process does have explanatory power in many instances and is good enough if one does not pursue mathematical purity.

When confronted with reality, the *tatonnement* process can also be criticized because a market often seems to be at equilibrium and yet shows an excess supply or demand. Involuntary unemployment, for instance, may be persistent. This opens the door to more complete models of behavior and to alternative definitions of equilibrium and to dynamics.

The Value of a Zero-Sum Game

Games are mathematical models to study strategic decision making. Zero-sum games are games in which the interaction among players does not create anything, like in a poker game or in the game of cutting a cake. In this class of games, and for the case of two players, the mathematician John von Neumann defined the concept of value, a payoff V with the property that Player 1 can guarantee himself V and Player 2 can guarantee herself $\neg V$. Then von Neumann proved the minimax theorem, which states that every two-person zero-sum game has a value. Furthermore, there is a nice behavioral procedure that leads to the value: If players play their maxmin strategies, they will receive the value. In a maxmin strategy, a player considers first the worst-case scenario after each option and then chooses the strategy that has the best of the worst outcomes. This is the best we can get—a definition of an equilibrium and a theory about how to get there. Unfortunately, this cannot be generalized to all games.

The Nash Equilibrium

When playing a non–zero-sum game, things get more complicated, and von Neumann's approach does not work. The mathematician John Nash proposed instead his theory: An equilibrium is defined as a choice of strategies in which no player has an incentive to change her or his behavior given the choice made by the others (a "Nash equilibrium").

Games are more general models than markets, and in many respects, the Nash equilibrium is a more general concept than Walras's. For instance, models to study oligopolistic behavior can be analyzed using the concept of the Nash equilibrium, which converges to the Walrasian equilibrium as the number of agents increases. It is thus no surprise that both share some methodological problems; in particular, the rationality assumptions in game theory are not enough to define a process leading toward a Nash equilibrium, thus repeating the situation found with the Walrasian equilibrium.

Dynamics

There are two main reasons to analyze the dynamics of behavior. First, a dynamic process that converges to the equilibrium may respond to the methodological criticism mentioned before. Second, the equilibrium analysis may require too much rational and analytical capability from the agents. A dynamics based on a learning rule, an adaptive process, an imitation reflex, a contagion mechanism, and so on, may explain better the observed reality.

In the end, the dynamic process may or may not converge to a strategy for each agent. If it does, the point of convergence is a kind of equilibrium, which typically, but not necessarily, is a Nash equilibrium. If it does not converge, the process can cycle or may show an erratic behavior.

The Use of the Equilibrium Methodology

The General Equilibrium Theory studies the conditions under which markets are efficient. These conditions serve two purposes: They guarantee, first, that a competitive equilibrium exists and, second, that the competitive equilibrium is efficient. This distinction is important in order to understand the scope of the amendments that are introduced in the theory to cope with other conditions. Next, we discuss three cases.

The absence of free entry, for instance, opens the door to a model of oligopolistic behavior where one can compute both the Walrasian and the Nash equilibria, which give different outcomes. The choice of the Nash equilibrium is made after the observation that the strategic and not the price-taking behavior is the more natural behavioral assumption in this setting.

The equilibrium analysis shows that markets are inefficient if externalities are present (pollution is just one example) and provides a diagnosis of the problem that may help design a correcting mechanism. Depending on the context, a bilateral negotiation after assigning property rights, a tax, or an emissions market are examples of such mechanisms. Sometimes the model will be solved by using the competitive equilibrium and some other times by using the Nash equilibrium.

In economics, as in game theory, rationality means not only that preferences and behavior must be consistent but also that agents can understand and analyze the situation as well as the modeler can. However, collecting all the information and analyzing all the data may be too demanding, and models that use a dynamic process of learning, imitation, or evolution, to name a few, may cope with this problem.

Problems With the Equilibrium Methodology

Realism

Critics of the equilibrium theory argue that the economy is never at rest and that the equilibrium is never attained. Two solutions can be found when confronted with this problem. First, if the state is not far from the equilibrium, the equilibrium methodology could be defended as a reasonable approximation to the observed phenomena. Second, if the approximation is not good enough, one probably needs to model behavior as a dynamics.

Existence

The determination of the conditions for the existence of an equilibrium will be important not only for the acceptance of the theoretical model but also as an indication of what to look for in real life to address the question of whether and when an economy can be said to be close to an equilibrium.

Multiplicity

A model that allows for multiple equilibria shows an undesired level of uncertainty. A better model may need to incorporate more details to have more predictable power. Alternatively, a refinement of the equilibrium concept may be enough to fix the problem. Which one is the best option cannot be determined a priori.

Stability

One particularly important refinement discards the unstable equilibria, as the real economy can hardly be in such a situation. The modeler needs to be able to tell them apart and use only the stable equilibria as her tool of analysis.

Essentialism

Rather than one view that goes by the name *essentialism,* there are many. This entry clarifies and emphasizes important differences and other relations between some varieties of essentialism.

But it is useful to begin with what most essentialisms have in common. They are views about *belonging*. Most of them further specify the general idea that for some entity to belong to a particular category or individual, it must have certain properties. Those properties are *essential properties* for belonging to the category or individual in question. For example, essentialism about the biological category "platypus" might say that an organism is a platypus *only if* that organism has a certain cluster of genes and a particular ancestry, where these genes and ancestry are essential properties for being a platypus. Essentialism about the March 2011 dissolution of the 40th Canadian Parliament (an individual event in Canadian politics) might say that any event belonged to or was a part of that dissolution *just in case* it was one of the important proximate causes of that dissolution. Additionally, most essentialisms imply that the properties essential for belonging to some category or individual together form the *essence* of (or essence of belonging to) that category or individual. If having a particular cluster of genes and a certain ancestry are the *only* essential properties of being a platypus, then together they form the platypus essence. More generally, an essential property for belonging to *X* is *necessary* for belonging to *X;* having the essence for belonging to *X* is, in ordinary environments, *sufficient*.

To see how varieties of essentialism elaborate this basic view in different ways, this entry first discusses *philosophical* essentialisms, including those in metaphysics and philosophy of science that are relevant to thinking about the nature of social science categories such as "economic individual," "urban city," "Black person," and "gay man." The entry then more briefly discusses *psychological* essentialisms concerning folk beliefs about such categories. The discussions reveal how several essentialist views connect with other issues, including categorization of kinds, induction, scientific realism, explanation, social constructivism, reductionism, the psychology of concepts, and social policy.

Philosophical Essentialisms

Of the many philosophical essentialist views and issues, this entry discusses metaphysical and then scientific ones.

Philosophy: Metaphysical Essentialist Views and Issues

Ancient Greek philosophers such as Aristotle were the first thinkers known to develop essentialist views, typically, to address metaphysical problems. These include explaining how anything can be generated out of other things and how a thing can persist through some changes but not others. One might say that a particular platypus can survive the loss of its tail because having a tail is not an essential property for being a platypus.

The popularity of metaphysical essentialisms has fluctuated dramatically since Aristotle's time. Working in the 1970s on the issue of linguistic reference (e.g., To what do the terms *Richard Nixon* and *gold* respectively refer?), the American philosophers Saul Kripke and Hilary Putnam initiated the present resurgence in metaphysical essentialisms. Some of these abstract from any particular sorts of entities to focus on entities in general (including objects, processes, events, groups, nations, etc.). These views often articulate theories about what properties entities have *necessarily.* A spectrum of such views range from the claim that any entity has all its properties necessarily, as the German philosopher Gottfried Leibniz claimed in the 17th century, to the view that the only properties that any entities have necessarily are trivial ones, such as the property of being either red or not red.

As metaphysicians have made their essentialist views increasingly responsive to work in other fields, general essentialisms have fragmented into more specific views about limited ranges of entities, for instance, linguistic, biological, or social entities. Nevertheless, some general metaphysical issues arise across several of these narrower views. One issue concerns the *ontological* categories with which essential properties associate. For example, take the view that some of an entity's essential properties are those without which it would not exist. Such properties individuate (set apart) the fundamental kinds to which entities belong, where "fundamental kind" names an ontological category. The essences formed by these essential properties are *kind essences*.

Another sort of kind essence is one that individuates a nonfundamental kind, one that an entity can pass in and out of without perishing. The essential properties constituting such an essence are required for belonging to the nonfundamental kind but not necessarily for existing. If "republic" names a kind, it is of this sort; Australia doesn't currently possess the essential properties for being a republic, but it might one day. Some of the problems that scientists and philosophers of science have perceived for essentialism tacitly presuppose that essentialism is only about fundamental kinds; but many kinds of interest in science are nonfundamental, and so such problems do not afflict them.

All kind essences, whether associated with fundamental kinds or otherwise, are ones that, in principle, more than one entity can have. Kinds can have more than one member. *Individual essences,* in contrast, are made of properties essential to and had by only one entity. If Australia has an individual essence, it probably involves the unique way it originated.

The ontological issue relates to *identity.* Essences that individuate fundamental kinds determine the metaphysical identities of the members of those kinds. For instance, were *platypus* a fundamental kind, then any organism with the platypus essence would fundamentally *be* a platypus; that essence would fix the organism's identity so that it could not cease to be a platypus without expiring altogether. Interestingly, some plausible interpretations of biology suggest that the species that evolutionary theory recognizes are not fundamental (kinds or otherwise), allowing that any organism could survive a change in species and even belong to no species or to more than one. This does not imply that *every* essentialism about these species is hopeless, because it leaves it open that each species that evolutionary theory recognizes is individuated by essential properties of the sort associated with nonfundamental kinds, such as "republic." Likewise, essentialists with respect to social science categories such as "free market," "woman," or "gay man" need not claim that the essential properties they recognize determine identity.

Identity issues underlie views concerning the *locality* of essential properties. Intrinsicalism is a common though seldom defended presumption about the locality of essential properties; it says that any essential properties must be *intrinsic* properties of their bearers. A subject's intrinsic properties are realized by that subject's internal features (e.g., some muscle internal to your chest realizes your property of having a heart). One motivation for intrinsicalism applies *only* to essentialism about fundamental kinds. Consider the following: Were any of the essential properties that individuate these kinds not intrinsic, they would be *extrinsic.* A subject's extrinsic properties are realized at least in part by features external to her, such as being related to other entities or processes in particular ways. But if such extrinsic properties are among those essential for belonging to a fundamental kind, then, absurdly, members of those kinds could perish due to changes in their extrinsic conditions and without any internal changes to themselves. In contrast, because the essential properties associated with nonfundamental kinds do not determine identity, they *can* be extrinsic without generating such absurdities. More generally, several authors have argued that there is no barrier to extrinsic property essentialism about nonfundamental kinds and that we often have good theoretical reasons to recognize these. This allows such forms of essentialism to agree with the common claim that membership in many social categories, such as "free agent" or "Canadian," is (partly or wholly) extrinsically or relationally determined.

Several other metaphysical nuances in contemporary essentialist views belie traditional understandings of essentialisms. Essentialism about kinds is often said to imply *fixity* or *immutability* about hierarchies or networks of kinds, for example, that all kinds of chemical elements form an unchanging and static set that the periodical table represents. But many essentialisms are compatible with dynamic networks of kinds, where some kinds are generated out of others. Indeed, the chemical elements probably arose in this way. Some authors worry that this ensures that the boundaries of these essentially determined kinds are *vague,* making nonarbitrary identification of them impossible. Authors such as Elliott Sober reply that there are reasons to think that a kind's having a vague essence and vague boundaries is compatible with its being determinate and nonarbitrary.

Perhaps the most startling check on traditional metaphysical presumptions about essentialism concerns *necessity.* On the increasingly popular homeostatic property cluster (HPC) view of some kinds, no single one of the properties that helps individuate an HPC kind need be necessary for kind membership;

rather, some subset of these properties is sufficient in each case. If "Irish person" names an ethnic kind, for example, it is probably one of these. There need not be one property that all Irish people share but rather a cluster of individuative properties of which each has some subset, with different Irish people having different subsets. (Some other people are neither determinately Irish nor determinately not Irish.) This descendant of Ludwig Wittgenstein's notion of "family resemblance" would be a nonessentialist view were it not for the possibility that the individuative cluster *is* necessary rather than any single property in it. On this possibility, although there is no single property that each Irish person must have, to be Irish a person *must* have some subset or other of the properties in the cluster. Such views have been made consistent with Kripke's and Putnam's work on linguistic reference and define a new form of essentialism that permits the prodigious variation within kinds that dooms many traditional essentialist accounts of those kinds.

Philosophy: Scientific Essentialist Views and Issues

Metaphysical and scientific essentialisms overlap. Work in various sciences and philosophy of science motivates some of the nuanced metaphysical positions described above. In the other direction, refinements in metaphysics have made essentialist views more applicable in some scientific domains than they previously were. Nevertheless, teasing out scientific essentialist views and issues from metaphysical ones clarifies issues both in *general philosophy of science* and in philosophies of *particular sciences*. Let us take these in turn.

In addition to renewing interest in essentialism among metaphysicians, Saul Kripke and Hilary Putnam helped rejuvenate the Aristotelian idea that essentialism is important to empirically minded philosophy of science. They did this partly by convincing many researchers that some scientific inquiry consists in an empirical search for and a posteriori discovery of kind essences. For example, chemistry has involved not only searches for chemical causes of certain phenomena but also determining what particular chemical elements and compounds *are*. Their results often seem to tie these kinds to *microstructural* essences: Having 79 protons is the essence of being a gold atom, and being composed exclusively of H_2O molecules is the essence of being (pure) water. Kripke's and Putnam's intuitively driven thought experiments have had a greater role in inspiring an essential interpretation of some scientific inquiry than their semantic theses.

Brian Ellis has developed an essentialist interpretation of some scientific inquiry, in a view he calls *new scientific essentialism*. Although he hesitates to apply the view to the social sciences, we will see why others are cautiously optimistic.

Ellis claims that his scientific essentialism best fits the facts of inquiry and discovery in much of physics and chemistry and that it offers the best philosophical analysis of the laws of nature discovered in those disciplines. Roughly, he proposes that laws of nature are grounded in the microstructural essences of the kinds over which those laws range. The laws are exceptionless *because* the members of the kinds over which the laws range all possess the essences that make the laws true. According to Ellis, those essences are metaphysically necessary and sufficient for kind membership.

On Ellis's view, essential properties of scientific interest must be an important part of the *explanation* of characteristic behaviors of the entities that have them. Having 79 protons, for instance, is an important part of the explanation of gold's melting behaviors and interactions with other elements. This explanatory salience of essential properties is supposed to make them relevant to the general philosophy of science issue of *induction* too. The explanatory salience of the essential properties ensures the predictive reliability of generalizations that range over the kinds individuated by those properties.

The new scientific essentialism connects with the further issue of the proper aims of science. It supports the traditional view that some sciences do and should aim to construct classifications comprising categories that represent kinds over which generalizations range. The classifications are theories about natural order. These improve as they more accurately represent kinds, laws, or generalizations and the relations between these. Whereas empiricists about the aims of science often transform this view into an instrumentalist or anti-realist one that nowhere appeals to microstructural essences, Ellis argues that his foundational appeal to such essences develops the view into a version of scientific realism. He claims that science discovers these real essences and discovers that they are essences and that they are intrinsic causal powers that members

of corresponding kinds have determinately without variation. The kind distinctions they underwrite are then nature's distinctions, not ours: real, absolute, and categorical.

Philosophy of the Social Sciences

The reality of essential distinctions and the naturalness of kinds are hotly contested issues when one moves from general philosophy of science to the philosophy of particular social sciences. There is an overwhelming consensus that most of the kinds these sciences study and generalize about are *not* individuated by real essences and are *socially constructed* rather than natural. Some examples are as follows: "individual" and "market" in economics, "Black" and "White" in race studies, "capitalist city" in urban sociology, "woman" in feminist political science and sociology, and "emerging adult" in developmental psychology.

When saying that essentialism about these categories is mistaken, most critics mean something like the "absolute" and "categorical" essentialism that Ellis favors for physics and chemistry. However, they typically do not have in mind Ellis's physical and chemical levels. One of the alternative levels they sometimes have in mind is the genetic level of biology. Any real essence distinctions here are widely thought to fail to account for the boundaries of the mentioned social kinds. This can be called failure of *categorical real genetic essentialism about social kinds* (CRGESK). CRGESK is a nonstarter for some social categories. Nobody ever thought that a genetic distinction accounts for the category "middleman." But for other categories, such as "White male," the failure of CRGESK is more interesting. This is because the best reason given for this failure leaves open other real essentialist accounts of some social kinds, and some authors note that several debates in social sciences are clarified once we appreciate this.

The best reason to reject CRGESK concerns variation and explanation. For any social kind, there are no genetic properties that both (a) are shared by all human members of the kinds and (b) explain behaviors common to those members. The evidence for this is inductive, from genetics and population studies. It entails that for social kinds, there are no genetic properties that could meet the necessity and explanatory conditions that Ellis places on real essential properties.

This leaves open two (combinable) options for alternative sorts of *biological real essentialism* about some social kinds. First, one can expand the candidate's essential properties to biological ones other than genetic ones. For instance, there is some evidence for common and explanatory neurological properties that may individuate *economic individual* as a real kind. These properties may be intrinsic properties of human persons. But as noted above, essential properties need not be intrinsic for the nonfundamental kinds that sciences study. Races are conceived as such kinds when authors argue that extrinsic, genealogical properties of people account for the race distinctions between them.

Second, authors such as Ron Mallon have argued that the social kinds in question are HPC kinds. This allows that the properties individuating them, whether neurological, genealogical, or of other sorts, need not be possessed by all kind members. The prevalence of variation among members of each social kind would seem to require this modification of any essentialist account of them, whether biological or not. Whether authors *call* the resulting view a new form of "essentialism" is beside the point.

Social Constructivism and Biological Properties

Authors have challenged the above-described essentialist move from genetic to other sorts of biological properties. However, authors are now realizing that the resulting debates between the biologically inclined and their critics are often ill formed. This happens when the socially constructed kinds to which the critics refer and those to which the biologically inclined refer are not coextensive. Consider the following: What a biological taxonomist refers to by using race names is sometimes not what the social constructivist has in mind. Although this suggests that parties to some of these debates are talking past one another, a different interpretation is that they tacitly have a normative disagreement about which kinds social scientists *should* focus on and analyze. Uncovering these tacit normative disagreements has motivated some parties to these debates to change their argumentative strategies, focusing on crucial normative points without epistemic or metaphysical distractions. This is one place, for instance, where practical concerns about the political dangers of *applications* of biological essentialisms have a traction that they *cannot* have when it is the mere truth of those essentialisms that is in question.

But even liberalized biological essentialisms often seem to fail to account for the kinds that interest social scientists, because, as social constructivists argue, the explanatory causes of the boundaries of these kinds are *social*. This biological versus social issue is primarily empirical. For instance, it is an empirical platitude that oppressive political systems are important causes of some of the gender and race distinctions that social science recognizes.

It is crucial to note, however, that social constructivism along these lines is consistent with real, social (rather than or also biological), and HPC essentialist accounts of some social kinds. The *realism* in any such essentialism only requires that the properties that distinguish kinds are or correspond with the actual causes of kind distinctions. It does not matter whether the actions of *people* and *social groups* are among these causes. The only social constructivism that is incompatible with a liberalized real essentialism is the extreme sort, on which social kind distinctions derive *only from the mere beliefs* (not actions) of social theorizers.

The main motivation for pursuing liberalized, real essentialist accounts of social kinds, whether biological or social, is to provide a socially sensitive scientific realist's ground for well-confirmed generalizations that range over those kinds. These generalizations nearly always have exceptions, as expected on a suitably liberalized essentialism. But some of the versions of metaphysical essentialism described above allow a realist interpretation that permits exceptions. And, of course, other avenues to a realist interpretation may be open without utilizing essentialism at all. Likewise, if realism fails, this may or may not be related to essentialism.

Psychological Essentialisms

Unlike the philosophical essentialisms discussed above, psychological essentialisms concern which essentialisms (if any) people tend to believe or imply, regardless of which of these beliefs are true or justified. Psychological essentialisms still have philosophical aspects and applications though, and the social sciences, including cognitive anthropology, ethnography, and various fields in psychology, often study them.

The "classical view" of the psychology of everyday-category concepts says that we use these as though we define them by tacit appeal to sets of singly necessary and jointly sufficient conditions for instantiating the concepts. This suggests that most people are *metaphysical essentialists* of one stripe or another about everyday categories. Experiments beginning in the 1970s initiated several attacks on and alternatives to this view. For instance, researchers have suggested that instead we are (sometimes from early childhood) *presumptive scientific essentialists* about at least some categories, such as biological ones or race and ethnicity categories. That is, we assign things to categories on the presumption that there is some set of underlying, typically unobservable, features that they uniquely share and that causally explain many of the observable features characterizing the category. Authors often claim that this widespread "essentializing tendency" is innate and evolved, part of a strategy to infer generalizations from experience.

Nick Haslam and Jennifer Whelan reviewed a host of empirical studies that argue that many people are scientific (and often genetic) essentialists in this way about several social categories, including "AIDS patient," "Jews," "gay man" (and other sexual orientation categories), gender categories (especially "woman"), personality categories, race and ethnicity categories, and categories of mental disorder. Two clusters of philosophical points about these studies are noteworthy.

First, critics have noted that many of these studies are not appropriately sensitive to the sorts of distinctions between the essentialist claims highlighted above. Although some psychologists, such as Frank Keil, have tried to test between crude essentialisms and nuanced essentialist positions (such as the HPC kinds view) with respect to folk beliefs about everyday objects and biological kinds, research on social categories has not reached the same level of conceptual sophistication. There is a concern that this has compromised its conclusions.

Second, many of the studies of folk scientific essentialism about social kinds purport to show that scientific essentialist thinking about some social categories generates stereotyping and prejudice. For instance, Nick Haslam and Sheri Levy find a correlation between (a) the essentialist belief that the category "gay man" is discrete and (b) antigay attitudes toward gay men. They note that researchers often interpret this sort of result to indicate that certain aspects of essentialist thinking about the category "gay man" are sources of antigay

attitudes about gay men and that this helps account for those attitudes. However, it is difficult to find anything in such studies that justifies the inference *from* a correlation between aspects of essentialist thinking and prejudice *to* the claim that aspects of essentialist thinking cause or explain prejudice. For instance, to adapt one of Nick Haslam's and Sheri Levy's own remarks, we need finer-grained empirical work to tell whether some essentialist responses made by study participants are (however irrational) post hoc defenses of prior or otherwise caused prejudice.

Suppose that such further studies happen to justify the causal claims about essentialist thinking. A further caution is known to arise. Researchers sometimes appeal to such causal claims to support negative assessment of essentialist beliefs. Ironically, this appeal commits the same sort of naturalistic fallacy that the researchers are tacitly or explicitly criticizing. From any putative essentialist facts about social categories, no justifications of normative prejudice follow. Likewise, from any putative facts about essentialist thinking causing prejudice, no justifications of normative dismissal of essentialist belief follow. In the relevant cases, social policy would be better justified and probably practically more effective if it corrected the object of its concern, shifting from essentialist belief to dubious inferences from essentialist belief.

Ethical Impact of Genetic Research

In assessing the ethical impact of genetic research, in which philosophical and social-scientific concerns merge, it is useful to discuss three different areas addressed in this entry: (1) the ethical impact that genetic research is already having on important bioethical concepts such as *informed or valid consent*, which influence the public trust necessary for the conduct of genetic research; (2) the possible impact that genetic research will have on concepts such as free will, an issue of major importance for the social

sciences, which aim to explain social action issuing from the free will of human beings; and (3) transforming into practical issues what seem to be purely theoretical issues, such as whether it is better to have a society of people who are relatively equal to each other in their natural attributes or to have a hierarchical society whose members have widely different natural attributes.

Issues of Information

Because a volunteer cannot expect any personal benefits in volunteering for medical research, whereas a patient expects to benefit from the treatment for which she is being asked for consent, it is universally recognized that the information about the risks of being a volunteer must be fuller than the information given to patients. It must include not only the medical risks, such as suffering some bodily injury, but also risks to one's privacy and the risk of finding out facts about oneself that one would prefer not to know. In the cases with which we are concerned, a researcher is often unable to provide information about these latter kinds of risks. Genetic research, such as gene transfer research and pharmacogenomic trials, does involve risks of bodily harm, but our standard human subject safeguards apply to these.

It is becoming increasingly common, however, to create *biorepositories* of genetic information, both where the content is collected with one's consent to research and where it is obtained from existing specimens, such as from hospitals or from state newborn-screening programs. In neither case is the future use of that genomic data known. Scientific interest in using available genetic data to identify genotypic–phenotypic or environmental associations may lead researchers to simply go looking for new information. If the research identifies genetic information that meets a threshold for clinical utility, questions arise as to whether such results should be returned to the person or become the basis of recruitment into a new study. Information about a person, say, having a medical condition or being at risk for it that standard practice would not currently disclose, such as in pediatrics, where carrier and adult-onset conditions would typically be disclosed only upon reaching majority, may now be disclosed. The current efforts to craft "global" or "broad" consent forms is one way by which genetic research has already had an impact on the bioethical concept of informed consent.

Another way in which the concept of informed consent is affected by genetic research is that genetic information about an individual also provides genetic information about some of the relatives of that individual, and in small isolated societies, it may even provide genetic information about all the people in that society. These other people may not have consented to have this information about themselves provided to researchers. Thus, a researcher may gain information about people who were not even asked to participate in the research and so were not provided with the information that is required for obtaining informed consent to participate in the research project. Their privacy, as well as that of the original individual, may be violated in the use and sharing of such genetic data. Because the genetic information obtained by genetic research may have monetary value, the question has arisen whether volunteers should be provided with some compensation for their genetic data.

Issues of Determinism and Free Will

The second area where genetic information is likely to have an ethical impact is on people's attitudes. People may suffer a stigma when they are discovered to have genes associated with mental disorders or mental disabilities, even though they do not exhibit any symptoms of either. This may result from regarding these conditions as being genetically determined, so that the person is regarded as having the condition even in the absence of symptoms. Researchers claim that all genetic research is for medical purposes, such as discovering the genetic contribution to various diseases and discovering genetic variations that account for why some medications work for some people and not for others. However, it is quite clear that the genetic contribution to normal behavior will also be discovered, with potential for stigma—for example, by identifying persons prone to risky behavior. We already know that the complex herding behavior of sheep dogs is inherited, so it seems quite likely that much complex human behavior also is inherited. This may have a significant impact on people's attitudes toward free will, changing people's attitudes toward holding individuals responsible for their behavior and affecting societal attitudes toward punishment. An emphasis

on genetic associations as central to all conditions and behaviors may also cause persons to regard that genetic information as the most salient, increasing the scope of various medical conditions to permit a greater range of phenotypic expression, resulting in, for example, an enlarged autism spectrum disorder and "mild" fragile X syndrome.

Altering Human Nature

The third area in which genetic research may have a significant ethical impact is more speculative. If genetic research shows that we can manipulate the genetic makeup of an embryo so as to create a human being with new and desirable traits, it may have a significant impact on the concept of *human nature*. The concept of human nature as something given may change, so that rather than working to make the environment more hospitable to human beings, some may want to make human beings more adaptable to the existing environment. We also will have to consider as a practical matter, not just a theoretical one, whether we want a society where everyone has the kind of genetic traits that now only a favored minority have. We would not purposely create less favored individuals, as was done in Aldous Huxley's dystopic 1932 novel *Brave New World,* but not every embryo would be genetically enhanced. Thus, genetic research may have an impact on people's attitude toward equality in its most fundamental aspect, equality in desirable genetic endowment.

Ethno-Epistemology

Western philosophy standardly defines *epistemology* as reflection upon the nature, goals, norms, concepts, and scope of evidence, justification, and knowledge per se and as evaluation of human cognitive activities from the standpoint of these norms and goals. *Ethno-epistemology* seeks a scientific understanding of epistemological reflection and evaluation. It views epistemology as a contingent and historically emergent natural phenomenon produced by a particular species of primate (*Homo sapiens*); a phenomenon that is, moreover, fully amenable to understanding from a broadly anthropological, a posteriori perspective that incorporates the relevant findings of cognitive psychology, linguistics, sociology, anthropology, evolutionary biology, and so on. The nature, aims, norms, theories, and concepts of epistemology—like those of morality, religion, science, and law—emerge from the concrete life circumstances in which epistemological inquiry is organically rooted and sustained. Epistemology, in short, is made *by* humans *for* humans. Ethno-epistemology accordingly approaches human epistemological practices without appeal to divine imperatives, transcendent norms of rationality per se, or nonnatural epistemological concepts, properties, or principles. As a scientific enterprise, ethno-epistemology extends the epistemology of the sciences (natural and social)—that is, their a posteriori evidential practices, styles of reasoning, and modes of explanation—as well as their substantive findings to the study of epistemological inquiry.

The scope of ethno-epistemology is universal in several senses. First, it examines the epistemological activities (i.e., the intuitions, judgments, norms, and goals—be they implicit or explicit) of ordinary people, of cognitive specialists (e.g., shamans, priests, jurists, linguists, cognitive psychologists, and physicists), and, most significantly, of professional philosophers, in particular professional epistemologists. This last involves subjecting to the anthropological gaze the epistemological activities of members of professional philosophical societies (e.g., the American Philosophical Association) as well as editors and referees of professional philosophy journals. Ethno-epistemology examines professional boundary work, such as how the dominant epistemological canon is constructed, how the contents of university epistemology textbooks are determined, who is deemed a "serious" epistemologist, what is deemed a "genuine" epistemological problem, and which epistemologists are mainstreamed in university epistemology courses and which are ghettoized in world philosophy, wisdom literature, or anthropology courses. It also examines professional gatekeeping activities, such as editorial decisions by professional journals, grant-awarding decisions by funding institutions (such as the National Endowment for the Humanities), admissions and degree-granting decisions by PhD-granting institutions, and academic hiring and promotion decisions.

Ethno-epistemology is universal in the second sense of viewing Western epistemology as one among many possible, contingent epistemological undertakings pursued by human beings. This approach decenters and provincializes the aims, norms, problems, intuitions, and conclusions of Western epistemology since it no longer regards these as inevitable, universal, or definitive of the epistemology standpoint per se. In so doing ethno-epistemology forsakes the double standard that exempts domestic (Western) epistemological practices from the same anthropological scrutiny and explanation that nondomestic (non-Western) epistemologies standardly receive. It likewise abjures the related double standard that privileges the epistemological activities of Western philosophers as "epistemology simpliciter" while marginalizing those of non-Western philosophers as mere "ethno-epistemology." Western epistemology is simply one ethno-epistemology among many, including pre-Han classical Chinese (e.g., Confucian), Mesoamerican (e.g., Aztec), and African (e.g., Yoruba) epistemologies. Ethno-epistemology thus resists converting being different from Western epistemology into being inferior to Western epistemology or, worse, into not counting as epistemology at all. It rejects the Hegelian evolutionary myth of the unfolding of reason in history, along with the Comtean- and the Darwinian-like social-scientific evolutionary myths of a single path of human intellectual development. There is no law of reason, thought, culture, or psychology requiring that all peoples follow the same path of epistemological development. Non-Western epistemologies do not represent earlier stages of Western epistemology.

Ethno-epistemology adopts the four methodological principles of the strong program of sociology of knowledge. They are as follows:

1. *Causality:* Ethno-epistemology examines the causal conditions governing all epistemological reflection and evaluation as well as the formation of belief and knowledge.
2. *Impartiality:* Ethno-epistemology explains both true and false belief, justified and unjustified belief, rational and irrational belief, and knowledge and ignorance in causal, a posteriori terms.
3. *Symmetry:* Ethno-epistemology invokes the same kinds of causes when explaining true and false belief, justified and unjustified belief, and so on.
4. *Reflexivity:* Principles (1) to (3) apply to ethno-epistemology itself. Ethno-epistemology is amenable to ethno-epistemological understanding.

Ethno-epistemology is conducted within science as a part of science. Its symmetry, impartiality, reflexivity, and universal scope notwithstanding, ethno-epistemology remains a definitively Western scientific project—one, it may be argued, that continues to colonize non-Western epistemologies. By forcing them upon the Procrustean bed of the combined epistemological and substantive standpoint of Western science, ethno-epistemology inevitably privileges the epistemological norms, concepts, and goals of Western science to the detriment of those of non-Western epistemologies.

Ethnography, Philosophical Aspects of

Ethnography is both a subfield within social anthropology and a methodological approach used throughout the social sciences. In the first sense, ethnographies are in-depth studies of a single culture, typically written up in the form of a monograph. As a methodology, ethnography uses diverse methods to achieve a broad and systematic understanding of a particular social group. In both senses, ethnography was developed at the beginning of the 20th century as a way to study non-Western cultures. It was later adopted by sociologists to study Western, urban communities. Today, it figures also among the methodologies of business, cultural studies, education, nursing, political science, public health, and women's studies.

This entry focuses on the methodological side of ethnography, offering an overview of the epistemological and other philosophical issues that it has raised within the philosophy of the social sciences.

Methodology

Among the methods of ethnographers, participant observation is perhaps the most iconic. The researcher lives among the subjects of her study, learns their language, and interacts with them in casual, everyday contexts. Ethnographers also use extended interviews (both structured and unstructured), as well as surveys, focus groups, discourse analysis, archival research, video and audio recording, and, occasionally, (quasi-)experimental methods. The variety of methods is required because ethnography aims at a "holistic" understanding of the social group that captures the insider's perspective. Holism is the view that the different aspects of social life cannot be isolated: The meaning of one symbol or the significance of one event depends on the meaning or significance of others.

Ethnographers draw conclusions about the particular social group they study. These are generalizations of limited scope but generalizations nonetheless. They raise at least two related philosophical issues. First, what kind of evidence supports these generalizations? Second, does ethnography suppose the existence of a distinct group of people with homogeneous beliefs, values, practices, and so on? That is, does ethnography presuppose that cultures exist? In its earliest formulation, the conceptualization of participant observation relied on a particular conception of culture. Cultures (or societies), many thought, were constituted by systems of rules or norms. An inquirer came to learn this system by "playing the game." Ethnographic conclusions were justified because the generalizations were primarily about normative systems, and these systems could be learned by living with the subjects. This epistemological and ontological stance has been questioned, and many social scientists have abandoned it.

Critical Issues

One problem noticed by social scientists was that the evidential grounding for ethnographic claims is often problematic. While the ethnographer would draw

conclusions about "the Nuer" (the ethnic group in South Sudan), his or her actual contact would often be fairly limited. In a society where activities were starkly segregated by gender, for example, a male ethnographer's evidence would be largely drawn from male informants. In addition, ethnographers often gravitated to "good informants"—loquacious and articulate individuals—without reason to believe that these individuals were representative. As long as ethnographers thought of cultures as homogeneous, these problems were no more than practical problems of empirical research. There was an independent object—the culture—of which different experiences provided glimpses. Because of the relationship between the concept of culture and the epistemic justification for ethnographic methods (particularly participant observation), critique of the idea that cultures or societies are homogeneous and distinct was an important source of concern for ethnographers.

One source of the critique comes from the recognition that conflict and change are normal conditions of human society. Non-Western cultures are not living fossils. Humans are always in contact with nearby communities, and interchange of ideas and practices is the norm. Moreover, many communities are constituted by a variety of constituencies with different perspectives on common symbols, rituals, or social events. The perspectives often align with differential power among the subjects. To represent one interpretation as "the culture" is to misrepresent at least, and at worst, it reinforces a political agenda. These arguments have had a profound influence on ethnographic practice. Ethnographers have become cautious about drawing conclusions about "the culture." And they often supplement participant observation and interviews with systematic evidence-gathering techniques that are intended to capture the breadth of different beliefs and attitudes.

A more profound critique of ethnography challenges the idea that ethnographies represent an independent object—homogeneous or heterogeneous—at all. These arguments add a critique of ethnographic writing to the considerations already discussed. Classical ethnographic writing employed the genre of realism, where the author uses rich descriptive detail to create a vivid sense of the scene. This technique, they argue, is essential to the creation of the ethnographer's authority as someone who was present and can tell the story. Ethnographic monographs, however, are typically a pastiche of people, places, and events. Indeed, ethical concerns often prompt ethnographers to disguise real people or events. In spite of its pretensions, ethnography is not a more or less accurate representation of an independent reality. Rather, it is the product of a particular interaction between the ethnographer and his or her interlocutors. On this view, expanded data-gathering techniques are beside the point. Ethnography is akin to fiction.

A variety of methodological experiments have arisen in response to these concerns. Some have maintained the commitment to realism (in the philosophical sense) and tried to justify their conclusions with more care. Others have tried to decenter the ethnographer by presenting multivocal ethnographies, where the subjects appear as cocreators, or even coauthors, of the research. For all ethnographers today, research requires careful reflection on the way in which evidence and interpretations are produced.

ETHNOMETHODOLOGY

Ethnomethodology has been an important field of social science in which philosophical and methodological issues about social inquiry loomed large, being an area directly descending from a specific philosophical school. This entry presents an overview of its protagonists and their ideas and explains the distinctive kind of ethnomethodological studies.

Origins

Ethnomethodology is a dissenting strand of sociology, developed by the American sociologist Harold Garfinkel (1917–2011) during the 1950s and 1960s, which remains an active and controversial area of work in the present. Its initial connection with philosophy was through phenomenology, itself the creation of Edmund Husserl (1859–1938) in the early part of the 20th century, though the most direct link was through the work of the Austrian social theorist and philosopher Alfred Schütz (1899–1959). Schütz's project, initiated in the 1920s, was to use phenomenology's methods to clarify the philosophical foundations of the social sciences. Schütz accepted the idea of sociology as the study of social action, broadly along the lines set out by Max Weber (1864–1920), but thought that Weber had not sufficiently worked out the basic assumptions he depended on. Weber's sociology is often called a *verstehende* (or "understanding") sociology, to reflect the emphasis that Weber placed on the use of the investigator's capacity for understanding the thoughts and intentions of those being studied; but Weber had not, in Schütz's estimation, sufficiently worked out the significance of the fact that "understanding" can serve as a method for sociology only because it already serves the conduct of social life—in other words, that those involved in society are capable of understanding one another.

The Protagonists and Their Main Tenets

One of phenomenology's founding purposes was to readjust the relations between our scientific and our non- or prescientific understandings, which were often imagined to be one of outright rivalry: There is the world as we ordinarily understand it, and there is the world as it really is—in other words, as it is shown to be by science. One of Schütz's main responses to this issue was to treat everyday and scientific understanding as having different roles. Science, to put it crudely, is a theoretical enterprise, while our everyday lives involve practical understandings—a grasp of how to get things done. Because of this disparity in character, the two are basically disjunctive rather than directly competitive. Schütz saw his own contribution as that of articulating more clearly the intricacies involved in adopting the theoretical or scientific attitude in the study of practical action.

Schütz's writings had a tremendous effect on Harold Garfinkel, who sought, during the late 1940s and 1950s, to show that Schütz's conception provided a viable systematic alternative to the various theories of social action that were then available (most prominently, those of Talcott Parsons [1902–1979], the then preeminent sociological theorist). One of the crucial issues that Garfinkel thought distinguished Schütz from other sociological theorists was his treatment of the notion of *rationality*. Rationality is commonly conceived as a matter of electing the most effective means for doing things, and *if one supposes* that science is the gold standard for determining what the world—the circumstances of our doings—is really like, then effective conduct will be that which accords with scientific understandings. "Rationality" becomes a yardstick for sociologists to use in the assessment of people's doings: Can what they are doing possibly be an effective way of going about things? Are their practices rational or irrational (which is still, in other contexts, a burning topic under the title of "the rationality debate")? A further result, in application to people's doings, was to conceive the character of rational action as very much akin to following a scientific type of procedure, one that involves the systematic application of very well-defined and extremely precise rules (rational action models have been back in fashion in sociology for some time). Schütz noted, however, that the notion of rationality had a life independent of science, one applied in daily life.

Garfinkel concluded that a better understanding of how people do act in social life would be gained if one gave up invidiously matching the organization of people's actual practical doings against an idealized standard specifying how they should act to satisfy the requirements of ideal scientific rationality. This conceives the organization of people's doings in negative terms and does not really answer the question

of how people do carry out their affairs in the life of their society in ways that *they* find effective. What counts for them as rational practice? For Garfinkel, this question was not to be answered in any general and a priori way but through investigation of cases to find what standards of practical rationality were applied in different areas of social life and in the local settings in which conduct was enacted. Garfinkel thus thought of ethnomethodology as essentially a program of studies. More recently, the extent and value of Schütz's influence have been debated, and reference to Maurice Merleau-Ponty (1908–1961), an important French phenomenologist, who placed more emphasis than Schütz on the embodied nature of activity, has been more prominent in Garfinkel's thought.

Garfinkel thought that the opportunity of understanding social life as a product of practical rationalities had not really been spotted by the social sciences. Other varieties of sociology had not really taken any interest in the features identifying the affairs of daily life in society—having dinner with the family, taking part in psychotherapy, filling in social security applications, selling insurance, and so on and on—as the recognizable and mutually coordinated matters that they are, their enactment as intelligible occurrence of repeatable social doings being important to people's ability to respond to each other in standardized and coordinated ways, something Garfinkel took to be essential to the possibility of social order.

Ethnomethodological Studies

Garfinkel thus initiated ethnomethodology; its name was meant to indicate its nature: the study of those methods for practically carrying out social activities that belong to the members of society.

The first exposure of Garfinkel's thought to the sociological public in the mid-1960s had an explosive impact. It seemed to many that it was a threat to the very idea of sociology, certainly to sociology as they understood and valued it, and it was responded to, at worst, as if it were just a kind of bizarre eccentricity, more often as if it was based in fairly stupid mistakes. At the same time, there were many sociologists who saw interest and promise in Garfinkel's ideas and undertook the kinds of studies they understood him to be calling for. A large number of such studies have been made, and among the variety of these have been studies of police officers working "skid row" districts, lawyers reaching for agreement on plea bargains, teachers asking pupils questions, Buddhist philosophers in live debates, software engineers writing code and working out designs, air traffic controllers managing air space, therapists identifying patient's motives, astronomers doing observatory work, orchestral musicians in rehearsal, mathematicians working on proofs, mechanics safely doing repair work, advocates contesting the admissibility of evidence in court, and shoppers in supermarkets. These studies are all concerned with the way in which doing activities involves ordering what is done so that it exhibits the patterns of standardization and reproducibility that are characteristic features of conduct in a social order.

The studies are made on the understanding that such ordering is pervasively adaptable to particular situations—social action is viewed as a "situated" matter and so in each case must be done in, and be responsive to, local and variable circumstances, thus realizing standard patterns in quite specific forms. Just as the studies are attentive to the situated details of action's organization, so too are they typically directed toward understanding the reasoning required for the competent execution of lines of action under real-world conditions and thereby toward such general and basic topics of philosophy of the social sciences as the supposed requirements of rational reasoning, those of meaning, description, rationality, inference, deduction, rule-following, fact, evidence, measurement, and proof—these are matters with which the members of society are concerned, no less than are philosophers and theorists, but those members are engaged with them entirely in relation to the everyday demands of their practical purposes rather than for the theoretical ends that the professional thinkers seek.

For example, one study focused on the nature and use of historical evidence, though not as that is thought about among professional historians but rather as it was articulated and contested in the politically contentious setting of the U.S. Congressional hearings into the—then very controversial—Iran-Contra affair of the 1980s, where attempts to establish historical facts were very much to the fore. This example should not suggest that general matters of meaning, evidence, and so on are confined to high-profile and socially important occasions; they are pervasive of society's practical affairs and can be encountered and investigated in

all kinds of ordinary, even relatively trivial, social situations (e.g., establishing whether drivers have committed speeding offenses).

Ethnomethodology's earliest studies were of the most commonplace and everyday doings, the sort of things that "anyone" could do, such as greeting another person and starting a conversation, making a purchase at a store, or joining a queue to acquire a visa. They were undertaken to emphasize that the most unremarkable and uneventful everyday occurrences were nonetheless socially organized occurrences and no less deserving of sociologists' attention and analysis than the putatively greater and more important matters of social life. Then attention began to focus more on studying activities that typically require extensive training and specialized competences, such as working as a lawyer in a court of law, carrying out laboratory investigations in a branch of neuroscience, understanding advanced proofs in mathematics, and mastering the martial arts. This strand of work relates again to stock concerns of the social sciences, particularly issues of understanding another culture, but reshapes these in line with ethnomethodology's persistent interest in how it is that activities get done, bearing in mind that in many cases, having a proper understanding of how an activity is done is a matter of being able to do it oneself. To understand mathematics as a practical activity, for example, is very much a matter of being able to do the calculations, to solve the mathematical equations, to follow the proofs, and so on, and this might, therefore, necessitate sociological researchers in this and similar areas getting themselves up to speed, even undertaking professional qualification in the specialist activities they investigate.

This latter line of thought reflects a view of what understanding social life involves that is very different from the one otherwise predominant in sociology. There, understanding is generally assumed to come from the application of methods and procedures that govern the collection and analysis of data, ones that have been especially developed for use by professionally trained social scientists. Thus, it is sociology's distinctive epistemological, ontological, and methodological conceptions that are taken to define what counts as a proper understanding of organized social life, but it is ethnomethodology's alternative supposition that the terms for "competent understanding" are set within the socially organized affairs themselves. Thus, ethnomethodology's studies are efforts at recovering the (in a broad sense) methodological understandings that are built into the socially organized arrangements making up the affairs of daily life. There is no need for specially developed methods to effect such recoveries because it is a feature of those same affairs that they are organized so that their participants can pick up on whatever methods of practical reasoning are integral to and distinctive of those activities.

Eugenics, Old and Neoliberal Theories of

The word *eugenics* first appears in Francis Galton's (1822–1911) work *Inquiries Into Human Faculty and Its Development*. It combines the Greek *eu,* meaning "good" or "well," with *genēs,* meaning "born." Galton (1883) defined eugenics as follows:

> We greatly want a brief word to express the science of improving stock, which is by no means confined to questions of judicious mating, but which, especially in the case of man, takes cognisance of all influences that tend in however remote a degree to give to the more suitable races or strains of blood a better

> chance of prevailing speedily over the less suitable than they otherwise would have had. The word *eugenics* would sufficiently express the idea; it is at least a neater word and a more generalised one than *viviculture,* which I once ventured to use. (p. 17, footnote)

He hoped that the new evolutionary understanding brought about by his cousin Charles Darwin would lead not only to better descriptions of the human species but also to improvements of it.

This entry opens with a concise and selective summary of the history of Galton's science of improving stock. That eugenics has a terrible history cannot be denied. What is less clear is how this history matters to current debates, in particular to those about the genetic technologies that have the power to reshape human beings. On one view, the story of eugenics serves principally as a cautionary tale. Education about eugenics tells practitioners of human genetic selection or modification what they should avoid. Another view denies that eugenics is intrinsically immoral. Once purged of its multiple moral and scientific errors, Galton's science of improving human stock can give rise to morally acceptable forms of eugenics.

The entry discusses two contemporary versions of eugenics. *Liberal eugenics* is a version of the view presented as compatible with liberal political philosophy. Eugenic ideas are present also in the radical endorsement of human enhancement called *transhumanism.*

Positive and Negative Eugenics

Galton divided eugenics into two tasks. There was *negative eugenics*. Galton lamented the tendency of the nascent social welfare system of Victorian England to hinder natural selection's elimination of poor-quality hereditary material. The feckless and unintelligent were now fed and clothed and so survived and reproduced. Negative eugenics would restore and amplify natural selection's power to purge poor-quality hereditary material. It would be combined with a program of *positive eugenics* that would encourage the well born to maximize their procreative efforts. Galton claimed to find support for this combination of negative and positive measures in the millennia of improvements of livestock effected by judicious mating.

The concept of eugenics is strongly linked in popular thinking with some of the worst crimes of the Nazis. The T4 program, which involved the murder of thousands of disabled people, was explicitly justified as eugenics. It is possible to view the Holocaust as the most brutal manifestation of Nazi negative eugenics. The Nazi determination to kill both old and young makes sense in light of their ambition to purge hereditary influences. The most widely discussed instantiation of Nazi positive eugenics was the *Lebensborn* program, which encouraged members of the German armed forces to impregnate racially approved female citizens of occupied territories.

A lamentable tunnel vision has tended to confine public awareness of eugenic crimes to their worst perpetrators. Eugenics became, in the early 20th century, a very popular idea. It found advocates and practitioners from across the political spectrum. For example, the socialist playwright George Bernard Shaw (1903/1963) insisted in his play *Man and Superman* that "the only fundamental and possible socialism is the socialisation of the selective breeding of Man; in other words of human evolution . . . We must replace the man by the superman" (pp. 723–724). In a chillingly prescient address given in 1910, Shaw mentioned a "lethal chamber" as an instrument of negative eugenics. Throughout Europe, North America, South America, Asia, and Australia Galton's science of improving human stock gave rise to injustices ranging from social exclusion to involuntary sterilization. The ideological diversity of late-19th-century and early-20th-century eugenics is well documented in the writings of the historian Daniel Kevles and the political scientist Diane Paul.

Advocacy of eugenics declined after World War II. Scholars have identified many mistakes in the eugenics movement initiated by Galton. There were some distinctively moral errors. Eugenicists mistakenly believed in the objective moral superiority of certain kinds of human being as well as of certain ways of life. There is now widespread support among serious thinkers for a moral egalitarianism that denies that some kinds of human being have a moral status superior to other kinds. In addition to this, liberal political philosophers have mounted powerful arguments for a plurality of morally legitimate conceptions of the good life. Liberals view surfers, solicitors, and soldiers as guided by different life

plans, each embodying different ideas about what matters.

Another failing, linked to the above, was the suppression of procreative liberty. As defined by the philosopher of law John Robertson, procreative liberty is the important freedom to decide whether or not to have offspring and to control the use of one's reproductive capacity. Eugenicists aspired to a population-wide coordination of reproduction. They would require those judged to have inferior hereditary material to refrain from reproducing and subject those judged to have superior hereditary material to an obligation to maximize their reproductive outputs.

These moral and political mistakes were compounded by egregious scientific errors. The eugenicists viewed the sorting of people into social classes and racial groups as allocating hereditary material according to quality, hence their plan to improve human stock by managing the reproduction of easily identified groups of human beings. There was an all-too-convenient identification of repositories of bad hereditary material with victims of popular prejudice.

The error of this picture of the human species has become fully apparent in the wake of advances in human genetics. The human genome, a rough draft of which was completed in 2000, shows a shared human genetic heritage. There are no working-class, Aryan, or Jewish genomes. Genetic analysis has revealed many variants of genes that increase or reduce susceptibility to certain diseases. These genetic variants often cluster in family groups. Some diseases are linked with certain ethnic groups—cystic fibrosis is more common in people of European ancestry, and people of African descent have a higher risk of sickle cell anemia. But no class or race bias has been found—or is ever likely to be found—in genetic variants linked with the character traits that particularly interested Galton and his followers.

Modern genetics has replaced early eugenicists' simplistic pictures of the role of hereditary influences in human development. We now recognize the traits of human beings as emerging from complex interactions of hereditary influences with environmental influences. Perhaps there are subtle, difficult-to-identify, genetic influences on fecklessness and criminality. But no genetic variant can cause feckless or criminal behavior unless combined with a fairly specific collection of environmental influences. A widely discussed study of the genetics of criminal offending illustrated the context-dependent nature of genetic influences. One version of the monoamine oxidase A (MAO A) gene seemed to make children particularly susceptible to the effects of maltreatment, raising their likelihood of subsequent criminal offending. Another version of the MAO A gene appeared to have a protective effect. Children with this genetic variant who suffered maltreatment were not more likely to criminally offend.

For the reasons summarized above, Galtonian human selective breeding is not a way to increase the level of human achievement.

Is Eugenics Still Relevant?

What is the practical significance of these many mistakes for the practice of eugenics?

In their discussion of the ethics of human genetic engineering, Allen Buchanan, Dan Brock, Norman Daniels, and Daniel Wikler present eugenics as a "cautionary tale." For them, it serves as a negative exemplar, comprising a collection of moral and scientific errors that liberal advocates of human genetic selection and modification must seek to avoid.

According to another view, eugenics remains a viable enterprise. Galton's presentation of eugenics as a science is instructive. Sciences endure through revolutions in key concepts. Although biology as practiced today is vastly different from Aristotle's biology, contemporary biologists are right to trace their discipline's history back to Aristotle. We've learned that human selective breeding is not only immoral but also ineffective as a means of improving human stock. We can ask whether there are other ways of improving human beings that target hereditary material. Indeed, Galton's definition of eugenics as the science of improving stock "by no means confined to questions of judicious mating" indicates openness to other mechanisms of human improvement. The timing of Galton's writings on eugenics, in the decades after the publication of Darwin's *On the Origin of the Species*, makes it unsurprising that he chose to focus on a possible evolutionary mechanism for human improvement. It's equally unsurprising that the decades since the description of DNA by Francis Crick and James Watson have seen a profusion of proposals to *genetically* modify or enhance humans. Human selective breeding does not work. The new genetics brings the possibility of

improving human beings without making the mistakes of Galton and his immediate followers.

The term *eugenics* is, as we have seen, strongly linked in the popular imagination with Nazi crimes. Is it needlessly provocative to retain the term for a practice for which one seeks endorsement? There are good pragmatic reasons for retaining the term. Suppose that the practices to which "eugenics" refers are not intrinsically immoral. They are, nevertheless, unavoidably dangerous. Consider another practice that we think of as intrinsically moral but unavoidably dangerous. Medical experimentation on human subjects plays an essential part in establishing the efficacy of new therapies. The history of medicine contains many cases in which the rights of human experimental subjects were ignored. Those who serve on research ethics committees are prepared for their roles by learning about these past abuses.

Acknowledging the deliberate infection of human subjects with syphilis as a medical experiment helps research ethics committees remain alert to similar abuses in the research proposals presented to them. The selection or modification of human DNA is, like medical experimentation on human subjects, unavoidably dangerous. Retaining the term *eugenics* for our current practices reminds us of past mistakes. It prevents a forgetting that the introduction of a new term might enable.

Furthermore, there is no readily available alternative term that covers the same ground as eugenics. Many philosophers use the concept of human enhancement to broach issues within the traditional purview of eugenics. But the scope of "human enhancement" differs from that of eugenics. The concept of human enhancement supposes a philosophical distinction between therapy, whose purpose is to restore or preserve levels of functioning considered normal for human beings, and enhancement, which aims to boost levels of functioning beyond human norms. Eugenics requires no philosophical distinction between therapy and enhancement. Galton's plan to improve human stock contained measures that we might think of as therapeutic—he wanted to eliminate congenital illness. But he sought also to promote hereditary factors associated with better-than-normal human functioning. Some philosophers challenge the legitimacy of the distinction between therapy and enhancement. They may find the concept of eugenics to be a more suitable label for their views.

We can identify two contemporary descendants of Galton's science of improving stock. The first, *liberal eugenics*, goes under a name that makes clear its intellectual debt to Galton. The second, *transhumanism*, though a recognizable descendant, has dispensed with the label.

Liberal Eugenics

One continuation of Galton's idea is liberal eugenics. This liberal version of eugenics defines itself in contrast to the authoritarian version envisaged by Galton and his immediate followers. Galton imagined representatives of state being informed about what kinds of human beings were best empowered to manage human reproduction accordingly. Liberal eugenics requires no assertion of the moral superiority of certain types of human being. It explicitly endorses a pluralistic view of the good life. Parents can appeal to their own conceptions of the good life for guidance on what kinds of modifications would be viewed as enhancements. They could view a change that potentially shifted their child closer to their conception of the good life as an enhancement. As we have seen, Galtonian selective breeding intrudes on procreative liberty. Liberal eugenicists would, instead, extend procreative liberty. Liberals leave untouched the established procreative freedoms, adding to these the freedom to choose some characteristics for their children. No one would be required to interfere with natural reproductive processes.

This liberal view presents the freedom to make eugenic choices as analogous to other liberties. There are no absolute liberties. The freedom of speech can be restricted if there is strong evidence of significant harm. But the onus is on those who would restrict speech to present such evidence. Liberal eugenicists would restrict procreative choices likely to result in harm either to the child or to society. But they set a high threshold for proof of harm. The harms that may result from supposedly poor procreative choices must be demonstrable rather than merely theoretical.

The liberal view focuses most directly on the procreative choices of individuals. But its advocates present it as improving human stock. Preimplantation genetic diagnosis is a currently available technology that enables the selection of human embryos to be guided by their genetic makeup. A policy of making

preimplantation genetic diagnosis available to prospective parents is compatible with procreative liberty. It enables parents to make a narrow range of choices about the genetic constitution of their future children. Suppose that the technology is mainly used to avoid passing on genetic variants linked with serious diseases. Individual eugenic choices will then have the effect of improving human stock. We may therefore achieve Galton's desired outcome without selective breeding.

Liberal eugenicists identify precedents for a freedom to use genetic technologies to choose children's characteristics. We permit parents to influence their children's characteristics by choosing environmental influences. It is permissible to provide your child with after-school tuition in mathematics. Liberal eugenicists present genetic choices as morally similar to these, a comparison that draws support from the modern understanding of human development. According to the interactionist view of development, a human being results from the complex interaction of tens of thousands of genes and uncountable environmental influences. We should ask the same kinds of moral questions of genetic enhancers that we currently put to those advocating educational or nutritional strategies of enhancement.

Opposition to Liberal Eugenics

Some thinkers oppose liberal eugenics. The German philosopher Jürgen Habermas finds liberal eugenics to be incompatible with the liberal principles from which it purports to draw support. Habermas argues that a parent who uses genetic technologies to enhance a child wrongly assumes "coauthorship" of the child's life. A parent's enhancing ambitions present to the child in a way that places them beyond challenge. Habermas opposes the comparison of genetic with environmental interventions. He argues that there is typically the option of resisting a parent's selection of environmental influences. A determined refusal to participate in tennis lessons should thwart parental dreams of sporting stardom. Parents may use bullying or bribery to overcome a child's resistance, but these measures do not eliminate the very possibility of opposition. According to Habermas, genetic enhancement works differently. A child has no say on how her early embryo got modified. When she acquires the capacity to make rational choices about her life's direction she is powerless to alter the fact that her embryo was altered. Habermas envisages that the child is forced to speculate about the origin of her desires—whether they are truly her own or are manifestations of her parents' plans for her. This asymmetry between the genetic enhancer and the genetically enhanced that Habermas claims to find undermines the egalitarian aspirations of liberal societies. In effect, today's genetic enhancers assume an illegitimate power over future generations.

A further challenge to liberal eugenics comes from the political philosopher Michael Sandel. Sandel's critique focuses on the liberal comparison of genetic with environmental enhancements. He proposes that the correct comparison is not with normal, healthy parenting but with managed, high-pressure child rearing, properly labeled "hyperparenting." Hyperparents pay little or no heed to the nascent interests of their children. They obsessively manage children's environments to turn them into academic or sporting stars. According to Sandel, hyperparenting exemplifies an unhealthy attitude to children, and so does genetic enhancement. Healthy parenting involves accepting that there is much about our children that is not up to us. This includes the formation of our children's genomes. Hyperparents view their offspring as objects of transformation. Genetic enhancement both facilitates and exaggerates this tendency.

These challenges have elicited responses. Habermas may overlook opportunities to resist the plans of parents who seek to genetically enhance their children. While you cannot make it the case that your embryonic DNA had never been altered, you can prevent the alterations from having the effects your enhancer was hoping for. According to the interactionist view of development, significant traits emerge not from the action of genes alone but from the interaction of genes with the environment. A child can successfully resist her parent's plans by refusing to place the modified gene or genes in the environment that they require to produce their intended effects. Suppose that you learn that your genome was altered with the aim of turning you into a champion rugby player. Such a plan requires a high degree of cooperation from you. If you refuse to ever set foot onto a rugby field, you are unlikely to excel at the sport. One response to Sandel accuses him of overstating the power of genetic enhancers. A realistic depiction of genetic enhancement supposes

control only of a small subset of the total collection of genetic influences. Parents who introduce into their child's genome a genetic variant linked with sporting success can claim to accept much about their children. Perhaps they will compensate for their limited intervention in their child's genetic makeup by adopting a less intrusive approach to her upbringing.

Transhumanism as a Form of Eugenics

Transhumanism is a movement whose goal is to eliminate aging and to greatly enhance human intellectual, physical, and psychological capacities. Transhumanists are vigorous advocates of human enhancement. Their vision of our future combines millennial life spans with dramatic multiplications of our cognitive powers. Transhumanists reject the suggestion that concern about the remaining humans might place limits on enhancement.

Is this eugenics? The term *transhumanism* was coined by the British biologist Julian Huxley in an article published in 1957 that urged that human existence undergo transcendence, shifting from "a wretched makeshift, rooted in ignorance," toward "a state of existence based on the illumination of knowledge and comprehension" (p. 16). In the years before World War II, Huxley had been a strong advocate of Galtonian selective breeding. After the war, his enthusiasm for the concept of eugenics waned. Modern transhumanists replace Galton's commitment to selective breeding with an interest in a variety of transformative technologies or therapies. Many of the technologies that interest them bypass human hereditary material altogether. For example, the futurist Ray Kurzweil advocates enhancement by grafting a variety of cybernetic implants to our bodies and brains. Transhumanists advocate no restrictions of procreative liberty. They believe extended life spans and enhanced cognitive powers to be so attractive that no violations of liberty will be required. Transhumanists do not view the members of certain social classes or races as superior to others. Indeed, they tend more toward a somewhat dismissive view of distinctively human characteristics. For transhumanists, our humanity is raw material fit for refashioning into radically improved forms.

The transhumanists want changes that are much more dramatic than those that could be achieved either by selective breeding or by the cautious modification of human DNA envisaged by liberal eugenicists. Some transhumanists envisage us changing to such an extent that we will no longer be human. We will be *posthuman*. This call for individuals to enhance to the point at which they are, or may be, no longer human has forced their opponents to clarify exactly what of value might be at stake in the loss of our humanity. There's an irony in eugenics, a movement whose original purpose was to improve human stock, giving rise to transhumanism, a movement that may lead to the abandonment of our humanity.

Events

This entry introduces the philosophical discussion on events in metaphysics, and goes on to point out the status of events and the role they can play in social ontology and social explanation. The importance of events in the philosophy of the social sciences lies, primarily, in that once their status is assured and their elements shown to be irreducibly social items (collective entities, social properties, etc.), this can be seen to bear directly on the holism–individualism debate in the philosophy of the social sciences.

Introduction

Events, as a special ontological category, have been the subject of systematic philosophical discussion only relatively recently, while they have been rather ignored, as such, by the philosophy of the social sciences. Yet we naturally talk, assess, or debate about social, political, and historical events in our everyday talk; social-scientific discourse, too, refers to, analyzes, and tries to provide explanations for social events, or classifies them into kinds and appraises their importance, especially in studying history, politics, or international relations. Virtually all social-scientific subdisciplines employ terminology that refers to events in one way or another, yet hardly any sustained theory about them has been offered in the philosophy of the social sciences. Unlike the latter, by contrast, even if only recently, philosophy has turned its attention to events as denizens of ontological domains, that is, as a genuine topic in metaphysics.

The discussion that follows covers, first, some of the most important issues focused on by this recent philosophical concern with events in metaphysics and then moves to the special case of social events and suggests a place for them in the philosophy of the social sciences. An obvious point where the metaphysics of events meets the social world is human action; philosophical theories of action and agent-causation have already been developed, but for the most part, this analysis has proceeded independently of the philosophy of the social sciences as such. These issues are treated separately in this encyclopedia primarily in the entries on the philosophy of action, agency, collective agency, and on causes versus reasons in the explanation of actions.

Events as an Ontological Category

The debate about events as an ontological category is spurred by the need for a special category that would help solve problems in a variety of philosophical areas: time and change; causation (What are the relata of a causal relation—events, facts, things, or something else?); action theory (Are actions a species of events? What is the relationship between actions and bodily movements? Can there be agent-causation as distinct from standard event-causation?); the mind–body problem (What is the relationship between mental events and physical events in the brain?); the structure of explanation; the logical form of action sentences involving adverbial modification; truth-making theory; and so on. In addition, science, and in particular physics (especially quantum mechanics) and biology, imposes certain requirements on what can count as an event, and therefore, scientific facts have to be taken into account rather than being disallowed by metaphysical theories or armchair theorizing. Thus, science may be allowed to have a legitimate influence on the philosophical analysis of events. The same holds for the social sciences. To the extent that they supply us with a number of (kinds of) events or a typology of social and historical events, the social sciences cannot be disregarded if a special ontology of social events is to be forthcoming.

The usual strategy in philosophical discussions about events has been first to take a position in favor of or against countenancing talk of events and then, if they are accepted, to give a theory or account of what sort they are.

Events, Facts, and States of Affairs

A natural starting point for deciding whether events constitute a separate ontological category is the

debate on whether events should be distinguished from kindred categories such as "facts" and "states of affairs" ("states" and "processes," though certainly not to be collapsed into the others, can for the present purposes be treated as similar sorts or as ongoing events or unchanging processes, in which case the notions of "event" and "change" are not necessarily or not always linked with each other, as our intuition would lead us to believe).

Earthquakes, elections, engagements, emissions, eruptions, and escapades are normally considered events in everyday talk. The first point that comes to mind, pre-analytically, is that events are happenings or occurrences and, hence, are things that can be said to "happen," "take place," or "occur" (and for some, though disputed, things that may "recur"), not something that "exists." For this reason, it is widely concurred that it is best to say that events *are* (rather than exist), if one decided to admit them as a separate ontological category. The second point that comes to mind is noticing how language effortlessly allows plural expressions of events—e.g., an earthquake as well as earthquakes, an evacuation as well as several evacuations—hence for those in favor of events as a bona fide category, such an ability to quantify shows that events are particulars (of a sort to be explained shortly) and therefore metaphysical items separate from facts or states of affairs, about which it is obviously quite unnatural to talk in plural constructions. "The earthquake that shook Shaanxi in 1506 was the deadliest ever" and "Yesterday's national elections in Erewhon had a record high in turnout" are different linguistic constructions compared to those employed to talk about facts, such as "the fact that the earthquake that shook Shaanxi in 1506 was the deadliest of all" or the embedded that-clause in the following sentence: "that yesterday's national elections in Erewhon had a huge turnout was a welcome development in that country's recent political life." Similarly, the linguistic differences between the phrases "Vesuvius's eruption" and "Vesuvius's erupting" are considered indications signaling a significant ontological difference between what is named by them: What is named in the former is a particular thing of a certain sort, an event, while in the latter something else.

While events are said to "happen" or "occur," states of affairs are said to "obtain" or "not obtain" and if the former, they are considered facts or "what is the case." In the sentence "The exposed radioactive materials were responsible for *Beta-particle emission* within the spacecraft," the italicized noun phrase names what happened—an event—while in "The postmortem scientific investigation showed that *the fact that beta-particles were emitted* was caused by exposed radioactive materials in the spacecraft," the italicized phrase refers to *that such and such was the case,* that is, to a state of affairs that obtained. Since the latter is something that is true or that is the case, it has been natural to think that states of affairs (and indeed those that obtain and are thus facts) must be expressed by true sentences or that they are identical to true propositions. Indeed, some philosophers have considered facts (or states of affairs that obtain) to be isomorphic to propositions or as what make propositions true (cf. the recent topic of truthmakers).

So it is not surprising that in recent discussions in analytic philosophy, a semantic analysis of event talk has been seen as a suitable way to make successful inroads into the metaphysics of events and as a useful way to distinguish between events and facts or states of affairs. In the examples above, we can discern what is called nominalization, that is, the construction of noun-phrases such as "yesterday's elections" or "Vesuvius's erupting"; the former have been called *perfect nominals* while the latter (containing gerunds) *imperfect nominals*. The linguistic differences between the two have been seen as reflecting a distinction between event-language versus fact-language; on this approach, syntactic and semantic differences indicate corresponding differences in the metaphysics of events and states of affairs/facts, respectively: only perfect nominals can replace a name or description of the subject of an event by a definite or indefinite article ("Vesuvius's destruction of Herculaneum" can be rephrased as "The destruction of Herculaneum" whereas "Vesuvius's destroying of Herculaneum" cannot; "radioactive materials' emission of β-particles" can be transformed into "the emission of β-particles" but not the noun-phrase "radioactive materials' emitting of β-particles"); only perfect nominals permit plural forms, as we have seen already, adjectives can be used attributively for perfect nominals whereas imperfect nominals are modified by adverbs (add, e.g., the words *slow* and *slowly* in our pairs just mentioned); and so on. Thus, perfect nominals name events while imperfect nominals name facts.

Syntax or the semantics of naming is not of course a convincing approach for those who dispute the

existence of events. One thing the aforementioned linguistic route to events shows is that, unlike facts or states of affairs that can be said (on some views) to be universals—existing necessarily, never existing necessarily (as with contradictions), or always existing but not necessarily (i.e., contingently), though they may obtain or fail to obtain—events are locatable and datable particulars: Events occur at specified places and times and, hence, are unrepeatable occurrences. Whether events are abstract or, in contrast, concrete particulars on a par with enduring objects, or so-called continuants, is another, disputed issue (leading to the debate whether more than one event can collocate at the same time, something important for action theory and social ontology—see below). At least the consensus would have it that, as long as events are not to be conflated with concrete particulars, like chairs and ballot slips, events are not like facts or states of affairs when it comes to their location in space and time: facts can be seen to be atemporal and nonspatial. But even though events are within space-time, as it were, they are not so in the same way that ordinary material objects are. The latter endure through time, occupying (perhaps different) places at different times while remaining present in all of them (they continue to exist, hence the term *continuant*), whereas events are "spread out" in time, that is, they have different temporal parts without wholly occurring in each of these time-slices. So, on the standard view (by all means not endorsed by everyone) events are said to "perdure" unlike material objects, which "endure" through time. However, if we take events to be changes in their subjects, we cannot also say that events move, as ordinary material objects do.

Events as Particulars

Two principal ways of construing events as nonrepeatable particulars have been offered: either as *structured* or as *unstructured* entities. These two views correspond to two of the most influential theories of events, Jaegwon Kim's and Donald Davidson's, respectively.

According to Kim's *property-exemplification* conception of events, an event is the having of a property by a specified object or objects at a specified time: A certain event, *e*, happens or takes place just in case a specified thing (the subject of the event, *s*) exemplifies or has some property (the constituent property of the event, *p*) at a certain point in time (the time of the event, *t*). Hence, an event, *e*, is a structured entity represented by the ordered triple $\langle s, p, t \rangle$: The earthquake that shook Shaanxi in 1506 constitutes an event since a certain particular, Shanxi province, exemplified a property, being shaken by an earthquake, on a certain day of that year. This view sees events as basically timed changes in a certain subject: John's having voted yesterday counts as a certain change in John, the subject, i.e., his exemplifying a certain property, voting. Similarly in the case of relations, e.g., "The Labour MP was reelected by the voters of the Brompton constituency last Thursday," we have two subject-items and the relation holding between them.

When it comes to providing identity conditions for events, it follows that on this theory, two events, e_1 and e_2 are identical just in case they share the ordered triple:

$$\langle s_1, p_1, t_1 \rangle = \langle s_2, p_2, t_2 \rangle \textit{ iff } s_1 = s_2, p_1 = p_2 \text{ and } t_1 = t_2.$$

For example, the Visigoths' sack of Rome in 410 CE is the same event as Alaric's army raiding Rome in 410 CE, to the extent that the constituent subjects, properties and times respectively, are identical. When properties diverge or when a property term is replaced by a different one (sacking, conquering, or liberating, for example), or when we have collective entities such as corporations or armies rather than single subjects such as a CEO or a general in the constituent subject position, then on this view of events, identity is affected—something evidently quite important for the social sciences.

On Davidson's theory, events are unstructured particulars any one of which can be described in a variety of ways, retaining its identity as a single event, even though different subjects and different properties are being mentioned in each such distinct description. Davidson's theory has been influential primarily because of its rationale, that is, what it was proposed for. Davidson wished to solve two problems by postulating events as quantifiable particulars: one, to find out what the relata of causal relations are, especially in action theory, and, second, to solve the problem of adverbial modification without going outside first-order predicate logic. "Sidney announced his resignation by reading it,

slowly yet irately, at the Quaker's annual meeting in London last Tuesday" names an event-action that is characterized or modified by a number of adverbs, of manner, place and time. If we start dropping all these adverbs one by one, does that sentence entail the ones we produce in that way, i.e., sentences like "Sidney announced his resignation by reading it slowly" or "Sidney announced his resignation by reading it in London" and so on? To do so, we must provide an account of the logical form of such action sentences as our original one, and this requires us to see them as covert existentially quantified sentences asserting the existence of an event, Sidney's announcement of his resignation, the adverbs being the adjectives of that event (that it was slow, that it involved reading a text, in a certain room, etc.). In this way, canonical notation already employed in first-order predicate logic is retained, together with the advantages of entailment preserving truth:

$$\exists e\,[(\text{Resignation announced (Sidney, } e)) \wedge (\text{Reading } (e)) \wedge (\text{Slow } (e)) \wedge (\text{Irated } (e)) \wedge \text{At } (\text{Quaker's annual meeting } (e)) \wedge \text{In}(\text{London } (e)) \wedge \text{On}(\text{last Tuesday } (e))]$$

This is our original full sentence put in logical form as a conjunction, and can be seen to entail any one of the other ones in which some or all of the adverbial modifiers are missing, since the truth of a conjunct is entailed by the truth of the conjunction containing it. So if the original full sentence is true, so is any one of its conjuncts, such as, e.g., "Sidney announced his resignation" where no other item of information is retained. Then to this sentence a number of adjectives (ex-adverbs) can feature as modifiers of the event named by it. Obviously such a proposal is significant when we come to construct explanations of social events where such information plays an important role in understanding what happened and therefore cannot be eliminated. But we should be careful here not to conflate two distinct issues; it is one thing to say that in such cases, the entailment holds, producing true sentences, and quite another to claim that we can fruitfully employ it in explaining. *Entailed* by is not (or not always) the same as *explained* by. The proposal we are discussing has to do with ontology (and truth-preserving), not social explanation, where our purposes diverge. However, it may be claimed that the proposal that uncovers a tacit quantification over entities such as events may provide fruitful notions for social ontology. One of the significant things about Davidson's proposal was that it turned the tables on the ontological priority of ordinary things, making events more significant.

Critical Issues

What are the relative merits of these two proposals —events as structured particulars versus events as unstructured ones? Problems turn first on the identity conditions for events (how to individuate events) proposed by each. Naturally, this is crucial, as we have already glimpsed, especially for the philosophy of action and the philosophy of the social sciences. For it matters greatly whether an action carried out by means of a certain bodily movement counts as one and the same event when it is described in different ways, as a socially defined or socially meaningful action in a social context or as a bodily movement; for example, is an action described as paying bus fare at the student rate the same event as someone's hand dropping coins into the fare box, or round metal things into a box? Furthermore, even if we disregard the level of bodily movement or the physical description of social objects like coins (invested with social meaning), and remain at the social level only, we can still ask whether events are the same when they are variously described, as we have seen above with the example of the sacking of Rome. When we describe an event with reference to different social entities or social properties than those figuring in the original description of that event, does this dramatically alter it so that the descriptions are no longer of the same event? Here the issue of extensionality allowing substitution of synonyms salva veritate is quite important. It also ties up with Russell's Theory of Definite Descriptions.

Furthermore, with respect to intentional action, Elizabeth Anscombe has famously suggested that when one acts with intention to do something, the action is intentional *under a description* that refers to the actor's reasons or intention; however, the same action can be seen as a physical event *under a different description*. In the latter case, it would be useless in any social explanation, yet with respect to the ontology of events (action-events here) we are concerned with, it matters equally greatly whether, explaining apart, they are one and the same event

from an ontological point of view (and it also matters equally insofar as moral responsibility is involved). Wittgenstein's followers, like Peter Winch, have made similar claims regarding the understanding of meaningful behavior within rule-following contexts (signing one's name on a piece of napkin, on a bank check or on a international peace treaty official document may require the same kind of bodily movement in all cases, though the actions [and hence the events] are distinct given the correspondingly distinct "rules of the game" within which each action is embedded so as to count as, e.g., signing a check and not as some idle pastime in calligraphy). Also, the issue of event-collocation arises here, for we have to decide whether more than one event is present when, for example, somebody makes a money transfer thereby also performing a bankruptcy.

The primary criticism of Kim's theory has been that it leads to excessive and unpalatable fine-grained distinctions. Once a slight change is registered in how any of its structural constituents is specified, we get a different event, thus multiplying events needlessly: John's pushing the ballot slip down the slot inside the voting booth is rendered quite a distinct event from John's exercising his voting rights at that time and place, once the constituent property is altered. Obviously, this is an important consequence, especially for social explanation. And it is more pronounced once we acknowledge that, as in the examples above, on a property-exemplification theory such as this, a different property makes a huge difference and equally so in the case where the subject of the events is a collective agent, such as a government, or a social-role occupier, such as a justice of the peace, or where the event-action is a joint or team action (given a team's changing membership while retaining its identity over time, a recurring action by such a team counts as the same kind only if we disregard individual membership). One way, pertinent to social explanation, to deal with these cases is to say that the different properties are instances or species of a generic property, but this leaves us with the next problem one level up, providing identity conditions for such property-hierarchies, genus and species, in a non-circular fashion. Other criticisms of Kim's view center around metaphysical issues (whether properties can be static, etc.). One way Kim defends the criticism is by drawing our attention to the distinction between a property being the constituent property of an event (one of its inner structural elements) had by the subject of the event and being a property of the whole event as such: predicate modifiers such as in our example above, by reading, slowly, irately, must be seen not as modifiers of the constituent property, resignation-announcing, exemplified by Sidney, but as characterizing the event as such, i.e., as slow, etc., hence blocking the unnecessary proliferation of events. This of course does not work with other adverbs that are not modifiers of manner or means, but adverbs in attributive positions denoting predicates stemming from legal or social norms and regulations, as for instance in "He passed a resolution illegally or against the organization's regulations" from which it follows that he did not in fact succeed at all in passing such a resolution in the end, and therefore there is no event that counts as "passing a resolution" to which the adjective *illegal* applies, for there is no such event at all. Another way of bypassing the criticism of unnecessary proliferation of events is by acknowledging a special kind of event as a "generic event" in each case (e.g., kissings, marriages, international treaties) and treating all the rest bearing adverbial modifications as subspecies.

Finally, another criticism against property-exemplification theories is that we may countenance (and some have) events that are subjectless, that is, events without any participants: Various examples of physical phenomena have been offered (and responses, too). But for our purposes, it may be interesting to note that this possibility of subjectless events, or of events lacking clearly identifiable participants may be of value to the philosophy of the social sciences. Such a possibility may indeed corroborate collective phenomena like group decisions or judgment aggregation processes, whereby no identifiable, enduring entity can be picked out as playing the role of the subject exemplifying a property (that of decision making). In addition, allowing subjectless events may corroborate structure theories as against agency theories in sociology, as discussed below.

In Davidson's case, besides criticisms regarding his specific proposal regarding the preferred logical form for taking care of adverbial modifications, which we have seen above, the most potent criticism centers around the other reason for his proposed analysis: the identity conditions of events. Two events are numerically identical, on his view, just in case they have the exact same causes and the same effects. But it is blatantly obvious that this is a

criterion inviting circularity, for unless we have such a criterion to determine sameness of events, we cannot call upon the sameness of causes and/or effects, themselves being events. Another worry is that there may well be events that lack either causes and/or effects, in which case the criterion breaks down.

In addition to criticisms centered on the proposed identity conditions in each approach, there are other concerns voiced. In Kim's case, an event being an exemplification of a property by a subject at a time involves a relation of instantiation of that property by the subject-item that has it; but this brings in the ancient-old problem of infinite regress in trying to ground a "link" such as instantiation or exemplification between an item *a* and the property *G* on yet another "linking relation," thereby bringing in continuously ever more such "links" ad infinitum.

Social Events?

Event-like items have been acknowledged in social theory since Durkheim's category of "social facts." Also, the philosophy of history has shown particular sensitivity to such entities (see, e.g., the foremost issue: Are historical events unique?). An earlier first attempt to provide a philosophical analysis of events suitable for social ontology has been offered by Kaldis (1993, Pt. III).

However, recent developments in social ontology involving theories of collective intentionality, joint action, or plural subjecthood, as well as the metaphysics of events adumbrated above, call for a renewed interest in events as a separate category over and above individual agents, collective entities, or social persons. Event ontologies where events are seen as the primary or most basic or irreducible ontological category vis-à-vis ordinary persisting things, like material objects, have been the focus of certain positions in metaphysics as well as of studies relating them to modern physics (like quantum mechanics and field theories), whereas there seems to be no comparable interest in the social sciences. Even reductionist approaches and those employing the concept of supervenience, which see events as ontologically derivative and ordinary things such as substances as primary, still allow talk of events (unless we opt for outright eliminativism), whereas yet other views allow for pluralism of ontological categories. A similar strategy may be followed in social ontology. Equally, while motion in physical space as a kind of change has been the focus of attention in discussions of events, no comparable interest has been shown in the social case, where events can be seen to be, ontologically, changes of sorts, irreducible to their individual participants. Furthermore, if change is, at least according to some views, what events should be characterized as (principally, as a change in the properties or relations of the subjects of events), then what counts as a bona fide "relational change" is a topic of particular importance to the study of social events that involve primarily such purely relational changes whereby no intrinsic change in the subjects themselves is involved.

Another issue that can throw light on social ontology and social explanation has to do with fact-causation versus event-causation. Those who reject the former by reducing it to absurdity (by so-called slingshot arguments) start by claiming that any causal relation worthy of its name must be (unlike causal explanation) purely extensional, whereby such a relation holds between entities irrespective of how they can be conceived or described by us. The distinction between explanatory relations holding in intensional contexts while causal relations remaining extensional has been usually evoked as a crucial difference, yet as mentioned above, it is a usual mistake in the philosophy of the social sciences to conflate the two or slide from the intensionality of the former to that of the latter.

In addition to the issue of intentional action under a description, which is central to social explanation and social ontology, the debate about the nature of events concerns the social sciences in many other ways as well. First, there are the two clashing answers to the issue of whether actions are events—one denying that an agent's causing of an event is itself an event, that is, an event locatable in space and time on pain of absurdity, and by contrast, the opposite view construing actions as events identifiable (on some readings) with bodily movements. The former view may be seen as placing too much emphasis on agency, construing actions as performances but events as happenings. The latter view remains devoted to what the action as such involves and not how it may be described or not as being a cause of whatever other event it brings about and that is thereby classified by its effect, as, e.g., a bank transaction. Given certain demands of explanatory contexts, the second view may go on to add the effects of

such an action-event and hence choose how to describe it. It seems that this distinction in philosophy corresponds, *ceteris paribus,* to something analogous in social science, the agency/structure dichotomy: If it matters how we describe a social event and also that it is primarily something that an agent performs, then the philosophical position that denies that actions are events is akin to agency theory in sociology, while if an action's consequences are ignored and all that matters is the event that an action is, then it is akin to structure theory in sociology.

Finally, a number of issues in metaphysics having to do with whether there can be instantaneous events, non-events (negative events: John did not kill the president), unique events, simple and complex events or modes of compositionality for events having other events as proper parts, can also be seen as important issues that are also applicable to social and historical events and as featuring both in social ontology and in social explanation.

Conclusion

Many worry whether a systematic theory of events proper can ever be constructed, arguing instead that events can be accepted as items in our ontological pictures of the world, without thereby providing any real theories for them independent of what they can be used for or in relation to other, more basic items included in those pictures. In addition many have felt more comfortable with a pluralist view of quite different event-kinds, according to which we do not need to stipulate universal ontological principles of eventhood, as it were, across the board, that is, provide a definition of *event* as such.

Evidence-Based Policy

This entry introduces the idea of rigorous scientific evidence needed for devising and evaluating public policies, explains the main techniques, and reviews a number of problems that need to be overcome. Rigorous social-scientific methods, as well as philosophical issues on causation, probability, and the like, thus enter (and should concretely be taken into account in) the area of policy making. The entry also explains the relation of evidence-based policy with what has been called the "audit society."

Predictions about the *success of policy interventions* should not be dictated by fashion, ideology, political pressure, lobbying, or habit. They should be based on *rigorous scientific evidence,* if possible on results from randomized controlled trials (RCTs), and certainly not on anecdote, casual observation, theory without experiment, or expert opinion. That's what counts as *evidence-based policy* (EBP), which is now widely mandated at local, regional, national, and international levels.

The central drivers for EBP have been the United Kingdom (UK) and the United States, though it is spreading in Europe and to international organizations like the World Bank. The Blair government committed the UK to EBP in its Modernising Government White Paper of 1999. In the United States, it became entrenched through the 1996 Congressional demand for "comprehensive evaluation of effectiveness" of federally funded state and local anticrime programs and then by the No Child Left Behind Act of 2001, which allowed federal funds only for educational activities backed by "scientifically based research."

The movement borrowed heavily from the *evidence-based medicine movement* of a few years earlier, both in rhetoric and in methodology, especially in the emphasis on RCTs. In 1993, the international nonprofit Cochrane Collaboration was founded to provide systematic reviews of the best available research evidence on health care interventions; in 1999, the Campbell Collaboration was founded to do the same for education, crime and justice, and social welfare.

EBP aims to find "What Works," as in the titles of the U.S. Department of Education's What Works Clearing House and the National Institute of Justice's report to Congress, *Preventing Crime: What Works, What Doesn't, What's Promising.* There are by now large numbers of guidelines available detailing what counts as rigorous evidence and agencies, like the Campbell Collaboration, using these guidelines to determine which policies are supported by rigorous evidence.

The call for EBP marched hand in hand with the rise of the so-called audit society, with its demand for accountability and control. Interventions are to be restricted to those backed by rigorous evidence, and rigorous methods of monitoring are to be employed to ensure that policies work once in place. Audits, though, require precise, measurable outcomes. So, too, do rigorous scientific studies. But policy goals seldom have the kind of precision required. We want school leavers to be competent enough at mathematics to function normally in life and in the kinds of jobs available. What kinds of tests show that they are? Whatever the tests, they are just symptoms or correlates of what we really want. Figuring out the most reliable correlates is a complex scientific task. Moreover, adopting a measure can have its own effects; for example, schools "teach to the test," which can bring about better test results without achieving the goal desired. One challenge still facing EBP is to develop guidance for policymakers on how to go about formulating their goals.

So far, work has focused on a later stage in the process: on predicting whether a policy will achieve an already operationalized goal. Much effort has gone into devising ranking schemes for study designs. The designs ranked are based on John Stuart Mill's "method of difference" for establishing causal conclusions, which in the ideal situation consider two groups identical with respect to everything that affects the outcome other than the policy under test. A difference in probability of outcome between the groups shows that the policy caused the outcome in some individuals in the study. Observational studies, where groups are matched on known causal factors, are low in the rankings. RCTs come out on top. That's because masking and randomizing are

supposed to make it likely that causes not known about are equally distributed in the two groups. There are, however, many other methods available in the social and biomedical sciences that can reliably establish causal conclusions (including causal Bayes nets, process tracing, derivation from sound theory, and restricted kinds of econometric modeling). So another task facing EBP is to learn how to evaluate when these other methods produce high-quality evidence and how to integrate evidence from them into synthetic reviews.

The highly regarded ranking scheme called GRADE defines quality of evidence in two contexts: The first is for *systematic reviews*, which are supposed to synthesize the best available evidence. There, quality reflects whether study designs make it likely that the study conclusions are reliable. High-quality studies provide high confidence in policy "efficacy": that the policy worked in the study population. GRADE's second context is that of *recommendation*. Policies can be accepted or rejected—and legitimately so—for many reasons, independently of how likely they are to work in the targeted setting—such as cost, the chance of beneficial or harmful side effects, political or moral acceptability, fairness, or the need to do something.

None of the study designs mentioned provides the kinds of evidence that might be relevant to these other considerations. Also, these study designs provide only very partial evidence for "effectiveness": that the policy will work here, in this new setting. Generally, policies work for a reason, and sometimes the reasons that make a policy effective in one place may not do so in another.

These reasons can usefully be classed into two categories:

1. *Support factors:* Policy programs, no matter how carefully devised, seldom contain all that is required for them to work in this or that concrete setting. Consider Street's (UK) microfinance program, founded on the example of Poland's Fundusz Mikro and other international microfinance schemes. This program did not work for the sample group in the UK, in part, it seems, because even poor people in the UK can get loans through credit cards. Inability to get credit elsewhere is a necessary support factor that was not given sufficient attention before the UK program was set up.
2. *Causal roles:* Independently of the presence or absence of support factors, a cause that can produce an effect in one place may not play the same role in another. Educating mothers about nutrition improved infant health in Tamil Nadu but not in Bangladesh, because in Bangladesh far more often the mother-in-law, not the mother, decides who eats what, and men do the shopping.

So policies need the right support factors to be in place in the setting where they will be implemented. The beauty of RCTs is that they are supposed to distribute these factors evenly between two study groups even if they are unknown. But knowing what they are and ensuring that they are in place in the target setting can make all the difference to success there. So, too, can understanding what it is about institutional structures, habits, norms, and behaviors that allows factors to play the causal roles they do. EBP is thus increasingly focused on categorizing this kind of additional information, investigating how it can be unearthed, and evaluating what kinds of evidence are relevant to assessing it.

Finally, the major challenge facing EBP is how to switch from the usual question "How can we get policymakers to use rigorous research more?" to "What decisions do various policymakers make, how can we help them make better decisions, and how can research evidence help?"

Evolutionary Ethics

In the most general terms, evolutionary ethics is the study of the relationship between evolution by natural selection and moral discourse and practice. That relationship is multifaceted. Contemporary evolutionary ethics covers a range of different research programs, from traditional moral philosophy to behavioral economics to neuroscience. In its earliest stages, not long after the theory of evolution by natural selection took hold, evolutionary ethics was principally a normative investigation—that is, an investigation into what the story of human evolution reveals about how we ought to live our lives. Current research is largely non-normative. On the one hand, cognitive scientists (from fields such as psychology, sociology, anthropology, and behavioral economics) are exploring the influences of natural selection on our (so-called) moral minds. Did we, they ask, evolve to think and behave morally? On the other hand, moral philosophers are exploring the relationship between natural selection and the nature of moral properties themselves. According to one increasingly popular metaethical view, natural selection favored creatures that *believed* that some acts are, for example, objectively prohibited, but apart from that influence, there are no independent grounds for believing that any acts *really are* objectively prohibited.

This entry explores both the empirical and the philosophical approaches to evolutionary ethics, beginning with the former.

Empirical Approaches

Contemporary empirical research into the evolutionary roots of our moral minds was energized by an approach to the mind inaugurated in earnest in the 1970s: evolutionary psychology (EP). The underlying premise of EP is that, like other observable phenotypic traits (e.g., the structure of the heart or skin pigmentation), some/many/all of our current mental traits were biological solutions to adaptive problems routinely confronted by our hominid ancestors. The mental traits of most interest to EP, of course, are those that issue in behavior. So, to take some of the more notorious traits, it has been maintained that the reason why males typically prefer nubile females while females prefer males of means and status is that these preferences tended, over time, to increase individual reproductive fitness.

From this vantage, it was reasonable to speculate that there must be evolutionary reasons why humans tend to deploy moral concepts. One reason that has figured in several contemporary accounts is that thinking morally was an effective means of ensuring social cohesion. Anthropologists maintain that individual survival depended critically on social cohesion. Beginning with one's immediate family, the spheres of interdependence spread outward to relatives, neighbors, and other members of the group. Cooperating with these individuals was essential for things such as child rearing, protection, food gathering, hunting, and so on. But while cooperation is a more prudential strategy than "going it alone," unswerving cooperation has its limitations. Occasions will inevitably arise in which one can gain more by exploiting the cooperation of others than by doing one's fair share (as powerfully demonstrated by Prisoner's Dilemma—style games). This strategy of occasional exploitation, however, is unstable under the assumption that most individuals interact regularly over time. For it is thought that regular interactions would inevitably expose cheaters. And over the long run, cheaters who were exposed suffered more than cooperators, who always refrained from exploiting others. It is here that some believe moral thinking earned its spot. An individual who believed that cheating others was prohibited—was *immoral*—and who felt the corresponding motivation to abide by that belief enjoyed the long-term benefits of appearing trustworthy. In rough outline, this is the evolutionary account.

Support for the evolutionary account is plainly intuitive. But some maintain that there is a growing body of empirical support as well. If our moral minds did have an evolutionary basis, then it should be part of our genetic inheritance. And if it is part of our genetic inheritance, then we should see it develop (ontogenetically) relatively early on and across many different environments. Some developmental psychologists cite evidence that children as young as 4 and 5 years of age demonstrate a moral competence that could not have been mastered simply by observing one's environment. For example, young children distinguish between moral rules (e.g., "Don't hit") and conventional rules (e.g., "Don't throw food") despite any apparent training. Around the age of 5, children suddenly begin to measure moral worth in terms of intentions as opposed to merely consequences, a reversal that does not appear grounded in environmental cues. Such poverty-of-stimulus arguments drive some to insist that such competencies must be innate. Additionally, some anthropologists insist that all extant cultures exhibit adherence to some moral code or other, and such cultural convergence is indirect evidence of a shared genetic program.

Skeptics, on the other hand, argue that the evolutionary account is not supported by conclusive evidence. For example, some insist that successfully accounting for children's moral competence does not require positing an innate moral faculty. It may be that children merely possess a disposition to acquire social norms from their environment, perhaps ones that are backed by strong emotions. And the evidence from cultural anthropology, according to some, suggests substantial cultural *disparity* in moral outlook —not what the evolutionary account predicts. Finally, any hypothesis about innate mental faculties will eventually need to link genes, brain, and behavior, for the evolutionary account ultimately comes down to the transmission of genes whose operation reliably produced adaptive behavior. But establishing those links has been difficult in the extreme, largely because genes appear to stand in a many-to-many relationship with phenotypic traits. Moreover, as all sides agree, there is no localizable brain system devoted to morality, so the task requires identifying a set of genes responsible for a set of brain systems, none of which exclusively underwrite morality.

We are, at any rate, in the early stages of this research. No one accepts the idea that moral development in individual humans is as biologically routine as, say, the development of sex organs. By the same token, no one accepts the idea that moral development does not require the deployment of multiple innate brain systems (no one, after all, learns to grow an amygdala).

Philosophical Approaches

The second broad area of inquiry concerns more traditional moral philosophical questions. In general, the aim is to understand the relationship, if any, between the principles constitutive of natural selection and the way we *ought* to live our lives. Perhaps the most tempting suggestion—and one that persists in some quarters—is that "survival of the fittest" is a moral imperative: Each individual should be responsible for each individual. We might be compelled to preserve cooperative arrangements, but only because these are good for each. We have no moral responsibility to sacrifice our own well-being for the sake of others, for intervening on behalf of the needy is interfering with what Herbert Spencer called a "large, far-seeing benevolence." According to Spencer, Darwinian evolution—if allowed to proceed unchecked —invariably leads to social harmony. Nature, it was thought, is self-correcting. (To the extent that advocates of laissez-faire capitalism sought moral justification for their view, it is hard to imagine a better fit.) This view came to be known as Social Darwinism.

Despite its early promise, however, Social Darwinism confronts sizable obstacles. The first is biological. Evolution by natural selection does not favor—in the short or long run—social harmony. Allowing evolution to "proceed unchecked" no more guarantees a species of socially harmonious creatures than it guarantees a species of disharmonious leaf eaters. The products of evolution are deeply contingent.

The second obstacle faced by Social Darwinism is conceptual and has, historically, assumed two forms. There is, first, what is sometimes called Hume's Law of "fact/value distinction," after the Scottish philosopher David Hume. Hume's Law prohibits deducing normative conclusions from exclusively non-normative premises or deducing an "ought" from an "is." In other words, claims about how things *ought* to be are never logically entailed by claims (all of which are) about how things *are*. Therefore, a complete specification of our species' evolutionary history (a fact) does not logically necessitate that we ought to do or to value one thing rather than another (an

ought). Second, the early-20th-century British philosopher G. E. Moore offered a distinct but related criticism in line with the fact/value distinction. According to Moore, any attempt to identify "the Good" (or "the Moral") with any other property, biological or otherwise, is bound to fail. It commits what Moore called the *naturalistic fallacy.* For example, suppose it is proposed that all, and only, acts that promote social harmony are good. Then, on this view, the Good *just is* whatever promotes social harmony. But this can't be correct, argued Moore, for if the Good is nothing other than whatever promotes social harmony, then for any act that promotes social harmony, we cannot intelligibly ask, "Is it good?" But we can. Such a question is indeed open. This, however, indicates that there is no necessary relation between whatever promotes social harmony and the Good. For "Good" and "socially harmonious" are not synonymous and hence do not form an analytic sentence or a logical tautology. Moore was thus led to the view that the Good is an unanalyzable, nonnatural property.

While any complete survey of Hume's and Moore's challenges to Social Darwinism will issue important qualifications (e.g., Moore failed to recognize that some identities [e.g., water and H_2O] may not be synonymous), the prevailing obstacles remain. Social Darwinism, at least for the time being, has been abandoned. But this does not mean that the philosophical interest in the relationship between evolution and ethics has in turn dried up.

Beginning in the 1970s, authors began to turn the relationship between evolution and ethics on its head. Instead of maintaining that evolution *justifies* a given moral system (as Social Darwinists maintained), contemporary authors argue that evolution *explains* our tendency to believe in moral systems generally. This latter hypothesis is put forward as a debunking thesis: We believe in right and wrong because it served a biological purpose during the long period of hominid development—not because our moral beliefs "track" independently existing moral properties. In other words, moral judgments are not the result of perceptual activity; we don't perceive "not-to-be doneness" out there in the world. Rather, they are the result of internal regulation. Our minds were designed to regulate and preserve (inter alia) social bonds. And one effective means of doing so involves the postulation of moral obligations and prohibitions (recall our earlier discussion of how our moral minds might have evolved). But this empirical hypothesis allegedly yields an important epistemological implication: Belief in the objective status of moral properties is unjustified.

The argument is sometimes expressed this way: If we have evidence that a set of beliefs has been produced by means *unrelated* to the facts that would make those beliefs true, then we ought not to assent to those beliefs. According to one proposal (see above), our moral beliefs (or, more specifically, our disposition to adopt moral beliefs) are the result of ecological pressures on early hominids, not rightness or wrongness itself. Hence, we should be agnostic about the objective status of morality.

One way of responding to this argument is by questioning the antecedent. It might be argued, for example, that while some moral beliefs are the result of ecological pressures, not all of them are. Alternatively, one might insist that morality itself consists in the very drive to social cohesion to which early hominids would have been sensitive; thus, it *was* a response to rightness and wrongness that shaped our moral minds. Another way of objecting to the argument might consist in questioning the conditional: Many of our beliefs were produced by means unrelated to the facts that would make them true (e.g., my belief that 2 + 2 = 4 was produced by the utterances of one Miss Peacock in the second grade), yet we are nonetheless justified in continuing to hold them.

Evolutionary Game Theory and Sociality

This entry introduces the novel notion of evolutionary game theory and its recent uses in explaining, naturalistically, the reality of social conventions as well as sociality in general. It explains what game theory aims at doing and how its borrowing conceptual tools from evolutionary theory in biology can help explain human social conventions and coordinated action, including social phenomena such as mutual trust. It focuses on explaining the main elements of such a naturalistic account, namely, the notions of conventions, equilibrium, reciprocity, and emergent phenomena, and ends by giving an example of how to naturalize along those lines a political theory of justice and egalitarianism.

Naturalistic Explanation

Evolutionary game theory has nothing to offer those who follow Immanuel Kant in seeking metaphysical foundations for human morality. Its role lies in providing a tool for those who approach moral issues from the naturalistic perspective of David Hume. John Mackie's *Inventing Right and Wrong* is perhaps the most vigorous modern exposition of this position. After a fierce critique of standard metaphysical arguments, he argues that alternatives need to be based on anthropological data analyzed using game theory as a conceptual framework.

Conventions

The idea that a social norm should be identified with a Humean convention was pursued in modern times by Thomas Schelling and then David Lewis, before being taken up by game theorists. Schelling speaks of *focal points* rather than *conventions*. Robert Sugden usually says *salient* rather than *focal*. Cristina Bicchieri and Herbert Gintis offer differing psychological definitions of the term *social norm* that would exclude many social conventions. Ken Binmore and Brian Skyrms hijack the traditional term *social contract* to refer to the collection of all social conventions or norms that regulate a particular society.

However, in spite of their differences, naturalists all agree that social conventions govern a wide spectrum of social behavior, from the trivial to the profound. Their range extends from the arcane table manners we employ at formal dinner parties to the significance we attach to the green pieces of paper we carry around in our wallets bearing pictures of past presidents (in the United States), from the side of the road on which we drive to the meaning of the words in the language we speak, from the amount people tip in restaurants to the circumstances under which we are ready to submit ourselves to the authority of others, from the order in which we arrange words in dictionaries to the criteria we apply when making judgments about fairness.

Coordination Problems

From the perspective of game theory, human social life consists largely of the play of a succession of coordination games.

Who goes through that door first? Who gives way to whom when cars are maneuvering in heavy traffic? Whose turn is it to wash the dishes tonight?

When interacting with people from our own culture, we usually solve such coordination problems so effortlessly that we do not even think of them as problems. It is only after a coordination problem has been modeled as a game that it becomes apparent that social criteria are needed to determine which of the various different ways of solving the game is to be used.

For example, most countries solve the Driving Game by operating the convention of driving on the right, but in other countries the convention is to drive on the left. Hume saw that the same considerations that apply to such humdrum coordination problems might also apply to the grand problems of running a whole society. If he is right, then our social contracts reduce to bunches of conventions that together isolate one of the many ways of solving our society's game of life.

Why Do Social Contracts Work at All?

The players of a society's game of life are its citizens—including kings, the police, and all other authority figures. Its rules are all relevant constraints that we are physically unable to break.

When we seek to paint on such a broad canvas, an immediate problem arises. What is the "cement" that holds societies together? It cannot be the law or the constitution. They are just words on pieces of paper. Nor is it the officers of the state. They are just people like you or me. Is it our sense of moral obligation? If so, what is its source? Why does it command authority?

Hume's answer is that stable social contracts need no cement. They hold together like a masonry arch. Each stone supports and is supported by its neighbors, without any need for cement. Game theorists express this Humean idea by saying that the mutual understandings built into a stable social contract succeed in coordinating our behavior on an *equilibrium* in our game of life.

Equilibrium

A *game* is any situation in which people or animals interact. The plans of action of the players are called *strategies*. A *Nash equilibrium* is any profile of strategies—one for each player—in which each player's strategy is a best reply to the strategies of the others. Nash equilibria are of interest for two reasons:

1. If it is possible to single out the rational solution of a game, it must be a Nash equilibrium—if Adam knows that Eve is rational, he would be stupid not to make the best reply to what he knows is her rational choice. *This is the basic principle of rational game theory.*
2. An evolutionary process that adjusts the players' strategy choices in the direction of increasing fitness can only stop when it reaches a Nash equilibrium. *This is the basic principle of evolutionary game theory.*

Because simple *evolutionary* processes stop working at a Nash equilibrium, biologists say that Nash equilibria are "evolutionarily stable" (usually ignoring the fact that their formal definition includes further small print). At an evolutionarily stable outcome, each relevant locus on a chromosome is occupied by the gene with maximal fitness. Since a gene is just a molecule, it cannot *choose* to maximize its fitness, but evolution makes it seem as though it had. This is a valuable insight, because it allows biologists to use the rational interpretation of an equilibrium to predict the outcome of an evolutionary process, without following each complicated twist and turn that the process might take or attributing cognitive abilities to animals (or humans) that are beyond their capacity.

Note that evolutionary game theory says nothing whatever about the psychological mechanisms involved in operating an equilibrium. If someone treats us unfairly, we may get angry and respond negatively. Game theory can explain that fairness norms would not survive if deviations were not punished, but it offers no insight into how it feels to be angry or what stories we tell ourselves to justify our not turning the other cheek. That is to say, game theory can only offer ultimate explanations of our behavior. However, the fact that proximate explanations are also available (and are much more interesting in many situations) does not invalidate the explanations offered at the ultimate level.

Cultural Evolution

For many applications, it is necessary to appeal to cultural or social evolution rather than biological evolution. Imitation, education, and individual trial-and-error learning then substitute for genetic replication. J. McKenzie Alexander and Skyrms have written books for philosophers that explain how such cultural processes can coordinate human behavior on the kind of focal points considered by Schelling.

Reciprocity

Confucius was once asked to summarize the secret of human sociality in a single word. He supposedly replied *reciprocity.*

Game theorists rediscovered his secret when characterizing the outcomes that can be supported as Nash equilibria in repeated games. The result of this work is known as the *folk theorem,* since it was formulated independently by several game theorists in the 1950s. It says that no social cement is necessary to persuade a collection of Mr. Hydes to cooperate like Dr. Jekylls. It is only necessary that they be patient and know that they are to interact together for an indefinite period in the future. The rest can then be left to their enlightened self-interest, provided that they can all monitor each other's past behavior without too much effort—as, for example, when humans were all members of small hunter-gatherer communities.

Repeated games satisfying the conditions of the folk theorem normally have an infinity of Nash equilibria, both efficient and inefficient. They therefore pose the equilibrium selection problem in an acute form. Our current convention might perhaps require us to operate in an inefficient equilibrium, but the folk theorem tells us that *any* efficient outcome that we all prefer to the status quo can also be sustained as a Nash equilibrium—and hence we could all be made better off by changing our convention. Robert Axelrod's computer simulations go on to suggest that we should expect evolution to organize such a reform spontaneously on our behalf if given long enough to operate in a stable environment.

Space limitations do not allow a discussion here of the difficulties that arise when seeking to see how far the folk theorem extends to a modern society in which each player's past history of play is often anything but an open book. On the other hand, the theorem does provide the beginnings of an explanation of how cooperation is possible in societies without any need to invent some kind of moral cement.

Emergent Phenomena

Game-theoretic models of sociality have no primitives for notions such as authority, blame, courtesy, duty, envy, friendship, guilt, honor, integrity, justice, loyalty, modesty, ownership, pride, reputation, status, trust, virtue, and the like. They are seen as *emergent* phenomena that describe aspects of whatever equilibrium may have evolved in a society's repeated game of life. Binmore's efforts in this area have been directed at explaining how the egalitarian intuitions of John Rawls's political philosophy developed in his classic *Theory of Justice* can be *naturalized* in this way. How is this done? Space allows only the briefest discussion of the much simpler notion of *trust*.

Alice delivers a service to Bob, trusting him to reciprocate by making a payment in return. But why should he pay up if nothing will happen to him if he doesn't? If Alice predicts this response, why should she deliver the service? However, people mostly do pay their bills. When asked why, they usually say that they have a duty to pay and that they value their reputation for honesty. Game theorists agree that this is a good proximate description of how our social contract works, but it needs to be supplemented with the *ultimate* explanation that the indefinitely repeated version of the game played by Alice and Bob has an equilibrium in which Alice always delivers and Bob always pays. We explain this *equilibrium* in real life by saying that Bob cannot afford to lose his reputation for honesty by cheating on Alice, because she will then reciprocate by refusing to provide any service to him in the future. In practice, Alice will usually be someone new, but the same equilibrium works just as well, because nobody will be any more ready than Alice to trade with someone with a reputation for not paying.

Conclusion

Criticism, of various sorts, has been directed at the naturalistic approach outlined here. Apart from the traditional philosophical objections, there are new complaints from behavioral economists, who see no need for a folk theorem at all.

Evolutionary Political Science

Evolutionary political science involves the application of principles from evolutionary biology and evolutionary psychology to concepts and problems drawn from political science. Evolutionary political science seeks to understand and interpret complex social and political behavior in light of the reproductive advantage offered by particular strategies. These theories explain aspects of behavior that involve universal characteristics, or the ways in which humans are similar. Thus, these theories remain distinct from models that focus on exploring the nature of individual difference. Most examinations of unique facets of human political behavior employ methods from behavior genetics. Evolutionary and genetic perspectives, while completely complementary, are not identical.

This entry explicates the basis of these evolutionary models and then discusses some areas of application to political science.

Evolutionary Models

Evolutionary models examine the ways in which humans and other animals adapted to repeated challenges over their ancestral past. Only those problems that occurred repeatedly and exerted an influence on reproductive success are subject to evolutionary pressure. From an evolutionary perspective, natural selection operates over time and across millions of people in such a way that the marginally more successful strategies proliferate in a population, while those that are less successful diminish in prevalence over time. As a result, evolutionary theory suggests that individuals are born into the world with certain inherent biological and psychological mechanisms. These mechanisms have a general content but often remain specific to a particular domain. This means that individuals will not respond in the same way across situations but rather will know to avoid predators but approach family members and other allies. As a result, the physical and psychological systems that often utilize the same responses, such as anger, must remain flexible enough to operate differently across various circumstances. Moreover, repeated problems have unique environmental cues or triggers to signal their appearance. For example, war represented a repeated challenge that required the evolution of mechanisms to recognize, develop, and maintain coalitions so that individuals could both work together to fight enemies as well as distinguish friends from foes. In this way, evolutionary models remain fundamentally contingent on environmental inputs.

Evolutionary models cannot explain everything. They would not expect psychological mechanisms to exist for problems that did not appear repeatedly in the ancestral past or whose successful resolution did not have an impact on reproductive success. Furthermore, evolutionary systems are backward looking: Strategies that proved successful in the past may not remain optimally adaptive in the current environment, but this does not invalidate the model itself. For example, efficient fat storage in the past would have protected individuals from the ravages of famine but could lead to obesity and heart disease in the modern world of sedentary lifestyles and fast food. However, environmental cues that triggered particular responses in the past, for example, territorial invasion causing desire for vengeance, may automatically trigger similar responses in the current environment.

Evolutionary models can offer predictive and testable hypotheses, but the nature of that prediction can differ from that offered by more established models in political science. Many political models strive for prediction that focuses on timing, attempting to specify when a particular event will happen. Others concentrate more on whether a certain event or action will occur. By contrast, evolutionary models focus on specifying and predicting the patterns of behaviors and events that might take place under particular environmental circumstances.

Applications to Political Behavior

There are many areas where evolutionary models can provide novel insight into enduring problems in political behavior. Evolutionary models offer a unique approach to the study of coalitional behavior, including problems related to labor recruitment, resource sharing, and reputation and status.

Evolutionary models can also inform understanding of the nature of leadership and followership. In addition, an evolutionary perspective supplies an alternative explanation for the nature of threats, conflict, overconfidence, and war.

Additional enduring problems in political science can benefit from applying an evolutionary lens. For example, evolution can help observers gain better traction on how political groups such as states, organizations, and institutions are perceived and represented by both individuals and other states. In particular, humans evolved in small hunter-gatherer groups and would not be expected to formulate automatic representations of large groups such as the modern nation-state in that context. As a result, humans likely represent groups as a kind of special category of individuals, infusing attributes of both unitary actor and intentionality to structures that in reality possess neither. An extension on this understanding could explain how coalitional action, such as alliance formation, maintenance, and dissolution, or institutional reform, might be facilitated by state actors or other organizations. Leaders and other coalitional entrepreneurs, for example, likely seek opportunities to strategically manipulate the coalitionary environment by using devices such as emotional outrage to prime and lubricate collective action, such as war. Such action may elicit instinctual responses from followers, although it may be in the service of individual leadership goals in a modern environment.

Finally, evolutionary theory suggests a new foundation for feminist theory in political science as well, since many of the behaviors explained by such models, for example, aggression, display demonstrable sexual dimorphism. For example, some interesting work has shown a link between anger, physical formidability, and aggression. Specifically, male, but not female, coalitional size and physical strength predicts support for aggressive foreign policy intervention.

In short, evolutionary models provide powerful and parsimonious models for explanation and prediction in political science.

Evolutionary Psychology

While it has long been recognized that humans are the product of evolution, progress in applying evolutionary principles to the study of the mind has been slow. Much of this delay has come from disagreements about ontology: What are the elements of which the mind is composed, and how are these shaped by evolutionary processes? This is the central question that evolutionary psychology seeks to ask. By decomposing the mind into its underlying functional processes, evolutionary psychology stands to shed light on many philosophical questions about the nature of the mind.

The research strategy of evolutionary psychology is to use empirical methods, guided by evolutionary considerations, to attempt to decompose the mind into its underlying information-processing components or adaptations. The mind is a complex organ that is likely to be composed of multiple, distinct adaptations rather than a single one, and the nature and arrangement of these adaptations must be discovered empirically. Since the field's origins in the late 1980s and early 1990s, evolutionary psychologists have developed a body of theories and methods that have been applied to diverse aspects of the study of the mind, from neuroscience and development to culture and social behavior.

Evolutionary Psychological Theory

Adaptations

Evolutionary psychology begins by treating psychology and the other social sciences as branches

of biology. Because brains and minds (used synonymously here) are parts of an organism's phenotype, the causes of their organization must ultimately be biological, and evolutionary, in origin. The design features of brains and their underlying mechanisms—mechanisms of perception, emotion, cognition, and learning—evolve because of the effects these mechanisms have on organismic survival and reproduction, or fitness. Mechanisms that evolve in this way are known as *adaptations*. Crucially, the fitness effects that shape mechanisms are not abstract but arise because of interactions between the organism and the environment. The set of environments that has shaped the evolution of a given brain mechanism is known as its *environment of evolutionary adaptedness* (EEA).

EEAs and Domains

Because the brain of any organism is an evolutionary mosaic, composed of multiple adaptations with distinct evolutionary histories (some ancient in origin, some more recent), there is no single EEA for an entire organism. For example, human adaptations for a meat-rich diet, which are relatively recent in origin, have a briefer evolutionary history than mechanisms in the retina for detecting light, which are ancient. Moreover, adaptations differ with regard to which aspects of the environment they interact with to influence fitness. This subset of features is referred to as an adaptation's *domain,* and the domains of adaptations differ. For example, the domain of our visual system (properties of visual light and the manner in which it reflects from objects) is distinct from the domain of our auditory system (properties of sound waves and how they reflect from objects). Because most psychological adaptations within the mind are designed to process information coming from elsewhere in the brain rather than directly from the external environment, their domains include internal information. For example, search-and-recall mechanisms in human memory have evolved to interface with human memory stores, so they must contain adaptations to the properties of memory storage. Finally, in a social species such as humans, the domain of psychological adaptations may also include the social environment. For example, adaptations for cultural learning are adapted to the environment of cultural information transmitted by other humans.

Phylogeny and Descent With Modification

Adaptations do not arise de novo, with no evolutionary history. Instead, they arise through variations on previously existing structures, a process Charles Darwin referred to as "descent with modification." This has important consequences for the study of psychological adaptations. It means that every adaptation contains elements, inherited from prior structures, that are not the result of selection for the adaptation's current function. It also means that many adaptations possess hierarchically nested design features, some ancient and some recent. For example, human mating psychology may contain human-specific features nested within a more primatewide or mammalwide mating psychology. Finally, it means that adaptations are distributed phylogenetically across taxa, such that an adaptation in one organism can be evolutionarily related, or *homologous,* to a modified version of that adaptation in another organism. This means that "human nature" must be considered largely as a set of modifications of more ancient mechanisms rather than as having arisen entirely since the chimp–human common ancestor.

Mechanisms

Evolutionary psychologists typically take a functionalist approach to thinking about psychological mechanisms, in which mechanisms take inputs (i.e., information from the environment or internally), operate on those inputs, and send outputs to other brain systems. Any aspect of a mechanism's input, output, or processing procedures that has been shaped because of its impact on fitness in ancestral environments is called a *design feature*. While this approach was originally applied to perceptual mechanisms, it can be and has been expanded to cover virtually all aspects of brain functioning, from reasoning, to decision making, to emotion, to mechanisms of learning and brain development.

Modularity

The concept of an evolved psychological adaptation, central to evolutionary psychological approaches to the mind, has sometimes been taken as synonymous with the concept of a "module" as it is used in psychology and philosophy of mind. In this traditional conception, modules are held to have

several properties, including encapsulation (inability to be influenced by conscious thought), innateness (identical development across individuals, without learning), automaticity (reflex-like operation independent of other brain processes), and fast, rather than slow, operation. While this concept of modularity might usefully describe some evolved mental adaptations, it is important to realize that not all adaptations are likely to be modular in this sense. For example, conscious processes, while typically held to be nonmodular, have almost certainly been shaped by natural selection, so the concept of a psychological adaptation should not exclude interaction with consciousness by definition. Similarly, while speed is a property that might be associated with some evolved processes, such as responses to immediate danger, other mental adaptations might be expected to operate over relatively long timescales, for example, processes of bond formation between mates. Instead of mental adaptations being identifiable by a fixed checklist of modular features, such as automaticity, encapsulation, and developmental canalization, it is likely that mental adaptations vary in their properties depending on the functions they have been selected to carry out, with only some corresponding to the traditional conception of cognitive modules.

Empirical Research in Evolutionary Psychology

In principle, all functional aspects of mental processing must be the result of adaptations interacting with the world, including developmental adaptations such as mechanisms of learning and plasticity. Therefore, an evolutionary psychological approach can be applied to any area of human psychology and behavior. In practice, early evolutionary psychological research was initially focused on specific topics such as mate choice and reasoning about social contracts. However, it has since expanded to include diverse areas of psychology and the social sciences, including philosophy, economics, literature, history, and anthropology.

Perception

Perceptual mechanisms deliver information from the outside world into the brain, and natural selection shapes these mechanisms because of the effects they have on survival and reproduction. This can explain both what organisms are able to perceive and what their brains do with the perceived information. For example, bees perceive high-energy ultraviolet light because flowers use it to signal the location of nectar, and deep-sea animals are tuned to be maximally sensitive to blue wavelengths that penetrate into deep water. Often, perception is not "veridical," as when we perceive an object that reflects a very different light spectrum in sunlight and in the shade as being the "same" color. This phenomenon of "color constancy" is thought to be an adaptation for tracking objects under different lighting conditions. Even within the perceptual array, what we are tuned to notice most easily also depends on fitness considerations, for example, we more easily notice the movements of animate than inanimate objects in a scene.

Emotion

Emotions and other affective states are the result of processes that add value to objects and situations, shaping organisms' motivations with respect to those things because of their effects on fitness. For example, disgust appears to be an adaptation designed to prevent organisms from ingesting pathogenic substances and is caused by perceptual cues that an object may be a source of contagion. Fear, on the other hand, is designed to cause avoidance of injury and is triggered either by harmful agents, such as predators, or harmful objects, such as weapons or cliffs. Other emotions cause us to approach objects or situations that may have fitness benefits: Hunger increases attraction to food, and sexual desire increases attraction to mates. Even social emotions have design features that make sense in fitness terms. For example, anger, or punitive sentiment, appears designed to prevent exploitation by others in social situations.

Reasoning, Judgment, and Decision Making

While some researchers have held that only "lower-level" brain mechanisms such as perception and emotion have been shaped by natural selection, it is clear that our higher-level faculties of thought, including conscious choice itself, must also be products of evolution. Whereas approaches to cognition in philosophy of mind often take standards such as truth and rationality as the normative benchmarks against which cognition should be measured, an evolutionary psychological approach assumes that

fitness is the primary factor that shapes cognitive mechanisms. When fitness considerations and rationality diverge, apparent irrationalities may result. Researchers in judgment and decision making have documented a host of such apparent rationalities that may have evolutionary explanations. For example, the "endowment effect"—the tendency to place a higher value on a good that one owns than on an identical good that one does not own—may appear economically irrational, but it could be a fitness-promoting strategy if owners have an advantage over nonowners in contests, which appears to be the case across many animal species.

Learning and Development

Mechanisms that shape organismic development, including mechanisms of learning, must also be the products of natural selection and therefore evolve because of their effects on fitness. Behaviorist psychologists originally held that all learning could be explained by two mechanisms: operant and classical conditioning. However, evolutionary research suggests that the landscape of learning may be much more complex. For example, among primates, humans are especially good at learning from observing others, and this likely requires specialized social learning abilities, such as the ability to make inferences about others' goals. Human infants do not "blindly" imitate but imitate what they infer another is trying to do, especially when being explicitly taught. Some classes of information—especially fitness-relevant information such as danger—are more easily learned than others, a phenomenon known as *prepared learning*. And, finally, development proceeds at different rates across domains, with some skills, such as understanding the mechanical properties of objects and attending to the mental states of others, learned early and with little effort and others, such as mathematics and reading, developing only later and under special cultural circumstances. This suggests the presence of adaptations for the early development of certain fitness-relevant skills in childhood.

Culture

The study of culture is increasingly coming to be a part of evolutionary psychology, with the realization that culture cannot be simply the result of general-purpose learning mechanisms. The kind of cumulative cultural evolution seen in humans is not present in other species. Evolutionary theorists have begun to study the specialized mechanisms that evolve because of the benefits cultural transmission provides, such as biases for conforming to societal norms and imitating the prestigious. Whereas culture and biology have previously been seen as mutually exclusive explanations for aspects of human behavior, the realization that culture is a human adaptation, enabled by specialized mechanisms, brings cultural phenomena into the spotlight of evolutionary explanation.

Evolutionary Psychology and Philosophy

Philosophical questions hinging on the nature of mind may be illuminated by an evolutionary approach. For example, an evolutionary approach to phenomenology may help answer ancient philosophical questions about perception, such as why experiences feel the way they do (e.g., why sugar tastes good and sand does not). Evolutionary approaches can be applied to questions in epistemology, as in the field of "naturalized epistemology," as well as semantics and pragmatics. Most recently, work on the evolution of cooperation and sociality has begun to be applied to questions in moral philosophy, with empirical work beginning to shed light on questions such as which aspects of morality are universal, and which are variable, across societies. Finally, an evolutionary approach that takes culture as a central part of human nature may speak to issues in social constructivism, including a better understanding of social norms, how they evolve, and how they influence human thought and behavior.

Existential Phenomenology and the Social Sciences

Existential phenomenology is often treated as the application of the German philosopher Edmund Husserl's general phenomenological method directly to the issue of human existence. Major figures in the phenomenological tradition after Husserl for whom concrete human existence is a focal point include Martin Heidegger, Jean-Paul Sartre, and Maurice Merleau-Ponty. For some readers, the movement from Husserl's "transcendental" concerns (i.e., seeking the absolute conditions of possibility for any "phenomena" whatsoever) to the more specific focus in these subsequent thinkers on the phenomenon of historically situated and embodied human existence marks a significant shift in the phenomenological movement. However, there are strong existential characteristics already present in Husserl's thought itself, and these are brought out well by highlighting his view of science.

Of particular note in the context of this encyclopedia is that Husserl accords a key role to the social and human sciences (*Geisteswissenschaften*) as distinctive sciences of human subjectivity. This entry uses Husserl's notion of a "crisis" in science as a way of highlighting the existential aspect of his phenomenology, outlining the particular contribution he thinks phenomenological philosophy makes to the social sciences and the subsequent influence of this view.

Husserl and the "Crisis" of the Sciences

Husserl's early analysis of calculative rationality in the 1891 work *Philosophy of Arithmetic* gives a formal sense of what can go wrong with scientific thinking. In this text, Husserl describes calculation as the human capacity to use symbolic number concepts and to engage in complex, higher-level operations without grasping how the concepts arose in the first place or possessing an "authentic" understanding of the operations within which these concepts are employed. This ability to calculate is for Husserl a significant aspect of our intellect; without this power to calculate, the human mind would be capable of little arithmetical progress. Moreover, this symbolic or "inauthentic" thought of calculation tends to be very efficient: It allows for the greatest result from the least amount of effort and hence is representative of the principle of "economy of thought" put forward by earlier thinkers such as the philosopher Richard Avenarius and the physicist-philosopher Ernst Mach, which figured significantly in conceptions of science at the end of the 19th century. However, despite playing a central role in the rapid progress that arithmetical science (and science in general) is able to make, there is a negative aspect to this power of calculation. Though economical, calculation also contains a type of "blindness" about itself. Paradoxically, it allows for a powerful "thinking" without much genuine thought. The "thoughtless thinking" of calculation, while not wholly negative for Husserl, can "get out of control" and devolve into a mere technique. What Husserl describes in one of his final works, *The Crisis of the European Sciences and Transcendental Phenomenology* (1935/1936), is precisely a full-blown critique of how natural science, human/social science, and philosophy itself have fallen into various types of "thoughtless" thinking that allow them to operate, often with great technical competence, but without genuine understanding of themselves and of the origin of their own operations.

That there is some sort of "crisis" of blindness in the natural sciences (*Naturwissenschaften*) may seem surprising. They appear to function well in their task of delivering a proper description of nature, at providing and ordering the empirical facts produced by observation. At a higher level, the natural sciences account for these facts by "discovering" essential laws of causality. These causal laws are binding in all circumstances, hence the claim of the natural sciences to both necessity and universality. The natural sciences achieve this status by excluding subjective elements in their determination of nature

and its causes. How a human subject might "feel" about a particular aspect of nature, for example, is not relevant to these sciences. They seek to describe nature as it is "in itself," regardless of the subject. This objectivity determines the procedure of the natural sciences. Their method and goal of understanding the world as nature is linked to the world viewed as a particular type of object.

In what ways, then, are the natural sciences in a crisis for Husserl? Put simply, they lose sight of their own origin, their ultimate foundation in human subjectivity. Only human subjects conduct science, and to overlook that origin or to treat the subjective origin of natural science in a purely objective way is to misconceive the starting point of the scientific project. It must be stressed that Husserl has some sympathy for this weakness of the natural sciences, for to function as natural sciences they cannot focus on their origin in human subjectivity. If they were to do so, they would become human sciences! Still, Husserl does critique the concealment of that subjective origin: The culpability of the natural sciences is not in their focusing on nature but in focusing on nature in such a way that the origin of this very subjective interest in nature is itself obscured or denigrated.

It is the task of the human or social sciences (*Geisteswissenschaften*) to pay attention to human subjectivity. In approaching "*Geist*"—that is, spiritual or cultural existence—these sciences seek, on a basic level, to provide a proper description and classification of (both individual and collective) human activity. On a higher level, they also seek to explain these human acts by determining the essential regularities that characterize subjective, human activity, what Husserl calls the laws of "motivation." It is possible to call these disciplines the sciences of *subjectivity*. Of course, one of the cultural achievements of the human subjectivity is precisely "natural science"—and so a clear consequence of Husserl's phenomenology is the need for a proper social-scientific understanding of the very human project of natural science itself.

Where, then, is the "crisis" of the human sciences? For Husserl, the main danger is the domination of the natural-scientific paradigm (naturalism) within social science. Due to the tremendous advancement of knowledge, capability of prediction, and technological manipulation, the natural sciences come to be seen as the model by which all true science is to be judged. That is, only objective sciences of "fact" are viewed as true sciences, and to be a science of facts means to treat the human world in exactly the same manner as the natural scientist does the natural world. On the basis of this domination of the natural-scientific paradigm, a dissolution of the human sciences takes place. There is a "colonization" of the human sciences by the natural sciences. The human subject is said to be treated scientifically only when done so according to the paradigm of the natural sciences; hence, human existence must be treated in an objective manner, as an object, just like the objects of nature described by the natural scientist. In this form of dissolution, the human sciences retain the status of science but do so by losing sight of their true goal and field of inquiry, namely, the subject *as* acting subject. The human sciences are, in effect, taken over by the natural sciences; they lose their autonomy, and ultimately, existence or culture is reduced to an appendage of nature.

For Husserl, the human and social sciences are more fundamental than the natural sciences. The "fundamentality" of the human and social sciences has to do with their field of investigation: In studying the working, achievements, and traditions of human cultures, the human sciences ground the natural sciences since they are ultimately sciences of that human subjectivity which is the source from which spring the objectivistic natural sciences. Due to this fundamental role, Husserl seems much harsher in his critique of the failure of the "human sciences," since these sciences seem all too willing to sacrifice "their" specific task of understanding human accomplishments to an inappropriate naturalistic or objectivistic paradigm.

Subsequent Appropriations of the Centrality of Human Subjectivity

The strong reaction to naturalism, and the focus upon human subjectivity, is thematized sharply in phenomenological thinkers after Husserl. In his *Phenomenology of Perception* (1945), Maurice Merleau-Ponty shows how no merely natural-scientific account of the human body can account for the experience of our own embodied existence. For Merleau-Ponty, "perception" as the basic structure of human subjectivity can never be reduced to objectively determined causal relations or accounted for in a fundamental way through natural science.

A proper phenomenology of embodied perception, however, would help ground the physicalist accounts of natural science, and it is not surprising that Merleau-Ponty's thought is the springboard for much of contemporary work on the relationship between phenomenology and cognitive science.

Martin Heidegger shares as well many of the main contours of Husserl's turn to human subjectivity. His description of the concrete life ("being-in the-world") of the human subject (*Dasein*) in his major work *Being and Time,* published in 1927, is framed within a critique of sciences (whether natural or social) that accept without question the "being" of their object of inquiry. Moreover, he shows how even previous philosophy when it did take human subjectivity as a theme did so with unwarranted assumptions. However, the exact manner of bringing this "subjectivity" into view also shows divergences with Husserl's project, as the issue of "history" makes clear. For Husserl, there is a danger in mere "subjectivism" as a reaction to naturalism. Just as the natural scientist has the tendency to look upon everything as nature, the social scientist can go too far in reaction to this naturalism and end up seeing everything as mere historical construction.

"Historicism" is for Husserl one of the most manifest signs of an inadequately understood science of human subjectivity. By an overemphasis on the historical aspect of human existence, Husserl felt that the entire idea of science as a name for absolute, timeless values was undermined. So if the danger of the naturalistic attitude is a restriction of science (as knowledge of what is true) to sciences of facts, the danger of the "historicist" position is that science itself seems to become impossible. This was most evident for Husserl in relation to philosophy itself. The historicist would regard philosophy as being the expression of the "worldview" of a particular historical period. There have indeed been many philosophies, and there has been conflict between these philosophies. For the historicist, this conflict is rooted mainly in the pretentious claim by these philosophies to a universal validity. Since the historicist sees philosophy as merely the expression of a particular worldview, there can be no claim to absolute universality.

Such a position represents for Husserl the complete abandonment of the idea of philosophy as a rigorous science that is methodically directed toward the establishment of universal, eternal truth. To view everything as historical is just as mistaken as viewing everything as nature; historicism leads to relativism and the complete undermining of the idea of science. Historicism has human subjectivity in view, but in a manner that results ultimately in the inability to say anything true (in an absolute sense) about that subjectivity. The mistake of the historicist might be said to be that subjectivity is construed in a false "subjectivistic" manner, that is, as merely particular, or relative. For Husserl, this conceals the crucial feature of subjectivity, namely, its transcendental aspect. So while the error of the naturalistic attitude is an objectivism that obscures subjectivity, the error of the attitude of the historicist is that of an improper subjectivism that obscures the true nature of subjectivity.

Husserl certainly viewed Heidegger's description of human existence as falling into such historicism. While Heidegger's clear intent was to yield the transcendental structure of human subjectivity, his very account reveals its irreducible historical character. The debate between Husserl and Heidegger regarding a proper account of human existence and subjectivity foreshadows much that follows in terms of the impact of phenomenology on social science. While existential phenomenology provides a solid framework for a critique of solely quantitatively oriented social science with its naturalistic assumptions and naive reflection on "culture" (*Geist*) as merely what Husserl calls "second nature," the positive task of working out the proper relation of the human, social sciences both to the natural sciences and to their own foundation in (transcendental) phenomenology has been a matter of ongoing debate and continues to play a significant role in contemporary phenomenology of social science.

Existential Psychology

Existential psychology is the branch of psychology that deals with the human being's relationship to the most essential life dilemmas, the so-called big questions of life.

Contents of Existential Psychology

Many psychologists, psychiatrists, and other therapists enter their chosen field because they are attracted by the pulsating and varied nature of human life. They are fascinated by the many unique ways in which human beings can unfold their lives. They love to relate to others and to help them unravel from their misery and redirect their lives in a more constructive direction.

These professionals need a body of psychological knowledge and understanding that respects their interest in specific human lives without reducing these lives to abstract categories, cause-and-effect relationships, and statistical averages. At our universities, this commitment to human uniqueness is often met by intellectual systems of categorization, diagnosis, and explanatory concepts. What is lacking here—from the perspective of existential psychology—is phenomenology and a commitment to the actual lives of human beings.

Amedeo Giorgi proposes the term *life world* as the crux of a psychology that respects the lived life of real persons. The relationships between living persons and the worlds in which they live should be the central focus. Other concepts that aim to capture what life is about are *life feeling* (the person's spontaneous sense of being alive, of being coherent, and of a right to be here), *life courage* (the person's life feeling combined with his or her determination to conquer fear and anxiety in order to carry out his or her life project), and *life energy* or vitality (the ability of the organism to survive even under difficult circumstances and to achieve longevity).

As conceived by existential psychology, the spontaneous unfolding of our human lives as depicted by these life concepts meets the basic conditions of existence, which are ontologically determined. The way each of us forms and molds our individual lives is a result of how we meet and interpret these basic existential conditions. Do we, for instance, hide ourselves and refuse to look directly at the facts of death and the other existential realities, such as, for instance, our aging, our actual life satisfaction, as well as our satisfaction with the present societal situation? Or can we look these realities squarely in the eye and learn how to relate to them constructively, thus living more openly and freely, in a more grounded and real way? Existential psychologists use the word *authenticity* to designate this genuine life, which is a possibility open to everyone.

There are different catalogs and lists surveying the basic life conditions. The most well-known is Irvin Yalom's enumeration of four basic existential conditions: (1) that we are going to die; (2) that in decisive moments, we are alone; (3) that we have the freedom to choose our life; and (4) that we struggle to create meaning in a world in which our life's meaning is not given beforehand. According to Yalom, these four basic conditions constitute a structure that is our premise, something that all human beings are born into. The four conditions set the frame and the agenda for the life of each individual. Many people would rather avoid thinking about, talking about, and relating to these basic conditions, including death, but this fact does not weaken their impact, rather the opposite.

Another theory about life's basic conditions, developed by Medard Boss with inspiration from Martin Heidegger, lists seven fundamental traits of human life: (1) human beings live in space; (2) human beings live in time; (3) human beings unfold through

their body; (4) human beings live in a shared world; (5) human beings always live in a particular mood, a certain psychological atmosphere; (6) human beings live in a historic context; and (7) human beings live with the awareness of their own death.

Other existential authors have developed similar lists and overviews of humankind's basic life conditions. As early as half a century ago, one particularly interesting exposition was formulated in the 1950s by Erich Fromm, the German American humanistic psychoanalyst and writer: All passions and strivings of humanity, he writes, are attempts to find an answer to our existence. Fromm then goes on to mention as basic points the individual's fundamental need (a) for love (relatedness), (b) for transcending oneself, (c) for developing rootedness and a feeling of being at home, (d) for finding one's identity, and (e) for finding one's orientation and meaning in life. According to Fromm, the most specific characteristics of any human being derive from the fact that our bodily functions belong to the animal kingdom, whereas our mental and social lives belong to a human, conscious world that is aware of itself.

Philosophical Roots

The philosophical roots of existential psychology consist of a variety of approaches in existential and phenomenological philosophy, most often drawn upon in an open and undogmatic fashion. Writings within existential psychology and existential therapy find their basic concepts and approaches in the phenomenology of Edmund Husserl and Maurice Merleau-Ponty and in existential philosophy of various positions, such as those of Søren Kierkegaard, Martin Heidegger, Jean-Paul Sartre, Karl Jaspers, Gabriel Marcel, Martin Buber, Paul Tillich, and others. These philosophical authors are not bound together by any agreement as to the answers to people's existential questions (e.g., they diverge on answers of yes or no to religion and on questions concerning political commitment in social and world problems). However, they are bound together by emphasizing the priority of *existential* questions as such—stressing that human *existence* is prior to human essence, assuming that the latter has any meaning at all, which is something disputable in existentialism. They are also united in their conviction that each of us, as primary an existence, in a certain sense lives in his or her own world and that each of us has a life task of coming to terms with his or her basic existential concerns.

Existential Therapy and Other Applications

The main application of existential psychology is in existential therapy and counseling. Recently, other applications have emerged in coaching, education, philosophical counseling, and management studies.

In therapy, existential views now form a part of several schools. The following main points refer to existential therapy in its pure form, as developed by Ludwig Binswanger and Medard Boss in Switzerland; Viktor Frankl in Austria; Ronald Laing, Emmy van Deurzen, and Ernesto Spinelli in England; and Irvin Yalom and Rollo May in the United States. Existential therapy is characterized by the following salient features:

1. The therapy consistently uses *phenomenological* methods in queries and conversations. Instead of cause-and-effect questions, the therapist might ask, "Try to describe to me what your life is like at the moment, as specifically and in as much detail as possible." Through such detailed descriptions, the therapist gradually unfolds the person's life experience so that it manifests itself clearly in the space established between client and therapist.
2. The therapeutic dialogue is based on a direct, personal relation between client and therapist, not a transference relation. The emphasis is on dialogue between equals, characterized by mutual respect. Collaborative examination of the client's situation is encouraged, carried by a common curiosity.
3. The therapeutic dialogue in existential therapy examines the connections between everyday experiences and the basic existential conditions. In some cases, these connections are self-evident, as in an acute experience of crisis. In other cases, the possible connections between an everyday occurrence and a basic category are explored in a more meditative and reflexive way in establishing a so-called ontic-ontological connection.
4. In existential therapy, there is little emphasis on diagnosis. Also, the therapist does not normally initiate the therapy by tracing the client's developmental history. Both diagnosis and childhood history are thought to easily block or hinder the client's insight into his or her

possibilities in life. Instead, client and therapist immediately address what life looks like right now for the client in all its aspects.

5. The aim of existential therapy is often defined as enabling clients to live as richly textured lives as possible and to unfold and realize their potential in the complex modern world. Existential therapy does not have as its primary goal to remove symptoms, even though these symptoms will most often be alleviated. The most important goal is that the person—in the words of Boss—will be increasingly able to meet the world freely and openly. Individuals should always be understood in their relatedness, their *being-in-the-world*. Boss calls the ideal state of being-in-the-world "composed, joyous serenity," a state where the individual embraces the world with clarity and openness.

Comparisons With Other Schools

Existential psychology is a branch of psychology proper, that is, a field of research with concepts and theories about the world that may be validated or refuted empirically. Existential psychology distinguishes itself from other disciplines within psychology by requiring that the main focus of psychology must be *human life* and each individual's relation to life's basic conditions and most important questions. Existential psychology differs significantly from *mainstream and cognitive psychology* in its explicit focus on essential *life* questions as the most important subject matter of psychology and in its insistence on the *phenomenological* perspective. Therefore, psychology should primarily account for life as experienced from within rather than as behavior observed from without. This difference gives existential psychologists less "safe" knowledge about people's reactions in, say, traffic situations or child development stages but more understanding of the real aspirations and real-life problems of human beings.

Compared with Freudian and Jungian psychology, there are a number of similarities concerning the psychologist's in-depth interest in the lives of individual human beings. An important difference, however, is that the psychoanalytic traditions attach considerable significance to the consequences of childhood events, whereas existential psychologists and therapists are mainly concerned with an individual's present and future state and with their continuous openness to change. Furthermore, existential psychologists and therapists do not propound interpretations "behind the backs" of their clients but advocate detailed descriptions of their life situations and life perspectives.

Existential psychology is to some degree related to phenomenological psychology, humanistic psychology, positive psychology, and some of the narrative (social constructivist) trends in psychology.

Experiment, Philosophy of

A philosophy of experiment has been slow in coming, although experimentation was discussed intermittently since the 17th century, when the concept of experiment began to be recognized as a necessary component of the scientific quest. The reason why philosophy of experiment is a late bloomer has to do with the history of philosophy of science; during the first half of the 20th century, when logical positivism dominated the scene, the emphasis was principally

on theory, its logical structure and representational features, while experiment and its physical execution were generally considered transparent and unworthy of philosophical investigation—a mere generator of data turned into evidence. So strong was the domination of the logical positivists that ideas concerning experimentation by thinkers such as John Stuart Mill (1806–1873), Claude Bernard (1813–1878), Ernst Mach (1838–1916), and Pierre Duhem (1861–1916) were not pursued. But since the 1980s, there has been a growing philosophical and historical interest in the process of generating experimental knowledge.

This entry looks at recent developments. First, it presents the structure of experiment and its two stages and four phases. It then outlines some of the corresponding philosophical issues associated with the methodology of experimentation, in which nature, artifices, methods, theories, as well as skill are intricately combined in the pursuit of securing reliable experimental evidence for scientific knowledge.

Structure: Two Stages, Four Phases

Experiment is a sequential scheme of action to generate data that can be recast as evidence with respect to a certain phenomenon or theory. The data obtained are the result of some (designed) interaction between the entity under investigation and a controlled setup, so that the properties examined in the former are correlated to the known properties of the latter. Thus, essentially, two different tasks are performed in the execution of an experiment: They may be termed *preparation* and *testing*. Experimenters prepare a system, and then they test it. A "preparation" is a specified, known procedure that is reproducible. A "test" is similar to a preparation in that it has a specified procedure, but in addition, it triggers the interaction between the entity under study and the controlled setup. Importantly, a test includes a step whereby information that was previously unknown is recorded and made accessible to an observer, that is, the experimenter. This information—the data—constitutes, after a suitable reduction, experimental knowledge—the evidence that is sought. Such recording is not trivial, not only because identical tests following identical preparations need not have identical outcomes but primarily because this information constitutes, after a suitable reduction, the new physical knowledge. Within certain material limitations and ethical constraints, experimenters are free to choose preparations and perform tests—this is their prerogative. However, they are not free to choose the outcome of a test. They are bound to accept the information acquired. Thus, in terms of human intention and action, the "preparation" is active and the "test" is passive.

This characterization of experiment highlights one of its fundamental features, namely, the method of *variation*. By varying (the test) a certain group of elements or a single one of the system under study (the preparation), other elements will vary too or perhaps remain unchanged (the binding information). The fundamental rule of variation facilitates the severing of the many antecedents and their consequents. However, the character of the experimental procedure is so rich and varied that it seems impossible to capture all its features deductively. Given this complexity, the fundamental dichotomy of the experimental procedure in terms of "preparation" and "test" appears to be useful. The "preparation" comprises theoretical and practical phases: (1) laying down the theoretical framework and (2) constructing the setup and making it work. The "test" too consists of two phases: (3) observing and taking readings and, finally, (4) processing the recorded data and interpreting them.

1. *Laying down the theoretical framework:* Any attempt to create artificially certain physical conditions with a view to studying a particular aspect of nature takes place within some theoretical framework. This is the "background theory." Experimenters rely on this theory to advance the claim that is put to the test. Furthermore, instrumental theories govern the performance of the instruments intended to be used. In particular, there is the theory that underlies the setup.
2. *Constructing the setup and making it work:* Whereas the first phase of background theory provides the theoretical framework, the second phase is concerned with the actual construction of the setup and operating the apparatus involved, that is, the hardware. This phase fulfills the theoretical requirements stipulated in the initial phase; in other words, this is the nuts-and-bolts phase.

3. *Observing and taking readings:* The testing stage begins with the recording of information as the preparation stage turns into test. The data can be recorded by a variety of means—manually, which involves direct observation, as well as by automated procedures, including facilities for storing the data obtained.
4. *Processing the recorded data and interpreting them:* Once the data have been amassed, experimenters arrive at the final phase of the scheme. To conclude the inquiry, that is, to obtain the final result, experimenters analyze the data and then recast them as evidence so that they can be put to use in either confirming or refuting a theoretical claim, or laying an altogether new foundation. This is the goal of the experiment. Two processes are therefore involved in this final phase: first, the process of reduction, of analyzing the data with a view to obtaining a coherent and consistent result, and, second, the process of interpreting the result—turning it into evidence.

Experimenters assume in the preparation stage a theory that is considered correct; it underpins the experiment. This theory, the background theory, and associated theories of the instruments and the setup itself are therefore taken for granted. They are not tested by the experiment. Then there is the process of realizing these theoretical requirements in practice. Once the theory and its physical realization have been put to work in the preparation stage, the second stage begins, namely, the test: Information is allowed to flow to the recording device. And, finally, a process of reducing the recorded data and interpreting the result takes place. This is the conclusion of the experiment—the outcome as experimental evidence. Clearly, this complex scheme, designed to generate knowledge, comprises many different categories and harbors intricate philosophical difficulties.

Philosophical Issues

Roles of Experiment

Experiments play critical roles in scientific methodology. They are designed, among other things, to test theories, to help articulate theories, to explore and call for new theories, to exhibit new phenomena, to create the conditions for effects, to offer evidence of new entities, to perform measurements, and, in general, to provide the basis for scientific knowledge.

Epistemology of Experiment

What is the ground for believing in the outcome of experiment? Experiment is a complex scheme involving a spectrum of categories, from theory and material realization through practice and skillful manipulation of instruments to stabilizing the result and interpreting it. In view of this complexity, why is it that experimental evidence is considered fundamental to scientific knowledge? What are the epistemic means for distinguishing between valid experimental results and artifacts that can lead one astray? The epistemology of experiment concerns, then, the reasons for believing in experimental results as physical knowledge. Since it seems impossible to infer deductively all experimental techniques, it remains to construct a list of strategies that are neither exclusive nor exhaustive. In the final analysis, experimenters believe that they can ground the results they obtained on physical arguments, that is, arguments that include physical assumptions. The stage of preparation may be considered a set of such presuppositions, while the test stage results in consequences "inferred" by some physical process.

Tacit Knowledge

One of the difficulties inherent in the epistemology of experiment is the fact that it relies on knowledge that cannot be expressed propositionally. This tacit knowledge may be described simply as skill. Experimenters develop skills that they acquire after spending much time with the system they experiment on. They cultivate a sensitivity for the setup, which essentially indicates when the experiment is functioning properly. This intuitive knowledge cannot be rendered rational in the strict sense of the term.

Regress

In the process of constructing the setup and running the experiment, experimenters make numerous assumptions. The most common of these is that the parts of the setup and their arrangement stand up to the required specifications. To be sure, it is possible to ascertain some of these assumptions by putting them to the test. However, since such tests involve

new preparations, a regressive sequence of preparations and tests results, which, for practical purposes, must be truncated. Moreover, experimenters have to ensure that the specifications are maintained while the experiment is carried out, or allow for any changes that may occur. An experimental apparatus that gives correct results is considered good, but there appear to be no formal criteria that can decide the issue of whether or not an experimental apparatus is working properly. An appeal to tacit knowledge is paramount.

Calibration

This is the process of determining the correct functioning of an apparatus. The essence of calibration is the comparison between a known magnitude, serving as a standard, and a measurement result of the apparatus. Such a ground is important for developing convincing arguments regarding the trustworthiness of experimental results. For example, it can help truncate the experimental regress.

Continuity

Conceptual and theory change does not bring about changes in the data obtained from experimental setups, apparatus, and measuring devices. Progress in theory and in experimental technique is not necessarily synchronized. The functioning of hardware is robust with respect to changes in concepts and theories, so that data remain intact across such changes. This fact amounts to continuity; the persistence of experimental results provides continuity across conceptual and theoretical changes. The slogan "Experiment has a life of its own" captures this continuity. Moreover, a setup may develop its own "career," detached from the theory that brought it about, thus becoming itself an object of research.

Experimental Errors

Experimental data are notoriously corrupted by various kinds of error introduced at all phases of the experiment. The standard practice is to appeal to the dichotomy of systematic and random error, but, from a philosophical perspective, this is not helpful. The dichotomy does not focus on the source of the error; rather, a mathematical criterion is applied. The criterion distinguishes between statistical analysis and nonstatistical methods, and it does not reflect the complexity of experiment, an ensemble of theories, materials, instruments, measuring devices, and, of course, experimenters. Sources of error are shaped by the different phases of the experimental procedure. Moreover, experimental results may be proved wrong, but even in those cases where everything turns out right, numerous pitfalls and confusions have to be overcome.

Experimenters are dealing not only with errors but also with misguided conceptions, dead ends, and reorientations. Still, the scientific method requires the use of data to assess the values of theoretical quantities. How is this done? One idea is to use error statistics in order to obtain a philosophical understanding of reasoning in science. Two modes are recognized, namely, the evidential-relationship approach and the "severe-testing" approach. The former is Bayesian, whereas the latter is a development of the classical Neyman-Pearson statistics. Such approaches probe experiment with error by characterizing the experimental (or testing) process itself as expressing how reliably the process discriminates between alternative hypotheses.

Constructivism Versus Rationalism

Despite the complexity of the experimental scheme and the many possible sources of error, there appears to be an understanding that consensus can be reached on experimental results. For the constructivist, this is a matter of contingency, the consequence of social brokering among individuals and powerful communities of researchers. By contrast, the rationalist holds that consensus can be reached because experimental results are trustworthy; they are the consequence of convincing arguments that reflect nature. In short, general metaphysical issues can be brought to bear on experiment, thereby creating a new context for old philosophical issues and extending traditional discussions of realism and objectivity to the empirical base of science. This becomes paramount when large research groups experiment with enormous systems on an industrial scale.

Experimental Systems

Many modern experimental procedures, especially in biology and the social sciences, no longer consist of single, well-defined experiments. Experimenters who construct systems of

experiments deal with systems that are not well-defined and do not provide clear-cut answers. As the working unit of experimental science at the cutting edge of research, experimental systems are designed to allow for surprising answers to questions that experimenters are not yet able to articulate. The experimental system is essentially hybrid; it is an assemblage of elements such as research objects, theories, technical arrangements, instruments, as well as disciplinary, institutional, social, and cultural apparatus. Such systems are open and, by design, have no clear boundaries. They thus pose new philosophical difficulties.

Experimental Philosophy

As with most topics in philosophy, there is no consensus on what *experimental philosophy* is. Most broadly, experimental philosophy involves using scientific methods to collect empirical data for the purpose of casting light on philosophical issues. Such a definition threatens to be too broad, however; for instance, taking the nature of matter to be a philosophical issue, research at the Large Hadron Collider would count as experimental philosophy.

Others have suggested narrower definitions, characterizing experimental philosophy in terms of the use of scientific methods to investigate intuitions. This threatens to be too narrow, however, as it would exclude work such as Eric Schwitzgebel's comparison of the rates of theft of ethics books with the rates of theft for similar volumes from other areas of philosophy, for the purpose of finding out whether philosophical training in ethics promotes moral behavior.

While restricting experimental philosophy to the study of intuitions is too narrow, this nonetheless covers most of the research in this area. Focusing on this research, this entry begins by discussing some of the methods that have been used by experimental philosophers. It will then distinguish between three types of goals that have guided experimental philosophers, illustrating these goals with some examples. Experimental philosophy provides the ground on which certain social-scientific disciplines and empirical approaches are used to draw conclusions on philosophical issues. It is sometimes said that experimental philosophy challenges "armchair philosophy."

Methods

In a typical study in experimental philosophy, the researcher uses the methods of experimental psychology to study the intuitions of some group of people—most often the intuitions of people without

training in philosophy (often called "the folk"). This is usually done by constructing one or more vignettes, or hypothetical stories, that are of philosophical interest. The vignette(s) are then presented to participants, who are asked to answer one or more questions related to the vignette, often on a 5- or 7-point scale. The researcher then analyzes the results, considering what the participants' responses reveal about the intuitions at issue.

While this describes the majority of the studies conducted so far, other approaches have also been employed. For example, Adam Arico, Brian Fiala, Robert Goldberg, and Shaun Nichols have measured reaction times to investigate the low-level cues involved in mental state attribution. Adam Feltz and Edward Cokely have used a personality inventory to investigate the influence of individual personality differences on intuitions. And Jonathan Livengood, Justin Sytsma, Adam Feltz, Richard Scheines, and Edouard Machery relied on a social-psychological questionnaire—Shane Frederick's Cognitive Reflection Test—to highlight an aspect of the philosophical temperament: Philosophers tend to be more critical of their spontaneous, "gut" intuitions than non-philosophers (even when one controls for the level of education).

Furthermore, there are a number of psychologists conducting research that can be readily classified as work in experimental philosophy. These researchers often employ methods that go beyond the use of vignettes to solicit intuitions. For example, Joshua Greene and colleagues have used *brain imagery* in investigating the processes generating moral judgments.

Goals

It is common for philosophers to turn their analytic gaze on their own discipline, and experimental philosophers are no exception: There has been a good deal of debate concerning how best to classify various projects in experimental philosophy. The most prominent distinction is based on experimental philosophers' attitudes toward the use of intuitions as evidence in philosophy. Advocates of the positive program support this use of intuitions but hold that empirical investigation is often needed to arrive at an adequate understanding of what those intuitions are. In contrast, advocates of the negative program are skeptical of the use of intuitions as evidence (even when supplemented by empirical investigations), and their empirical work is intended to substantiate their doubts regarding this practice. Furthermore, some work in experimental philosophy is not motivated by the question of whether intuitions can serve as evidence, but rather by an interest in people's intuitions themselves and in what they reveal about how people think about topics such as free will, the mind, or consciousness. We will say that such work belongs to the neutral program.

While it is often relatively easy to identify the goals of experimental philosophers, it is sometimes difficult to classify their work as belonging to one program or another. To illustrate, consider Sytsma and Machery's work investigating how people classify different types of mental states. This research examined the philosophical claim that phenomenal consciousness is an obvious aspect of our mental lives. If this claim is correct, then non-philosophers should tend to classify mental states in the same way that philosophers do. Their experimental work suggested that this is not the case, however; unlike philosophers, non-philosophers treated two prototypical examples of phenomenally conscious mental states (seeing red and feeling pain) differently, suggesting that they did not view them as being phenomenal. Rather, non-philosophers seem to categorize mental states into different groups depending on the extent to which they have an associated hedonic value (i.e., related to pleasure).

How should this work be classified? It might be thought of as an example of the positive program insofar as it investigates people's intuitions and calls on those results to make a philosophical argument. Alternatively, it might be construed as an example of the negative program: Taking the philosophers' claim to rest on their intuitions about different mental states, this work challenges the reliability of that supposed evidence. Finally, having found evidence that non-philosophers do not classify mental states in the same way that philosophers do, Sytsma and Machery went on to explore how non-philosophers classify mental states, taking this to be an interesting question in its own right.

Despite this shortcoming, the distinction between the positive, negative, and neutral programs does a good job of capturing some of the most prominent projects in the literature. This is perhaps most clear with regard to the negative program. For example, Edouard Machery, Ron Mallon, Shaun Nichols,

and Stephen Stich presented evidence that intuitions about the reference of proper names vary across cultures. They then argued that, lacking a principled reason to favor the intuitions of one group over another, the evidential value of such intuitions is called into question. Similarly, Stacey Swain, Joshua Alexander, and Jonathan Weinberg have provided evidence that people's disposition to ascribe knowledge sometimes varies depending on a seemingly irrelevant factor—whether or not the situation is contrasted with a clear case of knowledge. They then argued that this raises doubts about the evidential value of intuitions about knowledge.

Other prominent work in experimental philosophy is well classified in terms of the positive program. Consider the work of Eddy Nahmias, Steve Morris, Thomas Nadelhoffer, and Jason Turner on incompatibilism—the claim that free will and determinism are incompatible. Incompatibilist philosophers often assert that it is counterintuitive to hold that free will and determinism are compatible, concluding from this that in the absence of a decisive argument to the contrary, incompatibilism should be seen as the default position. Nahmias and colleagues undermined this argument by providing evidence that ordinary people take free will to be compatible with determinism.

Turning finally to the neutral program, Joshua Knobe found that when judging whether someone intentionally brought about a foreseen side effect, people are more likely to judge that a harmful side effect was brought about intentionally than a helpful side effect. On the basis of these and similar findings, he concluded that moral considerations play a significant role in folk psychology.

Experimenting Society, The

The idea of an *experimenting society* holds particular significance for philosophers and laypersons who seek greater understanding of the relationships between the methodology of the social sciences and public policy formation. The idea of social experimentation, while known to 19th-century thinkers such as August Comte and J. S. Mill, gained wide acceptance only in the era of the contemporary welfare state, when governmental programs were seen as appropriate means to solve problems of health, labor, education, and welfare. The idea of an entire experimenting society, however, originated in the writings of Donald T. Campbell (1916–1996), an applied social scientist and philosopher of science who during his remarkable 50-year career held regular and chaired professorships at the Ohio State, Northwestern, Syracuse, and Lehigh universities.

The Experimenting Society: A Methodological Utopia

In a widely circulated 1971 working paper titled "Methods for the Experimenting Society," the broad contours of the experimenting society were developed

as part of what Campbell viewed as an exercise in speculative utopian thought. Social scientists and policymakers, he argued, should attempt to find solutions to social problems through an open and self-critical process of social experimentation. Drawing on Karl Popper's *The Open Society and Its Enemies,* Campbell urged social scientists and policymakers to become a disputatious community of truth seekers.

Social scientists and policymakers would be servants of the experimenting society. They would justify their work on the basis of the seriousness of the problems facing societies, not on the basis of the supposed certainty of solutions to these problems put forth by social scientists, politicians, and "trapped administrators." There would be safeguards against the danger that social scientists become members of a self-serving elite, an elite that deliberately employs complicated statistical procedures and esoteric concepts and theories to render its ideas immune from criticism. Equally dangerous, however, is the false belief that social science advisors are inherently more knowledgeable than policymakers. In the experimenting society, policies would no longer be recommended as if they were certain to be successful, because the idea that one already knows precludes discovering through policy experimentation whether policies work or not.

Origins of the Experimenting Society

Contrary to conventional wisdom, the validity and practical relevance of social experimentation do not originate in the methods of the classical laboratory experiment or in the elegant field experiments conducted in the early 20th century to develop new statistical algorithms. This mistaken view is based on a failure to recognize that the experimenting society is not a mere extension of the randomized field experiment, a methodology developed for different purposes by Jerzy Neyman (1894–1981), a mathematical statistician, and Sir Ronald Fisher (1890–1962), a plant geneticist who, like Neyman, was a mathematical statistician.

On the contrary, Campbell based his work on early field experiments in education, including W. A. McCall's (1923) *How to Experiment in Education,* which presented views on randomization and research design that anticipated the work of Neyman, Fisher, and Gossett (aka "Student"). Their interests lay in theoretical subjects of probability and tests of statistical significance and not in improving schools, governments, or economies. The work of McCall was valued because of its practical contributions to knowledge about educational practice, not because of mathematical and statistical innovations such as random sampling, degrees of freedom, and the *t* and *F* distributions discovered by Gossett, Neyman, and Fisher.

The "True Experiment" as Ideal Type

The normative ideal of the experimenting society is the so-called true experiment—namely, an experiment in which an active intervention is randomly applied to randomly selected treatment and control groups, with the aim of establishing the causal relevance of the intervention (e.g., a new teaching method). The true experiment is a normative ideal by virtue of its specification of methodologically optimal procedures for testing the validity of causal inferences, inferences that relate one or more treatments, the presumed causes, to one or more treatment outcomes, the presumed effects.

The operational ideal of the experimenting society, however, is the *quasi-experiment,* namely, an experiment conducted outside the laboratory in a field setting where the random assignment of policies to randomly selected persons, groups, or contexts is impractical, illegal, or unethical. Although quasi-experiments may involve random selection of treatment and control groups (but not random assignment of a treatment to these groups), they are designed in and for complex field settings where manifold contingencies lie beyond the control of experimenters.

In contrast to the essentialist notion of causality, which contends that causal inferences must be based on joint necessary and sufficient conditions, the experimenting society proceeds from a recognition that a variety of uncontrollable contingencies are responsible for the complex causal texture of field settings, in contrast to the relatively simple causal texture of laboratory settings. This notion of *representative design* is important for understanding the differences between the simple problems addressed by true experimental design, and the complex problems addressed by quasi-experimental design.

The Theory of Representative Design

The theory of representative design, developed by Edward Tolman and Egon Brunswik, Campbell's

mentors at Berkeley, contends that optimally valid experiments should be carried out in the typical ecology in which interventions are expected to produce effects. The theory of representative design implies that it is not possible to control all or most contingencies, for example, through a standard pretest–posttest design with random assignment to treatment and control groups. To be sure, randomized clinical trials and other randomized experiments are carried out in field settings—for example, randomized clinical trials in biomedical research or agronomy. Nevertheless, the experimenters must contend with unmanageable contingencies by identifying and ruling out the influence of factors that lie outside their direct control. These effects are known as threats to validity, or plausible rival hypotheses, which typically combine with a policy intervention to render causal inferences equivocal.

The genius of Campbell and his collaborators was the insight that these unmanageable contingencies could be placed in a multifold classification scheme that contains a practically comprehensive set of more than 35 specific threats to the internal, external, construct, statistical, and context validity of causal inferences. The principal source today is Shadish, Cook, and Campbell's *Experimental and Quasi-Experimental Designs for Generalized Causal Inference,* a book that followed earlier seminal contributions in the 1960s and 1970s by Campbell and Stanley in *Experimental and Quasi-Experimental Designs for Research* and by Cook and Campbell in *Quasi-Experimentation: Design and Analysis Issues for Field Settings*. Together, these works are among the most widely cited sources on the methodology of field experiments in the social sciences.

Beyond Logical Positivism

At first glance, the methodology of quasi-experimental design in field settings may appear simply to be a variant of econometrics and other quantitative social science disciplines. However, quasi-experimental design, while employing multivariate statistical procedures to test and rule out rival hypotheses, is grounded in a post-positivist epistemology, methodology, and sociology of the social sciences. The post-positivist philosophy of the experimenting society stands in sharp contrast to the still thriving logical positivist sentiments of many social scientists, notwithstanding the abandonment of logical positivism by most philosophers of science by the mid-1950s.

A cardinal post-positivist tenet is the rejection of certainty as an attainable goal and its replacement by inductive plausibility as a defining characteristic of policy-relevant knowledge. For Campbell, the experience of "reality" is indirect and distal, mediated by a host of factors—psychological, social, political, economic, cultural—that render unattainable any notion of a complete correspondence of hypothesis and observation, word and object. In the experimenting society, we learn vicariously, by means of independently imperfect theories, methods, measures, and observers. The discovery of plausibly true beliefs—as distinguished from the justified true beliefs required by logical positivism—is an unending quest for approximate and socially contingent truths.

Coherence Theory of Truth

Policy-relevant knowledge demands a commitment to a particular philosophical theory of truth, the coherence theory of truth, which is distinct from the correspondence theory. The coherence theory asserts that truth arises from a comparison of two or more empirically grounded beliefs, in contrast to the correspondence theory, which asserts that truth arises from the agreement of beliefs with an erstwhile objective reality. In this context, social scientists are ethically bound to investigate the degree to which their empirically grounded beliefs cohere with those of other members of the experimenting society. The coherence theory rejects the logical-positivist claim that single operational measures define scientific concepts (mono-operationism). Instead, approximations to truth are achieved through multiple operational definitions (multiple operationism) and a strategy of multiple triangulation. In testing multiple theories, methods, observers, and observations, social scientists employ eliminative rather than enumerative induction. It is the falsifiability of knowledge claims, rather than their confirmability, that governs the process of testing and eliminating rival hypotheses, or threats to validity. These threats arise from the many unmanageable contingencies facing the experimenter.

The structures and processes of the experimenting society are closely related to the coherence theory of truth. The ideas of social scientists, policymakers, and citizens are brought together and examined

for their coherence, or lack thereof, in providing causally relevant explanations of why policies succeed or fail. Here, we see that experimentation is not the sole basis of what has come to be known as evidence-based policy; experimentation is not necessarily contrary to traditional wisdom based on the evolving experience of policymakers. The experimenting society is grounded in *evolutionary epistemology,* with experimentation best seen as a refining process superimposed upon cumulations of wise practice.

Experiments in Social Science

This entry reviews the kind of experimentation used in social science, delineates its essential aspects, and explains its role as well as the kind of validity appropriate in this case.

Controlled experiments in laboratory conditions are used in various branches of the social sciences. Whereas in some disciplines, like economics, experimentation is now part of the mainstream, in others, like political science, it is gaining a foothold with difficulty. Meanwhile, laboratory research is still considered marginal and is used only rarely by sociologists and anthropologists. Despite its controversial status, however, experimentation has always exerted an influence on those disciplines, like psychology, that use it regularly for the generation of scientific knowledge.

Measurement and Causal Inference

Experiments are designed for various purposes, the most important ones being *measurement* and *causal inference*.

When experiments are used as measurement devices, the goal is to detect and quantify a variable of theoretical interest. For example, one may want to measure the degree of cooperativeness of individuals belonging to a certain population, or their prosocial preferences in a controlled setting. *Replicability* and *robustness* are important virtues of experimental measures: Different research teams following identical protocols should generate statistically identical measures (replicability), and it should be possible to obtain the same measures using different measurement techniques (robustness).

Measurement in social science is rarely aimed at the determination of theoretical constants that hold universally but rather at the discovery and quantitative testing of *causal hypotheses*. In a competently performed experiment, each treatment or condition is designed so as to introduce variation in one (and only one) potential causal factor. Controlled experimentation thus allows underlying causal relations to become manifest at the level of empirical regularities. In a competently performed experiment, single causal connections can be "read off" directly from statistical associations.

Causal discovery requires variation—but not too much variation—and of the right kind. In general, one wants variation in one factor while keeping all the other putative causes fixed "in the background." This logic is exemplified in the *model of the perfectly controlled experiment* (see Table 1).

Table 1 The Perfectly Controlled Experimental Design

	Treatment (Putative Cause)	*Putative Effect*	*Other Factors (K)*
Experimental group	*X*	Y_1	Constant
Control group	—	Y_2	Constant

Source: Author.

The *Ki* are background factors, or other causes that are kept fixed across the experimental conditions. The conditions must differ with respect to just one factor (*X*, the treatment), so that any significant difference in the observed values of *Y* (Y_1–Y_2) can be attributed to the presence (or absence) of *X*. A good experimenter thus is able to discover *why* one kind of event is associated regularly with another kind of event—and not just that it does. In the model of the perfectly controlled experiment, one does not simply observe that "if *X* happens then *Y* happens" or even that "*X* if and only if *Y*." Both conditionals are material implications, and their truth conditions depend on what happens to be the case, regardless of the reasons *why* it is so. In science in contrast—and especially in those disciplines that regularly inform policy making, like the social sciences—one is also interested in "what would be the case if" such and such a variable was manipulated. Scientific intervention and policy making must rely on *counterfactual reasoning*. A great advantage of experimentation is that it allows checking what would happen if *X* were *not* the case, while keeping all the other relevant conditions fixed.

This marks an important *difference* between the experimental method and traditional statistical inferences from field data. Using statistical techniques, one can establish the strength of various correlations between economic variables. But except in some special or opportune conditions, the spontaneous variations found in the data do not warrant the drawing of specific causal inferences. This does not mean that total experimental control is always achieved in the laboratory. The perfectly controlled experiment is an idealization, and in reality there are always going to be uncontrolled background factors, errors of measurement, and so forth. To neutralize these imperfections, experimenters use various techniques, like, for example, *randomization*. In a randomized experiment, subjects are assigned to the various experimental conditions by a chance device, so that in the long run the potential errors and deviations are evenly distributed across them.

Internal and External Validity

Scientists are aware that the successful discovery and testing of causal claims does not automatically ensure that these claims can be generalized to nonexperimental circumstances. For this reason, distinguish between the *internal* and the *external validity* of experimental results. Problems of internal validity have to do with the drawing of inferences from experimental data to causal mechanisms in a given laboratory setup. External validity problems instead have to do with the drawing of inferences from experimental data to what happens in other (typically, nonlaboratory) situations of interest. External validity inferences rely on the effective combination of field and experimental data. Recent approaches to external validity include *analogical reasoning* (propounded by Guala) and *comparative process tracing* (propounded by Steel).

Experiments in the Social Sciences: Ethical Issues

Experiments, long the standard research setting in biology, chemistry, and physics, are increasingly important in the social sciences for testing derivations from theories. Experiments are research designs in which the investigator controls the level of one or more independent variables *before* measuring the dependent variable(s). The *control* and *time* elements distinguish experiments from other designs common in the social sciences, such as observation studies and ethnographies, surveys, content analyses, and historical descriptions.

Control, of course, introduces ethical issues, including responsibility of the experimenter. Experiments in the social sciences usually involve human participants, and that fact too entails ethical considerations. (Animal experimentation, not dealt with here, involves some comparable and some different ethical considerations.) The overriding ethical concern with human experimental participants is to protect their well-being throughout, even, where possible, improving it through new insights and experiences.

Professional and Governmental Guidelines

Professional societies, to which almost all faculty and organizational researchers belong, publish ethical guidelines for experiments involving humans. For instance, the American Psychological Association (APA) requires that psychologists "respect the dignity and worth of all people, and the rights of individuals to privacy, confidentiality, and self-determination," and the American Sociological Association (ASA) echoes that principle. APA, ASA, and other professional associations spell out the meanings of that principle in detail. Since 1979, U.S. governmental funding agencies, which support much of the social science research in the United States, have subscribed to a "Common Rule" for research protections. The European Parliament has passed some comparable regulatory requirements, though emphasizing pharmaceutical research.[1] While such guidelines go a long way toward ensuring ethical treatment, like all rules, they depend on interpretation and application by well-intentioned and knowledgeable researchers.

Issues in Designing Research With Humans

Designing experiments requires thorough planning, and it is helpful to remember the purpose of experimental designs: It is to compare outcomes (dependent variables—usually behavior and cognitive responses) among individuals in different groups that are alike except for the factors (the independent variables) under test. The requirement of similarity means that an experiment properly begins with the first contact—usually the recruiting of participants—and does not end until they have been escorted to the hallway and thanked after their participation. Experimenters should stick to scripts as much as possible. In particular, the recruiting process must be uniform; all potential participants should be solicited in the same ways, given the same information, offered the same incentives for participation, and so on.

Incentives

Participants may be solicited with a number of incentives, such as money, interest, and course credit. In the United States, introductory psychology courses routinely require students to sign up for research or other projects. Other social sciences and nonuniversity research organizations in the United States and most researchers in Europe are more likely to offer monetary payment. Naturally, institutional review boards (IRBs) look especially closely at proposed research with "vulnerable populations," including schoolchildren and prisoners, who may not be completely free to choose whether to participate. Studies have not found consistent effects of the main distinction —payment or course credit as incentives—so long as participants are treated considerately and respectfully, as, of course, they always should be.

Besides moral concerns, if participants feel that they have been mistreated or coerced, they can always behave in a bizarre fashion and produce misleading data. On the positive side, it seems that most participants volunteer out of interest and to

learn, rather than for money or course credit. When part of the incentive is entry in a drawing for money at the conclusion of the experimental runs, it often happens that not all of those who are notified turn up to claim their winnings.

General Design Issues

Along with scientific issues of design and operation, there should always be a concern for respectful, considerate treatment of the people who volunteer to participate in research. This extends even to a seemingly small matter such as word choice. People are "participants," not "subjects"; they will participate in a "study," not an "experiment," which has unwanted connotations for some; it is more respectful to ask how someone "responded" to something rather than the more passive "reacted." Researchers should keep in mind common sources of discomfort, such as potential public embarrassment or violations of privacy, and do whatever they can to assure participants that the research will not bring them those unwanted consequences.

Even with such attention to detail, many experimental designs necessarily include stressful aspects. Some ask participants to work on tasks at which they may do poorly; others ask them to make decisions pitting their own benefits against other people's. It is the researcher's responsibility to anticipate, reduce, and afterward to overcome any stressful elements of the experience. Participants deserve a complete post-session interview and explanation. The researcher must explain all aspects of the experiment—what the arrangements were and why, what the research questions were, and how the participant helped. The explanation must be in terms accessible to a normal member of the population, not in technical terms. Each person who participated in an experiment must feel that he or she has a good understanding of what he or she did, why the experiment was designed as it was, how the information is useful, how he or she contributed to the work, and what he or she gained from the experience.

Well-planned individual interviews are best for explaining an experiment, although sometimes that is not practical—for instance, when the number of participants in each group exceeds the number of researchers. In such cases, a group explanation, oral or written, may be used. Pretesting, in which individual interviews are conducted, is especially important here. In every case, whether individual or group explanations, each participant should be made to feel that he or she can ask for any clarification. Also, participants should be provided a contact point, such as an e-mail address, in case they have any questions later.

Deception

Some social science experiments are deceptive (e.g., the Milgram experiment—see below, also the Asch experiment); the designs do not always tell participants everything about the situation prior to their participation, and sometimes the design includes giving false information. There are many reasons for designs using deception. Sometimes the reason is to avoid self-presentation concerns affecting behavior: Studies of racial and gender bias are particularly sensitive to that. Or a design may test a theoretical derivation that occurs only rarely in natural settings, such as how often people will conform to others who they know for sure are saying something untrue. Sometimes the reason is efficiency: A theory under test might predict how likely interactants are to accept influence when someone disagrees with them, and a research design might therefore tell interactants that they are in disagreement much more often than they actually are, to avoid wasting everyone's time with instances where they do not disagree.

For those and other reasons, deception is a feature of experiments in most of the social sciences. Ethical codes and government regulations permit deception if it does not unduly stress or otherwise endanger participants, if there is no nondeceptive way to study the phenomena, and if the benefits to participants and to society outweigh possible negative effects on participants. Furthermore, the deceptive aspects must be fully explained as soon as possible after the data are collected. Deceptive research designs receive special scrutiny from IRBs, for obvious reasons.

Contamination

Contamination means something simple in reference to experimental research: talking about it in a way that hurts new data collection. Suppose that a research design involves deception, and suppose further that someone who has participated tells her friends about it. If they participate in the study later, they won't believe some elements, and so data from their sessions may be useless. Worse, even if they later participate in a nondeceptive design, they may

be suspicious, and that could affect their responses. The population would be contaminated.

Many economists, including economists who conduct experimental research, believe that deception should never be a part of experiments for that reason. They argue that any deception will contaminate a population, such as the student body of an entire university, and so make results of further experimental research invalid. Of course, it would not matter whether the deception causing contamination was done by an economist or, say, a psychologist, so this perspective leads to a view that nobody should be allowed to do research including deception.

This issue is far from settled. However, two points may be helpful.

First, the objection presumes that contamination will follow deception. Whether or not that happens depends on whether participants feel that they have been mistreated. If they do feel mistreated, it is easy to shut down a project by talking about it. On the other hand, if the researcher has treated participants well, they are likely to want to help with the research and keep confidence about it if they are asked to do so. The economists' objection is on empirical grounds, not ethical, and we do have evidence. Psychologists and sociologists have been conducting experiments, some of them including deception, for more than half a century, and reports of contamination hindering the research are rare or nonexistent.

Second, the ethical issue here is not whether to use deception. Economists' objections are on practical grounds, contamination, not on whether deception is ethically acceptable. The ethical issue is how much right one group of scholars—economists—has to restrict the activities of others—psychologists, sociologists, political scientists, and the rest. On one side, if, say, sociologists contaminated a pool, that would adversely affect economics researchers, and so they ought to have a say. On the other side, the issue of one scholarly group telling another how to conduct their lives may be troublesome. This debate seems unlikely to be resolved soon. One positive outcome is to underline the importance of respectful treatment of participants throughout, including full explanations afterward.

"Risk" and Psychological Stress

Historically, U.S. government rules for the protection of human subjects arose in response to some egregious misuse of humans in medical, not social, research. Among the protections was a requirement for *informed consent.* A person must know about a proposed treatment, any alternatives, and possible risks and benefits before agreeing to participate. While informed consent is essential for medical studies, it is not a full solution to ethical issues in social research.

The possible risks of participation in social research usually are social-psychological rather than physical: anxiety, discomfort, stress, worry about self-presentation, and so on. As noted above, researchers have the duty to anticipate and minimize these stresses when designing experiments. Why is informed consent not a full solution? Because most of us are not very good at anticipating how we will respond to new situations, or even whether a particular situation will be stressful for us.

In a notorious experiment conducted by the psychologist Stanley Milgram some decades ago, participants were told that they must administer electric shocks to another participant to punish him when he gave wrong answers on a test. The shocks were not real, and that fact was explained to participants afterward, but during the experiment the simulated pain of the person supposedly being shocked was vivid. If we ask college students now how that would affect them once they learned the shocks were not real, they say that they might be worried during the session but would feel fine once they learned the shocks were not real. Yet in the actual case, some participants reported sleep problems, even nightmares, weeks afterward.

A similar effect has been reported from much less dramatic experiments where participants played a game in which either they could win money by contributing to a group pool that would be split or they could win even more by failing to contribute while everyone else contributed. (Technically, this is a "mixed-motive deficient-equilibrium" game. This research did not involve deception.) Some participants who won by failing to contribute called the researchers days or weeks afterward, again reporting significant bad feelings and wanting to return the money they had won. The point is the same: We are not good at estimating how stressful strange experiences will be for us.

Therefore, it is the responsibility of researchers to anticipate and to minimize or eliminate sources of stress. Informed consent of participants, while important, is not enough. Researchers, social scientists by training and experience, ought to know better than untrained college students or other citizens

which aspects of a particular experiment might be stressful and how to deal with those. Again, researchers have an ethical responsibility to know what to do to protect participants and to implement that knowledge in research design and operations.

Ethical Experiments

The experimental method is not inherently ethical or otherwise, although particular experiments might be designed and conducted ethically or otherwise. Every step of the research process requires planning and monitoring; there is no once-and-for-all way to promote ethics in experimental research. Experimental researchers enter an ethical contract with humans who volunteer, even for incentives, to participate in the enterprise. To be worthy of that trust, researchers must use knowledge, sensitivity, and respect for their participants and for other scholars. In other words, researchers must fully acknowledge their humanity.

Explanation, Theories of

The concept of *explanation* as a subject for philosophical study, distinct from that of *knowledge* or *science,* came into its own in the 20th century and was fundamentally shaped by the initial contributions of Carl Hempel and Paul Oppenheim, although it can be argued that many systematic thinkers, such as Aristotle, held views that deserve attention in connection with the subject.

A theory of (scientific) explanation must answer these questions: What constitutes an explanation in science; whether different scientific subdisciplines proffer different products by way of explanation; whether therefore there are different species under the genus of explanation, and if so how they are related; and also how the genus of explanations that qualify as scientific differ from anything else that are referred to as explanations outside such contexts.

This entry surveys briefly the top contenders by way of philosophical theories of scientific explanation and then examines some of the distinctive philosophical issues raised for the topic of explanation by the social sciences.

Some History of the Topic

Aristotle's theory of science was one and the same as his theory of knowledge, which he understood as inquiry for its own sake. He held that inquiry falls into natural categories that today we might refer to as disciplines, and his primary contrast was that

between *knowledge* (the product of inquiry for its own sake, needing to serve no further end) and *common sense* (which serves many useful ends). Aristotle maintained that standards of inquiry varied across disciplines: for example, that logic and mathematics had standards of proof that differ from standards of evidence in the study of nature or in politics (which for Aristotle was also a discipline). And he was clear that common sense is not a form of knowledge because common sense has no standards at all. It is not a discipline but simply the result of a kind of practical activity of human life and so is to be evaluated by its serviceability in those activities.

Aristotle's theory of science had sought to answer the two most important questions in the area of (scientific) explanation: (1) How does a (scientific) explanation of something differ from a mere description or explication (or anything else) of it? (2) What makes such an explanation actually scientific, rather than something else? Aristotle's answers are that (1) scientific inquiry results in an understanding of essences, first principles, and definitions of key (discipline-defining) concepts that can be organized in syllogistic form and that answer the question "Why?"and (2) scientific inquiry is governed by norms orienting it toward truth—norms that do not govern common sense.

However, until we are presented with a clear sense of what the truth-orienting norms of science are and how it is possible to fall afoul of them, any pursuit or community of seekers can claim that it is governed by truth-orienting standards—from phrenology to the various forms of divination—particularly if the so-called norms explicitly provide that the uninitiated have no access (legitimate or otherwise) to its true (and possibley also actively shrouded) practice. Until philosophical light illuminates the norms associated with science proper, anything practiced in the shadows could raise itself to an unwarranted height. This is the gap that Karl Popper sought to fill in the early part of the 20th century—and for which he has rightly been widely esteemed by the scientific community.

Popper made it his fundamental concern to demarcate between science, as such, and things of lesser dignity. To this end, he focused on the idea of scientific progress—that certain ideas could be advanced ahead of others that precede them in order of appearance before the tribunal of science. Like many of his contemporaries, Popper took note of the fact that observation alone could not advance a hypothesis (of scientific credentials) ahead of its competitors, since any given body of observations will be consistent with numerous and mutually incompatible bodies of theory. And he brilliantly maintained that the core of a philosophy of science would account for how an idea, however initially outrageous in its original context, can grow in scientific stature, to the point of eclipsing or even displacing older, better-positioned, and perhaps even better-regarded theories. This account would spell out the method of scientific comparison, of the testing of one eligible hypothesis against another. For the distinction of "scientific method," Popper proposed the method of *falsification*. According to this account, theory is scientific to the extent that it excludes or prohibits certain possibilities that are in principle observable—and is ipso facto falsifiable; and conversely, it is corroborated to the extent that it survives tests aimed at falsifying it. Popper's critics were later to argue that the method does little in the way of providing a theory of comparisons—it is merely a measure of the severest test of a hypothesis and not against other theories but against nature itself. And rarely are the conditions for such a severe test available, because hypotheses can be shielded from falsification in numerous ways (that we need not discuss here). The point to note here is simply that Popper's contributions occasioned the philosophical community to mark an important distinction vis-à-vis the functions of scientific theory: On the one hand, scientific hypotheses receive attention as objects of scrutiny—by being subjected to *confirmational testing* (and of course on this matter, Popper's proposal is that they be subjected to *falsification*); and once so scrutinized (and surviving scrutiny), scientific hypotheses might subsequently be called on to perform a range of other services to which the label of *explanation* might be appropriate. Not everything eligible for scrutiny (eligible for conformational testing) is called on to perform the task of explanation. Theories of explanation take up the subject of what Popper leaves largely unelucidated in Aristotle's theory of science.

The first—and still most influential—theory to tackle the question of explanation in the 20th century is quite closely aligned with the first of Aristotle's answers. The *deductive-nomological* (DN) model of explanation was put forward by

Hempel and Oppenheim. The DN model drew an enormous quantity of criticism—all testifying to the philosophical importance of getting the account of explanation right. Some critics (e.g., W. Salmon and H. Kyburg) charged that DN allows too much to count as scientific explanation; others (e.g., M. Scriven) claimed that it disallowed too much from qualifying as genuine scientific explanations. The criticism of DN sparked a large literature, indeed an entire branch or industry in philosophy, that continues to bear fruit to this day. Efforts to meet some of the criticism resulted in the *causal-mechanical* (CM) model of explanation and the *unificationist* model of explanation—both attracting criticism of their own.

The CM model, propounded by Wesley Salmon in 1984, reflects the influential ideas on causation first expressed in the work of Hans Reichenbach. There have been a number of different ways of filling out the details of a CM model, each with different strengths and weaknesses but all sharing the fundamental idea that explanation of something must cite its causes. The different articulations differ in how they conceptualize a cause but are united in the single thought that DN explanations fail precisely when they neglect to cite causes. Of course, the CM models also have their critics. One of the most influential has been Philip Kitcher, who advanced instead the conception of explanation as the drawing together, into a more unified account or formulation, of a range of different phenomena. This would show how a range of apparently different facts or events can be profoundly illuminating. And such demonstrations have doubtless played an important role in the history of science: Isaac Newton's theory of gravitation wrought a unification of terrestrial and celestial motion, and James Clerk Maxwell's electromagnetic theory wrought a unification of electricity and magnetism—and the theory of light. Such unifications are greatly important for the advancement of science, but one might wonder whether unification is always required for explanation.

Another prominent contender on the topic of explanation in science (the last we will examine here) takes this question seriously, answering that there is no one single requirement of explanation. The logic of explanation, on this account due to Bas van Fraasen, is the logic of question and answer—more specifically, the logic of answers to why-questions. And since the proper answer to a given why-question depends on the reasons for which the question was posed in the first place, the logic of answers to why-questions must do so as well: There are a number of different profiles of question-and-answer communications, each with its own standards and requirements. Requests for explanation thus fall under a logic of communication.

The Genus Conception

The sciences have proliferated since the beginning of the 20th century. And with a growing appreciation of this variety that is science, philosophy is itself maturing vis-à-vis the philosophical topic of scientific explanation. A recent move in this philosophical space has been to suggest that explanation might be a genus, with several species falling under it sharing nothing especially obvious in form or overt presentation. Furthermore, to identify and articulate the form or structure of each species of explanation, one must gain an appreciation of the producing scientific subdisciplines and their subject matters. With this and related ideas, reductionism as the dominant approach in the metaphysics of science is also waning. Rather than espousing the idea that the laws of nature are basically the laws of physics, and that everything else comes in some sense "for free" once these are in place, philosophers are now in large numbers endorsing the notion of *emergence,* according to which new features (and so also new laws of nature) appear at a variety of levels of organization of matter. And these laws are not in some sense already contained in the laws of physics. In other words, theories devised in the discipline of physics are emphatically not theories that can even remotely cover everything.

Issues Raised by the Social Sciences

The social sciences bring a host of topics to the table. We have already mentioned the larger issue of reductionism, which bears also on the social sciences: Are the phenomena that are salient at a scale of social organization simply the result of more elemental facts about the relevant organisms, their constituents, and the situation? Are they, in other words, a kind of cipher for phenomena that belong more properly to the sciences that deal with smaller-scale entities, or do they rather possess a dignity of their own, demanding explanations that draw on features that appear only at larger scales of analysis?

These are questions that can be asked of any scientific enterprise outside physics (or even inside it). But associated with the social sciences are issues that get entangled with these larger issues in special ways, a topic to which we will now turn.

Are Social Sciences Different From Natural Sciences?

Economists by and large take individual consumption or investment behavior as the basic datum of their discipline; and sociologists include other categories of individual human behavior as basic. More generally, the social sciences take human individuals as the "fundamental" units of study (the smallest unit of the world that generate relevant data for their disciplines), even if their particular disciplinary focus is primarily on institutions and large-scale properties of social organizations or communities—in much the same way that the fundamental units studied in chemistry are atoms, even if the focus in the discipline is primarily on chemical processes and their properties on a larger scale. This truth is a double-edged sword. On the one hand, it provides social scientists with tools that enhance insight into a given phenomenon under study (the scientists can utilize such insights as they might have into human behavior, perhaps from first-person experience). On the other, it suggests a divide—indeed a veritable chasm—between the natural and the social sciences.

A school of thought in the 20th century called *interpretivism,* brought to prominence in the writings of the British philosophers R. G. Collingwood and Peter Winch and tracing its origins to Wilhelm Dilthey (1833–1911), has taught that natural and social sciences are fundamentally different: The former deal with broadly causal processes, whereas the latter do not. The character of the phenomena with which social sciences deal is construed by thinkers in this school as importantly different because their springs or grounds are what we refer to in common parlance as "reasons." Reasons also give actions their *meaning*—something that is not local to the action itself. Reasons have their life in the practices of redescription, which allow us to grasp the point (the purpose) of an action within its setting of rules, practices, conventions, and expectations—in other words, to place it in a wider setting that affords evaluation as to its rationality or as to some other form of appropriateness. And this—as they insist—is a normative rather than a purely descriptive or explanatory setting. And so the relations between an action and its ground cannot, on this view, be purely descriptive, or purely causal. And since meanings cannot be left out of any complete account of human behavior, a study of meanings cannot be purely a naturalistic discipline. An explanation in social science must always draw on acts of interpretation performed by (human) scientists.

And this suggests a parallel between the social and the natural sciences, vis-à-vis the topic of reduction: If natural sciences are beholden in a fundamental way to physics as ontologically the most basic, social sciences are beholden in a fundamental way to human action as ontologically basic. The phenomena of social sciences might then be reducible to that level—but no further. Indeed they *must* be reducible to that level, as yet another set of teachings declared.

Max Weber (*Economy and Society* [1978]), founder of the dominant *verstehende* school of social science, addressed a fundamental question of methodology in sociology—the question of how to conceive of actions and the agents who author them. Regarding multi-individual collectivities and institutions, he wrote, "In sociological work these collectivities must be treated as solely the resultants and modes of organization of the particular acts of individual persons, since these alone can be treated as agents in a course of subjectively understandable action" (1978, p. 13). In other words, Weber proposed reserving the term *action* for human behavior that proceeds from the machinations of an individual human mind that conceptualizes (or, in the language of the school Weber would eventually establish, *understands*) the behavior in question in a particular way. This concept of action is, far and away, the most enduring legacy of the *verstehen* school of social science. It issues in what is now referred to as *methodological individualism,* according to which the individual is the one and only unit of agency, because (again according to the doctrine) the individual is the one and only unit in which meaning and understanding, as rational enterprises, are manifest. This doctrine now dominates the social sciences, having worked to displace methodologies sympathetic to classical sociology. Many proponents of the idea propose Decision Theory, under an individualistic reading, as the explanatory fundamental of all social sciences.

While the doctrine of methodological individualism is widely criticized today, it is also widely embraced (at least where it is proposed that individualistic Decision Theory must be the queen of the social sciences), in some cases by the same researchers. And this too cries out for philosophical attention.

Statistical Laws

Émile Durkheim (1858–1913) was a pioneer of the discipline of sociology in France. In 1897, he published a seminal work, *Suicide,* a demographic study of the differences in suicide rates among Catholic and Protestant populations in Europe. The data indicated lower suicide rates among Catholics. And these facts occasioned an ingenious application —perhaps even a test—of the concept most closely associated with Durkheim's name: the concept of *solidarity* (or *integration* as it is sometimes translated). Durkheim argued that the higher level of solidarity among Catholic populations tends to protect against causes of suicide.

Durkheim reasoned that in modern societies, by contrast with traditional ones, the highly complex division of labor results in "organic solidarity." This is a condition in which different specializations in employment and social roles create dependencies that tie people to one another. In less modern societies, which he referred to as "mechanical societies," held together by "mechanical solidarity," subsistence farmers live in communities that are self-sufficient and knit together by a common heritage. Mechanical solidarity thus comes from homogeneity, when people feel connected through similar work, educational and religious training, and lifestyle. Mechanical solidarity is thus wrought by a sameness of mind and thought. However, an increasing division of labor begets a more diverse and varied individual consciousness. "Individualism" emerges as distinct from collective or common consciousness. And the individual often finds himself or herself in conflict with such collective or common consciousness as there might sometimes seem to be. This proposition can thus lead to predictions, as much as it leads to explanations, of observed data.

But how, precisely, does a proposition (e.g., to the effect that higher levels of integration protect against suicide) explain an instance of suicide? When someone from a Catholic community, or a Protestant community, commits suicide, how does Durkheim's theory apply? Should Durkheim's theory be understood as explaining the suicide of a given Catholic or a given Protestant recorded in the data? How can it explain both? And what exactly can it mean to say that a certain suicide was due to a certain level of organic solidarity in the relevant community? This is a question that might be brought against any statistical theory dealing with large-scale variables—whether it is suicide rates, college admission rates, or rates of alpha decay in a radioactive substance. But the question has a special poignancy when the topic is suicide rates. Here is the reason why.

All the same logical issues of how a statistical (nonuniversal) generalization explains an episode (whether positive or negative for the property in question—decay or suicide) apply. But in the case of an explanation in social sciences such as sociology, the predictions are rarely if ever precise: "More" or "less" is the rule. (Economics tends to generate more precise predictions, though again nowhere near as precise as the theory of spontaneous nuclear radiation.) Being less exact, the social sciences seem to have to work harder to legitimize their statistical theories as explanations.

Durkheim, for instance, has been criticized for committing the so-called ecological fallacy—the error of assuming that a member of a studied population possesses the average characteristics of the entire population as a whole. But the theory of spontaneous radiation is not criticized, although it makes the same move: A sample of plutonium is measured to possess a half-life, and immediately each plutonium atom is assigned the half-life of the sample utilized to make the initial measurement. And this half-life property is invoked in explanation of both individual events of radiation and collective events. The specter of fallacy does not loom, in spite of more recent discussion on the topic of what exactly a statistical "law" is supposed to explain.

What Is Being Explained?

Durkheim was very clear: Sociology is a science of structures. He himself never took individual events—such as incidents of suicide—as the subject of sociology. He was always clear that the science of sociology is a science of institutions and large-scale social facts—and that social structures, such as those

to which sociology drew attention, in turn explain the social facts. Taking Durkheim at his word, we should say that sociology never explains individual events or individual human actions. Sociology explains the differences between different incident rates in different populations. That is all.

But if this is right, then explanation in sociology cannot possibly be construed as falling under the DN model of explanation—at least not in that model's simple form. And if this is right, then it should have some consequences for how we think about statistical laws in physics too: We should not allow the "ecological fallacy" to go unpunished in theories of radioactivity. So in the end, the differences between the sciences—insofar as there are true differences—will serve as important data (as the genus conception of explanation suggests) for more subtle accounts of scientific explanation itself.

Explanation Versus Understanding

The distinction between explanation and understanding, taken as two different modes of inquiry, derives from basic features of modern Western philosophy, as articulated chiefly by René Descartes in the 17th century. In his epistemology, Descartes distinguished between an internal and an external realm: mind and body, *cogito* and *res extensa* (extended matter). While the former yielded to philosophical and psychological inspection, material or "natural" phenomena required a "scientific" approach leading to the causal explanation and

prediction of their occurrence. The division was continued in Enlightenment philosophy and, in due course, gave rise to efforts to delineate in ever more precise terms the separation of types of inquiry in the "republic of knowledge."

Naturwissenschaften, Geisteswissenschaften, and *Kulturwissenschaften:* Dilthey and Rickert

During the 19th century, the most prominent distinction was that between the natural and "mental" sciences, the *Naturwissenschaften* and *Geisteswissenschaften,* the former devoted to the explanation of natural processes and the latter to the understanding of "meaning." The most famous proponent of *Geisteswissenschaften* during this period was the philosopher and historian Wilhelm Dilthey (1833–1911). For Dilthey, the recovery of meaning served chiefly as a bulwark to stem the rising tide of "positivist" science. His arguments were directed primarily against British spokesmen of positivist empiricism, such as John Stuart Mill, but one should note some subterranean ties that link him to his opponents. Although an advocate of empiricist methodology for the purposes of sociological inquiry, Mill as a political theorist was also a great defender of liberal individualism; whatever his other preferences, Dilthey shared at least Mill's latter premise, although individualism in his view referred not so much to the ownership of possessions as to the capability of designing cultural artifacts. In elaborating his cultural and historical methodology, Dilthey drew heavily on the teachings of Friedrich Schleiermacher (1768–1834), a distinguished philosopher and theologian of the Romantic period, and also on the writings of the German "historical school." Both Schleiermacher and 19th-century German historians were strongly committed to the notion of *individuality,* construed as a microcosm or as the focal point of a given historical and cultural context.

Dilthey's outlook was molded not only by individualism but also, at least in his early writings, by what has been called *psychologism*. The choice of the term *Geisteswissenschaften* ("mental sciences") was itself an indication that the distinctive feature of the proposed approach was its focus on internal, psychic experience as contrasted to the occurrences of external nature. The basic task of the *Geisteswissenschaften,* which, in Dilthey's view, included history, the humanities, and even part of the social sciences, was to examine manifestations of human creativity and intentionality with the goal of recapturing in past documents and cultural records the original spirit that animated their authors. According to Dilthey, this type of inquiry was bound to produce more reliable and more intelligible results than any other cognitive endeavor, since, in his words, "only what mind has produced, mind can fully understand." The occurrences of the natural or physical world, on the other hand, were relatively opaque and could be rendered accessible only by means of the abstract explanatory constructs of natural science disclosing lawlike uniformities and causal connections: "Nature we explain; psychic life we understand [*verstehen*]."

Obviously, in its reliance on internal experience, Dilthey's approach could serve as a barrier to positivist hegemony only as long as the "mind" and "psyche" were themselves immune from scientific explanation. One of the chief developments during his life, however, was precisely the transformation of psychology into an empirical discipline. On this score, his strategy thus needed to be corrected—and was corrected by, among others, a group of Neo-Kantian thinkers led by Heinrich Rickert (1863–1936), who otherwise were wholly in sympathy with his antipositivist stance. In Rickert's writings, the remedy resided in recourse to the Kantian distinction between facts and (transtemporal) norms; this distinction, he argued, was crucial not only for combating "psychologism" but also for finding an ordering principle in history. Only through their relationship to normative values could historical events acquire cultural significance; for this reason, Dilthey's approach was recast by Rickert under the label of "cultural sciences" (*Kulturwissenschaften*).

Max Weber and Meaningful Action

The bifurcation of the natural and cultural sciences became a cornerstone of Max Weber's (1864–1920) sociology, although one should keep in mind that his methodological views underwent subtle modifications over the years. His early essay on "'Objectivity' in Social Science and Social Policy" (published in 1904) faithfully reflected Rickert's teachings. Sociology was presented by Weber (2011) as one of the cultural sciences, and the latter were defined as "those disciplines which analyze the phenomena of life in terms of their

cultural significance." The significance of cultural events was said to derive from a "value-orientation" toward these events, since "empirical reality becomes 'culture' to us because and insofar as we relate it to value ideas" (p. 76). The examination of social phenomena in terms of cultural meaning, Weber added, was "entirely different from the analysis of reality in terms of laws and general concepts" (p. 77)—although the focus on causal and logical relationships performed an important "preliminary task."

Similar notions can still be found in Weber's monumental study titled *Economy and Society* (published posthumously in 1921), but the gap between cultural understanding and causal analysis was narrowed, and sociology was treated more clearly as a general or systematic science. Weber (1978) defined sociology as "a science which attempts the interpretive understanding of social action" (p. 4), where the term *action* covered "all human behavior when and insofar as the acting individual attaches a subjective meaning to it" (p. 4), while *social* implied that the action "takes account of the behavior of others and is thereby oriented in its course" (p. 4). Meaningful action was segregated in the study from merely externally induced or "reactive behavior" unrelated to an "intended purpose"; but Weber cautioned that the dividing line could not "be sharply drawn empirically" (p. 4). Regarding the notion of action, one should add that it referred only to "the behavior of one or more *individual* human beings" (p. 13)—a carryover of Dilthey's (and Rickert's) individualism. Social aggregates or groupings, in Weber's (1978) view, could never constitute genuine units of analysis.

> For the subjective interpretation of action in sociological work these collectivities must be treated as *solely* the resultants and modes of organization of the particular acts of individual persons, since these alone can be treated as agents in a course of subjectively understandable action. (p. 13)

Weber's Reception

Weber's impact on social science and social theory has been profound and complex. By and large, positivist social scientists have tended to be apprehensive about his notion of interpretive understanding, while many critics of positivism have been attracted to his work precisely because of this feature. Actually, however, reactions on both sides of the fence have been more variegated. Despite his endorsement in some nonpositivist circles, resolute defenders of "cultural" inquiry have found his legacy too deeply imbued with systematic and empiricist leanings to provide an adequate rallying point for their cause. Attitudes in the other camp also have tended to differ. Some champions of a scientific sociology concluded that Weber's work was sufficiently close to their own aspirations to serve as a precedent or springboard for "rigorous" inquiry, given certain corrections or amendments. According to Talcott Parsons (1902–1979), the leading proponent of this view, the major correction needed was the introduction of a general or systematic perspective. While strongly approving the pivotal role assigned to social action, Parsons argued that to permit scientific analysis, human behavior needed to be seen as part of an overarching network or a "social system."

On the whole, Parson's reformulation remained an isolated venture in Weberian scholarship; the bulk of his sympathizers were too apprehensive of "cultural" exegesis to follow his lead. The dominant posture adopted by positivists, and especially by logical empiricists, was to treat Weber indeed as a herald of social research but as one who never caught sight of the promised land. Interpretive understanding in particular—to the extent that it was not completely exorcised—was viewed not as an integral ingredient but as a prefix or embroidery in the anteroom of research, useful for generating "heuristic" insights and for aiding in the formulation of hypotheses. As Otto Neurath (1882–1945), one of the early logical empiricists, once formulated the issue, while helpful for increasing the serendipity or alacrity of the scientist, understanding was as little a part of his actual empirical work as a cup of coffee consumed in the course of his investigations. This "cup-of-coffee" theory of understanding was quickly picked up by other members of the logical-empiricist movement and became a standard weapon in its intellectual arsenal. Typically, the term *understanding* in this context tended to be identified with psychological empathy or with the reenactment or "reproduction" of mental and emotive processes.

Analytic Philosophy Versus Continental Philosophy

Battles sometimes continue to be fought when the original motives have vanished or been seriously

modified. While the empiricist offensive against Weber's legacy was still in full swing, developments were already afoot that were destined to recast the underlying issues in completely new terms. These developments occurred in two very different settings and involved very divergent lines of argument: One arose within the largely Anglo-American confines of the "analytical philosophy of language"; the other emerged on the Continent, under labels such as *phenomenology* and *existential analysis*. Despite their heterogeneity, the two developments moved toward (at least partial) convergence with regard to the role of interpretive understanding; using a shorthand formula, one might say that both initiatives threw a new light not only on the much belabored issue of "psychologism" but also on the much more weighty and age-old heritage of methodological "individualism" (still prominent in Weber's case).

Analytic Philosophy and the Linguistic Turn: Wittgenstein and Winch

In the analytical context, the turn toward language signified first of all a realization that empirical reality could not be directly grasped without an adequate conceptual and linguistic framework; in the long run, however, the same turn carried with it another implication important for social inquiry: the insight that human action is social from the beginning, since the meaning of an action cannot be articulated even by the individual actor without recourse to language, that is, a shared pool of significations. Initially, it is true, language analysts—like their positivist companions—shunned all reference to purposive meaning, whether individual or social, and to the enterprise of interpretive understanding. The contours of a rapprochement emerged only in the later writings of Ludwig Wittgenstein (1889–1951), especially in his emphasis on ordinary language and the notion of "language-games" embedded in commonsense conventions. Once linguistic practices were seen as intimately "interwoven" with concrete "life-forms" and worldviews, the feasibility of a "cultural" interpretation became apparent. Nevertheless, Wittgenstein's own attitude in this matter remained ambivalent to the end, as he left open (or failed to block) the road to an empiricist treatment of language and the reduction of meaning to behavior.

Whatever Wittgenstein's preferences may have been, a number of followers—foremost among them being Peter Winch (1926–1997)—have developed the notion of language-games into a springboard for cultural and social analysis. Winch's classic *The Idea of a Social Science* (2008) placed decisive stress on the task of interpretive exegesis, or on "the central role which the concept of understanding plays in the activities which are characteristic of human societies" (p. 21). As the study tried to show, however, the interpretation of social behavior could not rely solely on the intentions of an individual actor, since these intentions were intelligible only within a language community and in terms of the rules of conduct and language usage operative in that community. Social analysis thus was predicated on the understanding of intersubjective standards: "It is only a situation in which it makes sense to suppose that somebody else could in principle discover the rule which I am following that I can be said to follow a rule at all" (p. 28). Basically, Winch argued that social understanding involves "grasping the *point* or *meaning* of what is being done or said" and thus an effort "far removed from the world of statistics and causal laws" and "closer to the realm of discourse" (p. 108).

The aspect of Winch's (2008) study that occasioned the most lively controversy among reviewers was the thesis of the uniqueness and virtual incommensurability of individual language-games and life-forms. Viewing life-forms as closely knit webs of opinions and ideas, Winch considered it "nonsensical to take several systems of ideas, find an element in each which can be expressed in the same verbal form, and then claim to have discovered an idea which is common to all the systems"; rather, the "very nature" of human society was "to consist in different and competing ways of life, each offering a different account of the intelligibility of things" (p. 103). His argument on this score has been criticized from many quarters—most vocally by adepts of a "critical positivism" committed to the proposition that scientific research, although fallible and in need of constant revision, is destined ultimately to grasp objective reality independently of historical conditions and cultural variations.

The Continental Approach: Husserl, Heidegger, and Schütz

The argument was also challenged from the side of Continental thought. In that context, phenomenology was to some extent a continuation of Dilthey's

and Rickert's efforts to elucidate the dimension of "meaning" as a counterpart to scientific explanation. Paralleling Rickert's initiative, Edmund Husserl's (1859–1938) early writings launched a broad-scale attack on "psychologism" and on the reduction of thought to empirical processes; by comparison with Neo-Kantianism, however, Husserl from the beginning extended the scope of inquiry beyond normative values to the full range of (natural and cultural) phenomena amenable to human cognition. While reformulating and sharpening the insights of his predecessors, Husserl remained at least in one respect heir to their perspective: in the attachment to individualism or to an individual-egological "consciousness." At least in this respect, his approach replicated the solipsistic dilemma of early language analysis and of much of modern philosophy: To the extent that consciousness was presented as the "transcendental limit" of the world, the domain of intersubjective understanding and clarification of meaning was obliterated. In his later writings, Husserl sought to overcome this dilemma by introducing the notion of the "life-world," or the world of mundane experience, but the relationship between mundanity and consciousness was never fully clarified.

By that time, the thrust of phenomenological analysis had already been profoundly reshaped by Martin Heidegger's (1889–1976) delineation, in *Being and Time,* of a "hermeneutical phenomenology" or "existential ontology." Understanding of meaning, in Heidegger's conception, was no longer the prerogative of individual cognition or consciousness but a basic attribute of man's existential condition or *Dasein,* construed as "being-in-the-world." Far from occupying the role of an alien spectator, *Dasein* was seen as enmeshed in a fabric of "pre-understanding" and "pre-predicative" experience, a fabric that was basically intersubjective and cultural in character. As it happened, neither Husserl nor Heidegger was concerned with articulating the implications of their thoughts for social inquiry. The elaboration of a "phenomenological sociology" was chiefly the accomplishment of one of Husserl's students, Alfred Schütz (1899–1959). In one of his first major works, *The Phenomenology of the Social World,* Schütz tried to effect a merger of Weberian sociology and Husserl's teachings by tracing the notion of meaningful social action to an underlying stratum or stream of constitutive consciousness. In his later writings, he grew steadily weary of egological methodology and was increasingly preoccupied with the domain of the "life-world," the domain of "common sense" and everyday activity. Drawing, at least in part, on Heideggerian insights, he treated "understanding" not simply as an individual cognitive faculty but as a multidimensional category denoting an existential or "experiential form of common-sense knowledge of human affairs" as well as an epistemological problem and a "method peculiar to the social sciences."

Recent Developments: Habermas, Apel, Gadamer, and Ricoeur

The tension between invariance and contingency, individualism and intersubjectivity are not the only predicaments besetting social inquiry today. Conjoined with these issues, the sketched skirmishes and developments have engendered a quandary that touches the core of cognition and the basic structure of the republic of letters: the quandary regarding the relationship between science and understanding, knowledge and self-knowledge. Although universally noted, the dilemma has been debated in recent years with particular intensity by German and French thinkers; preponderantly, these debates have centered on the proper range or scope of interpretive exegesis. One argumentative strategy, favored by representatives of the "Neo-Frankfurt School" of social research, has been to maintain the integrity of traditional types of inquiry while resisting the tendency toward segregation or one-sided hegemony. Thus, dedicated to the long-range prospect of human self-understanding and emancipation but disturbed by the quasi-natural constraints of modern society, Jürgen Habermas (1929–) and Karl-Otto Apel (1922–) have advocated the juxtaposition of hermeneutics and scientific analysis (and also their combination for purposes of critical social inquiry). On the other hand, hermeneuticists influenced by Heidegger have tended to redefine interpretive exegesis by deemphasizing the aspect of subjective purpose and intentionality; in his *Truth and Method,* Hans-Georg Gadamer (1900–2002) presented history not so much as an emanation of individual practice but as a complex learning process in which "man" is able to decipher himself only through encounters with a great variety of cultural practices and

institutions. Seen in this light, the scope of hermeneutical understanding is bound to be broad and devoid of clear-cut boundary lines. In the French context, Paul Ricoeur (1913–2006) has argued in favor not only of the coexistence but also of an intimate reciprocal dialogue and symbiosis of understanding and scientific explanation.

Drawing mainly on Gadamer's and Ricoeur's hermeneutics, some political theorists have recently launched the project of a "comparative political theory" where understanding (coupled with some explanation of social background) aims to transgress national and cultural boundaries in the direction of a cosmopolitan mode of discourse.

FALSIFIABILITY

This entry gives an account of *falsifiability* both as championed in particular by Karl Popper and also more generally and examines its wider implications for scientific methodology. It may be useful to start by pointing to the connection between falsifying in science, as a desideratum for choosing scientific theories, and the related logical argument form of *modus tollens: p→q/¬q/therefore ¬p*.

Falsifiability—or more accurately, *empirical falsifiability*—is a central notion in Karl Popper's philosophy of science, and more particularly in his strategy for *demarcating* science from *pseudoscience*. Roughly, a theory is (empirically) falsifiable if it is refutable by experience. More accurately, we might say that a theory is empirically falsifiable if there is a possible observation statement with which it is logically inconsistent. Consider the theory "All rabbits are brown" and the statement "There is a black rabbit." These cannot simultaneously be true; hence, the former must be classified as false if the latter is classified as true. Now we need only to add that "There is a black rabbit" is a possible *observation* statement—a statement that might be made on the basis of sensory experience—in order to conclude that "All rabbits are brown" is *empirically* falsifiable.

Here, however, we reach the first hurdle. It is dubious that existential statements such as "There is a black rabbit" are direct, or pure, statements of what we observe. Rather, it would seem that two people might have the same sensory inputs at a point in time but disagree on what those inputs show to be true *in virtue of having different theories*. I may be convinced that a black-looking rabbit has just had its fur dyed, after discovering a fiendish plot by a rival scientist to lead my investigations into lagomorphs astray. But another person, upon seeing the same thing at the same time, might take the rabbit to be genuinely black. And fictional tales aside, the history of science shows the actual methodological significance of the *theory-laden* nature of observation. For example, Galileo observed Neptune more than 200 years before its recognized "discovery" (which we will discuss later), but he mistook it for a star.

On the face of it, this recognition is not too problematic. What's observable becomes a matter of theoretical context, as well as physical context, and what's falsifiable becomes similarly contextual as a result. However, to demand that all scientific theories be falsifiable then becomes troublesome—at least, that is, if we require that our observation statements should only ever be laden with *scientific* theories. Imagine that observation statement *O* laden with theory *T* conflicts with theory *T*. If we are to take *O* seriously, must we demand that *T* be falsifiable, in turn? If so, then the observations that could falsify it will also be theory-laden. Thus, we should demand that those further theories be falsifiable too. And so on, back in an infinite regress or around in a circle. Popper's response to this kind of difficulty was to say that there is no firm place to stop and that we can always go on testing. One problem with this view, for those inclined to a realist view of science (where science makes continual progress toward the truth), is that it is hard to see how stopping in one

place rather than another is anything more than a pragmatic matter.

But what if—against the views of Popper and Thomas Kuhn—some observations are not theory-laden? For the sake of argument, let's imagine for the remainder of this discussion that *no* observations are theory-laden. Is it then correct to say that all scientific theories should be empirically falsifiable?

Unfortunately it would seem not, because most scientific theories, if not all scientific theories, predict nothing whatsoever *when taken in isolation*. As Pierre Duhem noted, writing about physics, experiments cannot condemn isolated hypotheses. Consider, for example, Newton's first law of motion: A body remains at constant velocity (or rest) unless a resultant force is acting on it. Nothing in this statement tells us what kinds of forces there are or how to determine when they are present. So the law does not predict what any actual body will do in any actual situation. The upshot is that an observation of an accelerating body could only ever falsify Newton's first law *in combination* with an additional *theoretical* account of what forces there are, how to measure their magnitudes in particular instances, and so forth.

A natural response is to say that this law is part of an empirically falsifiable *system* of theories; Popper suggested as much, albeit rather briefly. So might one then suggest that science contains such systems of theories, whereas pseudoscience does not? Again, there are serious difficulties. If the claim is to be that *any* discipline involving empirically falsifiable systems of theories is scientific, then this is consistent with highly dogmatic, and inflexible, rules for theory selection/preference. To see this, it will help to consider the methodological consequences of Duhem's aforementioned thesis. What should we do when faced with an observation statement that falsifies some system of theories? For all that logic tells us, it is always acceptable to preserve a favored component of the system and apportion blame elsewhere. This is illustrated beautifully by the story of Urbain Leverrier's investigations of planetary orbits.

Using Newtonian mechanics and hypotheses concerning the orbits of the known planets—note that these orbits had a theoretical character, insofar as only the positions of the known planets at particular times were directly measured—it was possible to predict the orbit of Uranus. Yet observations indicated that Uranus did not have the predicted orbit. This did not, however, shake Leverrier's belief in Newtonian mechanics. Instead, he thought that the problem lay with the other, auxiliary, information used to derive the prediction. In particular, he considered the possibility that the information was incomplete and that there was a previously unknown planet exerting gravitational influence on Uranus. Hence—and do not underestimate the mathematical difficulty of this task or the considerable guesswork involved (because, e.g., a hypothetical mass for the planet had to be selected)—he was able to suggest a place to look. And sure enough, Neptune was found.

Several years later, it was noted that the orbit of Mercury was similarly aberrant; that is to say, Mercury did not move in the path predicted by Newtonian mechanics and the available auxiliary hypotheses concerning other bodies in the solar system. Unsurprisingly, Leverrier sought to repeat his previous trick. He predicted a planet Vulcan. But Vulcan does not exist. And we now know that the orbit of Mercury can be explained by relativity theory.

The point behind the story is that the circumstances in these two scenarios were highly similar, but in one case a central physical theory was retained and in the other it was abandoned. But Newtonian mechanics need not have been abandoned *on logical grounds*. When Vulcan was not found, indeed various different possibilities were examined—the existence of multiple unknown planets, of other massive bodies such as asteroid belts, and so forth. And no matter how many such possibilities were ruled out, countless many—infinitely many, some philosophers would urge—remained. Multiple invisible bodies might even have been posited. And before you dismiss this as crazy, consider the "dark matter" posit of more recent astrophysics.

The lesson to draw from the story is that to adopt any old falsifiable system is not to do science. Rather, what one does and what *one is willing to do* with the given system is crucial. (Alternatively, one may think at the level of science itself and of the functions *it* fulfills.) In many pseudosciences, some hypotheses are never questioned or held open to revision. Think, for example, of the way astrologists merely accommodated the existence of Neptune, rather than questioning the notion that planetary positions have some effect on our lives.

In closing, one further difficulty with requiring falsifiability of scientific theories, which is independent of the prior considerations, is worthy of note. This concerns *probabilistic* laws or theories, such as those in quantum mechanics. Consider the hypothesis that a given coin is fair—that is, that the

probability of a heads result is equal to the probability of a tails result when it is flipped. Strictly speaking, this is compatible with an observation statement of the form "The coin has landed on heads on the last *n* flips," where *n* is any natural number. Yet it would not be unreasonable to abandon the theory that the coin was fair if *n* were sufficiently high.

Feedback Mechanisms and Self-Regulatory Processes in the Social Sciences

This entry introduces the notions of *feedback* and *self-regulation,* together with their variations used in mechanisms employing loops as analytical tools of modeling social phenomena in systems theory. It explains the importance of such interactive processes and why such systems thinking is ubiquitous in social science; the entry also offers a number of helpful examples.

Background

Beginning in the 1940s, the engineer's concept of *feedback* entered the social sciences. The essence of the concept is a circle of interactions—a *closed loop* of action and information. Something, presumably causal pressures or information, "feeds around" a hypothesized loop of interactions and eventually "feeds back" to its point of origin. Such loops are essential for automatic control devices ranging from Watts's centrifugal governor for a steam engine to modern thermostats, toilet tank fill valves, and automobile cruise controls. But the thinking that underlies the notion of feedback loops is not simply an engineering idea but rather a much more general and pervasive perspective with a rich history in the social sciences.

The notion traces back implicitly at least 250 years in social science literature, and more than 2,000 years more generally. When the loop character of societal reasoning has been explicit, it has been variously characterized as mutual or circular causality, homeostasis, control, recursion, self-reference, reciprocal relations, interdependence, and the like. Thus, feedback loops, by whatever name they are known, are at the heart of the social and policy sciences. It is not an exaggeration to say that great social scientists are feedback thinkers and great social theories are feedback thoughts.

Feedback and Self-Regulation

Self-regulation is the tendency of an individual or group to try to hold itself in some preferred condition. The generic idea postulates a *goal* of some sort and a perception that may align with the goal or create a discrepancy. A discrepancy between the perceived and preferred states creates pressures to take some actions to close the gap and bring the system back into some balance. Figure 1 captures the general idea.

Early terminology called such loops *negative* feedback loops because tracing around a change in such a loop produces pressures that try to counter or negate the change. Current terminology calls such loops *balancing* or *counteracting*.

Examples abound for such *balancing* or *counteracting* loops. If one is too cold (a gap between desired and actual conditions), one puts on a sweater or coat, thus working to close the gap and be comfortable. If the supply of some commodity is insufficient to satisfy the demand, prices would tend to rise, pulling the demand back closer to the supply (one of Adam Smith's "invisible hands" at work). If a population outstrips its ability to feed itself, various mechanisms would act to limit growth (if the food supply can't be increased fast enough, Thomas Malthus saw socially conscious "preventative" checks and nasty, unavoidable "positive"

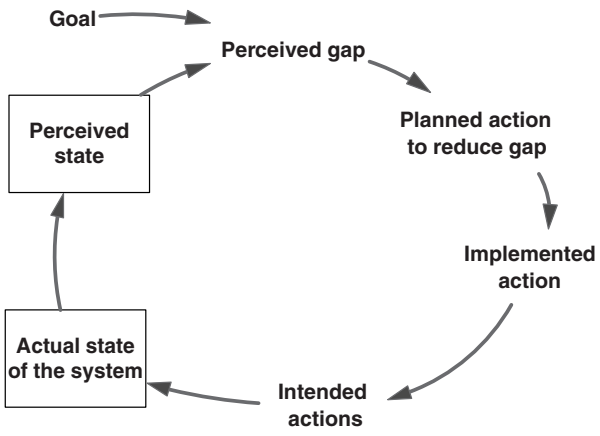

Figure 1 Generic Self-Regulating Feedback Loop: A Goal-Seeking "Balancing" Loop for an Individual or Group

Source: Author.

checks, both of which create balancing loops). If government excesses emerge in a democracy, the self-interests of the governed should produce actions that would control the excesses (the authors of the *Federalist Papers* explicitly argued for such self-regulatory governmental mechanisms in the U.S. Constitution). More modern social and behavioral science examples include Leon Festinger's notion of the motivating power of "cognitive dissonance"; the importance of vision, mission, and monitoring to guide planned action in strategic management; and the actions of the Open Market Committee of the U.S. Federal Reserve to adjust interest rates to try to keep inflation in check and the economy on a stable growth path.

Self-Regulatory Loops in Context

Suffice it to say, all *purposeful* self-regulatory action of an individual or group can be thought of in terms of one or more balancing feedback loops of the sort generalized in Figure 1 (sometimes without an explicit identified goal). In practice, things are much more complex than that single loop, for two reasons.

First, in any social, economic, or political setting we have many actors, not just one, and thus many goals and many goal-seeking balancing loops interacting over the same issues. The picture becomes complex very quickly. Second, in any one of those balancing feedback loops, there are often implicit goals that people have not expressed, even to themselves; actions often have unintended consequences; and while efforts focus on closing some perceived gap between goal and perception, the system can move of its own accord under a host of other forces, including explicit resistance to implemented goal-directed actions. Figure 2 suggests this more complicated picture.

The diagram in Figure 2 contains six feedback loops. With more actors or stakeholders and more interconnected sets of loops as in Figure 2, the interacting complexity grows dramatically, and we have the complicated dynamics that social, economic, and policy sciences struggle to understand. Furthermore, some of the loops in Figure 2, or a more complicated version with more actors, may not have the balancing or self-controlling character of the loop in Figure 1. Some of those loops could be so-called positive or reinforcing feedback loops.

Reinforcing Feedback Loops

Unlike balancing loops (the aforementioned *negative feedback loops*), which tend to counter a change, *reinforcing loops* tend to move further in the direction of change and amplify it, adding instability.

Again, examples abound, many of which were recognized in the social science literature before the emergence of the engineers' uses of feedback: John Stuart Mill noted that speculators, seeing a rise in the price of a stock or commodity, come to expect the rise to continue and so increase their purchases, thus driving up the price still further. In a *vicious circle,* a term that in the 1600s flagged faulty logic, we now have a bad situation that leads to its own worsening. And when supporters of some social or political movement grow and attract still more supporters simply because of growing popularity, we have what's called the "bandwagon" effect, named for the tendency of people to be attracted to crowds following the first vehicle in a circus parade. The *self-fulfilling prophecy* was so labeled by Robert K. Merton to flag a prediction that starts out false but becomes true because people come to believe it. Merton's examples were predictions of the insolvency of a bank, the fear of failing a test, and the prejudices that discriminate and limit the accomplishments of a group or race and thus reinforce the prejudgments.

Balancing and Reinforcing Loops Together

The importance of self-regulating and self-reinforcing feedback loops in social science stems from what we can understand by employing a feedback perspective. Whether stated, implicit, or unrealized, interconnected balancing and reinforcing

feedback loops are at the heart of our deepest social and economic theories and understandings. But this takes a complex view. Figure 3, for example, shows a glimpse of the complex interactions of feedback loops that computer simulation shows us can by themselves generate the patterns of growth, stagnation, and decay we observe in our urban centers.

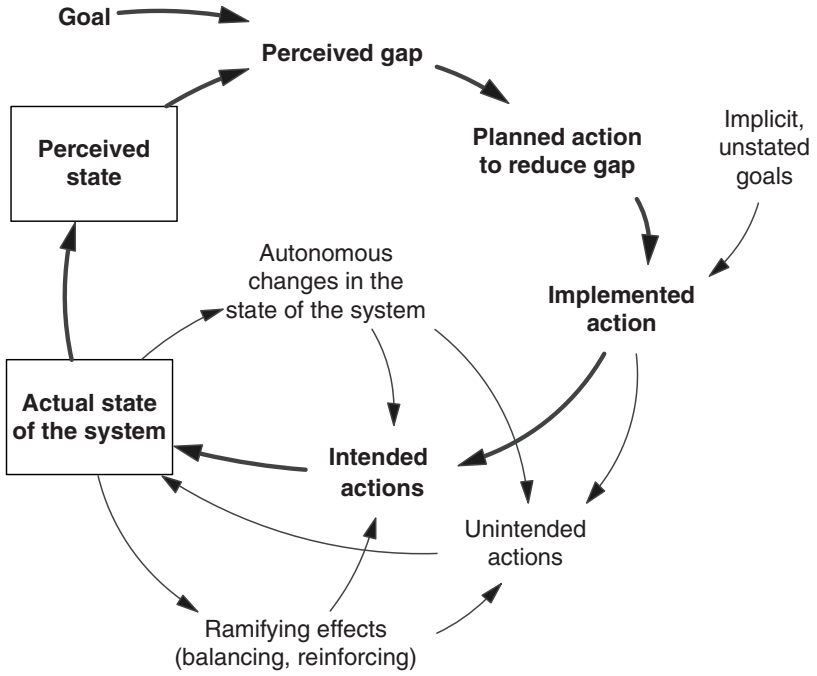

Figure 2 Goal-Seeking Balancing Loop of Figure 1 Complicated by Implicit Goals, Unintended Consequences, and Systemic Changes That Can, and Often Do, Thwart Attempts at Self-Regulation

Source: Author.

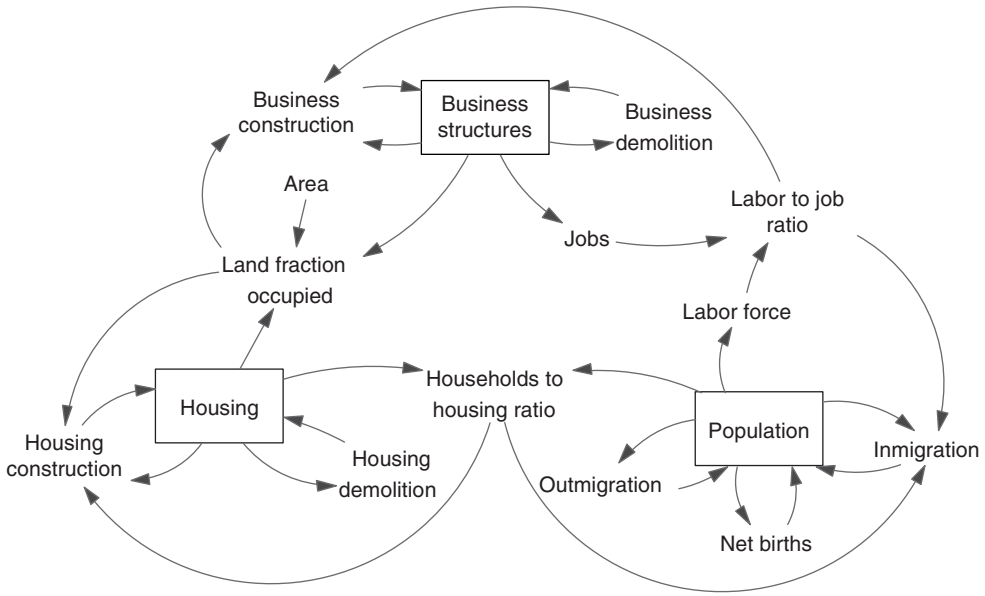

Figure 3 Self-Regulating and Self-Reinforcing Feedback Loops in the Dynamics of a City, Creating an Endogenous Theory of Urban Growth, Stagnation, and Decline

Source: Author.

The importance of a feedback perspective in the philosophy of social science rests on the endogenous point of view exemplified in Figure 3. Our strongest social science theories are *endogenous theories*. Feedback loops enable the endogenous point of view and give it structure.

Feminism: Schools of Thought

Feminist schools of thought are many and diverse. However, in one way or another, all of them are concerned with improving women's status, autonomy, and/or socioeconomic circumstances. Furthermore, almost all schools of feminist thought examine gender relations in the public and private realms and/or attempt to rehabilitate characteristics traditionally associated with women. Among the main schools of feminist thought are the following: liberal, radical (libertarian and/or cultural), Marxist-socialist, psychoanalytic and care focused, existentialist and postmodern, multicultural and global, ecofeminist, and third wave. Although some feminist schools are highly controversial and/or daunting to the average person, they are all worthy of consideration. Taken together, they provide new perspectives on knowledge, reality, and social justice.

Liberal Feminism

Liberal feminism has its roots in English philosophers such as Mary Wollstonecraft (1759–1797), John Stuart Mill (1806–1873), and Harriet Taylor Mill (1807–1858). It also traces its beginnings to the women's suffrage movement, especially in the United States. In the 19th century, liberal feminists like Mary Wollstonecraft emphasized that if women were to receive men's education, women would stop behaving like children or, worse, caged birds, potted plants, or ornamental objects for men. Agreeing with Wollstonecraft, John Stuart Mill and Harriet Taylor Mill emphasized that women's autonomy also necessitated women's movement into the public sphere (particularly the paid workforce). The Millses also pushed women's suffrage as a corrective for women's subordination to men. Armed with the vote, women could express their interests and values, thereby gaining power in society. Suffrage did not come easy for women, however. In the United States, for example, it took about a half-century for the passage of the 19th Amendment to the U.S. Constitution, which enfranchised women.

Like the Millses, 20th-century liberal feminists claimed that women's subordination to men is predicated on a set of assumptions about women's gender identity and roles. These assumptions are used first to justify women's near confinement to the private realm, where they are expected to perform most of the domestic chores and care of dependents, and second to limit women's access to the public realm (advanced education, the political arena, the marketplace, and the high-status and high-paid professions). Largely, through the efforts of 20th-century feminists and contemporary organizations like the National Organization of Women (NOW), women in the United States, for example, are now comfortable in the public realm, working as chief executive officers, legislators, professors, physicians, lawyers, and so forth. Still, NOW's 1970s Equal Rights Amendment has not been ratified by enough states, and women still do most of the household's domestic and care work. For example, a 2002 survey found that women do 70.6 hours of domestic work a week, whereas men do 37.3 hours of domestic work a week. Similarly, women do 9.1 hours of elder care work per week, whereas men do 5.7.

Radical Feminism

Radical feminists alleged that the liberal feminist agenda is a weak program of reform rather than a strong revolutionary movement aimed at the heart of patriarchy. They claimed that patriarchy—a state

of affairs in which male "fathers" rule—is characterized by competition, hierarchy, and brute power. According to radical feminists, patriarchy cannot be reformed; it needs instead to be destroyed. It is not just patriarchy's legal, political, and socioeconomic structures that must be overhauled, its sexual and cultural institutions (especially the family) must also be reconceived.

There are two types of radical feminists: (1) radical-libertarian feminists and (2) radical-cultural feminists. Radical-libertarian feminists rejected the notion that the only kind of sex that is "good" for women is to be found in a long-term love relationship between a married heterosexual couple. Instead, they claimed that any kind of sex that gives women pleasure is good: sex between men and women, sex between women, sex with both men and women, autoeroticism, sadomasochistic sex, and even intergenerational sex. In addition, radical-libertarian feminists put forward another controversial view—namely, that natural reproduction be replaced by technological reproduction. They thought that thinkers such as Shulamith Firestone were correct to argue that no matter how much educational, political, and economic equality women achieve, they will not be liberated from men unless they stop bearing children. Radical-libertarian feminists also applauded when Firestone claimed that it would no longer be necessary for men to display only masculine identities and behaviors and for women to display only feminine ones. Instead, men and women would become encouraged to mix and match feminine and masculine characteristics in any way they wished. As a result of this new choice, not only men and women but also all of culture would be androgynous. Furthermore, as this new androgynous culture developed, the categories of the technological and the aesthetic, together with the categories of the masculine and feminine, would self-destruct.

Disagreeing with radical-libertarian feminists about both sex and reproduction, radical-cultural feminists claimed that sex in general, but certainly sex between women and men, was inherently dangerous. Indeed, they said that as it has been experienced so far, heterosexuality is a "compulsory institution" that justifies male sexual abuse of women representatively in pornography and actually through the use of prostitutes, sexual harassment, rape, and domestic violence. Radical-cultural feminists therefore encouraged women to tap into their own sexuality, a sexuality not created in service of men's desires, and to explore the "lesbian" within themselves.

Equally as suspicious of artificial reproduction as of institutionalized heterosexuality, radical-cultural feminists urged women to view high-tech infertility services and plans for an artificial womb not as procreative options for women but as a means for men to seize control of women's reproductive power. Radical-cultural feminists stressed women's need to safeguard their ability to bring life into the world through their own bodies, for without this life-giving power, men would have more leverage over women than ever before.

Marxist Feminism

Marxist-socialist feminists criticized both liberal and radical feminists for neglecting women's class status. Although it is true that women in capitalist patriarchies occupy a subordinate position relative to men on account of their sex, this does not mean that all women are equally oppressed. Specifically, it is worse being a poor woman than a rich woman in a capitalist patriarchy.

Marxist-socialist feminists realized that it is somewhat contradictory to be both a Marxist-socialist and a feminist at one and the same time. Should class be used as the primary lens through which to interpret women's (and some men's) oppression? Or should sex be the primary lens, with class playing a secondary role to it? Or was there some way to make class and sex equally important in interpreting women's oppression?

According to the feminist thinker Chris Beasley, Marxist-socialist feminists developed three different approaches to the questions just raised, regarding three ways of seeing the relationship between the two systems of oppression (class and sex)—that is, the relationship between an economic or political analysis in terms of "class" and a feminist-psychological one of "sex." Beasley labeled these three approaches (1) the two-tier or dual-systems approach, (2) the unified-system or capitalist-patriarchy approach, and (3) the "dynamic-duo" approach. Ultimately, none of these approaches to mesh Marxist-socialism with feminism has been entirely successful. Class and sex remain competitors for the soul of Marxist-socialist feminism, with class being given a greater or lesser edge over sex. Although Marxist-socialist feminists easily agree that women's low socioeconomic status is multiply determined by women's role

not only in production but also in reproduction, the socialization of children, and sexual relationships, most of them feel that women's place, or lack of place, in the paid workforce best explains women's low socioeconomic status.

Psychoanalytic and Care-Focused Feminists

To the degree that liberal, radical, and Marxist-socialist feminists focus on the macrocosm (patriarchy or capitalism) in their respective explanations of women's oppression, psychoanalytic and care-focused feminists look to the microcosm of the individual, claiming that the roots of women's oppression are embedded deep in the psyche. Some psychoanalytic feminists relied on Freudian constructs such as the pre-Oedipal stage, during which all infants are symbiotically attached to their mothers, whom they perceive as omnipotent, and the Oedipal stage, during which boys much more successfully than girls are integrated into society by giving up their first love object, the mother. In contrast, other psychoanalytic feminists relied on Lacanian constructs such as the *symbolic order* (society's language system) and the *prelinguistic imaginary.* In either event, psychoanalytic feminists claimed that gender identity is rooted in the experiences infants/children have during these stages. These experiences, most of which we scarcely remember, are supposedly the cause of individuals viewing themselves as males or females, as masculine or feminine. Moreover, these same experiences are the cause of society's elevating masculine values, accomplishments, and desires over feminine values, accomplishments, and desires. Hypothesizing that in a nonpatriarchal society where, for example, men and women "dual parented" their children, masculinity and femininity would be both differently constructed and valued, psychoanalytic feminists recommended that we work toward such a society by changing our early infantile experiences or, even something more radical, by transforming the linguistic structures that cause us to think of ourselves as men or women.

Like psychoanalytic feminists, care-focused feminists probed women's (and men's) psyches, trying to find there more information about society's privileging of things masculine over things feminine. Care-focused feminists stress that at least in Western societies women as a group are associated with values, virtues, and characteristics such as interdependence, community, connection, emotion, body, nature, and care. In contrast, men as a group are associated with values, virtues, and characteristics such as independence, autonomy, separateness, reason, mind, culture, and justice. Care-focused feminists explain these associations in a variety of ways, attending to the ways in which societies systematically shape men's and women's distinct identities and behaviors. But whatever explanation they offered, care-focused feminists regarded women's capacities for care as a human strength rather than a human weakness. Moreover, care-focused feminists spent considerable time developing a feminist ethics of care as a complement to, or even a substitute for, a traditional ethics of justice. As they saw it, were men to do as much caring work as women do, women's status would rise.

Existential and Postmodern Feminists

Looking into women's psyches more deeply than even psychoanalytic and care-focused feminists, Simone de Beauvoir provided an ontological-existential explanation for women's oppression. In *The Second Sex,* an authoritative text of 20th-century feminism, she argued that woman is oppressed by virtue of her otherness. Woman is the other because she is not man. Man is the free, self-determining being who defines the meaning of his existence; woman is the other, the object whose meaning is determined for her. If woman is to become a self, a subject, she must, like man, transcend the definitions, labels, and essences limiting her existence. She must make herself be whatever she wants to be.

Postmodern feminists took de Beauvoir's understanding of otherness and turned it on its head. Woman is still the other, but rather than interpreting this condition as something to be rejected, postmodern feminists embraced it. They claimed that woman's otherness enables individual women to stand back and criticize the norms, values, and practices that the dominant male culture (patriarchy) seeks to impose on everyone, particularly those who live on its periphery. Thus, otherness, for all its associations with being excluded, shunned, rejected, unwanted, abandoned, and marginalized, has its advantages. It is a way of existing that allows for change and difference. Women are not unitary selves, essences to be defined and then ossified. On the contrary, women are free spirits.

Multicultural and Global Feminism

Multicultural and global feminists challenged "female essentialism"—that is, the view that "Woman" exists as some sort of Platonic Form. They also confronted "female chauvinism"—that is, the tendency of some women, privileged on account of their race or class or some other characteristics about themselves, to presume to speak on behalf of all women. Thus, it is not surprising that both multicultural and global feminists insist on highlighting women's differences from each other.

In the United States, as in other multiracial and multiethnic societies, multicultural feminists stressed the inseparability of the structures and systems of gender, race, and class. They claimed it was wrongheaded for women to focus exclusively on their oppression as women, as workers, or as members of a certain racial or ethnic group. Instead, they claimed that each woman, or each relatively distinct group of women, needs to understand how everything about her—the color of her skin, the amount of money in her purse, the condition of her body, the object(s) of her sexual desire, the date on her birth certificate—provide part of the explanation for her status as a woman. Women are jeopardized in multiple ways, and systems of oppression are interlocking. Racism, sexism, and classism are never separable in fact, even if they are separable in theory, and there is no way to eliminate one of these isms while not eliminating the others. Thus, the fundamental task of multicultural feminists is to fight against all oppressive forces, including one's own self-doubting and self-denigration.

Agreeing with multicultural feminists that the definition of feminism needs to include class and race as well as sex, global feminists emphasized that being an oppressed woman in a developing nation or an authoritarian regime is generally a worse state of affairs than being an oppressed woman in a developed nation or a democratic polity. Committed to the task of dispelling misunderstandings and creating alliances between women in developed nations and women in developing nations in particular, global feminists aimed to widen the scope of feminist thought. They insisted that feminists needed to attend to women's political, economic, and social problems as seriously and passionately as they have attended to women's sexual and reproductive concerns.

As they began to grow in number, global feminists summoned women in all nations to work together. Specifically, they urged women to view their differences positively rather than negatively and to use them to secure genuine freedom and well-being for each other. "Sisterhood" does not require a woman to keep her counsel for fear of offending others. On the contrary, it requires her to speak her mind, confident that those to whom she speaks can appreciate her difference as much as she can appreciate theirs.

Ecofeminism

Like multicultural and global feminism, ecofeminism not only strives to show the connections among all forms of human oppression but also focuses on human beings' attempts to dominate the nonhuman world, or nature, which has been associated with women from time immemorial. According to ecofeminists, we are connected to each other but also to the nonhuman world: animal and vegetable, at least. Unfortunately, human beings do not always recognize how much their own well-being depends on nature's well-being. As a result, we overuse and misuse the world's natural resources, we pollute the air and water with toxic fumes and materials, and we stockpile weapons of mass destruction. We do these things, said ecofeminists, because we falsely believe that we are benefiting ourselves, but in fact, we are only harming ourselves and future generations. No one, including women, can expect to be free in a regime that systematically destroys nature. Without nature thriving, human beings cannot expect to survive, let alone thrive.

Third-Wave Feminism

Most recently, a third school of feminist thought, so-called third-wave feminism, is emerging. Third-wave feminists are more than willing to accommodate diversity and change. They are particularly eager to understand the ways in which gender oppression and other kinds of human oppression cocreate and comaintain each other. For third-wave feminists, difference is the way things are. Their world is a Heraclitean world (an ever-changing one, consisting of the conflict of opposites), not a Parmenidean world (of everlasting stable essences or permanent categories). Moreover, contradiction and conflict are expected and even welcomed by third-wave feminists. They believe that if feminism

is to develop, it must learn how to better handle conflict and contradiction.

As part of their study of interlocking forms of oppression, third-wave feminists engage in research and writing that attends to the lives and problems of specific groups of women. A typical third-wave feminist text will include articles about women who represent a wide variety of multicultural perspectives: Hispanic American, African American, Asian American, Native American, and so on. Indeed, one would be pressed to find an article authored by a third-wave feminist that is not heavily hyphenated.

The fact that the majority of the U.S. population is no longer White has profound implications for the development of third-wave feminists. Third-wave feminists wonder what it means to be an ethnic or racial "minority" in a city or state where one's own kind of people constitute the largest group of people. They also point out that the always contested categories of race and ethnicity are being further tested by phenomena such as increased intermarriage and people identifying themselves as "some other race" than the racial categories traditionally used on U.S. Census Bureau forms. Clearly, being a third-wave feminist in the 2000s, where a growing number of people *choose* their racial or ethnic classification, is different from being a feminist in the days when racial and ethnic identity were largely imposed by White hegemonic forces.

Conclusion

Interestingly, some schools of feminist thought have had more of a direct impact on society than others. To be sure, psychoanalytic, care-focused, existentialist, and postmodern feminists have helped women better understand themselves and their identities. They have also helped society in general understand that gender—the concept of male/masculine and female/feminine—is per se contestable and that care is of equal value as justice. But it is the other schools of feminist thought that have so far led to concrete social change.

Liberal feminists have pushed women into the public realm, both in the political arena and in the paid workforce. They have brought to society's attention the need for women's suffrage, education, action, and advancement, and they have not been afraid of using affirmative action policies to strengthen women's social position.

Marxist-socialist feminists have put on society's collective radar socioeconomic issues such as the wage gap between men and women, equal pay and comparable worth controversies, and the devaluation of women's domestic work, especially their care work. Like care-focused feminists, Marxist and socialist feminists have underscored how wrongheaded it is to think of women's work as "free" work. Just because women care for the vulnerable family members (children, the infirm, the disabled, the elderly) at home and just because women cook and clean in their own houses, does not mean that their work does not contribute to the economy. If women were to refuse to do their "homework," then someone (men?) or some institution (the state?) would have to pay professional cleaners and care workers a substantial amount of wages, if only the minimum wage.

Despite the provocative nature of their writings, radical feminists have made sexual variation less of a taboo in society, and they have gone a long way to normalize lesbian and gay relationships and to improve sexual relations between men and women. Thanks to radical feminists, pornography, sexual harassment, prostitution, and certainly domestic violence and rape have become phenomena of great concern in society. In addition, radical feminists have pushed society to reconsider the pros and benefits of reproduction-controlling technologies (contraception, sterilization, and abortion) and reproduction-assisting technologies (donor insemination, in vitro fertilization, surrogacy, egg donation, and egg freezing).

Reflecting on all schools of feminist thought, it seems clear that multicultural, global, and ecofeminists have very much increased society's awareness of oppression. Oppression does take a variety of forms—sexual, racial, ethnic, national, religious—and these varieties of oppression clearly reinforce each other. Becoming aware of the ways in which we make life better or worse for each other is the first step for people of good will to take in the quest for social justice. Similarly, ecofeminists have been leaders in the animal rights, environmental improvement, and sustainability movements. Nature needs to be respected by culture, or the human community will find its future generations without water, fuel, and food.

Finally, third-wave feminists are shaping a new kind of feminism that is not so much interested in getting women to want what women *should* want as in responding to what women say they want and not second-guessing or judging whether their wants are authentic or inauthentic. Third-wave feminists describe the context in which they advocate such a feminism as one of "lived messiness." According to Heywood and Drake, part of this messiness includes

people who change their sex and/or gender and wear their multiraciality proudly. Third-wave feminists are pushing society's envelope, exploring the implications of living in a diverse society where the old categories of "us" and "them" are ambiguous and always changing.

Although feminists continue to have women and gender as their primary focus, most schools of feminist thought now stress that all pernicious isms—sexism, racism, classism, colonialism, nationalism, speciesism—need to be overcome if the status of women and men in all countries is to be equalized. Feminists will not feel their work is done until and unless all women live in societies where everyone's freedom and best interests are recognized and realized. There is as much a need for feminism today as ever before.

Feminist Critiques of Social Science Applications

This entry assesses the relationship between feminist research and social-scientific analysis. Although employing many of the tools of social-scientific research, feminists have been critical of those tools and developed uniquely feminist approaches to the social sciences.

From the beginning of the contemporary feminist movement, feminists have had an uneasy relationship to the social sciences. On the one hand, some of the core assertions of contemporary feminism are

rooted in the social sciences. Beginning with Simone de Beauvoir's *The Second Sex,* feminists have made empirical claims about the status of women in society: their inferior position, the discrimination against them, and the denigration of the feminine in our culture. These social-scientific facts have formed the core of contemporary feminism. On the other hand, however, feminists have also claimed that the social sciences are inherently masculinist and that this bias pervades all social-scientific disciplines. They assert that this masculinist bias marginalizes the experience of women in society and precludes an accurate assessment of the status of women.

Perhaps the most contentious issue in the relationship between feminism and the social sciences is the status of empiricism. At the root of much, although not all, social-scientific analysis is the set of assumptions about facts, values, knowledge, and objectivity that defines empiricism. From the outset, feminists have been critical of empirical social science, claiming that it renders the experiences of women invisible. They further claim that the objectivity that is the goal of empirical research is illusory. This has led many feminists to reject empiricism out of hand and adopt alternative approaches to social-scientific analysis. But this rejection is neither universal nor unambiguous. A total rejection of empiricism has consequences that put feminists in an awkward position. If feminists cannot assert the truth and objectivity of claims about the status of women in society, then much of the force of feminist critique is lost.

As a way out of this dilemma, some feminists have called for a "new empiricism" to guide feminist research in the social sciences. Feminists such as Sandra Harding and Lynn Hankinson Nelson have argued for a definition of empiricism that recognizes that all knowledge is situated and perspectival. While not rejecting the notion of objective knowledge that grounds empiricism entirely, these feminists argue that we must significantly redefine it in a way that takes account of this situatedness and the reality of women's lives. They also claim that all knowledge is biased and that objective, value-free knowledge is unobtainable. These theorists agree with Dale Spender's claim that there is no one truth, no one authority, and no one objective method that leads to the production of knowledge. But they also claim that we can and do seek knowledge of women's lives in society and that this knowledge is valid.

Feminists' skepticism about empiricism has caused some to turn to alternative approaches to the social sciences. But in adopting these approaches, feminists have in every case developed a method that is critical and distinctively feminist. One approach is phenomenology. Feminists such as Dorothy Smith assert that feminist research must begin from an examination of the lived experience of women. Although phenomenology emphasizes lived experience, phenomenologists have, to a large extent, ignored women's experiences. Feminist phenomenologists have sought to correct this by focusing on the actuality of women's lives.

A closely related feminist approach has its roots in Marxism. Marxist standpoint theory offers an alternative to the objectivism of empirical social science. But for Marxists, standpoint theory was only applied to the position of the proletariat; women did not figure in the equation. Feminist standpoint theory, developed by theorists such as Nancy Hartsock, extended Marx's theory to the sphere of women. Arguing that women and men have different standpoints and hence different conceptions of knowledge, Hartsock and other standpoint theorists argued that women, like the proletariat, have a clearer understanding of the truth of society because of their marginalized position.

In the latter half of the 20th century, many disciplines in the humanities and social sciences were caught up in what has been referred to as the *linguistic turn.* Adherents argued that language is the single constituent force of social reality and that social analysis is exclusively linguistic analysis. Feminists were deeply influenced by this movement. Linguistic analysis, most particularly postmodernism, became the focus of much of feminist analysis. Feminists' analyses of concepts such as "woman" and "sex" produced much valuable work, clarifying the origins of the inferiority of women in society. But again, the feminist approach to linguistic analysis was distinctive and oppositional. Women were missing from most linguistic analyses in the social sciences. Feminists, focusing on how language constructs the social reality women inhabit, sought to redress this omission.

In recent years, the dominance of the linguistic turn has been challenged by an approach labeled the "new materialism." The new materialists seek to bring the material back into the equation without losing the advantages of the linguistic turn. Feminists have been on the forefront of this movement with their analyses of the materiality of women's bodies.

Along with the new materialists in the natural and social sciences, feminists are reshaping our conception of truth and knowledge.

Feminists have been and will continue to be concerned with the status of women in society and how that status can be improved. This brings them in close connection to the social sciences. But feminism can never be simply classified as one of the social sciences. Feminists' insistence on perspectival knowledge, an oppositional stance, advocacy, and the critique of objectivity flies in the face of mainstream empirical social science. Feminists are and must remain critical, challenging the fundamental tenets of established social science.

Feminist Economics

Feminist critiques of economics emerged as a counterpoint to the economic theories built around core ideas of self-interested individualism and contractual exchange. The conceptual framework of 20th-century economics focused on the marketplace and relegated nonmarketed human interactions to its marginalized fringes or to other disciplines, largely ignoring economic life outside the market—arenas in which women's lives are disproportionately involved. With the establishment of the International Association for Feminist Economics and its journal, *Feminist Economics,* in the early 1990s, feminist economics emerged as a distinct area of economic inquiry, broadly focusing on reconstructing economic theory to present theories and policy tools more responsive to women and their lives and promoting of gender justice. Calling attention to theoretical constructions that deemphasized or ignored women's lives, such as the idea that only remunerated employment should be counted as productive work, feminist economists argued that the whole economy includes interdependent paid and unpaid sectors, each influenced by policies directed toward the other, and that economic policies should promote the flourishing of all human life rather than focusing exclusively on measures of economic output or growth. Feminist economics is growing rapidly and putting forward new insights into all areas of economics. This entry describes several of the most important ideas and their implications for economic policy.

Theorizing Gender Inequality

Amartya Sen calculated that in the 20th century more than 100 million women have died disproportionately to men because of lack of equal access to food, medical attention, and other survival-related resources. Subsequent studies replicated this result, revealing that more women and girls have died from causes relating to gender inequality than those who died in both world wars. With further evidence of pervasive gender inequality occurring in education, health care, work, wealth, and income, feminist scholars have argued that gender inequality should be treated as a central economic concern meriting theoretical explanation and policy remedies.

Gender Relations and the Family

In challenging economics to provide more complete theories, feminist economists have called for models that look within the family to examine how gender relations influence economic outcomes. Since economic approaches that rely on aggregated measures

of economic output, such as gross domestic product, do not reveal how resources are distributed within families, they obscure gender inequality and provide no help in illuminating either its causes or its impact.

Standard economic models treat the family either as an amicable homogeneous unit or as a civilized bargaining game. In contrast, feminist economists point to unequal gender relations, ranging from simple devaluations of women and their work to exploitative gender relations often accompanied by violence. Linking women's lower economic status to their greater role in unpaid reproductive and care work, feminist economists have sought to understand how social norms relating to such work influence economic distributions in the home and marketplace.

Human Interconnections and Care Work

Whereas standard economic models treat people as independent agents, able to operate in markets and take care of themselves, feminist economists point to the interconnectedness of human life. One aspect of human interconnectedness is the need for care and support from others, beginning at birth. Care work, disproportionately unpaid and performed by women, provides essential support not just for children but also for the sick, the disabled, and the elderly and, more generally, for the daily work of cooking, cleaning, and caring for families.

Feminist economists argue that work doesn't have to be paid to be valuable and that this insight has important implications for economics. For example, if economic models do not acknowledge the value of care work, policies based on such models may have unanticipated consequences and adverse outcomes. Cutbacks in health care may mean that sick people will remain ill longer and therefore need more care from family members. The caregiver, typically a woman, will need to reduce paid work hours or work more intensively; or those who need care may not get enough of it, resulting in greater morbidity and a higher likelihood of death. Cutbacks in publicly provided child care may similarly lead to more demands on family caregivers; or children may just receive less care and have fewer skills, reduced productivities, and lower well-being. Feminist economists argue that such examples reveal the benefit of economic approaches that recognize the interdependence between the marketed and unmarketed sectors of the economy. Feminist research also provides insight into other aspects of family life and domestic relationships, including variations resulting from other family configurations, such as same-sex and single-mother households.

Gender-Aware Economic Policies

A widely held view among feminist economists is that gender justice should be a goal of economic policy and that efforts to end gender inequality must be based on gender-aware economic models that more fully reflect all human lives and not just those of male or European-descended populations. Gender mainstreaming, the idea that public actions should be thoroughly evaluated and monitored to provide equal benefit to women and men, is one such economic policy. Gender budgets similarly are designed to ensure that public expenditures have equal impact on women and girls as compared with men and boys. Feminist economic research, more broadly, points to the potential success of a wide variety of policies designed to enhance gender justice and women's well-being.

Feminist Epistemology

This entry presents, both historically and thematically, the birth and development of feminist epistemology.

Why Feminist Epistemology?

Succinctly put, the mission of feminist epistemology is to supply an answer to the question "Is the sex of the knower epistemologically significant?"—which was posed by Lorraine Code in a 1981 article by that title. The question, which is germane to postpositivist knowledge-producing projects in the physical and social sciences and in everyday life, does not admit of an easy "yes" or "no" response. In a tradition where the goal of achieving objective certainty in knowledge depended on the interchangeability of knowers in replicable observational conditions, the idea that any subjective property—such as the sex—of such knowers could claim epistemological significance contests the basic principles of empirical inquiry. Although the question may sound facile, its implications are complex and far-reaching. It asks whether certain specificities of subjectivity could count among the conditions that make knowledge possible or could impede its achievement. It comes neither from a simplistic thought that what is true and valid for women might not be true and valid for men, and vice versa, nor from an urge to promote "women's ways of knowing," but from a conviction that the diverse circumstances of human lives from which subjectivities are constituted are such as to contest the reductivism from which universal human sameness—and epistemic interchangeability—are presupposed.

For non-philosophers, epistemology is an esoteric inquiry, relevant to philosophers alone; but reliable, authoritative knowledge is integral to feminist practices of developing informed analyses of social-political oppression and marginalization and engaging in emancipatory projects. In addition, epistemologists seek to articulate principles and procedures for evaluating knowledge claims for their veracity and their social-political implications. Feminists have to *know* the social-structural implications of women's marginalization in public knowledge, as knowers and known, so as to account for women's continued underrepresentation—their minimal epistemic power and authority—across intersections of gender, race, class, ethnicity, sexuality, ability, and disability. Hence, they have to know the social, discursive structures well enough to show how they sustain hierarchies of power and privilege, in projects that frequently involve learning to see what was previously invisible, taken for granted, or dismissed as showing that women are incapable of the "best" kinds of knowledge. Thus, while "mainstream" epistemologists evaluate sources of evidence and methods of inquiry that are generically conceived, seeking universal, necessary and sufficient conditions for achieving certainty and refuting skepticism, feminist epistemologists are also committed to analyzing the nature and positioning of knowers and the (gendered) politics of knowledge and to discerning what "universal" conclusions fail to address.

Historically, Western philosophy has aligned mind/reason with maleness and body/emotion with femaleness, representing emotions as irrational and invoking women's alleged emotionality to disqualify them as knowers. Yet feminists, indebted to Genevieve Lloyd's *The Man of Reason,* have shown that maleness or femaleness are not incidental to but constitutive of subjectivities and cognitive possibilities, variably throughout Western history. In consequence of "different" (from affluent White male) embodiment, people have been assigned marginal epistemic status by criteria that assimilate knowing to a single norm, and they thence assume universal access to uniform experiences for which differences are dismissed as irrelevant aberrations yet exposed as exclusionary by feminists and other Others.

Informed by the consciousness-raising practices of the 1960s, feminists, latterly in concert with antiracist and other postcolonial theorists, have exposed cognitive dissonances and incongruities between women's multiple and diverse experiences and theories and conceptual schemes implicitly but routinely derived from a White male norm, which purport to explain—to *know*—the physical–social–material world and to know women's and other Others' experiences as a part of it. Eschewing aims of determining how ideal, abstract, and infinitely replicable knowers ought to know, feminists such as Donna Haraway in *Situated Knowledges* and Lorraine Code in *What Can She Know?* have produced sophisticated, critical-constructive analyses of how diversely situated and embodied knowers can

and do know and how normative epistemic requirements can and should be fulfilled by real knowers.

Beginnings

In the 1980s and early 1990s, feminist epistemologists tended to occupy one of two positions: (1) feminist empiricism or (2) feminist standpoint theory. Some, such as Sandra Harding in *The Science Question in Feminism* and Helen Longino in *Science as Social Knowledge,* accorded biology and the social sciences the centrality, if not precisely the paradigm status, post-positivist epistemology had accorded the physical sciences. Others, including contributors to Linda Alcoff and Elizabeth Potter's *Feminist Epistemologies,* drew on mainstream epistemology as well as its philosophy-of-science offspring. In the 21st century, feminist epistemology can no longer adequately be mapped within these categories, even by enlisting postmodernism—the third initial category to address the remainder; yet the postmodern import of the *antiessentialism* that characterizes all three positions is apparent.

Briefly, feminist empiricists focus on evidence gathering, advocating a method alert to the exclusionary effects of androcentrism in judgments of what counts as evidence worthy of note, while standpoint theorists focus on the constitutive effects of the historical-material positioning of women's lives, practices, and experiences. For feminists, an empiricism committed to evidence gathering and justification that honors objectivity, yet is informed by feminist insights and commitments, can produce more adequate knowledge than classical empiricism, oblivious of its complicity in sustaining a pervasive sex/gender system. An enhanced vision enables feminists to enlist empiricist tools to expose the sexism, racism, and other "isms" that, often silently, inform knowledge production and circulation. In Longino's social empiricism, communities, not individuals, are knowers: Their background assumptions contribute to shaping knowledge as process and product. Taking genetic research as illustrative, Longino shows how assumption (value)-driven differences in knowledge production contest the possibility of value neutrality while endorsing respect for evidence and collaborative cognitive agency. Lynn Hankinson Nelson, in *Who Knows: From Quine to a Feminist Empiricism,* develops from "naturalized epistemology" a neo-empiricism for which communities, not individuals, are the primary knowers; and knowers come to evidence through webs of belief, available for communal critique. Because the marginalized cannot realize their emancipatory goals without understanding the intractable aspects of the physical and social world and its malleable, contestable features, they have to achieve a fit between knowledge and "reality," even when "reality" consists of social artifacts such as racism, oppression, or pay equity. For feminist empiricists, an empiricism alert to gender specificity in its multiple intersectional modalities can achieve just this. Thus, for Sandra Harding, politically informed inquiry introduces a "strong objectivity," to yield a better empiricism than inquiry conducted from an allegedly neutral "view from nowhere" can achieve.

For standpoint theorists such as Nancy Hartsock, in *Money, Sex, and Power: Toward a Feminist Historical Materialism,* empiricists lack the conceptual resources to address the historical-material diversity from which people produce knowledge. Standard-setting knowledge in Western societies has derived from the experiences of White, middle-class, educated men, with women (like Marx's proletariat) occupying underclass epistemic positions. As capitalism "naturalizes" the subordination of the proletariat, patriarchy "naturalizes" the subordination of women, and as engaging with material-social experiences from the standpoint of the proletariat denaturalizes these assumptions, so does starting from women's lives denaturalize the patriarchal order. A feminist standpoint is a hard-won product of consciousness raising and social-political engagement, in which the knowledge that enables the oppressed to survive under oppression is enlisted as a resource for initiating social transformation.

Neither empiricist nor standpoint feminism can resolve all the issues. Even the new empiricism falls short of fully addressing the power-saturated circumstances of diversely located knowers or of engaging with questions about how evidence is discursively constituted and whose evidence it suppresses in the process. Nor can standpoint theory alone avoid obliterating differences. Its "locatedness" offers a version of social reality as specific as any other, albeit distinguished by its awareness of that specificity. But empiricism's commitment to exposing the concealed effects of gendered and other specificities in knowledge production cannot be gainsaid, nor can standpoint theory's critical analyses of women's experiences, with its focus on how hegemonic values, entrenched power structures, and

taken-for-granted assumptions about human sameness work to perpetuate marginalization.

In the decades since empiricism and standpoint theory seemed to cover the territory, with postmodernism posing anti-epistemological challenges to both, feminists have found these alternatives neither mutually exclusive nor able, separately or together, to adequately explain the sexual politics of knowledge production and circulation. Cross-fertilizations have proven more effective than adherence to methodological orthodoxy: The idea of a unified theory, or of the unity of knowledge, has—productively—been discredited in its putative status as a regulative ideal.

Differences

Feminists cognizant of the differences that difference makes do not, in fact, hope to achieve a unified standpoint. Thus, Patricia Hill Collins, in *Black Feminist Thought: Knowledge, Consciousness, and the Politics of Empowerment,* advocated an "outsider-within" Black feminist standpoint: an Afro-centered epistemology that shows how knowledge produced in racially subordinated groups fosters resistance to the hegemonic knowledge produced at the putative "center." And Maria Lugones, in "Playfulness, 'World-Travelling' and Loving Perception," advocated practices that eschew, and move self-consciously away from, a too particular, self-satisfied location at a hitherto uncontested social and epistemic center, to travel, literally or metaphorically, to "other worlds" and learn how it is there. Donna Haraway recast the subject and object of knowledge as radically located and unpredictable and knowledge construction as learning to see from positions discredited in dominant accounts of knowledge and reality. Taking women's cognitive practices seriously can enable feminists to eschew the individualism and universalism of mainstream theory, to examine specifically situated knowing, where theory, materiality, and practice are reciprocally constitutive and where knowers are diversely positioned and active within them. Thus, Evelyn Fox Keller's biography of the geneticist Barbara McClintock, *A Feeling for the Organism,* presents a scientist engaged with her objects of study and attuned to differences, as evidence for a psychosocially gender-inflected style of research. And in *What Can She Know?* and *Ecological Thinking,* Lorraine Code examines how power and privilege yield asymmetrically gendered, racialized, and class-inflected standards of authority in medical knowledge, in the experiences of welfare recipients, for testimonial credibility, and in women's responses to sexist and racist challenges. Her ecological model of knowledge and subjectivity unsettles the "master" model that governs mainstream epistemology.

Recent Developments

Noteworthy for this account are developments that build on and incorporate aspects of the early positions while no longer aligning with the original taxonomy. The issues to be discussed in this section are the significance of testimony for social epistemology; the blurring of boundaries between epistemology, ethics, and political theory; and the new epistemologies of ignorance.

For Anglo-American epistemologists, the principal sources of empirical knowledge were perception, memory, and testimony, listed in this order to show their comparative levels of reliability—perception being the most reliable because it is the most "grounded," while testimony, with its reliance on other people, ranking a distant third, was often assimilated to reliance on opinion or hearsay rather than on the putative security of direct perception and memory. Recent developments in social epistemology, to which feminists are among the most innovative contributors, contest this ordering, returning epistemology to the real world, where it is clear that only a very small proportion of what people reasonably claim to know is theirs by virtue of direct perceptual experience or memories thereof. "We," whoever we are, are multiply interdependent in our knowledge-productive activities: Whereas formal analytic epistemology sought to transcend interdependence, social epistemologists—and feminists prominently among them—take it as a given and analyze its multiple modalities. Clearly, reliance on testimony as a source of knowledge requires taking the subjectivities of testifiers into account, for decisions about who can be trusted become crucial. It is in engaging with this issue that some of the most productive recent feminist inquiry has been produced. For theorists who engage with the centrality of testimony, questions such as those Lorraine Code raises in *Epistemic Responsibility* and Miranda Fricker in *Epistemic Injustice* and issues in the politics of incredulity move to central places in epistemological inquiry. The tasks facing epistemologists become increasingly complex as empirical observational inquiry is itself shown always to be inflected

by the social-political positioning of knowers and the known, and conceptions of objectivity (which is by no means eschewed in such inquiry) become entangled with the assumptions born out of a dominant social-epistemic imaginary whose constitutive part in shaping received views of knowledge and epistemic subjectivity has itself to be subjected to analysis.

Crucial too in understanding the diverse facets of these developments are the new epistemologies of ignorance discussed by the contributors to Shannon Sullivan and Nancy Tuana's edited volume *Race and Epistemologies of Ignorance*, where theorists examine the moral-political effects of the ignorance inadvertently or otherwise produced by, or alongside, received bodies of knowledge. All these developments show how feminist epistemology continues to be a vibrant and challenging field of inquiry. Some of these thoughts come to fruition in texts such as George Yancy's collection *The Center Must Not Hold*, whose title and content capture a governing insight and inspiration of the best feminist and anti-racist epistemology of the early 21st century.

Feyerabend, Critique of Rationality in Science

This entry introduces the work of Paul Feyerabend and reviews in particular his criticisms of scientific rationality as well as counterarguments and rejoinders. Feyerabend has been an influential critic of

accounts of scientific rationality and the role scientific rationality plays in our lives. His criticisms of scientific rationality are different in different periods of his career. However, there is an important underlying assumption throughout his work, which is that the choice of a scientific way of life is primarily an ethical choice. It is not one dictated by rational or empirical canons of rationality.

In the work Feyerabend wrote between the 1950s and the early 1970s, his criticisms focus on naive empiricist pictures of science and on narrow conceptions of the scientific enterprise. Like Karl Popper, he sees science properly conducted as part of a critical attitude that has an important and positive role in human life. The 1961 lectures titled *Knowledge Without Foundations* contain a clear encapsulation of his early view. In them, he argues that the scientific attitude involves two components: first, producing bold and broad theories that go beyond and against appearances and, second, producing and seriously considering important criticisms of those theories.

It is Feyerabend's later work that has been highly influential. In that work, his criticisms focus on the role of science in society. He sees that role as rationally unjustifiable and ethically dubious.

Critique of Scientific Rationality

Feyerabend's later work contains at least four criticisms of scientific rationality:

1. The first criticism already occurs in his early work. It is a criticism of philosophical reconstructions of scientific reason and not of science. The criticism is that there is no universal scientific method in the form of fairly precise formal rules that has been used by successful scientists or by the scientific community. This criticism was highlighted in the book *Against Method,* which first appeared in 1975. In it, Feyerabend defends the principle, ironically, that if one wants to make progress in science, anything goes. He calls this the principle of "epistemological anarchism." His primary argument for his claim is contained in a careful case study of Galileo's fundamental contribution to the Copernican revolution.

Feyerabend argues that Galileo proceeds counterinductively rather than inductively in producing his version of Copernicanism; relies on poor observations, which he rhetorically puffs up; defends inertia in an ad hoc manner; and bolsters his theory through various forms of trickery. Furthermore, many of Galileo's predictions on the basis of his version of Copernican theory were falsified.

Feyerabend's friend Imre Lakatos was inclined to agree with much of what Feyerabend had argued. However, he attempted to create a framework for assessing the rationality of research programs in the long run, which would have allowed Galileo and others to get off the hook. On Lakatos's account, it is essential to science for some individual scientists to play a risky game by producing bold hypotheses that go against the observable evidence. Sometimes such strategies pay off because the bold hypotheses eventually predict great numbers of startling novel facts and radically simplify and reorganize the known information. Nevertheless, the scientific community as a whole is rational because journal editors and funding bodies will eventually (rightly) prefer research programs that predict novel facts and unify knowledge to those that have failed to do so.

In response, Feyerabend argues in *Against Method* that Lakatos's theory is a form of epistemological anarchism in disguise—Lakatos has failed to show that any move by scientists or the scientific community could be rationally ruled out. After all, Lakatos admits that some scientific theories, like atomism, had only paid off after thousands of years and had been permitted over a long time to continue to exist even though they had not predicted a single novel fact for ages. All Lakatos does is call any move by scientists that happened to be regarded as successful later "rational."

Feyerabend does not seem to have intended his first criticism to undermine the status of science. Rather, he seems to have intended to agree with Thomas Kuhn that scientific method is learned through examples of good scientific work and is not reducible to general rules.

Recent commentators have been inclined to agree with Feyerabend's criticism of simplistic formal accounts of a universal method. However, his analysis of the Galileo case has been undermined by detailed historical work. This work has exposed a number of important problems, including the following. Galileo did not introduce the notion of inertia ad hoc. Rather, he introduced it after careful experiments with inclined planes. His defense of the use of the telescope involved careful work that showed in detail that ordinary observation of bright objects at night is worse than telescopic observation. Furthermore, Galileo used the commonsense

principle of inference to the best explanation to justify many of his claims.

2. Feyerabend's second criticism of scientific rationality relies on his claim that science contains incommensurable theories. On Feyerabend's account, two theories are incommensurable if they are comprehensive cosmological schemes, and if not, a single primitive descriptive term of one theory can be defined in terms of any primitive descriptive term of the other. He claims that Newtonian mechanics and Einstein's Relativity theories are incommensurable in this way. Both deal with the entire universe and everything in it. Each describes any item in a way that presupposes a radically different view about the nature of things. For instance, the mass of an object is an intrinsic property in Newtonian mechanics—namely, the amount of matter in an object. In Einstein, it is a relational quantity. This means that not only this property but also what it is to be an object vary between the two theoretical frameworks.

Incommensurable theories cannot be tested using descriptions that are independent of the theories, as the theories are comprehensive. For example, we cannot test Einstein's claims about mass while using the term *mass* in its Newtonian sense, since our description of the experimental test presupposes that Newtonian mechanics is true. In his early work, Feyerabend argues that this is not a serious problem unless we are wedded to some naive empiricist ideas about scientific testing. He proposes methods for testing the relative merits of incommensurable theories. Each theory can be tested by using its own descriptive terms to describe the result of an experiment. If there is an inconsistency between the predicted result and the result obtained, then the theory has been refuted using its own descriptive terms.

By the time he wrote *Against Method* and his more radical 1978 work, *Science in a Free Society,* Feyerabend had come to think that incommensurability posed much deeper problems for the rationality of science. The reason is threefold: First, the ontologies of two comprehensive cosmological schemes sometimes differ far more radically than he had initially thought. Second, the most fundamental standards for judging truth sometimes differ between theories. Third, comprehensive cosmological schemes constitute the world—they do not merely describe an independently existing world.

Feyerabend spells out his claims primarily through a detailed discussion of the worldview of the archaic Greeks shortly before the appearance of philosophy. He claims that Homer treats gods as everyday observables that we would describe instead as psychological states. For instance, what is perceived by Homer's heroes as a direct experience of Athena is, we would say, a sudden rush of adrenaline. Dreams are perceived by Homer's heroes as things that are sent by the gods and literally arrive top down. They are not mental events. The conception of knowledge in Homer is radically different—knowledge is conceived of as lists not as theories. Feyerabend claims that this makes independent tests impossible. Indeed, he claims that the disappearance of the Homeric worldview at the hands of Greek philosophers was literally the disappearance of gods and their replacement by things like atoms in empty space.

Feyerabend's second criticism seems to collapse into incoherence, for if he is right, one cannot be thinking about the same things when one is thinking as a Homeric Greek and when one is thinking as a modern westerner. This implies that Feyerabend cannot be explaining to us in our world what people in the Homeric world are thinking. This is because (a) if Homeric people are in the other world, they are not in our world, and if they are in our world, they are not in the other world and (b) Homeric descriptions will not refer to anything in our world. What we understand to be Homeric talk in our world thus cannot be incommensurable with our talk, and Feyerabend cannot prove his case that there is another, radically different world.

Feyerabend was inclined to water down incommensurability to deal with this objection. In later works, he criticizes relativism, though he still argues that when dealing with very different outlooks, simple-minded comparisons are trivial or irrelevant. He seems to continue to argue that we cannot reasonably judge that a very different outlook is false or inferior from a transcendent standpoint. However, critics of Feyerabend would respond that this is irrelevant if outlooks are not incommensurable with one another.

3. Feyerabend's third criticism of the rationality of science is aimed not so much at science but at the role science plays in our lives. He argues that whether science tells us the truth or not, it should not have to play a crucial role in our lives. Whether scientific knowledge is useful or not depends on how we choose to live. We might rationally decide that a way of life in which science plays very little part is better than a way of life in which it does. Science

may well reveal a world that is dull, offers us little consolation, is threatening, and so on. We might well be better off living with consoling falsehoods than with unpleasant truths. Furthermore, science does not exist in abstraction from real societies. On the contrary, it is developed in real societies that have structural tendencies to apply it in ways that threaten human interests. Feyerabend criticized the demand for logical preciseness in a similar way when he noted that "a logically precise idea of tap dancing might give us persistent cramps." Logic, like science, not only exists as a bunch of abstractions, it is used by real people in real situations, and its effects on real people need to be studied before we can confidently pronounce that its widespread use will be useful. A useful illustration of this point can be found in the documentary film *The Fog of War.* In the film, the former U.S. Secretary of Defense Robert McNamara praises his training in logic. He then goes on to explain that in the U.S. Air Force in World War II he used the skills he learned to help him calculate the maximum damage that could be achieved from minimum input in firebombing Japan.

As a consequence of this third criticism, Feyerabend argues that we should separate the state from science in the same way in which advanced societies had separated the state from religion. Citizens should be free to choose what role science plays in their lives and the lives of their children.

Arguments against the third criticism include the following. First, even those who reject a scientific way of life will need to know a considerable amount about science to protect themselves from its effects. A romantic primitivist will need to know something about the effects of nuclear power to deal with a proposal to build a nuclear power station. Second, the use of nonscientific standards by citizens often constitutes a serious threat to others. For instance, medieval views about witches and how to discover them pose a serious threat to those accused of witchcraft. It is legitimate to prevent such attitudes of mind from developing by educating people to judge matters scientifically. Third, children need to be protected from the actions of their parents. Most people do not find science threatening. Indeed, they find science very useful. To deprive children of a scientific education because of the views of their parents is unjustified. It should be noted that none of these arguments is a decisive and complete rebuttal of Feyerabend's third criticism of the rationality of science. Feyerabend thinks that such arguments at best show that the separation of the state from science needs to be qualified.

4. Feyerabend's fourth criticism of the rationality of science is related to the third criticism. It is best put in his posthumously published work *The Conquest of Abundance*. He argues that science creates abstractions and idealizations, which, though useful in limited ways, fail to capture the richness and diversity of being. Science is of some limited use to us, but this gives it no rational warrant to replace other aspects of our picture of the world. This criticism is tied to the claim that various nonscientific ways of conceptualizing and dealing with being can be successful according to a range of criteria for success. Some of his central arguments for this criticism cannot be easily explained abstractly as they are analyses of episodes from the history of philosophy, of science, and of cross-cultural contacts. A central theme in those analyses is that philosophical and scientific arguments for views about being presuppose the merits of rationalism or science—they do not show that science and rationalism are correct. There has not been much debate about the fourth criticism. Nevertheless, it may be argued that we do not need rationalism and science to judge science as being superior to traditional views in important respects. We can instead use commonsense criteria to choose predictively powerful and more coherent theories. Science is on a continuum with some parts of everyday thought in every human culture. This, of course, does not indicate that rationalism and science are superior in every respect to other belief systems. So perhaps Feyerabend is partly right.

Whether parts of Feyerabend's critique of scientific rationality are cogent is still a matter of considerable debate.

Folk Psychology

Folk psychology (FP) is the commonsense understanding of other minds; it is the kind of psychology one does without any formal training. This entry reviews FP and the debates in it as well as recent developments and alternative theories on offer.

FP and related philosophical discussions have important repercussions on how to explain the way people routinely understand each other's beliefs and actions by employing pretheoretical, everyday psychological notions. In that sense, it is a social practice. So FP accounts are obviously important for the future of various social sciences.

Folk Psychological Notions

When we speak about what people "desire," "believe," "hope," or even "remember" and "see," we are appealing to *folk* (everyday pretheoretical) notions that, for the most part, were not introduced by scientists as either explanatory or predictive posits. The folk use these terms to make sense of behavior by putting it in context or identifying purported causes of behavior. In this way, we, the folk, attribute mental states to other people.

On the traditional narrow understanding of FP, the notions are limited to those attitudes that take a proposition as an object—that is, *propositional attitudes.* These are attitudes like *believe that* and *desire that,* such as "Poppy believes that the flowers are red." Attitudes that do not take propositions as their objects or instances of an attitude that don't have a proposition as an object, as in "Poppy desires cake," would not count as folk psychological attributions on this narrow view. A wide understanding of FP includes such attributions, as well as additional elements such as emotions and personality traits. Attributions such as "Poppy feels guilty" or "Poppy is considerate" fall within the scope of FP on this view.

Some attributions can be interpreted both widely and narrowly. Consider the term *sees,* which is sometimes translatable into *believes.* For example, "Poppy sees that there is a cake on the table" means "Poppy believes that there is a cake on the table." When the term *sees* takes an item as its object, it would not count as FP understood narrowly, as in "Poppy sees cake." The psychologists Michael Tomasello and Josep Call claim that chimpanzees understand seeing and can attribute perceptual states to others but that there is no evidence that they attribute beliefs, suggesting that chimpanzees may be folk psychologists on a wide, but not narrow, reading of FP. Another example is *knowing.* The same team, along with the psychologist Juliane Kaminski, does not hesitate to claim that chimpanzees know what others know, despite the fact that philosophers often define knowledge in terms of belief.

The FP-narrow concept is closely related to *theory of mind* (ToM), or the capacity to ascribe

propositional attitudes to others (also called *mind reading*). The psychologists David Premack and Guy Woodruff introduced the term in 1978 when they asked if the chimpanzee has a ToM, and the topic was taken up by the developmental psychologists Josef Perner and Heinz Wimmer. This research led to the conclusion that by age 4 human children are able to attribute propositional attitudes to others in terms of false beliefs. More recently, the psychologist Renée Baillargeon introduced nonverbal ToM tests, and some interpret the data as evidence that infants have a ToM before their first birthday. Despite the lack of experimental evidence for ToM in other animals, anecdotal evidence, the behavior of enculturated chimpanzees, and concerns about prior methodology leave open the possibility that other animals may share this capacity with humans.

The use of FP in science has been challenged in terms of its usefulness for individuating behaviors in psychology and neuroscience. For example, Angeline Lillard argues that FP-narrow concepts are not culturally universal, and Paul Churchland claims that FP-narrow concepts will be eliminated once we gain new and more precise notions from a mature neuroscience.

Theories of Folk Psychology

While the focus is on the FP practices of predicting and explaining behavior, the practices of FP are much broader than this, and they include everything from judging and coordinating behavior to teasing and flirting. Attributing FP notions alone is not sufficient for FP practices; what is needed is some understanding of how these notions relate with one another and with behavior.

The mind-reading debate between *Theory Theory* and *Simulation Theory* versions of FP was a matter of much discussion, though it has largely ended with many of the players accepting some hybrid view. These views are fully presented as their own entries in this encyclopedia.

Others working in FP eschew that debate—and the mind-reading label. Embodied, normative, and pluralistic views of FP stress the low cognitive demands for many FP practices. For example, Kristin Andrews suggests that the quotidian acts of prediction (of others' behavior or beliefs) involve a host of different cognitive processes, including inductive reasoning, trait attribution, and stereotype activation, and that these are distinct from belief attribution. Daniel Hutto suggests that such quotidian practices are examples of mind minding, or attending to the objects of intentional attention. Tadeusz Zawidzki suggests that mind shaping, or setting up regulative ideals that shape behavior, is behind our successful predictions.

Theories abound about the evolution of FP-narrow abilities in humans and the distribution of them among species. In his version of the Social Intelligence Hypothesis, Nicholas Humphrey argues that humans and perhaps other primates developed the ability to think about others' minds as a strategy for succeeding in a Machiavellian world of cheaters and thieves. Daniel Hutto's Narrative Practice Hypothesis suggests that it is having language, which allows us to develop and hear stories about people's reasons for their actions, that led to the uniquely human ability to understand others' actions in terms of their beliefs. Kristin Andrews argues that our understanding of others in terms of beliefs and desires rests on an understanding of social norms and a desire to explain norm violations and that these may be capacities we share with other species.

Formal Epistemology

Formal epistemology is the application of formal methods (logic, probability theory, and algebra, etc.) to an analysis of the operational properties of knowledge and related epistemic phenomena such as belief and information. Just as in the physical sciences we use formal methods to construct mathematical models of physical phenomena, in formal epistemology, we use formal methods to construct mathematical models of epistemic phenomena.

The earliest example of *epistemic logic* is to be found in Jaakko Hintikka's 1962 work *Knowledge and Belief,* itself influenced by Georg Henrik von Wright's 1951 *Essay in Modal Logic*. The starting point for epistemic logic is to encode knowledge and belief with the *modal operators K* and *B*. In this case, *agent α knows that A* and *agent α believes that A* will be encoded syntactically by (1) and (2), respectively:

1. $K_\alpha A$
2. $B_\alpha A$

If something is known, then it is true (on account of knowledge being factive). It is also believed (on account of knowledge implying belief), hence its negation is not believed. Thus, we have the axioms (3), (4), and (5):

3. $K_\alpha A \rightarrow A$.
4. $K_\alpha A \rightarrow B_\alpha A$.
5. $K_\alpha A \rightarrow \neg B_\alpha \neg A$.

Furthermore, axioms may be added in order to account for additional epistemic capacities. Note that the converse of (5), $\neg B_\alpha \neg A \rightarrow K_\alpha A$, does *not* hold, at least not without the additional assumption that agent α is maximally opinionated. Hence, *K* and *B* are not *duals* in the sense of other modal operators such as *necessity* $\Box$ and *possibility* $\Diamond$, where we have it both that $\Box A \leftrightarrow \neg \Diamond \neg A$ and $\Diamond A \leftrightarrow \neg \Box \neg A$. However, *K* and *B* do share some important properties with $\Box$ and $\Diamond$, respectively, namely, that the first member of each pair is a universal modality and the second member of each pair is an existential modality. To understand universal and existential modalities, we need to move beyond the syntax of epistemic logic to its semantics.

Modal operators may have their semantics specified by *possible worlds,* as first discussed by Saul Kripke. Possible worlds are simply abstractions of different ways the universe might have been. In basic epistemic logic, a *model* **M** is a triple consisting of a set of possible worlds *W,* a binary accessibility relation $\rightarrow_\alpha$ between members of *W,* and a valuation relation $\Vdash$ that assigns truth-values to propositions at worlds. In this case, *K* and *B* will have the following evaluation conditions with respect to **M** (where $w_@$ is the actual world).

6. $w_@ \Vdash K_\alpha A$ *iff* for all $w_i \in \mathbf{M}$ such that $w_@ \rightarrow_\alpha w_i$, $w_i \Vdash A$.
7. $w_@ \Vdash B_\alpha A$ *iff* for some $w_i \in \mathbf{M}$ such that $w_@ \rightarrow_\alpha w_i$, $w_i \Vdash A$.

It is in the sense specified by (6) and (7) that *K* and *B* are respectively universal and existential modalities, since *K* requires that *A* is true at *all* worlds accessible by α, while *B* requires that *A* is true at *some* worlds accessible by α. This is as we would expect, since belief, unlike knowledge, allows for the possibility that the proposition falling within its scope be false.

Contemporary research into epistemic logics and related areas is vast. One direction of expansion involves the switch from possible worlds to *information states*. Unlike possible worlds (which are complete and consistent), information states increase the modeling flexibility of the resulting logical systems by representing incomplete and/or inconsistent information. This allows for a very fine-grained analysis of real-world epistemic scenarios. Another direction of grain increasing is the distinction between *implicit* and *explicit* beliefs.

Perhaps the most important recent development in the logical area of formal epistemology is the move from *static* to *dynamic* epistemic logics. Dynamic

epistemic logics allow us to model the epistemic actions that facilitate the flow of information that underpins knowledge and belief. Information may flow between an agent and her brute physical environment, in which case the relevant epistemic actions will be *observations;* between two or more agents, in which case the relevant epistemic actions will be *announcements;* between different states of explicit awareness of a single agent, in which case the relevant epistemic actions will be *inferences;* and more.

Both static and dynamic epistemic logics may have their semantics given by information states and the relations between them. But a collection of objects with relations between them will correspond to an *algebra*. As such, there is a flourishing research program into algebraic models of epistemic phenomena, which extends into models carried out in extremely powerful mathematical frameworks such as *quantum logics* and *category theory*.

All the formal epistemic frameworks introduced so far have been *qualitative*. They allow for comparisons and combinations of bodies of stronger or weaker beliefs, more or lesser knowledge, more or less information, and so forth. In short, we may *order* such epistemic phenomena. In order to measure it—to impose discrete numerical values or weights to beliefs or bodies of information—we move from the qualitative frameworks of formal epistemology to the *quantitative* ones.

The canonical quantitative framework in formal epistemology is based upon *conditional probabilities*. The *conditional probability function* is $P(B|A)$, where $P(A) > 0$, given in (8):

8. $P(B|A) = P(A \cap B)/P(A)$.

Bayesian epistemology is a family of approaches (Fitelson, in press) founded upon *Bayes's theorem* (9), which, following immediately from (8), is a fundamental theorem of conditional probability. Bayes's theorem calculates the conditional probability (P) of a hypothesis (H) given some evidence (E), written as $P(H|E)$, as follows:

9. $P(H|E) = P(H)P(E|H)/P(E)$.

The probability measure is then taken as a *normative prescription* on your degree of belief. The rational degree of belief in H given one's total evidence E is just $P(H|E)$, calculated as stipulated by (9). Following Frank Ramsay, one's degree of belief is taken to be the odds that one would take on a bet that the proposition(s) encoded by the hypothesis is true, and one's total evidence is whatever evidence it is that caused one's belief to have the degree of confidence that it enjoys.

An important consequence of this shown by Ramsay is the Dutch Book theorem: If one is prepared to adjust one's betting pattern so that it maps onto one's degrees of belief, then these degrees of belief are governed by the probability calculus if and only if one cannot be outwitted by a sequence of bets constructed by any betting opponent, no matter how cunning.

Quantitative belief revision is underpinned by *conditionalization*. Conditionalization states that one's degrees of belief should map onto the probability calculus and that the revision of one's beliefs should proceed according to (8) or (9). In other words, in light of our observing B, our degree of belief in A specified by $P(A)$ should be adjusted according to the basic tenets of the probability calculus. Hence, belief revision is another *dynamic* turn in formal epistemology.

An important theorem for quantitative belief revision is *de Finetti's theorem*. Informally, the theorem's contribution is that granting certain conditions, as two agents increase their evidence bases with respect to an event series, their degrees of belief with respect to the likelihood of a future event in the series will meet.

Like research into the qualitative logical aspects of formal epistemology, research into the quantitative decision-theoretic frameworks of formal epistemology is extremely active. Normative quantitative frameworks for rational decision making group under Decision Theory. A powerful research subarea is Social Choice Theory, which contributes to sociology by providing analyses of group decision-making scenarios, such as voting outcomes.

Qualitative and quantitative approaches to formal epistemology merge and intersect at many places, both with models of belief aggregation and models of the information flow that underpins such beliefs. Game theory is a formal epistemic framework that provides both qualitative and quantitative models of a range of epistemic phenomena.

Formal epistemology interacts with a wide range of research areas. Such areas include the philosophy of science, with models of theory change and other belief revision frameworks such as AGM Theory (after the initials of the authors who established the

field—Alchourron, Gardenfors, and Makinson); artificial intelligence, with models of inference; theoretical computer science, with models of reasoning resources via linear logics; and more. Given that formal epistemology models epistemic phenomena and given the ubiquitous presence of such phenomena across research into rational behavior, this is as we should expect it to be.

Foucault's Thought

Michel Foucault was a French philosopher and historian of ideas who was born in Poitiers in France in 1926 and died in Paris in 1984. Since his death, his work has had a steadily increasing impact across the social sciences and humanities, generating new research methodologies, new areas of empirical interest, and a whole panoply of theoretical concepts. Foucault produced some 11 books during his lifetime, and a collection of 364 of his shorter writings was published in 1994. From 1970 to 1984, in his capacity as Professor of Systems of Thought at the research institution the Collège de France, he also produced an annual series of lectures reporting on his research. These lectures have gradually

appeared in print since 1997. This entry provides an overview of Foucault's overall philosophy and methodology, looks at key concepts in his work, and provides descriptions of his best-known books.

Philosophy and Methodology

Central to Foucault's work is the idea that all human experience, and knowledge and organization of the social and physical world are historical, from the most esoteric of philosophical abstractions to the most mundane of everyday activities. Notions that had hitherto more commonly been regarded as unchanging givens are historicized in Foucault's work—objects that include power, madness, sexuality, delinquency, the normal and the pathological, science, truth, knowledge, the subject (self), and ethics. For Foucault, not only is human existence entirely historical but also all social, cultural, and material practices embody processes of human thought. Knowledge and our perceptions of truth are not static but the direct result of our ever-changing interaction with our physical environment and with each other. Such an assumption opens the way for a variety of explanatory approaches that use detailed empirical work as a support in areas previously regarded as the province of speculative philosophy.

A strong social justice agenda also lies at the heart of Foucault's historico-philosophical approach. Foucault was part of a more general post–World War II social and intellectual movement that drew attention to the experiences of marginalized and colonized populations and the social strictures to which they and also more mainstream members of the social body were subject. Foucault also sought to examine bodies of knowledge that had been neglected and silenced by triumphalist accounts of scientific, technical, and social "progress."

If the subject matter of Foucault's writing often deals with the darker side of human existence (madness, illness, crime, abnormalities of all kinds, and the multiple restrictions around sexual practice), he is a fundamentally optimistic thinker in that he believes that by exposing this dark side, people will find certain aspects of the accepted status quo intolerable and be encouraged to develop more socially just practices. For all this, Foucault's view is that we will probably never reach that utopian point, promised by so many 19th-century post-Enlightenment thinkers, where all our social ills have been eradicated. Each solution brings an attendant set of new problems, which, in turn, need sustained work and reflection.

Foucault maintained a fairly consistent methodological approach throughout his career, even if he changed his descriptive labels. He deliberately sets out to oppose certain traditional notions and assumptions that were common currency in 19th- and 20th-century history and philosophy. These assumptions include belief in ideas of historical continuity, progress, and a universal unchanging subject of consciousness and action. He also challenges the notion that unchanging objects are "discovered" by this universal subject. Instead, what we see is a constant process of historical redefinition of both subjects and objects and a complex set of negotiations and relations between these terms that Foucault described in terms of knowledge, power, and truth.

Knowledge, Power, and the Subject

If Foucault's approach is held together by an overall philosophical and methodological unity, there are also three distinct periods in his work, marked by differences in emphasis, subject matter, and terminology. The first period, which is from 1954 to 1970, is characterized by a focus on the history and philosophy of science, in particular the medical sciences and the human sciences. To distinguish his work from standard approaches in the history of ideas, Foucault uses the word *archaeology* to describe his methodology during this period.

During the second phase of his work, from 1970 to 1981, he changed both the subject matter of his analyses and the emphasis of his methodology. While still working with the same historical period (from the mid 18th century to the mid 19th century, with some brief excursions into earlier European history), Foucault focused on the history of techniques designed to organize and govern populations. These techniques were deployed in institutions such as prisons, schools, hospitals, asylums, armies, and the state. He adopted a new term, *genealogy* (borrowed from Nietzsche), to describe his method. If archaeology focused on discourses and the ordering of knowledge systems, genealogy shifted the focus to a stronger and more explicitly detailed emphasis on the role of relations of power in the organization

of knowledge and institutions. In the third phase, during the 1980s, Foucault surprised his readers by shifting his focus away from broad sociocultural, institutional, and political arrangements to a focus on historical processes relating to the way individual subjects, the self, and ethical systems were constituted in classical antiquity and the early Christian era.

Foucault's Major Works

1954–1969

Foucault's first publications in the 1950s dealt with the history of psychology and psychiatry, and his first major work, which appeared in 1961, *History of Madness,* essentially rewrote standard histories of psychiatry. In this book, Foucault addresses the changing medical, economic, political, institutional, philosophical, ethical, artistic, and literary practices, which, from the 13th century onward, in Western culture, helped define madness as a cultural, social, and scientific category. He challenges traditional accounts demonstrating that the birth of modern psychiatry in the 19th century was not the result of the inevitable progress and victory of enlightened science over ignorance and superstition. It was instead the result of changes in what was accepted as valid knowledge in relation to a complex biological and social phenomenon as well as changes in practices relating to its institutional and political management.

In *The Birth of the Clinic* (1963), Foucault once again takes issue with traditional accounts in his account of the birth of clinical medicine between 1769 and 1825 in France. Standard histories held that a dubious reliance on superstition and ancient texts was replaced by a more enlightened scientific focus on visible and empirically observable symptoms. For Foucault, however, it is more a matter of a shift in the rules of what counted as valid and true knowledge. New notions of illness (the object) and what constituted medical practice as embodied in the doctor (the "gazing" or observing subject) were developed along with new institutions that recodified the identities and relationships among doctors, patients, and illnesses. The notions of the "gaze" and visibility have found considerable fortune in the secondary literature and tie in with Foucault's later work in *Discipline and Punish* about the growth of a disciplinary society that uses surveillance as one of its primary mechanisms of social control.

Perhaps Foucault's most obvious and direct engagement with the human and social sciences can be found in his 1966 work *The Order of Things,* which examines the origins of the modern disciplines of economics, linguistics, and biology. The book also includes a final chapter that deals with the formation of the disciplines of sociology, ethnology, history, and psychoanalysis.

If specialists remain interested in the intricacies of the arguments in *The Order of Things,* what has generally been popularly retained from this book are two notions. The first of these is the idea that the humanist subject, far from being universal, is a 19th-century creation. The second notion is the "episteme," similar in some respects to Thomas S. Kuhn's notion of the paradigm. It describes a configuration of scientific knowledge lasting roughly around 150 years that sets the rules for the production of knowledge regarded as valid.

Foucault's next work, *The Archaeology of Knowledge,* published in 1969, addresses a notion that has become familiarly associated with his work—namely, "discourse." At the most general level, Foucault uses this term to designate the material traces left by words in history: Discourse and words are not just transparent signposts to an external reality, they have their own substance and rules. Discourse is also a structured way of organizing particular forms of knowledge (e.g., psychiatry, economics, and biology) and a way of speaking about the world.

1970–1984

Like many other French intellectuals, Foucault was politicized by the social unrest and student and worker protests of 1968, and his inaugural speech at the Collège de France introduced specific references to the notion of power. From this point onward, Foucault's interest in the relation between knowledge and power took a practical as well as a theoretical turn. Demonstrating that he was no armchair philosopher, he took part in committees and demonstrations, as well as signing numerous petitions to support the rights of prisoners, health care workers, and immigrants and, later, Polish trade unionists and boat people. During the 1970s, Foucault introduced a number of productive concepts centering on power, which have been widely adopted in the secondary literature. These include

power-knowledge, discipline and surveillance, biopower, and governmentality.

The year 1975 saw the publication of *Discipline and Punish,* a history of the birth of the prison as the modern punishment of choice for criminal behavior and an account of what Foucault describes as the birth of the disciplinary society. Focusing on the period between 1757 and 1838, he argues that there was a move away from corporal punishment that took place in the public arena to punishment that focused on the deprivation of liberty and rehabilitation of socially deviant identities. Foucault proposes that the 18th-century British philosopher Jeremy Bentham's model prison, the Panopticon, where prisoners were watched round the clock by unseen guards or members of the public, serves as a metaphor for modern society, which relies on mechanisms of surveillance and discipline operationalized by a variety of institutions, including schools, prisons, hospitals, and armies.

In *The History of Sexuality: Vol. 1. The Will to Know* (1976), Foucault reverses the commonplace that European sexuality underwent a massive repression between the end of the 17th and the end of the 19th century, arguing that, far from repression, there was an immense expansion of knowledge around sexuality. This knowledge was one element in the control of the health and life cycle of populations so as to maximize the power and cohesion of modern industrialized nation-states. Foucault uses the term *biopower* to characterize this arrangement.

Foucault also developed his theories of power across a number of other shorter publications during the 1970s. His ideas challenge mainstream theories such as the idea that power is principally a property of the state and the ruling classes and, further, that power is by definition repressive. Instead, Foucault argues that power only exists as a relationship between different parties. If Foucault started with a fairly broad notion that opposed relations of power and resistance, eventually he adopted the position that all those involved in power relations necessarily had some degree of freedom of choice. When that freedom is shut down by violence or slavery, it is no longer a relationship of power. In short, power has its limits as a description and explanation of social relations.

In his 1977–1978 lectures, Foucault introduced the notion of governmentality, a notion that has become widely applied. If initially he used the term in relation to the rationalization of the exercise of state power and administrative management of populations, he gradually broadened it in the early 1980s to encompass an analysis of how individual subjects are governed and govern themselves and the techniques that allowed people to work on themselves and in relation to others.

Foucault's last two books, Volumes 2 and 3 of *The History of Sexuality: The Use of Pleasure* and *The Care of the Self,* published in 1984 a month before his death, examine techniques of self-formation in the work of the Ancient Greeks and Romans and early Christians. Of particular note is his development of a schema he uses to describe how people have historically constructed themselves as moral and ethical subjects. He systematizes this process into four levels: (1) the part of the self to be worked on (e.g., desires, acts, feelings), (2) the authority that makes an individual recognize his or her moral obligations (the Bible, rationality, etc.), (3) the work people do to transform themselves (meditation, diet, physical training, etc.), and (4) the desired outcome (everlasting life, salvation, self-mastery, etc.).

The sheer breadth of Foucault's interests and the flexibility of the philosophical and methodological tools he offers continue to make his work a fertile starting point for researchers across a wide diversity of theoretical and applied disciplines.

Frankfurt School and Critical Social Theory

Critical theory comprises a loosely associated group of philosophers, sociologists, political scientists, artists, and theologians who write incisive critiques of Western philosophy, ethics, law, and culture. These thinkers belong to the heritage inspired by the Institute of Social Research, founded in the early 1920s at the University of Frankfurt by Carl Grünberg and Felix Weil. The Institute had emerged as an academic and intellectual response to the collapse of the German political, social, and economic orders in the period immediately following World War I. Inspired by the social theory of the so-called Western Marxists, such as Georg Lukàcs (1885–1971), Karl Korsch (1886–1961), and Antonio Gramsci (1891–1937), the members of the early Institute examined certain Marxist tenets that they thought could be taken up and modified to confront these problems.

By the 1930s, Max Horkheimer (1895–1973) became the Institute's leader and chief theoretician. In his influential essay of 1937, "Traditional and Critical Theory," he outlined a broad program of theoretical and empirical-practical research for the Institute. But since most of its members were Jewish, the Institute was dissolved during the prelude to World War II, forcing most of the members and its associates into exile. Max Horkheimer, Walter Benjamin (1892–1940), Theodor Adorno (1903–1969), Erich Fromm (1900–1980), Herbert Marcuse (1898–1979), and Leo Löwenthal (1900–1993) fled Germany, with all but one, Benjamin, ending up in the United States. After the war, the Institute was formally reassembled in Frankfurt and continues to this day. Jürgen Habermas (1929–) and Karl Otto-Apel (1922–) emerged in the 1960s as the most representative and influential members of what is considered the second generation of critical theory. Now, a third generation, representing scholars from around the world, is emerging and continuing in the same critical direction.

Theoretical Principles

Critical theorists were united initially in opposition to the prevailing positivism of the day. On their account, positivism held that social, economic, and political questions could be resolved solely by objective, and thus uncritical, means. For example, historical studies were dominated by the conviction that a historian could in principle find invariant laws governing historical events. The Institute's work, though informed by science, stipulated that scientists must be critically aware of the historical conditions of their own specific research. Critical theorists were inspired in great part by Max Weber's (1864–1920) *Verstehende* sociology, according to which the researcher's own interpretive perspective is considered constitutive of what is studied. Critical theorists also adopted elements of Freudian psychology, both its distinction between the pleasure (*eros*) and death (*thanatos*) drives and its utilization of the structural models of the id, ego, and superego. These conceptual schemes became a template on the basis of which sociological phenomena could be analyzed. With them, critical theorists analyzed dominant social ideologies latent in the family, the mass media, and other cultural and political systems.

Critical theorists also found themselves in opposition to phenomenology and existentialism, two philosophical movements also gaining influence in the interwar period. The phenomenological method, developed principally by Edmund Husserl (1859–1938), was intended to be a rigorous science of consciousness that reduced everyday experience to a series of noematic essences. Critical theorists saw in the method, however, merely a way to keep dominant class interests protected by leaving all power of interpretation to social and economic elites. They saw in existentialism—a method of reduction not to essences but to existence itself—the same adoption of a structure of meaning and truth immune from comprehensive historical social critique. In response, Benjamin developed, in his *Origins of*

German Tragic Drama (1928), a theory of interpretation derived from the notion of ideas. Ideas emerge not from a conceptual analysis of things but by a formation of phenomena into "constellations." The relation between ideas and phenomena is no longer understood as a mutual participation grasped by an intuition. Rather, ideas are articulated through "allegorical experience" that expresses a form while grasping its origin simultaneously within a historical epoch. In his *The Work of Art in the Age of Mechanical Reproduction* (1935), Benjamin indicated that, when understood in this way, the expressions of artworks, particularly film, could serve powerful political ends.

The principal method employed by the Frankfurt school was, and continues to be, that of an *immanent critique* of social phenomena. Immanent critique gives up on a correspondence theory of truth, according to which the mind is understood to conform itself to a fixed reality, and instead employs only targeted inquiries into a historical lineage preceding a current mindset or social practice. For example, critical theorists argue that the historical development of capitalism parallels the growth of a dominating and inescapable system of instrumental reason. Early critical theorists like Benjamin, as well as Horkheimer and Adorno in their seminal 1943 work *The Dialectics of Enlightenment,* held that the contemporary world teetered on the edge of catastrophe and escape from it could come only from a complete withdrawal from instrumental (enlightenment) rationality. Horkheimer and Adorno employed a critique of the "culture industry" that exposed the way in which literature, film, music, and the fine arts had all been co-opted by the profit motive of capitalist systems. Though Horkheimer and Adorno remained pessimistic regarding the possibility of any lessening of social domination, Marcuse in his 1964 book *One-Dimensional Man* argued that science and technology could be oriented away from capitalism's "false needs" toward nonrepressive and liberatory ends.

When the Institute was revitalized in Germany after World War II, critical theorists confronted social conditions no longer of economic crisis and war but rather of robust economic recovery and relative political stability. Now their immanent critique concentrated rather on the problems of social conformity and psychological repression characteristic of this prosperity. In this period, Benjamin's work on aesthetics and ethics in the 1920s and 1930s became more salient. Inspired by this, Adorno's publication of his aphoristic ethical work *Minima Moralia* (1956) contained a broad critique of everyday social mores.

In the 1960s, Adorno turned from his cultural and ethical critique to a more theoretical direction. His *Negative Dialectics,* published in 1966, traces the way in which both the critical thinking of Kant and the positive dialectics of Hegel set the stage for a philosophical thinking ordered toward the ideal of freedom. However, neither project succeeded, since both failed to challenge the social ideal, operative in their times, of a "free" bourgeois subject acting on the basis of its own self-interest. Instead, Adorno defended a nonidentity thinking that, while emergent from the prior development of identity thinking and its emphasis on subjectivity, shifts toward the "primacy of the object." Nonidentity thinking considers the enlightenment impulse toward universalization as inherently incomplete. Adorno envisioned not a positive structural metaphysics where form dominates matter but a "rescuing metaphysics" in which particulars, while in dialectical tension with universals, resist subsumption by them.

By the late 1960s, critical theorists had earned a measure of public notoriety. In the United States, Marcuse's works were read by students and public intellectuals supporting the idea of a counterculture and social revolution. In Germany, Adorno and Habermas were solicited by students for support for numerous leftist causes. However, both Adorno and Habermas refused to support the tactical proposals of the students, responding instead only with theoretic analyses that they thought would keep the movements from becoming reactionary or sensationalistic. This led to bitter disappointments on the part of many of the students. Adorno's untimely death in 1969 and Habermas's transfer from the University of Frankfurt to the Max Planck Institute in Starnberg in 1971 ended the strained dialogue.

Meanwhile, a new theoretical direction was emerging in Habermas's work. He characterized the critique of the Enlightenment by his former mentor Adorno as a mere "philosophy of consciousness" that, as such, was bereft of emancipatory potential. In his 1981 work *The Theory of Communicative Action,* Habermas broadened the scope of the theory of rationality from the analysis of subjectively produced instrumental actions to a comprehensive

mapping of all intersubjective communication. Initially, he defended a consensus theory of truth, on the basis of which truth was understood to be identical with its mode of intersubjective verification by the assent of all those potentially affected by the norm in question. But later, in his *Truth and Justification* (1999), he turned from this solely verificationist model toward a more realist model that distinguishes between verification processes and invariant truth.

Drawing from Karl-Otto Apel's work on formal pragmatics—based on the grasp of how the absence of performative contradictions gives evidence of a rational procedure—Habermas also developed a verificationist moral theory, termed *discourse ethics*. Discourse ethics presumes that just as we garner valid scientific conclusions from dialogue and discussion, so do we also draw the rightness of moral norms from discourse among those affected by them. His early version of discourse ethics appealed to an "ideal speech situation," from which perspective all affected by the eventual norm could be guided toward consensus. In later versions, however, he spoke of how discourse is guided rather by "idealizations," such as that of an orientation toward universalization and inclusiveness on the part of all those affected in any way by the norm in question. Regardless, he never urged that any absolute rightness of a norm could be derived from discourse. Moreover, he relied on the legal theory of Klaus Günther to develop criteria by which verified moral norms could be applied in unique situations.

One critic of discourse ethics was Albrecht Wellmer, who questioned its limiting of truth and rightness only to the redemption of validity claims in a formal pragmatic structure. Other critics similarly rejected its exclusion of contextual conditions—such as gender, social status, and psychological considerations. But Habermas developed, in *Between Facts and Norms* (1992), a political and legal theory on the premise that laws are necessitated by the inability of moral and ethical discourse alone to provide norms that cover all situations and contingencies. He argues that the discourse principle itself can reveal how individual rights (private autonomy) and institutionalized but changeable public laws (public autonomy) mutually presuppose one another so as to then guarantee the efficacy of principles of justice for all citizens.

The Third Generation of Critical Theory

Third-generation critical theorists, from a number of diverse academic disciplines, are today moving critical-theoretic analysis in many new directions.

Responding to Foucault's analysis, Axel Honneth traces social pathologies to struggles for power and recognition among individuals and groups. He shifts from structural to individual and intersubjective bases of pathologies. Thomas McCarthy, whose translations of Habermas's work facilitated the spread of critical theory in North America, has turned critical theory toward an analysis of the problems of race. David Ingram has done similar work. Rainer Forst analyzes a critical-theoretic model of justice able to address the persistence of social and political intolerance in contemporary societies. Lambert Zuidervaart shows how Adorno's work contains a critical social theory able to deal with issues of economic domination. Nancy Fraser and Seyla Benhabib focus on the inability of prior critical theory to take sufficient account of women's and minorities' unique difficulties with regard to communicative and recognitional access. Joseph Heath has taken up rational choice theory in an effort to make the rationality critique of critical theory more salient. Cristina Lafont works in the area of moral and political theory, particularly regarding the issues of political illegitimacy. Similar work has been done by David Rasmussen regarding violations of human rights. James Bohman works on social analysis that aims to take into account the new world situation brought about by increasing globalization. William Rehg has analyzed extensively both discourse and argumentation theory, particularly that which would inform the social sciences. In the area of psychoanalysis, Joel Whitebook argues that a theory of sublimation can provide an analysis of genesis and validity that can avoid the difficulties of reliance on idealizations. Finally, several theologians, such as Helmut Peukert, Thomas Schmidt, and Francis Schüssler Fiorenza, employ a critical-theoretic analysis of dogmatic forms of theology.

In the future, critical theory will undoubtedly continue to develop both theoretical models of emancipative thinking and practical ways of living aimed to challenge—as Horkheimer famously called them—*threats to freedom*.

Free Will, Philosophical Conceptions of

This entry charts the philosophical terrain held by different positions on free will in relation to moral responsibility.

Free Will and Moral Responsibility

The problem of free will and moral responsibility arises from a tension between two powerful considerations. On the one hand, we human beings typically believe that we are morally responsible for our actions, which would require us to have some type of free will. On the other hand, scientific and theological views about the nature of the universe motivate causal determinism, and our having free will and determinism being true are in apparent conflict.

The history of philosophy records three standard reactions to this tension. *Compatibilists* maintain that it is possible for us to have the free will required for moral responsibility even if the universe is deterministic. Others argue that determinism and the contention that we have this sort of free will cannot both be true—they are *incompatibilists*—but they resist the reasons for determinism and affirm that we do have this free will of this kind. They advocate the *libertarian* position. *Hard determinists* are also

incompatibilists, but they accept that determinism is true and that we lack the free will required for moral responsibility. Especially since David Hume's discussion of these issues, the concern about the existence of the sort of free will required for moral responsibility has been extended to whether it is compatible with the *indeterminacy* of actions. This development has challenged the value of the threefold classification, despite its persistence in the contemporary debate. Some, like Galen Strawson, maintain that the free will required for moral responsibility is incompatible not only with determinism but with indeterminism as well.

Libertarianism

Libertarians prior to the modern period include the Epicurean author Lucretius, the early Christian theologian Origen, and among the scholastics, John Duns Scotus, William of Ockham, and Francisco Suarez. More recent times have witnessed the explicit differentiation of three major versions of libertarianism. In *event-causal libertarianism,* actions are caused solely by prior events such as an agent having a desire at a time, and indeterminacy in the causation of actions by events of this kind is held to be a critical requirement for moral responsibility. Detailed event-causal libertarianism positions have recently been set out by Robert Kane, Laura Ekstrom, and Mark Balaguer. A concern is that based on this picture the events preceding a decision will leave it open whether it will occur, and so whether it does is not settled by anything about the agent. Thus, whether it occurs or not is just a matter of luck, and intuitively, the agent lacks the control required to be morally responsible for the decision. This *luck objection* motivates *agent-causal libertarianism,* according to which free will of the sort required for moral responsibility is accounted for by the existence of agents who, as substances, possess a causal power to settle whether a decision is made without being causally determined to do so. To avoid the luck objection, it is essential that the causation involved in an agent's settling whether a decision is made not be a matter of causation among events but rather be an instance of the agent *as a substance* causing a choice. The agent-causal position is developed by Immanuel Kant, Thomas Reid, Richard Taylor, Roderick Chisholm, Timothy O'Connor, and Randolph Clarke. A third type of libertarianism is *noncausal* and has been proposed by Henri Bergson, Carl Ginet, Hugh McCann, and Stewart Goetz. A concern that motivates the noncausal proposal is that if our decisions are governed by any sort of causal law, they cannot be freely willed. Bergson argues that although action occurs in time, the time of conscious agency does not resolve into the kinds of quantities or magnitudes that allow them to be subject to causal laws. On Ginet's conception, the key conditions for a basic action's being free are simply that it be uncaused, that it has an agent as a subject, and that it features an "actish phenomenological" feel. Instead of the "actish" feel, McCann specifies that the action must be intentional, and intrinsically so.

In opposition to the noncausal view, critics have argued that without a causal relation between agent and action, the agent will not exercise the kind of control required for moral responsibility. Against all varieties of libertarianism, it has been objected that the sort of free will proposed cannot harmonize with our best physical theories. Our choices produce physical events in the brain and in the rest of the body, and these events are governed by physical laws, which may, for example, be deterministic. It would appear that an agent's undetermined choice could not cause an event in the body that has a deterministic causal history that traces back to a time before the agent came to exist. In response, the libertarians have attempted to make it credible that our actions could be freely willed in the sense they advocate, given the evidence we have about the physical laws.

Compatibilism

Retaining the legitimacy of our ordinary attitudes toward human actions and at the same time regarding them as causally determined has been so attractive that a large proportion of philosophers, both historical and contemporary, classify themselves as compatibilists. Two varieties of this stance might be differentiated. The first, and more common, sort aims to differentiate causal circumstances of actions that exclude moral responsibility from those that do not. The core idea is that moral responsibility requires some type of causal integration between the agent's psychology and her action, while it does not demand the absence of causal determination. This type of compatibilism is usually developed by surveying our

intuitions about blameworthiness and praiseworthiness in specific kinds of examples—involving, for instance, coercion, addiction, mental illness, hypnotism, and brainwashing. These reactions are then employed to motivate conditions on the causal integration required for moral responsibility. Important compatibilisms of this kind have been proposed by the ancient Stoics, Thomas Hobbes, John Locke, Gottfried Leibniz, and David Hume and in the past half-century by Harry Frankfurt, Gary Watson, John Martin Fischer and Mark Ravizza, Daniel Dennett, Susan Wolf, R. Jay Wallace, Ishtiyaque Haji, Alfred Mele, Dana Nelkin, and Michael McKenna.

The second kind of compatibilism, developed by P. F. Strawson, with a historical precedent in Hume, claims that the truth of determinism is irrelevant to whether we have the sort of free will required for moral responsibility. In this view, the basis of moral responsibility is to be found in reactive attitudes such as indignation, moral resentment, guilt, and gratitude. For example, the fact that certain kinds of immoral actions occasion moral resentment or indignation is what constitutes their agents being blameworthy for performing them. Moreover, justification for claims of blameworthiness and praiseworthiness ends in the system of human reactive attitudes. Because moral responsibility has this type of basis, the truth or falsity of determinism is immaterial to whether we are justified in holding agents morally responsible.

One major objection to compatibilism builds on the idea that the sort of free will at issue is the ability to do otherwise, and this ability is precluded by determinism. The *consequence argument,* crafted by Carl Ginet and Peter van Inwagen, among others, sets out this idea with rigor and precision. The crucial contention is that if determinism is true, then facts about the remote past and the laws of nature fix or entail every subsequent fact, including facts about actions, and this rules out the ability to do otherwise. Another prominent type of argument against compatibilism begins with the intuition that if an agent is causally determined to act by, for example, scientists who manipulate her brain, then she is not morally responsible for that action, even if she meets the proposed compatibilist conditions on moral responsibility. The next step is to argue that there are no differences between such manipulated agents and their ordinary deterministic counterparts that can justify the claim that the manipulated agents are not morally responsible, while the ordinary determined agents are. Such manipulation arguments have been advanced by Carl Ginet, Robert Kane, Derk Pereboom, and Alfred Mele.

Determinism

Hard determinism is espoused by Baruch Spinoza, Paul Holbach, Joseph Priestley, Ted Honderich, and Bruce Waller. Galen Strawson and Derk Pereboom argue for the related view according to which we lack the sort of free will required for moral responsibility whether determinism or indeterminism is true. Critics of such a skeptical view about free will have objected that it threatens our self-conception as deliberative agents, it renders morality incoherent, it undermines the reactive attitudes that lie at the core of human interpersonal relationships, and it jeopardizes any effective means for controlling criminal behavior. Skeptics have countered by arguing that if determinism were true, the beliefs, desires, and choices that constitute the deliberate process would be causally efficacious, and thus our self-conception as deliberative agents would remain in place; that the skeptical position would not undercut the truth of moral principles because they are independent of claims about free will; that while this conception might count attitudes such as indignation and resentment as irrational, alternative attitudes that are legitimate by its standards, such as moral concern and sorrow, could still be sufficient to sustain good interpersonal relationships; and that the skeptical view can endorse measures such as preventive detention and rehabilitation, which are sufficient for effectively dealing with criminal behavior.

Free Will in the Social Sciences

Free will is the notion that, despite myriad causal factors that may influence human action, each one of us holds the trump card in making the final decision over our own behavior. Free will is not the claim that human action is random, which is fortunate because that would seem open to empirical refutation (and would also reduce human behavior to a simply haphazard concatenation of movements). Instead, it is a claim about the in-principle "openness" of human systems, given the virtually limitless capacity for human thought and the power that our ideas seem to have over our actions.

Some philosophers have held the view that the problem of human free will—second only perhaps to the problem of consciousness—is the most difficult one in philosophy. Indeed, one thing that makes it so difficult is that free will seems to be an irreducibly philosophical matter, in that there appear to be no obvious experiments that social scientists could perform to settle the matter. Consequently, we are left with the difficulty that we have ample subjective evidence for our feeling of freedom, but none of it is scientifically measurable or even shareable with other people. This puts us in a situation where each of us is all but certain that we have free will, but when the time comes to prove it, we are stuck with nothing more than our internal feelings, which have shown themselves to be unreliable in other venues.

In the absence of hard evidence, and the presence of strong feelings, we are left to argue.

One of the main arguments that philosophers have had concerning free will is whether it is compatible with determinism. *Incompatibilists* believe that it is not; that the truth of determinism would obviously undermine the notion of human choice—and with it the idea that humans are morally responsible for their actions—because it degrades the causal efficacy of intentions that is necessary for both freedom and responsibility. This conclusion is disputed by *compatibilists,* who maintain that the truth of determinism would not necessarily undermine human freedom (or moral responsibility) by pointing to several thought experiments where our notion of free choice would seem to survive the idea that our behavior was completely predictable or even fully determined (e.g., if there were a Deity). A third view—sometimes called *libertarianism* or the *Theory of Agency*—argues that compatibilist accounts are misguided but that, fortunately, this makes no difference since determinism is not true. The philosophical argument required to demonstrate this claim is difficult and seems to hang on the notion that the causal power of human action is unique and can be located squarely within human decisions. Critics of this view, however, have maintained that this account is simply tantamount to saying that humans have free will, and thus, this brings us back to the beginning of the debate.

In light of the notorious failure of philosophers to make progress in solving these questions, it is tempting to revisit the possibility that one can gather empirical evidence that is relevant to the question of free will. Indeed some neuroscientists have been searching for a way to test the subjective hypothesis of free will by looking past the social sciences and focusing directly on the brain.

In one such experiment in 1983, Benjamin Libet famously discovered that brain activity correlating with a person's decision to move his or her finger can be detected 300 milliseconds *before* the person's conscious decision to act. This finding is widely taken by some to threaten the notion of free will, in that it purports to show that unconscious brain processes can commit us to a certain course of action even before we become aware of it. This study has been challenged, however, for relying too heavily on a subject's self-report of when he or she formulated the intention to act, as well as because of the obvious problem that it would take a certain amount of time for a subject not only to *decide* to act but also to decide to *report* that he or she had decided to act, which may account for the interval. Follow-up studies, which have eschewed subjective reports in favor of direct examination of the brain using functional magnetic resonance imaging machines, have deflated such criticisms while providing evidence that corroborates the direction of the original effect.

Even as experimental evidence mounts in favor of the existence of an interval between brain activity and conscious intention, some commentators have been reluctant to draw any ominous conclusions for the notion of free will, arguing instead that what we need is to revise our views of the mechanism by which human actions take place. Perhaps human decision making is best understood not as a conscious intention followed by an overt action but instead by the subjective feeling that occurs when the brain transforms an unconscious plan into action. Others have said that perhaps human decision making is merely the occasion upon which both our intentions and our actions arise as collateral effects of an as yet unknown brain process. Whether such reconceptions of intentionality (and causality) would allow for the survival of traditional notions of human free will remains a matter of ongoing debate among neuroscientists and philosophers.

Thus, whether human action is truly free or whether we are merely manipulated into thinking so by some causal mechanism that guides both our thoughts and our actions is one of the great unanswered questions of contemporary philosophy.

Game-Theoretic Modeling

This entry exemplifies the process by which models of strategic behavior are constructed (requiring a modicum of mathematics for a full appreciation). Strategic behavior arises when the outcome of an individual's actions depends on actions taken by other individuals. For example, whether it is advantageous for drivers negotiating a four-way junction to assume right-of-way depends on whether other drivers concede the right-of-way. Likewise, whether one prospers from moral behavior depends on whether others do the right thing. If an interaction among individuals gives rise to strategic behavior and can be described mathematically, then we call this description a game and each individual a player. Thus, a game is a model of strategic interaction, and game-theoretic modeling is the process by which such games are constructed.

A game has four key ingredients. First, there are at least two players, who may be either specific actors or individuals drawn randomly from a large population: Drivers at a four-way junction may be either neighbors or strangers. Correspondingly, the game is either a community game or a population game. Second, each player has a set of feasible plans of action—or strategies—which are constrained by the information structure of the interaction. For example, drivers at a four-way junction can condition their behavior on their lateness relative to others only if they are sufficiently aware of it. Let the lateness of two such drivers who wish to turn left simultaneously be represented by the random variables X and Y, taking values between 0 (*unbelievably early*) and 1 (*desperately late*); the sample space for their joint distribution is the unit square $0 \le x, y \le 1$. Then it is possible for the first driver, or Player 1, to play a strategy u, defined by "Go if $X > u$; wait if $X \le u$," while the other driver, or Player 2, plays strategy v, "Go if $Y > v$; wait if $Y \le v$." We call this game "Crossroads."

Third, there is a well-defined reward for each player from any potential strategy combination. In Crossroads, let τ be the time it takes a driver to traverse the junction, and suppose that the drivers discount this delay by a fraction η of their earliness. Thus, if $X \le u$ and $Y > v$, then the delay of τ as Player 2 traverses the junction is experienced as $-\tau\{1 - \eta(1 - X)\}$ by Player 1, whereas if $X > u$ and $Y \le v$, then the delay of τ is experienced as $-\tau\{1 - \eta(1 - Y)\}$ by Player 2 but is 0 for Player 1. If both drivers either "Go" or "Wait" in the first instance, then there is an additional delay of δ or $\in$, respectively, with $\delta > \in$, as they sort out who will subsequently drive away first. Assuming that it is equally likely to be either driver and that delays should be as short as possible, so that the negatives of delays serve as payoffs, Player 1's payoff is the random variable

$$F_1(X, Y, u, v) = \begin{cases} -\tau\{1 - \eta(1 - X)\} & \text{if } X \le u,\ Y > v \\ -(\delta + \tfrac{1}{2}\tau\{1 - \eta(1 - X)\}) & \text{if } X > u,\ Y > v \\ -(\in + \tfrac{1}{2}\tau\{1 - \eta(1 - X)\} & \text{if } X \le u,\ Y \le v \\ 0 & \text{if } X > u,\ Y \le v \end{cases}$$

Player 1's reward from the strategy combination (u, v) is the expected value of F_1, which we denote by $f_1(u, v)$. That is,

$$f_1(u, v) = \int_0^1 \int_0^1 F_1(x, y, u, v)\, g(x)\, g(y)\, dx\, dy,$$

where g is the probability density function of X and Y's common distribution. By symmetry, Player 2's reward is $f_2(u, v) = f_1(v, u)$.

The last main ingredient of any game is a solution concept. An appropriate one for community games is the Nash equilibrium, a strategy combination from which no individual has a unilateral incentive to depart. Equivalently, a Nash equilibrium is a combination of mutual best replies. In Crossroads, if lateness has a uniform distribution, or $g(x) = g(y) = 1$, and drivers are fast enough to ensure that $\frac{1}{2}\tau < \delta$, then $f_1(u, v)$ is maximized for a given v by

$$u = \begin{cases} 1 & \text{if } 0 \le v \le 1 - \theta \\ \dfrac{1 - \theta + \lambda - v}{\lambda} & \text{if } 1 - \theta < v < 1 - \theta + \lambda, \\ 0 & \text{if } 1 - \theta + \lambda \le v \le 1 \end{cases}$$

where $\theta = (\in + \frac{1}{2}\tau)/(\in + \delta)$ and $\lambda = \frac{1}{2}\eta\tau/(\in + \delta)$. Because $\frac{1}{2}\tau < \delta$ implies $\lambda < \theta < 1$, 0 or 1 is the unique best reply to 1 or 0, respectively, and $v^* = 1 - \theta/(1 + \lambda)$ is the unique best reply to itself. Thus, by symmetry, there are three Nash equilibria, namely, (0, 1), (v^*, v^*), and (1, 0). An appropriate solution concept for population games is John Maynard Smith's evolutionarily stable strategy, or ESS. Strategy v is an ESS if, when adopted by a population, it does not pay anyone to switch from v to any other strategy. For Crossroads, v^* is the unique ESS.

Space constraints preclude a discussion of the numerous subtleties that arise in connection with game-theoretic modeling. For example, a theoretical distinction is often observed between noncooperative games, in which any agreements are self-enforcing, and cooperative games, in which all agreements are externally enforced and the Nash equilibrium is superseded by various cooperative solution concepts. The distinction is not always useful, however, especially in games of coalition formation. These and other subtleties are discussed at length in the suggested further readings.

In philosophy and the social sciences, game-theoretic modeling is valuable because it enables one to explore the logic of a verbal argument rigorously. For example, in a population of drivers at the ESS of Crossroads, the average delay is $-f_1(v^*, v^*)$ and is readily shown to decrease with η. Thus, drivers who discount experience shorter average delays than drivers who do not discount; and the more they discount, the less they wait. Although this result may be highly plausible on the basis of a purely verbal argument, only a game-theoretic model can convincingly nail it down.

GENEALOGY

Genealogy is an approach for the study of formative historical events, pioneered by Friedrich Nietzsche and developed further by Michel Foucault. There are also important links between genealogy and comparative historical sociology, visible in the works of Max Weber and some of his followers. The genealogy of a particular political institution or social practice is concerned with the exact manner in which it emerged and the lasting effects it might exert even after the institution or practice ceased to exist.

Nietzsche

In philosophy and in the social sciences, the term *genealogy* is closely associated with the work of Friedrich Nietzsche, in particular *On the Genealogy*

of Morality and *The Birth of Tragedy.* These are Nietzsche's only books that are sustained philosophical investigations, not aphorisms, showing the significance of genealogy for Nietzsche. The central underlying idea is that contingent historical events might play a decisive role in the very formation of institutions or even personality structures that are taken for granted, or considered as "natural" or "rational." What looks like a systematic whole is therefore a sum of historical layers, which only become saturated with rationality because of the durability of components.

The clearly combative intent is revealed by the subtitle of the *Genealogy,* often omitted in English translations: "A Polemical Tract." It also transpires from the word *genealogy* itself, associated with aspects of the *ancien régime* most unacceptable to the modern mind: the long lineages of patriarchs, culminating in the genealogy of Jesus in the house of David and the similar family ancestry of feudal aristocracy.

Genealogy, as championed by Nietzsche, implies two specific claims about studying a concrete phenomenon, be it morality, modernity, or a political system. The first, indicated by the word *birth,* is that the manner in which a particular entity comes into being matters. Thus, political institutions or social practices coming into being at a certain moment are concrete and specific responses that gather their "justification" over time. The second is concerned with lasting effects: Even once a particular institution ceased to function, its ways of acting and thinking might be carried over for a considerable time.

Questions of birth or emergence can be considered as relevant in two different manners, corresponding to Darwinian or Lamarckian approaches about heredity. In one case, something positive is transmitted, whether as genes, modes of behavior, or a certain "spirit"; in the other, the particular conditions characterizing a "birth" will be carried over. Here, there is a significant displacement of emphasis in between Nietzsche's two major relevant books. This is visible in dropping the original subtitle of *Birth of Tragedy,* "Out of the Spirit of Music," in the second edition published just before the *Genealogy,* and in the preface to the *Genealogy,* best epitomizing Nietzsche's new focus on conditions of emergence.

Still, in contrast to deconstruction in the style of Jacques Derrida, this does not mean that for Nietzsche genealogy was a purely negative undertaking. Continuity, or the ability to persist, had a value for Nietzsche, just as he was interested in the rebirth of what lay dormant (see the Renaissance). This animated his interest in the cultivation and promotion of human qualities, as was visible in his concern with questions about "what is noble" and who is the "good European." Genealogy for Nietzsche also had a self-reflexive component: It was an attempt at a self-understanding.

Foucault and Weber

Michel Foucault explicitly returned to Nietzsche's genealogy, using "birth" in titles or subtitles and being credited with developing a "genealogical method." He defined the middle part of his work as "genealogy of power," acknowledging the second essay of the *Genealogy* as the inspiration behind *Discipline and Punish*. The period is marked, at both ends, by crucial methodological statements: the 1971 essay "Nietzsche, Genealogy, History," a meticulous study of Nietzsche's related writings; and a 1978 roundtable discussion, which focuses on the significance of events for historical understanding. Foucault's final statement about genealogy as method is in the introduction to *The Use of Pleasure.*

Foucault's works had a great resonance over broad areas in the social sciences. However, Nietzsche's approach had a major impact on historically oriented social and political theorists decades before. The central figure is Max Weber, whose comparative sociology of religions and civilizations followed a genealogical design. This is visible in *The Protestant Ethic and the Spirit of Capitalism,* which claims that the moving spirit of capitalism is rooted in the inner-worldly turn of medieval monastic asceticism (the third essay of the *Genealogy* was devoted to the "ascetic ideal"); the first page of the section on religion in *Economy and Society,* focusing on the conditions and effects of social actions; and the importance attributed to "stamping experiences" in the introduction to the *Economic Ethic of World Religions*. Such a Nietzschean inspiration characterizes those who followed the spirit of Weber's work: Norbert Elias, with his sociogenesis and psychogenesis; Eric Voegelin, who argued that the spirit of the modern nation-state, characterized as "intramundane eschatology," grew out of the apocalyptic expectations of medieval sects and who introduced the term *historiogenesis;* and Reinhart Koselleck, with his "pathogenesis" of modernity.

The genealogical approach has its significance for philosophy as well, as it tries to move beyond Hegelian dialectics and the phenomenology of Husserl, efforts to correct the ahistoric formalism and rationalism of Kant. Hegel attempted to render Kantian categories dynamic and historical, but his dialectic was entrapped in the same dichotomizing and dualistic thinking. In contrast to this, Nietzsche's genealogy emphasized the "middle," with polarization into extremes being a possible outcome, not a precondition for understanding. Husserl wanted to go back to "the things themselves," beyond Kantian and Hegelian abstractions, but the absence of a historical focus compromised concreteness. Genealogy combines a historical analysis of categories of thought with a study of formative events.

Problems With Genealogy

Nietzsche-inspired genealogy faces two main problems. The first concerns meaning and value: A genealogy that is purely deconstructive, ironically showing that our cherished values are historical constructs, can be charged with nihilism. In contrast to this, there is a "positive" aspect of genealogy, of which Foucault's late work about care of the self and truth telling is a good example. Second, neither Nietzsche nor his followers managed to specify the manner in which conditions of emergence might leave a "stamp." Concepts developed by anthropologists, like *liminality* (Arnold van Gennep and Victor Turner) or *schismogenesis* (Gregory Bateson), offer a solution. Such a perspective also illuminates the similarities between Nietzsche's genealogy and William Dilthey's philosophical anthropology as a "critique of historical reason."

Genetic Indeterminism of Social Action

After decades of discussions over whether social action may be "caused" by biological/genetic or other factors, newer research shows that any human behavior and most human traits are shaped by a dynamic interaction of diverse factors. Most of them cannot be neatly pinned down to the realm of genetics, biology, or the social environment. This entry will provide a brief overview of the development of genetic and other research on human traits and behavior and show why it is now well established that social action is a complex phenomenon that is far from being determined by any one factor.

Studying the Role of "Nature": The Twin Study Design

Studies with twins have been seen as a particularly fruitful mode to learn about the heritability of human traits. Heritability is defined as the proportion of variation in a trait in a population that can be explained by genetic factors. Twin research designs compare identical twins, who share virtually

100% of their genetic material (DNA), with nonidentical (fraternal) twins, who share about half, just like regular siblings. For example, if a study shows that identical twins *always* have the same eye color while the eye color of nonidentical twins is different in half of all cases, then the conclusion is drawn that eye color is a strongly heritable trait. The twin study design does not, and cannot, however, tell us anything about which or how many genes and mechanisms are involved in passing on heritable traits. Moreover, unlike eye color—a trait that is almost entirely heritable—most traits, such as predispositions to common diseases, certain aspects of our personality, or physical attributes such as height, are neither entirely heritable nor entirely environmental (whereby *environment* means "everything that is not genetic," including lifestyle factors, social environments, toxin exposures, etc.). Thus, in most contexts, twin studies can give us only a rough indication of the extent to which genetic and environmental factors may be involved in shaping a trait.

From Nature Versus Nurture to Gene–Environment Interaction

For a long time, social scientists, biologists, psychologists, and scholars in other disciplines argued about what factor was primarily responsible for shaping human traits in general and behavior in particular: "nature," understood as the allegedly inalienable genetic dimension of humans, or "nurture," comprising child rearing, education, and other dimensions of our social environment. Apart from racist or conservative hardliners who have a vested interest in arguing that certain characteristics are hardwired into particular groups of people, hardly anyone discusses human behavior in terms of nature *or* nurture anymore. Now, research and discussions focus on how nature and nurture interact. Not only has research in many academic disciplines shown that hardly any trait is shaped entirely by either genetic or social factors, but recent advances in research have discovered that environmental and genetic factors shape each other: They interact in complex ways that are not necessarily additive (their combined effects may be different from the sum of their individual effects). *Epigenetics* has been particularly informative in this regard: It is a multidisciplinary approach to understanding why some environmental influences, such as the consumption of particular foods, can change the way genes are chemically switched on or off. These changes to how genes are regulated (switched on and off) can be passed on to the next generation, yet without changing the DNA sequence as such.

Recently, critiques of sociobiology, such as that of Richard Lewontin, have revisited the environment–gene dichotomy, or the "inside–outside" divide, offering more subtle analyses of reciprocal interaction and intercausal change between the two relata.

What Social Sciences and Philosophy Can Contribute

Current models of behaviors and disease predispositions posit that genes and environments interact in a dynamic and potentially intergenerational manner. Yet the term *environment,* as mentioned earlier, is understood widely, including the molecular or biological environment of genes and organs, "lifestyle" and other behaviors, and the wider physical and social environments. Biological scientists may see environments as more difficult to conceptualize and operationalize than genes. This means, according to critical social scientists and philosophers, that even in contemporary research, genetic factors still tend to be prioritized or seen as the starting point, while environments external to the body tend to be poorly specified. For example, as the cultural anthropologist Margaret Lock argues, recent research on the causes of Alzheimer's disease has focused on variations at the molecular level (difference in DNA, proteins, and other cell components), sometimes in conjunction with a small number of—inadequately conceptualized—environmental influences such as gender, ethnic background, and level of education. This has come at the cost of more fine-grained investigations of the ways in which human relationships across the life span may affect gene regulation and developments in the brain.

To the "Geneticization" of the Social (and Back Again?)

Current work on genetic and environmental factors involved in shaping human action therefore highlights a place for more detailed and sophisticated ways of conceptualizing and incorporating social dimensions into epidemiologic and basic research. Beyond this, the social sciences and philosophy have provided a number of important concepts for understanding the wider significance of genes for society.

The concept of *geneticization,* for example, encapsulates the idea that genetics has increasingly become the dominant lens through which human health and behavior are understood. This is seen to have a number of negative repercussions: for example, that genetic research has attracted an unjustifiably large proportion of intellectual and financial resources, detracting from social and environmental research and initiatives.

The concept of *biosociality* turns the idea that biology determines behaviors on its head, to suggest that human interventions will, in the end, shape biology. Biosociality also implies that people are increasingly forming groups on the basis of shared biological or genetic characteristics, for example, being at risk for a particular disease, so as to influence research and ultimately the health of those with whom they share a genetic risk. Here, then, social interaction aims to determine biology.

Far from genes being immutable, and determining social action, we have learned that the effects of genes and the environment are interwoven and *both* may be seen as malleable.

Gestalt Psychology

This entry presents the Gestalt school of psychology, which, among other things, in developing theories of experience and, in particular, theories of perception, provided not only the famous Gestalt-switch notion employed by Kuhn and the Wittgensteinians to assess either a certain view of radical theory change in science or the seeing-as-conception of understanding but also the general idea of wholes that was found congenial by holist views in the social sciences. The part–whole relations studied by Gestalt psychology, especially in visual or acoustic perception, offered support to specific ways of establishing anti-individualist arguments in the philosophy of the social sciences. In particular, they emphasized "functional wholes," "dynamic events," and "fields" in experience, which were also true in physics.

A usual mistake is to portray the Gestalt holist stance as espousing the motto "The whole is more than the sum of its parts." This is not actually what they maintained, since they had a more sophisticated understanding of whole–part relations. As one of the founders of Gestalt psychology, Kurt Koffka (1935/2001), put it, "It is more correct to say the whole is something else than the sum of its parts, because summing is a meaningless procedure, whereas the whole–part relationship is meaningful" (p. 176).

Definition of Gestalt

Gestalt psychologists emphasized the study of consciousness, but not in the same way as structuralist psychologists did, who used controlled introspection in sensory experiments. Unlike atomist conceptions of psychology, which searched for the elements

of experience regarded as primary, Gestalt theory emphasized that both perceived forms (*Gestalten*) and the experienced world are already structured wholes: Experience involves "sensory organization" in which the parts (of experience) are dependent on the whole. Gestalt theorists rejected the view of structuralists and associationists that consciousness consists of associated elements. For example, the reversible figure of the Rubin vase, which also appears as two faces, is fundamentally different from collections of sensations—that is, a mere aggregate of sense-data. Later Gestaltists accepted behavioral wholes, such as the demonstration of an ape that uses insight to put together two bamboo sticks to reach a banana, instead of learning gradually through trial and error. Though they emphasized consciousness, they linked it with the brain by assuming isomorphism.

In terms of methodology, classical Gestalt psychology depended heavily upon the single demonstration or *experimentum crucis;* however, by the mid-20th century, Gestalt social psychology had bridged experiment and social action.

The Austrian psychologist and philosopher Christian von Ehrenfels, who fist coined the term *Gestalt* in the special sense to be adopted by Gestalt psychologists, spoke of *Gestaltqualitäten*. Going beyond the definition of Gestalt as mere shape or form, he emphasized the presence of such qualities in all experience by pointing out that no sensation arises by local stimuli alone but, rather, in relation to sets of stimuli or in a "togetherness" with a background environment or perceptual context, thus pioneering the notion of "whole" in experience.

Prehistory of Gestalt in Philosophy and Medicine

Although Gestalt psychology adhered to scientific naturalism and experiment, it had deep philosophical roots. Philosophers following Kant began to distinguish the act of judging from the judged object. The proper object for idealist philosophers was not a mental picture but the entire object or situation. "Cheetahs exist" or "It's raining" are unitary judgments of a "state of affairs" (*Sachverhalt*), also translated as "atomic facts," which are not combinations of ideas in a proposition. The philosophers Hermann Lotze, Carl Stumpf, Alexius Meinong, Kasimir Twardowski, Franz Brentano, Edmund Husserl, and Ludwig Wittgenstein developed this critique of judgment. In Berlin before and after World War I, Carl Stumpf agreed with William James that we experience a "stream of consciousness" from which we distinguish "mental functions." In visual space, we perceive location directly, not through muscle movements in the retina. Two tones sounded together yield a third tone different from the component tones.

In 19th-century perception research, Ewald Hering challenged Hermann Helmholtz's description of the eye as a camera in which we bring together sensations by unconscious inference. A zigzag hole in a white cardboard can appear as a black patch or as a hole. Each perception has psychological reality as a "seen object," even if the retinal image is the same. Christian von Ehrenfels noted that one can play a melody in one key and then in another key and immediately recognize the tune. Similarly, Austrian philosophers in Vienna and Graz contributed a model of cognition based on the Müller-Lyer illusion, in which the length of two lines is judged longer or shorter based on illusions created by arrows at their ends.

In the early 20th century, Gestalt psychologists experimented with tone color, figural aftereffects, illusions, and perceptual constancies. Brain scientists explored equipotentiality and mass action, behavioral neurology, and self-actualization. Social psychologists extended Gestalt theory to social *fields* of force in a life-world and to humanizing the workplace. Gestalt therapists encouraged healthy contacts with the world through reorganization of the self in a social field.

Gestalt in Human Perception and Animal Insight Experiments

Stumpf's students in Berlin, Max Wertheimer, Kurt Koffka, and Wolfgang Köhler named and popularized Gestalt psychology elsewhere, principally in the United States, based upon a wide range of perceptual, learning, and cognitive experiments. Wertheimer's classic phi phenomenon experiment used slits of light in a revolving tachistoscope wheel to produce a perception of apparent motion. Exposure intervals, as well as the color, arrangement, and size of the stimuli, could be varied.

Kurt Koffka introduced the "white tablecloth experiments," where a subject encounters a white and a black tablecloth, but the black one has greater illumination. Subjects have no difficulty identifying that the white is white, even though the "proximal stimuli" of the black one are brighter. The subject utilizes a "color gradient" to make a Gestalt perceptual judgment. This involved a new understanding of stimulus. A hungry fish bites the worm, but the satiated one does not; the same stimulus object may elicit a different pattern of response as a "direct experience correlate of the stimuli." No hypothetical psychological processes are involved. In his book *The Growth of the Mind,* Koffka applied the anthropologist Lucien Lévy-Bruhl's concept of the primitive mind to the child, maintaining that the child's mind grows by differentiation, from the whole to the parts. In Russia, the developmental psychologists Lev Vygotsky and Alexander Luria drew on the work of Koffka, Kurt Lewin, Tamara Dembo, and Anita Karsten, bringing a Gestalt perspective into their cultural-historical school.

In the Tenerife Island experiments with apes during World War I, Wolfgang Köhler observed apes overcoming obstacles to reach a goal object—by stacking boxes. He and others (Carl Bühler, Charlotte Bühler) argued against Edward Lee Thorndike's learning experiments with cats, in which a cat engaged in random efforts to get out of a puzzle box and the experimenter graphed the time taken to do so by a learning curve. Such instrumental learning abstracted from the animal's behavior, whereas Kohler's insight phenomenon has face validity.

Also in Germany, Kurt Lewin treated actions as "behavioral wholes" in which emotion and volition contribute to a specific situation with an end product. Bluma Zeigarnik and Maria Rickers-Ovsiankina showed that memory is better for uncompleted tasks. Tamara Dembo manipulated the experiment–subject relationship by causing frustration in subjects trying to complete an assigned task.

Gestalt Social Psychology

Dembo's observation of "firmness" and "loosening" of tension systems led to Lewin's later concepts of psychological "life space" and "social fields of force." Evgenia Hanfmann and Rickers-Ovsiankina took Lewin's program into counseling, giving attention to the orientation of students to the clinical situation. The work of many of Lewin's students contributed to social action research by the Society for the Psychological Study of Social Issues in the United States.

Lewin also focused on how the situation appears to the actor, and he diagrammed the needs of the person in different layers. He included motivation forces, as well as self and field, but opposed historical explanation by childhood experiences (psychoanalysis) or past learning (behaviorism). Physics provided the concepts of *field of force* and *vectors* and ahistorical laws by which social Gestaltists described personality and *social fields.*

The experimenter first became a subject of psychological attention in Lewin's research. By contrast, contemporary research about character types and mental traits is abstracted from groups of persons, and the experimenter is invisible. Lewin's largely East European female research group had a cosmopolitan awareness of social-psychological questions, recognizing that personality is embedded in social situations.

Another émigré, Fritz Heider, proposed balance theory: If A dislikes B and B dislikes C, then he predicted that A would like C. Or if a person likes President Eisenhower and he was reported to have done something bad, then one could protect equilibrium by disbelieving this report. Taking this balance theory further, Leon Festinger found that if students were offered a small reward for giving a speech that contradicts their beliefs, they are more likely to change their attitude than if they were given a larger reward. He called this "cognitive dissonance." Heider and Festinger did not share Lewin's emphasis on the Gestalt social field; theirs was an individual social psychology.

In medicine, the neurologists Jakob von Uexküll, Konstantin von Monakow, and Kurt Goldstein emphasized "holism" in brain science. Some cultural psychologists defended a "racializing" national socialism with ideas of "racial soul," "purity," and "folkish study of humanity." Others built early careers by publishing in Nazi journals and weaving in statements of party orthodoxy.

Since the mid 20th century, many personality and social psychologists have argued that the historical approach based on frequencies can be joined with social field accounts employing experimenter–subject interaction. David Krech and R. S. Crutchfield, in their 1948 textbook, included historical frequency data along with group phenomena; however, the emphasis was on the psychological states

of individuals. By comparison, when Solomon Asch performed multiple trials with confederates to produce a conformity effect in the subject's judgment of the length of a line, the emphasis became the individual and the group: They mutually influence one another in socially engaged psychological behaviors. Muzafer Sherif and Carolyn Wood Sherif manipulated groups of boys at summer camp to become friends, then to compete as rivals, and finally to reconcile through working toward a superordinate goal. Their concern with the origin and development of norms marks them too as truly social psychologists, the direction in which Lewin had pointed.

Gestalt Therapy

A vibrant clinical branch of Gestalt therapy grew out of the work of Fritz Perls and Laura Posner Perls (who studied color contrast with the Gestaltist Adhémar Gelb in Frankfurt and cowrote *Ego, Hunger and Aggression* in 1947). Paul Goodman then wrote *Gestalt Therapy* with Fritz Perls and Ralph Hefferline in 1951. They emphasized the client's "resistance" or bodily armor, drawing from their mentor Wilhelm Reich and from Jacob L. Moreno's psychodrama. In doubling or "hot seat," clients kneel to symbolize the hidden aspect in their lives while saying what they would feel but never tell.

Since the 1950s, Gestalt therapy schools have arisen across North America and the world. The psychoanalytic concept of "mechanisms of defense" (Anna Freud) evolved into the restrospective "resistances to contact" (Perls). For example, clients may be asked to pay attention to bodily sensations while walking in a circle. Erving and Miriam Polster changed the emphasis to "working with the resistance." A therapist should look at the person the way you would view a sunset, with love and affection. One technique is mining for stories. A client dreamed that she and her sister had escaped together. From whom, asked the therapist. From people. From what people? From our parents. By insisting upon concreteness, the therapist facilitates the client's transition from A to B. Then, focused emotional work becomes possible.

Relativism Versus Realism: Philosophy of Science Versus Gestalt Psychology

Philosophers of science debated the significance of the so-called Gestalt switch in terms of realism versus relativism. This raises issues of the foundations of scientific truth when (Kuhnian) paradigms change.

Wittgenstein, in his *Philosophical Investigations* (1952), introduced the figure of a duck-rabbit. It can be involuntarily seen as one, then the other, but never as both simultaneously. Here, the same sense-data (lines or figures perceived) give rise to two different perceptions (either duck or rabbit)—in other words, to one precept at a time. So, the argument goes, the underlying reality or fact of the matter may be one, but it is perceived differently given the diverse theories affecting our observation—hence the relativism in scientific theory formation. Transposed to how a paradigm switch (as a Gestalt switch) works in scientific theory replacement, we can understand the difference, for example, between how Tycho Brahe (a geocentrist) saw the sun rising and Kepler (a heliocentrist) saw the earth's revolutions lowering it with respect to the sun. While the underlying reality is supposed to be one, the theoretical lenses through which it is viewed are different. In the hands of N. R. Hanson and Thomas Kuhn, a paradigm switch worked like a Gestalt switch.

Wittgenstein explained this by sensory and intellectual contributions, a legacy perhaps of his predecessors in the Austrian school of philosophy, including Franz Brentano and Edmund Husserl. In another example, three dots are seen as a triangle; the dots are the sensory portion, and the triangle is the judgment.

Gestalt psychologists argue that this returns us to the intellectualism of the tradition they rejected. They are realists in asserting that perception itself is structured. Reality is given to us with a rich phenomenology. The conditions that produce this Gestalt switch depend on the "definiteness" of stimulus conditions; if they are poor, switching may occur. Such conditions occur in everyday life, yet we perceive accurately.

The implications for philosophy of science were profound. If the Gestalt switch consists of both sensory and intellectual entities (the underlying facts plus the theoretical lenses), they must be connected by associations. How can scientists then communicate about the facts if they simply interpret according to their experience? Thomas Kuhn's use of the duck-rabbit to illustrate a scientific paradigm shift thus invokes an older epistemology, one that Gestalt psychologists argued against with their perceptual experiments. He represents the relativism that has emerged in the philosophy of science since the mid 20th century; the early-20th-century Gestaltists remain perceptual realists.

Given, Myth of the

The *myth of the given* is Wilfrid Sellars's name, introduced in his *Empiricism and the Philosophy of Mind,* for a broad epistemological strategy shared between a wide variety of empiricist traditions. The work was originally delivered as lectures at the University of London (Special Lectures on Philosophy for 1955–1956), on March 1, 8, and 15, 1956, under the title *The Myth of the Given: Three Lectures on Empiricism and the Philosophy of Mind.* Subsequent editions appeared.

The American philosopher Wilfrid Sellars (1912–1989) took as uncontroversial the insight that there is a distinction between seeing that something is the case and inferring from experience that it is the case. Empiricism in the grip of the myth of the given improperly transforms this fact into a foundationalist epistemology of immediacy, according to which there is some layer of entities of which we have direct receptive awareness—he names "sense contents, material objects, universals, propositions, real connections, first principles, even givenness itself" as contenders—that can function autonomously and directly as "data" from which we can infer. Although his primary targets were his recent predecessors—most noticeably sense-datum theorists such as the British philosophers G. E. Moore and Bertrand Russell—Sellars's critique of this myth of the given is, by his own description, analogous to Hegel's critique of immediacy (throughout Hegel's *Phenomenology of Spirit* but presumably most directly in the "Sense-Certainty" chapter of that work). Sellars makes it clear that he wants his critique to be broad in its historical target; at various points, he uses the myth of the given as a tool for criticizing not only the sense-datum theorists but classical empiricists of the 17th and 18th centuries, such as John Locke, Bishop Berkeley, and David Hume, and 20th-century logical positivists and behaviorists, such as Rudolf Carnap, A. J. Ayer, and Gilbert Ryle.

According to sense-datum theory, taken as a form of epistemological foundationalism, knowledge has two distinct sources: (1) sensory data, which are mind-dependent results of observation of which we are directly aware, and (2) a faculty of reason that draws conclusions from these empirical raw materials. In Section 6 of his work, Sellars argues that

sense-datum foundationalism is committed to the following "inconsistent triad":

A. *x* senses red sense content *s* entails *x* noninferentially knows that *s* is red.
B. The ability to sense sense contents is unacquired.
C. The ability to know facts of the form *x* is ø is acquired.

Without Proposition A, sensory data would not supply any premises for inference. Without B, sense-data would not be foundational. C asserts that the capacity to make conceptually articulated, truth-valuable judgments is something we develop rather than an innate capacity. Put together, the three propositions say that we have an unacquired capacity (to sense red sense contents) that entails that we are in a state that depends on our having an acquired capacity (to know the fact that *s* is red). Whether or not these count as technically inconsistent, they are certainly in strong tension with one another.

The sense-datum theorist needs A and B, but why must she be committed to C? A major project for Sellars (1997) in *Empiricism and the Philosophy of Mind* and elsewhere is to argue that the ability to make propositionally structured judgments is a holistically determined capacity that depends on our being embedded in a normatively structured "space of reasons" in the right way; it requires that we are capable of drawing inferential connections between those judgments and others and of making normative assessments of their justification:

> The essential point is that in characterizing an episode or a state as that of knowing, we are not giving an empirical description of that episode or state; we are placing it in the logical space of reasons, of justifying and being able to justify what one says. (sec. 36)

We return to his reasons for thinking this below. But assuming for the moment that Sellars is right, such normative holism poses a serious challenge to any version of a foundational, autonomous given. If what is directly and noninferentially given in experience is not a conceptually articulated, truth-valuable content but rather a "mere look" or something of the sort, then it doesn't seem like the given can serve as an epistemic foundation justifying judgments. For such a thing doesn't have the right form to be a premise in an inference at all; its relationship to our conceptually articulated, propositionally formed beliefs seems to be merely causal.

Subsequent philosophers took similar positions. Donald Davidson embraces this conclusion, insisting that nothing can justify a belief except other beliefs, and hence in his view the (outside) world plays a merely causal role in constraining belief. In this case, the given is not functioning epistemically, as it is supposed to *ex hypothesi*. John McDowell argues that assigning observation a merely causal role leads to an unacceptable coherentist picture in which the whole is spinning in the void without friction from the world, as he famously puts it. Otherwise, a defender of a nonpropositional sensory given is stuck, claiming that a merely causal relationship between the world and our observational states can count as a normative justificatory relation, which seems to miss the holistic character of normativity. If, on the other hand, what is directly and noninferentially given in experience is something that is *already* propositionally formed, so that experience becomes inherently judgmental and we *see-as* in the first instance, then Sellars's holistic and normative account of judgment implies that it cannot function as relevantly "given" after all—we can't have an autonomous, innate capacity to make such judgments that doesn't depend on any other epistemic capacities. Either way, there is no given.

Sellars argues for both the holistic normative embeddedness of propositional judgment and the nonfoundational status of mere sensory contents in a variety of ways. The two arguments are combined most powerfully and memorably in his parable of John, the necktie salesman, who doesn't understand that colors look distorted in different lighting and can only be reliably detected under standard conditions. John thinks he sees that a necktie in his store is green, but his colleagues teach him that he needs to take the tie outside to see its blue color properly. In response to this training, he learns to say that the necktie only *looks* or *appears* green under artificial light but he can *see that* it is blue once he takes it outside. Sellars's point here is (at least) twofold. (1) If we think immediate sensory appearances are epistemically foundational, we might assume that *looks-talk* is prior to *seeing-that* talk. But in fact the logic of looks is *derivative upon* the logic of

seeing-that. It is only by *withholding* our judgment that we are justified in believing what we seem to see that the notion of mere looks or appearances gets a grip. (2) In turn, judgmental epistemic states such as seeings-that are in fact *normative* and *holistically determined* states. It is only once we can understand the conditions under which our judgments are justified and can draw a variety of inferential connections between these judgments—which requires knowing a variety of facts, such as what count as standard viewing conditions for colors—that we can properly count as *judging* that things are thus and so. Observational judgment does not *itself* require inference, but it depends on our already having reasonably sophisticated capacities to negotiate inferential and other connections in the space of reasons. Hence, propositionally structured seeings-that are not amenable to the kind of foundationalist analysis that those in search of an autonomous "given" seek. Sellars (1997) sums up thus:

> While [John's, the necktie salesman's, story] does not imply that one must have concepts before one has them, it does imply that one can have the concept of green only by having a whole battery of concepts of which it is one element. It implies that while the process of acquiring the concept green may—indeed does—involve a long history of acquiring piecemeal habits of response to various objects in various circumstances, there is an important sense in which one has no concept pertaining to the observable properties of physical objects in Space and Time unless one has them all—and, indeed, as we shall see, a great deal more besides. (sec. 19)

Sellars distinguishes two dimensions of epistemic dependence: inferential or evidentiary dependence, on the one hand, and what we might call a constitutive dependence, wherein the capacity to be in one epistemic state depends on the capacity to be in others. He takes the assumption that these track on another—that is, the assumption that one epistemic state presupposes another only if the second is its premise—to be a version of the myth of the given itself, as he explains in the following:

> One of the forms taken by the Myth of the Given is the idea that there is, indeed must be, a structure of particular matter of fact such that . . . each fact can not only be noninferentially known to be the case, but presupposes no other knowledge. . . . It might be thought that this is a redundancy, that knowledge . . . which logically presupposes knowledge of other facts must be inferential. This, however, as I hope to show, is itself an episode in the Myth. (sec. 8)

Observations have an asymmetric evidentiary relationship to indirect knowledge claims. I might claim to know various Galilean laws concerning the acceleration of balls on an inclined plane. Each of these generalizations are, along one dimension, based on a range of observations of the form "Ball *b* took *t* seconds to fall *n* inches down plane *p* with inclination *i*." But at the same time, my capacity for such observational knowledge is not something I have innately. For my sensory engagement with the experiment to count as *seeing that* the ball took *t* seconds to fall, I need to understand what it would mean for my observational state to be justified or not. Accordingly, I must understand that my observation is only reliable if the plane was reliably produced by skilled craftsmen, my clock is accurate, I am not intoxicated, there is adequate and nondistorting light in the room, and so on. Hence, I don't count as seeing *that* something is the case, in a way that is inferentially fecund, unless I know all these other facts as well. Thus, Sellars concludes that the ability to see that things are thus and so (or, more derivatively, that they look thus and so) is a capacity that requires already an ability to know that things are thus and so, even though along another logical dimension the former can sometimes count as evidence for the latter. While observational knowledge is noninferential, it is not *immediate* in the sense of being an autonomous source of information that we could have prior to and independently of any acquired epistemic capacities.

Sellars claims to secure an epistemological position liberated from the myth of the given, in which each of the following is true:

1. We know many things about the empirical world.
2. Our knowledge is constrained by our noninferential observations of that world.
3. This constraint is normative: To see that *x* is red is to *know* that *x* is red and to be in a position to justify my belief that *x* is red; it does not merely cause me to have that belief.
4. Observation is at one and the same time a noninferential source of knowledge and not a source of an autonomous given foundation for knowledge.

The question of how to develop the details of a post-Sellarsian epistemology that avoids the myth of the given has been central for philosophers such as Robert Brandom, John McDowell, and Donald Davidson. In turn, some contemporary philosophers, such as Richard Heck and Michael Luntley, have challenged Sellars and his descendants by accusing them of being committed to an overly conceptual, propositional picture of what content has to be like for it to be epistemically fecund; they have defended instead an epistemic role for nonconceptual content.

Goal-Directedness

Goal-directedness is not a fully systematized topic. It includes several subdomains, with open issues, some contradictory definitions, different approaches, and various research trends. This entry mainly focuses on foundational issues, leaving aside some important and growing domains, such as studies and models about the "control" of intentional motor action, experimental evidence, and neural correlates (e.g., Marc Jeannerod's work); the crucial research on *intention recognition, mind reading, simulation, mirror neurons,* and so on (as, e.g., in the work of Giacomo Rizzolatti or Vittorio Gallese); or, more generally, the theory of *intentional action.* All these topics are addressed in other entries in this encyclopedia.

The study of goal-directedness is crucial for social action, since the latter must unavoidably be construed in terms of its underlying ends and functions.

The Return of the "Final Causes"

The year 1943 marked a turning point in science, with the simultaneous publication of the works of Kenneth Craik, Warren McCulloch, Walter Pitts, Arturo Rosenblueth, Norbert Wiener, and Julian Bigelow. Science resumed the concept of *end*—that is, of final cause or teleology—which had been driven out of it and still continues to elicit misunderstandings and problems.

"Teleological" Versus "Teleonomic" Systems

There are several uses of the term *goal directed* (GD). The most important are (a) behavior with a cybernetic goal-based control system and (b) purposive/functional behavior not internally regulated by a goal representation. So "goal directed" is used as a synonym for "finalistic" or "teleological." Analogously, "goal" is used to denote either (a) an internal guiding anticipatory representation or the functional/selective effect of the action or system feature responsible for its reproduction and maintenance (it must be remarked that these two notions are frequently mixed up in the relevant literature) or (b) the external object or "target" of an action.

It is better to use the biologist Ernst Mayr's terminology, which clearly disentangles two kinds of GD systems, distinguishing "teleonomy" from general "teleology." This distinction between two kinds of finalistic behavior is really crucial: (1) the "goal-governed" (GG) or "goal-driven" systems (controlled from inside by an internal representation of the goal state or set point) and (2) the merely "goal-oriented" (GO) ones, where the behavior has a specific goal or, better, a function to be realized, which, however, is not internally represented and anticipated and guiding/governing the performance. These two kinds of finalistic behavior are not one and the same things; in evolutionary terms, the goal-based internal control of behavior may be viewed as a specific—evolutionarily advanced—way of providing teleology to behavior; it is the internal flexible implementation of its adaptive function.

Internally Represented Goals Versus Functional Results

There is also a distinction between internally represented "goals" and goals as functional results. Still, these two are frequently mixed up. For example, after correctly defining *goal* as a cybernetic representation, some scholars ascribe the goal of "survival" to living systems. This clearly is a high-level "function" of living systems, not a represented and "pursued" goal. Similarly, several authors of emotion theory, while correctly claiming that there are emotions only because there are goals (since emotions are signals about the possible realization or frustration of relevant goals), do not carefully distinguish between emotions "about" internally represented and pursued goals (e.g., joy, envy, guilt, etc.) and emotions that are simpler and merely reactive affective states whose goal is not represented.

This distinction within goal-directedness between GG and GO behavior also applies to social action. "Cooperation" among insects is not in view of some represented goal. Humans can cooperate for realizing a mentally shared goal and formulate the goal of jointly acting, or a common plan. The same holds for "communication," which necessarily is teleological. In many animals communicating is not a case of goal-directedness, while in humans it usually is intentional, but linguistic communication is not necessarily intentional.

Goal-Directedness and Anticipation

The distinction between two kinds of "anticipation" and "anticipatory" behaviors/systems is crucial in goal-directedness studies. We can distinguish between

- *cognitive anticipation,* where the system activates/builds the "expectation," the representation of the future event, and behaves accordingly, and
- *functional* (but not representational) *anticipation,* where the behavior just has the function of (has been selected or learned for) coping with an impending event and is elicited by some announcing signal.

In this respect, GG behavior exploits a cognitive anticipatory device, a representation of the future, of *what doesn't exist* (yet) or is *not perceived*.

However, not all cognitive-anticipatory systems/behaviors are GG. There are simpler, and probably more primitive, mechanisms exploiting anticipatory representations ("expectations" proper), which do not imply goals in strict control theory terms. They are the "anticipatory classifiers": a simple rule (Condition ⇒ Action) plus the prediction of the relevant outcome (expectation): C ⇒ Act + Exp. The animal *reacts* to the stimuli, performs the action, and is expecting the reward and checking for it. The confirmation of that prediction will feed back on the strength, activation probability, and persistence of the rule.

Some kinds of behavior (e.g., a behavior resulting from "instrumental learning") may look like a real GG act, in that it is "finalistic" and there is an anticipated mental representation of the outcome playing

a role in that behavior. However, GG behavior is not necessarily its proximate mechanism in this case; that behavior might also be explained as anticipatory-classifier based. The internal stimulus (e.g., a drive like hunger) and the external one (a particular environment, e.g., a red button—i.e., specified "conditions") activate the right "rule" (classifiers), that is, the associated action/response, and also the expectation of the outcome (food). In GG behavior, what activates the behavior is not the "condition" (a stimulus) but the mismatch between the goal representation and the perceptual/doxastic (belief centered) representation of the current state of the world.

The TOTE Model

This is the psychological version of the cybernetic model of goal-directedness—the TOTE (Test–Operation–Test–Exit) model of Miller, Galanter, and Pribram.

In a sense, the system starts from the goal representation, which is not yet or necessarily an "expectation" about what will happen (it might already be true, or it might be assumed as impossible, i.e., never true), and uses it (a) for evaluating the current state of the world, (b) for activating or even searching in memory for the appropriate action (an action with such an "expected" result), (c) for planning by finding context-related subgoals, (d) for monitoring the execution and adjusting it, (e) for terminating the action (when the outcome matches the goal), and (f) in affective systems, in particular, for eliciting the appropriate felt or affective response (pleasant/unpleasant depending on the "success" or "frustration") or emotion, which are always goal related and usually caused by the realization or frustration of true internal goals.

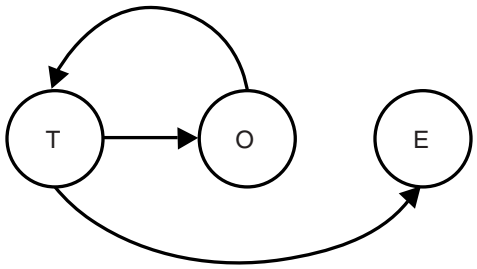

Figure 1 TOTE Model (Test–Operation–Test–Exit)

Problems With the Cybernetic Definition

Some problems with the original cybernetic definition of purposive (GD) behavior are as follows:

1. A basic problem was due to the strictly behavioristic approach of Norbert Wiener and associates, aimed at avoiding the necessary "internal" (mental) representation, hence Taylor's objection that this mechanism cannot capture real (human) purposive behavior, based on "desires" or "beliefs," that is, on "subjective" states. Also, the ideas of "final cause," of the backward causation, loop, circular causation, and so on, were eliciting a lot of criticism about the violation of natural causality or about its interpretation.
2. The cybernetic model was too primitive: There was no subgoaling but just "Mismatch ⇒ Action activation/execution"; there was no action selection, just a unique goal; there was no managing of several simultaneously active goals (possibly incompatible with each other), and thus a model of goal selection or even true decision/deliberation was lacking; similarly, there was also no model of goal dynamics, activation, abandon, and so on, or of goal hierarchy (see the next problem).
3. There was no concern for the "value" or hierarchy of more than one goal (i.e., questions related to the level of activation, felt intensity, calculated utility, etc.), something unavoidable when one has several goals and has to "choose" among them.
4. In the original cybernetic-inspired goal models imported into psychology, goals were only conceived as represented states of the external world, whereas we know that specific cybernetic representations (motor or proprioceptive) and feedbacks control the execution of the action from inside. Goals are not only about the "external" (final) result on the world, but they are about the internal effects of the movements, step by step, and they finally control and adjust the behavior accordingly.
5. Goals useful for psychology (and artificial intelligence) are seen as explicit (and manipulable) representations that can be generatively produced, changed, analyzed, combined, and compared; one can "reason"

about them and manipulate them. They can be either sensory-motor or symbolic representations (e.g., propositional attitudes), but in all cases they are understood as real mental objects to be managed. A problem, however, is this: Not all the "cybernetic" goals are "mental," control our "action," or assume the subjective forms of motor control, of desire, intention, or objective, or of a project to be pursued, and so forth. There are also real cybernetic (set-point based) homeostatic regulations in our body (e.g., maintaining our body temperature around 35–40°C) that are, however, not mentally represented; that is, they are not "subjective" goals and do not strictly speaking regulate our "actions," when the latter are taken as appropriate to intentional agency or conscious social acting. It might also be the case that some function (e.g., "survival") is implemented not just in stimulus–response rules but in internal set-point goals (e.g., "be far from the threat"); however, this is not a representation of the end "survival."

Properties and Functions of Goals

Motives

In GG behavior, taken as "motivated" behavior, the following basic idea is maintained: A mental goal "motivates" the action. Spelled out, this means that

- the action wouldn't be performed if not in view of that result—that is, the goal is *necessary* for choosing and performing that action;
- the behavior is stopped if there is no such expectation, either because the expected result is already realized or because it is considered impossible;
- the goal bestows "value" to the action, and the action (in competition with other possible actions) receives "value" from its goals—we choose between goals (outcomes), not between actions; and
- the goal is the explanation, being the "reason" of a given action—that is, its "motive."

Real Goals

The second issue to be clear about is specifying people's real goals. The explicit identification of the subject's goals is thus fundamental for understanding GD (and especially GG) behavior. But this contrasts with certain developments in the social sciences, in particular with the divorce of classical economics from psychology (at least since Wilfredo Pareto). One ought to be able to explain why people go to vote or have the so-called sunk-costs bias; taking into account the actors' subjective goals, the resulting behavior may be seen as antieconomic. Yet it cannot be seen as "irrational" relative to the given goals. Normative economics cannot prescribe to people the "right" goals to have.

Hierarchical Organization

Goals have a "hierarchical" organization. Over any action, there is a means–end goal chain: A goal has subgoals and superordinate goals.

For realizing a given goal, we need some action; performing it becomes the subgoal. But an action requires specific skills and external conditions: They generate another subgoal level, and so on. "Planning" therefore is necessary: To put Cube A on Cube B, B must be "free" (i.e., this is a condition); if it is not free, we have to act to make it free (subgoal, subaction). The "deep structure" of action is not therefore a mere "sequence." Actions are assembled by their goals: Actions cooperate in "plans"; actions are composed of other, simpler and subordinate actions. We are both able to build new plans for solving new problems and also memorize and reuse complex actions and plan structures, both in individual and in collective actions—that is, create and use scripts. Goal-based scripts and plans (memorized and shared, or created) are not just behavioral sequences: They "coordinate" social action.

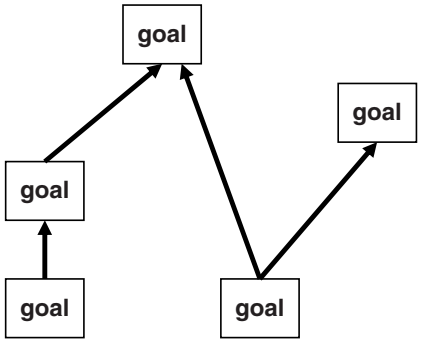

Figure 2 Goal Hierarchy

Source: Author.

Abstraction

Current neural and experimental studies are rightly focused (also thanks to the current impact of the "embodied" view of mind) on motor action control and on "concrete" goals (sensory-motor representations). However, we must not forget that "action" is not equivalent to "motor action" and "goals" are not equal to "perceptual goals." An action can be "abstract"; it can just be *to bring it about that . . .* or *to see to it that . . .*, without specifying "how"—that is, without specifying its motor implementation, the subactions that will be its vehicle. For example, to *offend* is an action, but did we write or say something offensive to that guy, show him the finger, or simply intentionally ignore him? Similarly, a goal can be abstract, like *to make money* or *to win some competition*. Abstract goals raise an important problem: How can it be checked whether they have been achieved or not? On the basis of which particular set of specified evidence and beliefs? Abstract goals therefore have to be "translated" into more concrete cues and signals of their realization.

"Goals" or "Desires and Intentions"?

An important tradition in philosophy, psychology, artificial intelligence, and logic is the so-called BDI (beliefs–desires–intentions) approach, where the behavior ("action") is clearly GG and purposive (or, rather, intentional). However, scholars in that tradition do not use a unifying category of "goal" but introduce two motivational independent "primitives": *desires* (not necessarily pursued, possibly contradictory, etc.), on the one hand, and *intentions* (chosen/planned, coherent, implying the agent's commitment, etc.), on the other. They add important distinctions like "intention that" versus "intention to do," "intention in action" versus "prior intention" (as in John Searle's terminology), and "future-directed intention" versus "commitment."

Is Internal Goal-Directedness Equal to "Selfishness"?

There is frequently a dangerous confusion between goal-driven or self-motivated agents and "selfish" ones. Self-interested or self-motivated agents are simply *endowed with and guided by their own internal goals*. The fact that they are "autonomous," necessarily driven by their internal ends and taking into account the value of their own motives, does *not* make them "selfish." This is a matter of motives, not of mechanisms. They may have any kind of motive: pecuniary or in general economic, moral, esthetic, prosocial, altruistic, self-sacrificial, and so on. Whether they are selfish or not depends just on the basis of the *specific* motives they have and prefer, not on the basis of their being driven by internal or endogenous motives.

Is Behavior Goal Directed/Goal Governed or Pleasure/Utility Directed?

Do we have several final, independent goals (motivations) or just one dominating and monarchic, as it were, goal, like "utility maximization" or "pleasure"? Maximizing utility is for sure a *function* of the goal-processing mechanisms, but is it a real represented "goal" we always pursue, while our specific motives would just be instrumental subgoals? The same goes for pleasure. Is it our overarching (unique) goal? Is it really and always our explicit goal? Or is it just a fundamental feedback of purposive behavior, a reward for learning goals? It is simply false that any goal achievement implies a pleasure experience; what about subgoals like putting a stopper on a bottle or pushing the button of the elevator?

A Paradox of Goal-Directedness: Akrasia

How is it possible that we "choose" and pursue some goal that we would not like to pursue, that we do not consider to be in our best interest, or that we self-consciously consider to be immoral and that it ought not to be pursued? (This is the ancient Greek philosophical notion of *akrasia,* which Socrates, Plato, and Aristotle struggled with, giving distinct answers.) In modern terms, the question may be phrased as follows. Is there a real choice, a real conflict between two intentions (one perhaps unconscious)? Is there an unconscious "rational" choice of our best preference, with calculation of secondary advantages? Or is it a fight between our intentional control system and other, more impulsive, automatic systems, which, though unintentional, may control our purposive behavior? (See also the "dual-processing" literature.)

Conclusion: "Goal-Directedness" as a Frame

It can safely be maintained that not only is "behavior" or "action" GD and GG (and social behavior and relations too) but also cognition itself. Our

beliefs (and their acquisition, elaboration, and use) are in relation to and a function of our mental goals (occurrent or potential). Our reasoning is an instrument for goal selection, planning, and achievement. Learning, too, is driven by "success" or "failure." Also, emotions are goal guardians and signifying signals of the achievement or thwarting of our goals, as well as activators of goals. Goal-directedness and management of goals is thus the real structure of behavior and mind. Mind and action must be principally read by means of a theory of their goal-directedness. Moreover, to understand and model social attitudes, social actions, and social structures, we have to model their underlying goals, intentions, and functions.

Governmentality and Regime

Governmentality is a term, most often derived from Michel Foucault's lectures, that focuses on the field of practices, techniques, and forms of knowledge through which we govern in modern societies. It concerns, but is not restricted to, the political government of the state. It has several meanings and usages. First, governmentality refers to the chronological process by which the state comes to accept responsibility for governing the population, economy, and civil society and within which economic knowledge will assume an important role. Second, it is a field of power relations that is concerned with governing through the self-government of individual and collective actors. Third, governmentality is a form of analysis that links the study of the government of self and the government of others and is a dimension of Foucault's broader project of making intelligible the historical conditions of contemporary experience. Finally, governmentality studies have become a distinctive subfield of study in the social sciences.

Regime is a term meaning the more or less organized ways we produce truth and knowledge (as in "regime of truth") and seek to govern others and ourselves ("regime of practices" and "regime of government").

This entry examines the meaning of "governmentality" in the work of Foucault, the impact of the term in governmentality studies, and key issues pertaining to the concept of regime.

Foucault and Governmentality

The central sources for Foucault's conception of governmentality are his 1978 and 1979 published lectures (*Security, Territory, Population* and *The Birth of Biopolitics*), in which he introduces the concept as an object, a chronological process, and a field. As an object, it is a specific historical "ensemble" that takes population as its target, political economy as its form of knowledge, and the apparatus (or *dispositif*) of security as its technical means. Chronologically, it is the process of how the "state of justice" and the "administrative state" in Europe become "governmentalized" beginning in the 18th century. As a field, it is a kind of *power,* distinct from others such as sovereignty and discipline, that has become preeminent. This kind of power is closely related to the emergence of what Foucault calls a "liberal art of

government," which emerges from the critique of the claims of state sovereignty to omniscience and omnicompetence in early-modern doctrines of reason of state and police. More recently, the welfare state has been transformed partially as a result of the "neoliberal" suspicion of the pretensions of state intervention, state regulation, economic planning, and social provision. Liberalism can be characterized as anxiety that one always governs too much.

In the same lectures, Foucault traces the emergence of this modern governmentality from the Christian pastorate and stresses the idea of the government of conduct. Conduct here is not only the art or activity of conducting but also the way in which one conducts oneself. Government, in a very broad sense, becomes the "conduct of conduct." It is possible to talk of governing families, souls, populations, states, and even oneself.

In later lectures in 1982 and 1983 (*The Hermeneutics of the Subject* and *The Government of Self and Others*), Foucault is concerned less with modern power and more with ancient ethics and ascetics. Here, he expands upon a relational conception of governmentality, which is capable of linking and analyzing power relations, governing the self and others, the relation to oneself, as a chain that makes it possible to connect political government with ethical self-government, politics to ethics. A further expansion of the concept occurs when Foucault places the analysis of governmentality in relation to other dimensions of his work. His general approach is to uncover the conditions and practices through which apparently given, stable, and universal entities emerge. Here, "procedures of governmentality" move beyond the history of domination and state in the same way as "regimes of veridiction" displace the history of knowledge and a "pragmatics of the self" replaces the history of subjectivity.

Regime

Foucault applied the term *regime* throughout his work to refer to more or less organized ways of producing truth and knowledge or of governing individual and collective actors for particular ends. At its most abstract, he discusses "regimes of practices" as organized ways of governing conduct, on the one hand, and sites for the production of knowledge, on the other. In *Questions of Method,* for instance, he argues that his principal concerns are the regularities, logic, and strategy embedded in a regime of practice, these practices being shaped through programs and rationalities concerned with conduct and giving rise to certain kinds of knowledge. A regime of practices is a way then to characterize how humans seek security, punish, cure or care, and so forth.

However, there is another term, *dispositif,* which has given rise to a broad discussion and which has been translated as apparatus, assemblage, device, and dispositive. Foucault uses this term to discuss regimes of law and sovereignty, discipline, sexuality, and security. Other contemporary philosophers such as Gilles Deleuze and Giorgio Agamben have sought to install this notion of dispositive as a kind of master key to Foucault's work. Like the concept of regime, it stresses the articulation between rationalities, technologies, fields of visibility, forms of subjectivity, and ends sought, which appear in a given domain of practice. This term delineates a greater immutability and breadth of impact than the idea of regime.

Governmentality Studies

In Anglophonic countries and more recently Germany and Scandinavia, Foucault's writings on governmentality have given rise to a literature that is capable of studying anything from social welfare practices to human resource management, corporate social responsibility to risk, and criminality. This has been called *governmentality studies,* although most of its practitioners would have reservations about the term. Such studies have often concerned themselves with "advanced liberalism," less as an expression of neoliberal philosophies and more as a series of techniques, rationalities, and devices that bear a mutual resemblance. Questions of the dominant logics of government of and by the state remain matters of debate and investigation, particularly the relationship of governmentality to the sovereign powers of the state and the international state system.

Grounded Cognition and Social Interaction

This entry explains novel approaches of grounded cognition and mental representation where sensorimotor simulation is central, as well as how these relate to accounts of *social interaction* in which embodied cognition of higher social concepts or the grounded nature of affect and emotion are vital themes. An introduction to grounded cognition is followed by a discussion of social interaction informed by grounded cognition approaches.

Grounded Cognition

Cognition is the ability to mentally represent the world and to manipulate those representations in order to understand, remember, use language, plan actions, and reason.

Sensorimotor Simulation

Whereas more traditional theories in cognitive science assumed that such mental representations consisted of abstract symbols, the psychologist Lawrence Barsalou, building on prior philosophical ideas, proposed that representations consist of sensorimotor simulations. On this account, the *perceptual symbols theory,* cognition shares processing mechanisms and neural systems with perception and action.

During an experience, neural patterns are activated in modality-specific areas for sensory and motor processing. Higher-level association areas (*convergence zones* in Antonio Damasio's words) capture these activation patterns at different levels. Association areas in modality-specific areas capture activation patterns within modalities, and higher-level areas integrate patterns from different modalities.

Representation is essentially the reenactment of previous experiences. Higher-level association patterns activate lower-level association areas, which activate patterns in sensorimotor areas. Rather than an exact replica of experiences, however, these patterns are distorted and represent only partial experiences. In Barsalou's theory, simulators capture patterns of activation for a particular category of experiences. As a result, they represent a distributed pattern of experiences with a concept such as *chair* or *apple*. Simulation of experiences is dynamic and flexible and can even represent imaginary events.

Research has shown that representations are organized along sensorimotor modalities and contain modality-specific information. Representation and perception share processing mechanisms and have been shown to support or interfere with each other. For example, (a) after a shift in sensory modality, similar costs in processing occur between and within perceptual processing and mental representations, and (b) people recognize object pictures faster when their orientation, shape, or motion matches the values implied by language. Neuroscientific studies have indicated that overlapping brain areas are involved in representation and sensorimotor processing.

Cognition for Action

A related but slightly different view, proposed by Arthur Glenberg, is that cognition is for action. On this account, the function of memory is to support actions. This is achieved by *meshing*, a process that integrates properties of the environment, embodied memories, and properties of the body into potential action patterns. The meshing process serves both to understand the current environment and to mentally represent situations.

Social Interaction

Research on social interaction has long assumed that the body, and its mental representation, is closely tied to the processing of social and emotional information. In fact, the central concept in social psychology—attitude—has been thought more than a century ago as grounded in motor dispositions. Thus, Charles Darwin proposed that attitudes are collections of motor behaviors,

and Francis Galton thought that attitudes consist of *body* inclinations. Research on the role of the body flourished since then, with researchers showing, for example, that (a) nodding the head, as in agreement, while listening to persuasive messages leads to more positive attitudes toward the message than shaking the head, as in disagreement, and (b) objects associated with approach actions (e.g., arm flexion) are subsequently evaluated better than objects associated with avoidance actions (e.g., arm extension). Such phenomena fit the grounded cognition framework, which assumes that bottom-up bodily states are an intrinsic component of social information processing.

Embodiment of Higher-Order Social Concepts

Crucially, the grounded cognition framework goes beyond simple concepts and holds that high-order mental processes operate on perceptual symbols. Thus, even complex concepts involve partial reactivations of the sensorimotor states that occur during an individual's original experience with the world, as well as simulation of new sensorimotor experiences. Evidence that such processing occurs for complex social concepts has been obtained in several domains. For example, (a) making a fist influences people's processing of words related to the concept of power and (b) washing hands changes people's perception of moral responsibility or luck.

Simulating Affect/Emotion

The grounded cognition approach naturally applies in the domain of affect and emotion, where it is straightforward to conceive of emotion knowledge as a process of internal simulation of an emotional experience. Clearly, these simulations may not constitute full-blown emotions, must not simulate every aspect of emotion, and may not even be conscious. Nevertheless, such simulations can generate enough sensorimotor information to support conceptual processing. Evidence for simulation of emotion knowledge ranges from (a) activity of similar brain networks when people experience actual disgust and when people simply think about disgust, even in its abstract moral form, to (b) facial muscular activity when people abstractly think about concepts such as anger and happiness, to (c) activation of general introspective processes after people have been focused to think about abstract emotional concepts from an experiential perspective. Again, these mind-to-body findings are consistent with body-to-mind evidence that manipulating the motor processes can change the experience of the emotion, as well as its perception. Thus, people in a slumped posture feel less proud than people in an upright posture, and blocking expressions of happiness interferes with recognition of that emotion.

Imitation

A classic finding is that people imitate emotional expressions, gestures, and mannerisms even when not encouraged to do so. This phenomenon of spontaneous imitation can be understood by theories of grounded cognition, which view it as part of the bodily reenactment of the experience of the other's state. In fact, there is evidence that the lack of imitation may cause problems with social interaction.

Conclusion

The grounded cognition framework, with its proposal that mental processing is simulated experience, provides an essential theoretical account for understanding the mind. On this account, social interactions are supported by simulations of emotions, motor actions, and other people's states. Thus, social behavior is grounded in the body.

Group Beliefs

A group belief is a belief held by a group of two or more people, such as a couple, a club, a corporation, or a state. The question of whether groups may literally be said to have beliefs, and if so when, has significant implications for explanation and evaluation of group and institutional behavior in the social sciences and in ethics. If groups have beliefs, then their behavior may be explained and predicted by knowledge of what those beliefs are. When group beliefs lead the group to harm others or the environment, it may be appropriate to hold the group as a whole morally responsible.

This entry focuses primarily on the *ontological* debate about the existence and nature of group beliefs. First, the early division between holists and methodological individualists is briefly discussed; then, the current debates within the field of philosophy about the proper analysis of group beliefs are surveyed. The entry concludes with a brief discussion of recent work on group beliefs within epistemology.

Consider the following examples of group beliefs:

> We believe that Susan is the best candidate for the position.
>
> British Petroleum believes that technology is key in tackling the challenges faced by the biofuel industry.
>
> Mathematicians believe that Fermat's Last Theorem has been proved.

We often attribute beliefs to groups in order to explain the actions of individual members and the group as a whole. There is disagreement, however, about whether or not groups literally have beliefs. Some argue that such statements of group belief are merely a figurative way of speaking that should not be taken literally. Even among those who hold that there are genuine group beliefs, there is disagreement about what conditions must be satisfied for a group to have a belief.

Group Minds and Methodological Individualism

The attribution of beliefs to groups as a way to explain individual and group behavior was prevalent in sociology and psychology at the turn of the 19th century. Émile Durkheim, for instance, held that we could explain individual behavior by looking at the "collective consciousness" of the society of which the person is a part. Later theorists rejected this "holist" view as implying the existence of a metaphysically mysterious "group mind." According to *methodological individualism,* which arose early in the 20th century, we should explain all social phenomena in terms of the beliefs and behavior of individuals. On this "summative" view of group beliefs, statements of group belief are equivalent to statements about the beliefs of the *sum* of the members of the group.

Rejectionists and Believers

It had to wait until the late 20th century for a serious program of analyzing group concepts to begin. Such analyses are the focus of philosophers working on "collective intentionality," most notably Raimo Tuomela and Margaret Gilbert. Theorists of collective intentionality seek to analyze and understand how groups of individuals can share intentional states such as intentions to act, beliefs, and, in some cases, even emotions or perceptions. Tuomela and Gilbert each developed a theory of collective intentionality that rejects the assumptions of the methodological individualists, arguing that collective intentions are not simply a "sum" of individual intentions. In line with this, they each proposed a nonsummative account of group belief.

In response to such so-called believers, who claim that group beliefs exist, "rejectionists" have argued that there are no group beliefs. Rejectionists claim that groups may *accept* propositions but they cannot believe them. Rejectionists point out that there are a number of differences between beliefs and acceptances, and they argue that all group "beliefs" have the features of acceptances and frequently fail to have the features of genuine beliefs.

Table 1 Beliefs and Acceptances Compared

Beliefs	*Acceptances*
Involuntary	Voluntary
Aim at truth	Aim at pragmatic success
Follow evidence	Follow interests and desires
Ideally coherent	Allow for contradiction
Come in degrees	Categorical

Source: Kay Mathiesen

Interpretation or Agreement

Among "believers" who accept the idea that there are genuine group beliefs, different accounts are offered of the existence conditions for group belief. On the "interpretational" approach, advocated by Deborah Tollefsen, a group has a belief when the activities of the group and its members can be fruitfully explained by attributing beliefs to them. This approach is inspired by the "intentional stance" theory of intentional states, which holds that an entity has a belief just if we can give an illuminating explanation of its behavior by attributing a belief to it.

On the "agreement" approach, for there to be a group belief, the members of the group must each accept the proposition that is believed. Most notably, Margaret Gilbert's "plural subject" account proposes that a group forms a belief just when the members of the group "jointly accept" the proposition that expresses that belief. Once the members have jointly accepted a proposition, they are committed "as a body" to that proposition. This means that each individual member of the group is obligated to act and speak consistently with the group belief when they are acting as members of the group.

Extended Minds and Collective Epistemology

Recent work on group belief has extended beyond the original debate in social ontology to philosophy of mind and epistemology. The theory of the extended mind, developed by Andy Clark, brings a new perspective to the question of group beliefs. According to the extended mind hypothesis, minds are not contained within single individuals but can be spread across two or more persons who share cognitive resources. The emerging field of collective epistemology asks different questions about group belief than the ontologist, such as "Can groups have beliefs that may form the basis of knowledge?" If so, are groups knowers in their own right, of equal importance with individual knowers?

Group Identity

In the social sciences, discussion of group identity has tended in recent years to revolve around the ways in which groups shape the practices, attitudes, and values of their members and the ways in which such membership leads to their political and social marginalization. The group and its identity is defined or characterized in terms of, say, ethnicity, gender, sexual orientation, religion, language, or region. Indigenous peoples in North America or Australasia have, for example, been excluded (both de facto and historically de jure) from or forced to assimilate into the political and economic mainstream because their groups were regarded as excluded from or outside of the norms of full or proper citizenship. The relationship between political and social norms defined in relation to a dominant group and other groups not conforming to those features or practices underpins the rise in real-world political discourse, sociological analysis, and philosophical thought of "identity politics," or "the politics of difference."

This discussion of the significance of group identity, though, suffers from an omission, which has been characteristic of much of the social-scientific literature, which fails to consider and spell out the *ontological* commitments of social-scientific discourse. In talking of the effects of group membership, the claim for group rights, the role of a group in bringing about some event or state of affairs, or the demand of one group to be compensated for the wrongs inflicted by another, social scientists and philosophers are brought to an old question: *What is a social group?* Hard on its heels come others: How can we individuate one group from another, and what makes a social group the very same one through time? Of course, these questions connect the philosophy of social sciences to more general issues

in *metaphysics* concerned with the individuation of objects and their diachronic identity conditions.

For the social sciences these old questions might now be regarded as superannuated, coming to be superseded by, inter alia, interests in social properties, collective intentional states, and systemic approaches to society. Notwithstanding the interest and importance of such issues, the old—ontological—questions have never gone away, for they are at the core of an understanding of the nature of the social sciences. The truth conditions of many claims about the social world depend upon the existential or referential status of groups such as nations, peoples, classes, communities, teams, tribes, and families. A proper understanding of what is said—of what we mean—turns on how we are to treat references to social groups. The justification of moral evaluations, the articulation of practical judgments and actions, and the formation of policies depend upon the objects of such judgments or actions being appropriate ones. In particular, it must be the kind of thing capable of sustaining such judgments and of being responsive to particular policies and actions.

The majority view among philosophers is that these questions can be answered in a very straightforward fashion. Groups can (at least in principle) be excluded from social-scientific discourse. Labeling a diverse set of views as *individualism,* this position maintains that individuals and their relations enjoy ontological and explanatory priority. Depending on its form, individualism holds groups to be identical to sets (or mereological sums of individuals or person stages), mere fictions or reductively analyzed out of social-scientific discourse.

The truths about groups are held to be expressible, without loss, as truths about *individuals.* The very notion of group identity becomes shorthand for the ways in which individuals relate and, typically through standing in certain kinds of relationships, conceive of themselves.

Others have argued that social groups cannot be identified with sets or aggregates or reductively analyzed out of our social-scientific descriptions, explanations, and predictions. The realist thesis holds groups to be composite material particulars capable of standing in causal and explanatory relations. A variant of a realist thesis disavows the materiality of social groups. Social substances, such as countries or social institutions, are taken to be spatiotemporally locatable but nonmaterial entities. But such entities are puzzling.

For (materialist) realism, then, at a high level of taxonomic categorization, groups feature alongside kinds such as organisms and artifacts. This entitlement to individuate groups as material objects relies on two key claims: first, that reference to groups in social-scientific and everyday discourse is ineliminable and, second, that ineliminability from our best theoretical model is the hallmark of realism in general. Granted these claims, realism cashes out group identity as a thesis for the individuation of a type of entity. It is now—the realist may insist—the job of the social sciences to elucidate why particular groups have certain features and to trace the ways in which different types of groups are treated and the impact of such treatment on their members.

Realism about the identity of groups brings with it the burden of addressing two challenges. First, the possibility of synchronic coextensive memberships of groups (e.g., the philosophy department and the wine appreciation society) suggests that two material particulars of the same kind can be in the same place at once. This appears to fly in the face of our commonsense understanding of material particulars. Second, the realist owes an account of the survival conditions of a group. A group can undergo change through time while remaining the same group, most obviously through changes in its membership. For most objects, the very same thing survives change in its parts, provided its parts continue to be organized through time in the form characteristic of that kind of object. Groups, though, by being composed of intention-forming persons, seem more prone to mergers, divisions, and changes in their defining characteristics (e.g., the prevalent attitudes and values) than artifacts or organisms. To hold that group identity is more than a way of talking about individuals in relations and refers to the identity of a group as such through time, these issues must be addressed by the realist.

In concluding, it is important to note that the issue of the ontological status of groups runs through or cuts across the question of whether a proper understanding of the social sciences is naturalistic, interpretive, critical, or postmodern. No position on the nature of the social sciences can ignore the further question.

Group Mind

Talk of group minds has arisen in a number of distinct traditions, such as in sociological thinking about the "madness of crowds" in the 19th century and, more recently, in making sense of the collective intelligence of social insects, such as bees and ants. In this entry, we provide an analytic framework for understanding a range of contemporary appeals to group minds and cognate notions, such as collective agency, shared intentionality, socially distributed cognition, transactive memory systems, and group-level cognitive adaptations.

Introduction

While individual agents—for example, people, other living things, robots, and computer systems—are the most commonly invoked cognitive agents, the positing of group minds has a rich and diverse history in the cognitive, biological, and social sciences. Much of this history threads its way into contemporary discussions of group minds and closely related notions. For example, in envisaging a universal knowledge network that would serve to advance human civilization, 18th-century French encyclopedists, such as Denis Diderot and Jean D'Alembert, provided an intellectual anchor for contemporary thought about the Internet and the World Wide Web functioning as the hardware for a "global brain"—Francis Heylighen being among those who contributed to the latter notion. The evolutionary biologist David Sloan Wilson has drawn explicitly on 19th-century work on group minds in arguing that group-level cognitive adaptations could evolve by group selection. And Irving Janis's cautions about "groupthink" and its negative consequences echo the historically popular work of Gustav LeBon and others in the 19th century warning of the dangers of fermenting conditions that thwart individual rationality and behavior.

While there is much more to be said about the history of such appeals to group minds and their relationship to ongoing discussions, this entry focuses on the contemporary discussions themselves. In particular, it provides an overview of the major strands of recent work structured around what is *shared* within a group of individuals usefully thought of as constituting or producing some kind of group mind.

Collective Cognition and Group Minds

Contemporary proponents of the idea that groups can be the subjects of psychological properties in their own right often express their views without using the group mind idiom. This is at least partly because the vernacular concept of mind is closely intertwined with consciousness and a first-person awareness of our inner mental lives. Thus, speaking of "group minds" may seem to commit one to an implausibly strong ontology, one blurring the distinction between science and cybernetic fantasies about the technologically driven emergence of collective forms of consciousness, as Heylighen shows. Yet minds that stop short of having the full range of properties that our minds have are commonplace. Newborn human infants, nonhuman animals, and certain kinds of machines are recognized as possessing such minds, manifesting only some of the psychological states or abilities characteristic of the minds of normal adult human beings.

Contemporary proponents of collective cognition typically restrict their claims to particular kinds of psychological predicates taken to be shared by individuals and groups. Such predicates can be drawn from folk psychology (e.g., belief, intention, rational agency), may refer to classical mental faculties (e.g., memory, decision making, or problem solving), or involve more theoretically driven notions (e.g., adaptive information processing).

Such an approach to group minds retains the core of the older emergentist idea that a group as a

whole can have cognitive properties that none of its members has, properties that are irreducible to the properties had by those members, as for example, Georg Theiner and colleagues show. Group cognition is not simply the unstructured aggregation of individual cognition but the collaborative outcome of a division of cognitive labor among cognitive agents. The social interactions between individual agents can have unintended cognitive effects at the group level, similar to the self-regulating "invisible hand" of the marketplace. Analyzing social processes in terms of cognitive functions such as memory or problem solving serves to highlight certain important information-processing patterns that can also be observed when the same function is performed by individuals.

Three Kinds of Group Cognition

To further understand contemporary work relating to group minds, we focus on what it means to say that some psychological property or process is collectively possessed, enacted, or otherwise *shared* by a group of individuals. We distinguish three different interpretations of this claim (ranked in the order of ascending strength): coordinated cognition, collaborative cognition, and joint cognition.

Coordinated Cognition

The first and weakest interpretation corresponds to the sense in which two or more people can share tokens of the same type of mental state or attitude as a result of being members of the same group. For instance, the memories of individuals that are part of long-standing groups, such as religious groups, nations, or social classes, tend to converge toward a shared stable rendering of the past that actively shapes, and is also continually shaped by, the community's collective identity. The critical role of social interactions here is to provide a mechanism of cognitive alignment whose function is to enhance some (frequently nonpsychological) capacity of the group. Accordingly, the central feature of shared cognition in this first sense is the homogeneity or at least substantial similarity of individual members' perspectives. We suspect that many if not all appeals to group minds of this kind can be reduced to claims about individual minds, together with accounts of the social and other mechanisms coordinating the psychological states of those individuals.

Collaborative Cognition

A second, and stronger, way in which cognition can be collectively shared that is less readily reducible in this sense is exemplified by the way in which a group can share a cognitive workload by apportioning that workload among its members. Here, the emphasis rests on the integration of distributed cognitive resources within a group by various social and cognitive mechanisms that pool complementary pieces of information from its members. A particularly striking illustration of the cognitive virtues of this form of shared cognition is the "wisdom of crowds" effect, in James Surowiecki's phrase, which refers to the ability of intellectually diverse collections of independently acting individuals to make better decisions or predictions than those of its best members, provided that there is an efficient mechanism for aggregating individual knowledge that is immune to the dysfunctional influences of social conformism. Prediction markets (e.g., Intrade.com) are a successful real-world application of this phenomenon.

However, many complex cognitive activities that are collectively performed by groups are achieved in an even more collaborative fashion, involving levels of cognitive interdependence that require much more intimate forms of cooperation than those that are necessary to participate in a decentralized market mechanism. Much of contemporary work on group minds falls under this heading, often focusing on the performance of small groups concerned with highly structured cognitive tasks that lend themselves to a clear differentiation of functional roles. Consider three prominent examples.

Daniel Wegner coined the notion of a *transactive memory system* to express the idea that people who stand in continuing close relationships (e.g., as couples, families, coworkers) may develop a kind of supra-individual memory system. In principle, a transactive memory system is capable of remembering more than the sum of its members. However, this potential assembly bonus is often difficult to realize in practice, because members often do not know whom to ask, how to ask, and how to cue each other effectively. Only groups whose members trust one another's expertise, have a shared awareness of how encoding and storage responsibilities are apportioned, and have developed efficient practices of retrieval coordination are capable of producing emergent group-level memories.

The framework of *distributed cognition* differs from other collaborative approaches to collective information processing by placing a strong theoretical emphasis on how the material structure of the collaborative work environment, such as workspace design, tool use, or the physical format of verbal or written representations, sculpts and facilitates the social distribution of cognitive workload in space and time. For example, Edwin Hutchins (1995) concludes his celebrated computational analysis of coastal ship navigation aboard a Navy cruiser with the observation that "organized groups may have cognitive properties that differ from those of the individuals who constitute the group. These differences arise from both the effects of interactions with technology and the effects of a social distribution of cognitive labor" (p. 228). By considering the extended mechanisms that enable the real-time coordination of heterogeneous elements in support of various cognitive functions, rather than the spatial boundary between what's inside the head and what's not, proponents of the distributed-cognition approach aim to break down the traditional categorical divide between cognitive ("inner") and social-cultural ("outer") factors.

A third example of what we are calling collaborative cognition is drawn from the evolutionary literature on group selection. David Sloan Wilson has defended the view that whenever between-group selection dominates within-group selection, there are evolutionary pressures toward modes of social organization in which social groups begin to function like higher-level organisms. According to Wilson, the occurrence of such a major evolutionary transition during early human evolution has had a profound impact on our psychological makeup, such as the evolution of altruism, cooperation, religion, and morality. With an eye on tightly knit religious communities as a prime historical example, Wilson (1997) has argued that group selection can be strong enough to create situations in which "individuals might cease to function as independent decision makers and become part of a group-level cognitive structure in which the tasks of generating, evaluating, and choosing between alternatives are distributed among the members of the group" (p. 358).

Joint Cognition

The third, and strongest, sense in which cognition can be collectively shared requires that two or more people are jointly committed to assume particular mental states as a collective body, that is, to act as a plural subject of intentions, beliefs, or knowledge. For Margaret Gilbert, the formation of a joint commitment forges a special kind of nonsummative unity that is not an aggregate of individual commitments. Nor, she argues, does it, properly speaking, have any parts but instead brings into existence what Gilbert calls a "pool of wills" to which all group members are bound simultaneously and interdependently. Joint commitments in this sense give rise to distinctive group obligations and entitlements to which its members ought to adhere, including epistemic norms to which plural subjects can be held accountable. This creates the potential for genuine conflicts between individual and group rationality. As Christian List and Philip Pettit argue, group agents who have the capacity to recognize these obligations, and respond to them in a manner characteristic of reasoning subjects, constitute real, albeit nonnatural, persons.

H

Habitus

This entry traces the development of the concept of habitus in philosophy and sociology and focuses on Pierre Bourdieu's systematic theory of it, especially as a theory of action.

Classical Sources of the Concept

Habitus is a concept originally introduced by Aristotle, reworked by Thomas Aquinas, and used sporadically and unsystematically by some 19th-century European social theorists. The notion was revived and recruited for understanding the practical embodied bases of action by the French sociologist Marcel Mauss and the French philosopher Maurice Merleau-Ponty. But it was only in the work of the French sociologist and anthropologist Pierre Bourdieu that the concept was reintroduced with a more systematic intent into social theory as a viable analytic tool for the job of accounting for the cognitive components of action.

In its initial Aristotelian formulation, the notion of habitus is captured in the idea of *hexis* (habitus is the usual Latin translation of this Greek word). This refers to the state of possessing (or "having," Latin *habere*) an acquired, trained disposition to engage in certain modes of activity when encountering particular objects or situations. For instance, the essential capacity to regularly engage in virtuous action was understood, in the context of Aristotelian ethics, to be the primary exemplification of *hexis*. Aquinas would refine the application of the concept to ethical reasoning in further specifying the nature and content of the moral virtues. In Aquinas's rendering, the full virtuous personality is one who has, through effort and training, cultivated the proficiency to act in the morally required manner without effort, that is, a person for whom moral behavior becomes *second nature*—as put forth originally by Aristotle.

The Central Problem in the Sociology of Knowledge

In the sociology of knowledge, an attempt is made to account for the social or external bases of thought. This has a long tradition in Western social theory, but the two main classical sources are the essay on *Primitive Classification* written by the French sociologist Émile Durkheim and his nephew Marcel Mauss in 1902 and the monograph translated into English as *Ideology and Utopia* (1936), authored by the German sociologist Karl Mannheim. The Durkheim and Mauss essay is known for its bold claim that the categorical relations with which persons organize their understanding of the world of things are modeled after the social relations that govern the classification of persons as members of distinct groups. Mannheim, for his part, emphasized how the agonistic context of intellectual fields molds the content of ideological systems. In both of these statements, *a link between social structure and structure of systems of thought* is made, but the mechanisms that mediate this linkage remain murky.

Habitus as a Solution to the Central Problem

It was in his attempt to rebuild and rework this intellectual tradition—leaving behind its most egregious distortions and oversimplifications—that Pierre Bourdieu first resorted to the notion of habitus. His initial source of inspiration was admittedly an odd one: a book written by the art historian Irwin Panofsky (*Gothic Architecture and Scholasticism*) arguing how the aesthetic rules of composition of Gothic architecture—most clearly appreciated in the construction of the Gothic cathedral—were isomorphic to the habits of thought and learning inculcated in the medieval scholastic institution—most clearly appreciated in the construction of the *Summa,* the major scholarly treatise in which systems of ideas were expounded. In a postface written for the book in 1967, Bourdieu is struck by how in resorting to the Aristotelian notion of habitus to make sense of this correspondence, Panofsky is able to partially avoid the dilemma that plagued traditional sociology-of-knowledge proposals of a similar sort.

Habitus and the Theory of Action

The Connection Between Position and Disposition

Bourdieu would go on to systematize the idea of habitus for a more general understanding of the nature of social action in his subsequent work. In Bourdieu's rendering, which creatively melds a wide range of influences from Piagetian psychology, phenomenology, the history of epistemology, and onward to Lévi-Straussian structuralism, habitus is an *acquired system of schemes* that allows for everyday instances of perception, categorization, and the production of action and, most importantly, for the production of mundane judgments (e.g., judgments of moral propriety or impropriety, of likelihood or unlikelihood, or of certainty or uncertainty, or judgments of taste, e.g., likes and dislikes). The habitus endows action with a finality that is immanent or implicit in practice and that only appears *after the fact* as if it had been planned beforehand. The habitus, thus, subsumes the rationalistic theory of action inherited from utilitarian thought as an unnatural exception rather than the rule from which an understanding of action should be built.

In Bourdieu's rendering, the habitus is not just the producer of actions and reactions, but it is a *product* of the environmental conditions that the person encounters during ontogenetic development. In its essential status as a being open to (being modified by) the world, the person is bound to internalize the immanent necessities inscribed in that world in the form of habitus. As a form of internalized necessity, the habitus biases our implicit micro-anticipations of the kind of world that we will encounter at each moment, expecting the future to preserve the experiential correlations encountered in the past. This linkage of habitus to social position thus makes the concept of habitus inseparable from a theory of the differential distribution of social positions, which in Bourdieu's work takes the (natural) form of a field theory.

There has been some debate as to whether the habitus is a "collectivist" (holist) concept or is instead an "individualist" solution to the classic problem in the sociology of knowledge. The main point to note here is that in proposing that habitus emerges from experience, Bourdieu moves the debate beyond the traditional parameters of the sociology of knowledge because he locates the relevant realm upon which (whatever) regularities can be observed back into the (nonarbitrary) features of the world. In this respect, he moves beyond the impasse produced by the Durkheimian assumption of the arbitrary nature of the cognitive components of action and perception, which came to bedevil cultural anthropology.

Adaptation, Anticipation, and Change

Because the habitus is the product of adaptation to conditions, it is heavily predisposed to attempt to re-create the very same conditions under which the systems of skills and dispositions that it has most proficiently acquired can be most profitably put to use. The (tacit) recognition of this situation to skill match or mismatch is in effect the most obvious form of "practical reason" stored in the habitus. Conversely, the habitus tends to avoid those environments and situations for which it is not well adapted, in effect "refusing" that which is in fact objectively unavailable to it and liking or loving that which is already best fit to it. In this respect, the habitus is heavily weighted toward the past and biases choices in a way that lead to the conservation and constant reinforcement of already acquired capacities.

In its capacity as already accumulated (and thus "sunk-in") skill, the habitus carries with it a heavy load of inertia and only changes when external

conditions are so dramatically transformed as to permanently disrupt the capacity of the habitus to implement those strategies that worked in the past. This process of readaptation and reskilling is necessarily disruptive, and to some extent traumatic. Insofar as the habitus encompasses that which is most essentially a person's self, any rejection or transformation of the things that we do as second nature is in effect a rejection or a transformation of what a person "is" in the most fundamental sense.

Hayek and the "Use of Knowledge in Society"

This entry explicates Friedrich Hayek's (1899–1992) social epistemology, an epistemology that gives due consideration to both the workings of the individual mind *and* the mechanics of the ambient sociality in which mind is enmeshed. On Hayek's account, mind and sociality are coevolved connectionist-like systems, the latter scaffolding the inherently constrained mind, thereby significantly reducing the epistemic transaction costs involved in the harvesting of knowledge.

Hayek's Basic Insight

Hayek's most abiding philosophical insight is the idea that "perfect" knowledge is unnecessary, impracticable, and irrelevant, and indeed for these very reasons, its indiscriminating pursuit can be pernicious. Hayek's specific targets were two species of "rationalism": (1) central planning (favored by collectivism) and (2) the abstract individualism of homo economicus (favored by orthodox economics). According to Hayek, these rationalisms fail miserably to appreciate that cultural complexity offers both the *fabric of possibility* and the *fabric of inherent constraint.* If one understands sociality to be a complex and necessarily *dynamic* weave of innumerable "spontaneous orders," then on Hayek's account, knowledge, paradoxically, can become less incomplete only if it becomes more dispersed.

Hayek's social epistemology is spread across his work and is not coextensive with the essay "The Use of Knowledge in Society," which appears in this entry's title. Hayek's core presupposition—that mind is subject to terminal cognitive and epistemological constraint—crucially informs his social epistemology, philosophy of social science, and social theory. Indeed, Hayek made a very distinctive link between mind and freedom: All institutions of freedom are essentially adaptations to the fundamental fact of cognitive constraint. Hayek's philosophical psychology is set out in its most extended and technical form in the much-neglected *The Sensory Order,* but its concerns are to be found in attenuated form throughout his substantial corpus.

Cognition and Sociality

"Cognitive constraint" connotes the idea that the human mind is terminally subject to cognitive and epistemological opaqueness, not only concerning its own mechanics (the mind–body problem) but also in terms of collective intentionality. The *fundamentum* and the *residua* of practical reasoning of multitudes condense into customs, practices, and traditions,

entailing that mind is inescapably culturally saturated: Knowledge is modulated and particularized. Cognition, is therefore, always epistemically perspectival despite a universally shared cognitive architecture. In order to "harvest" knowledge, Hayek postulates a *dynamic,* connectionist-like theory of mind (the nervous system characteristically being a universal pattern–seeking mechanism).

In many respects, for Hayek, mind is the analog of his connectionist-like theory of sociality; that is, both mind and sociality are conceived as classic instantiations of mutually *coevolved* spontaneous orders. This idea is absolutely critical to understanding Hayek. In much the same way that synapses are strengthened while unused linkages weaken and wither away, so too are paths to salient social knowledge strengthened or weakened—*social* connectionism, if you will.

Action and Social Knowledge

As a guide to action, social knowledge (know-how) cannot be reduced, abridged, or restated propositionally (as knowledge-that) without remainder. It is for this reason that the demand for a demonstrative and deliberate use of *reason* in matters of sociality will defeat the cognitive capacity of any one individual or too heterogeneous a group of individuals. Hayek at different times in his career variously attributed this inappropriate rationalism to certain economists, central planners, "scientistic" social theorists, and ideologues of both the Left and the Right. That knowledge cannot be aggregated, centralized, or otherwise fully harvested is, in Hayek's view, a misplaced pessimism. On the contrary, this state of affairs facilitates "computational" and cognitive efficiencies by enabling individuals to exploit environmental and social resources rather than having to encode everything relevant within the confines of the brain. It is this "situated" perspective that motivates Hayek's social externalism. For Hayek, this is the mark of advanced cognition—humankind's evolutionary propensity to diffuse propositional and practical knowledge or wisdom through external epistemic structures.

Communicative Systems of Knowledge

For Hayek the conditions for epistemic veracity are best fostered through the manifold of *spontaneous orders* or "communications systems" that compose the fabric of the civil (liberal) condition. Hayek was centrally concerned with the *communicative* aspect of knowledge—the acquisition, mediation, and transmission of (for the most part, third-party) knowledge in complex communities of knowers. A healthily functioning communications mechanism promotes computational efficiencies, a coordination mechanism for diverse wants, preferences, and interests. It should be noted that at no time did Hayek give ontological priority to the market (attributions of economism to Hayek are thoroughly misplaced). Whatever the market's epistemic strengths (and they are considerable), for Hayek the healthy functioning of a market presupposes other institutions and spontaneous orders. Indeed, a manifold network of spontaneous orders (science and democracy being two other prominent orders) best promotes the conditions for moral and political freedom or autonomy. No one order should subsume or impinge upon another: The exercise of epistemic immodesty within and between orders is bound to impoverish the liberal condition. It is the sine qua non of the liberal condition that there will always be inherent tensions—to make one order answerable to another order's metric is both rationalistic and, indeed, antiliberal.

Concluding Remarks

Hayek's intellectual fortunes have ebbed and flowed: his popularity with the public counterposed by his lack of popularity within the academy, his reputation being tarnished from having been sequestered by—and consequently unfairly associated with—the laissez-faire community. Hayek's appeal is now significantly broader and his prescience in matters epistemological and in the philosophy of mind is now much more richly appreciated. The lived subjectivity emphasized by the Austrian tradition, the Scottish Enlightenment's emphasis on emergent properties, the "situated" non-Cartesian wing of cognitive science, analytical social epistemology, and network theory—all find a confluence of interest in Hayek's work. If there were a slogan that captures Hayek's lifelong project, it is that Hayek socializes the mind and "cognitivizes" social theory.

Hegelianism and Contemporary Epistemology

This entry on Hegelianism and contemporary epistemology construes the latter as analytic philosophy. In recent years, as analytic figures turn increasingly to Georg Wilhelm Friedrich Hegel, Hegelianism has become one of the strands in contemporary epistemology. Analytic thinkers tend to read on the basis of prior analytic commitments. The complex relation between analytic philosophy and Hegelianism has evolved greatly over the past century. The entry starts by going over the earlier historical ground that led to the recent resurgence of Hegelianism in the hands of analytical philosophers. The crucial primary element in this has to do with the rejection of idealism by early analytic philosophy and its subsequent rereading of idealism's patriarch, Kant, by later representatives of the analytic tradition.

The analytic approach to Hegelianism is influenced by factors such as the general analytic reception of idealism, Wittgenstein's later attack on empiricism, and the analytic reading of Kant. The general analytic reception of idealism resembles the Marxist reading of idealism. Marxism has always defined itself as the negation of Hegelianism, and Hegel is routinely understood as a German idealist. The Marxist turn away from Hegel was reprised by analytic philosophy as it was emerging in England around the turn of the 20th century. Bertrand Russell and G. E. Moore, the founders of analytic philosophy, both wrote dissertations on Kant, Russell on his views of mathematics, and Moore on his views of ethics. Both for a short time considered themselves to be idealists, and both later turned against it. Kant famously added a "Refutation of Idealism" to the second edition of his classic, the *Critique of Pure Reason,* to distance himself from "bad" idealism. Moore attacked idealism of all kinds, which, he claimed, denied the existence of the external world. Moore's attack resulted in the analytic interdiction of idealism, which has never been lifted.

A specifically analytic reading of Kant emerged in the writings of Anglophone philosophers like Graham Bird, Jonathan Bennett, Peter Strawson, and others. Strawson presented a reading of Kant shorn of transcendental idealism. Kant, of course, rejected naturalism in adopting transcendental idealism to respond to Hume. Strawson's naturalistic approach to Kant read the critical philosophy as if it were an early form of analytic empiricism.

Early analytic philosophy was thoroughly empirical. Russell featured various logical forms of empiricism, while Moore espoused both commonsensism and sense-data theory. In the meantime, Wittgenstein launched an attack on Moore in favoring a kind of contextualism.

The analytic attack on idealism turned attention away from Hegel, which was turned back to Hegelianism by the later Wittgenstein's attack on empiricism and the emergence of a specifically naturalistic, nonidealistic approach to Kant. The analytic turn or return to Hegel was further strengthened by Wilfrid Sellars in attacking the notion of givenness under the heading of *méditations hégéliennes.*

Building on the later Wittgenstein, Sellars clearly signals his receptivity to Hegel in his frontal attack on classical empiricism, which he calls the myth of the given. He borrows Hegelian arguments in turning

Hegel's critique of sense certainty against empiricism. If the immediate given cannot be known, then empiricism as it has been understood in the English tradition and perhaps even in Kant, if Kant subscribes to a successor form of English empiricism, is indefensible. In restating Hegel's argument in an analytical idiom, Sellars rejects the idea of immediate givenness, or in Hegelian terms *immediacy,* as no more than a myth in favor of the justification of claims to know within the so-called logical space of reasons. Although the critique of traditional empiricism is closely Hegelian, numerous other features in Sellars's theories, such as a scientism of sorts resulting from his appeal to the so-called space of reasons, are non-Hegelian, even anti-Hegelian.

Sellars's intervention in the debate helped reverse Hegel's bad analytic reputation while deepening the later analytic revolt against empiricism. His Hegelian approach to immediacy facilitated a modest analytic rapprochement with Hegel, yet always with Hegel shorn of his idealism. After Gottlob Frege, the problem of semantic reference became the main theme in analytic philosophy. Analytic figures attracted to Hegel were often among those who turned away from the traditional analytic concern with semantic reference. They include contemporary philosophers such as the late Richard Rorty, always a maverick among analytic writers; his former students Robert Brandom and John McDowell, who both approached Hegel through Sellars; Pirmin Stekeler-Weithofer, a German philosopher; the Australian Paul Redding; and others.

Analytic readings of Hegel are not always closely tied to the texts. Rorty, who describes Hegel as one of his main influences, advances an idiosyncratic view of the German thinker. In a well-known account of the pragmatist philosopher John Dewey, Rorty depicts Hegel as defending a historicism that amounts to the claim that we will not be destroyed by a giant comet.

Turning to the contemporary scene, Brandom and McDowell together constitute the Pittsburgh school of analytic Hegelianism. They have sharply divergent views of Sellars and of Hegel. Among current analytic philosophers, Brandom has most closely identified his position with pragmatism and Hegel. Brandom does not distinguish between idealism and a neo-analytic pragmatism. Hence, his reading of Hegel requires the most careful scrutiny; his pragmatic interpretation of Hegel is firmly intertwined with, even inseparable from, his interest in what he calls "inferentialism." Brandom has attracted attention for his suggestion that inferentialism, his name for a restatement of the familiar idea of inference to the best explanation, is anticipated by Hegel. Brandom's inferentialism is associated in his mind with a variation on traditional analytical metaphysical realism. His metaphysical realist claim that reality makes our views, say, of electrons or aromatic compounds, true or false is apparently incompatible with Hegel's empirical realism. McDowell is critical of both Rorty and Brandom. Unlike many other analytic figures, for instance, Brandom, who reads Hegel through Sellars, McDowell reads Hegel directly through the texts as well as through such Hegel scholars as Robert Pippin. McDowell avoids conflating Hegel with metaphysical realism. He contends that Hegel does not fall behind, but rather goes beyond, Kant in developing an approach to knowledge that, unlike Sellars's "space of reasons," clearly preserves an empirical constraint. This observation suggests that analytic figures interested in Hegel should breach the interdiction concerning idealism established by Moore more than a century ago. In a recent work, Paul Redding points to continental idealism, including Hegel, as potentially a *third way* between scientific naturalism, or analytic philosophy, and orthodox theism.

Herder's Philosophy of History

This entry provides an overview of Johann Gottfried Herder's (1744–1803) philosophical views on history and in particular his championing of "hermeneutic historicism," his rejection of the divide between nature and history or culture, and his critical stance vis-à-vis the Enlightenment. Herder's views have become important in recent discussions of the philosophy of history and, especially, in relation to what the Enlightenment is claimed to have bequeathed to the social sciences.

With his two major books, *Another Philosophy of History for the Education of Mankind* and *Ideas for a Philosophical History of Mankind,* Herder became a seminal figure in the emergence of *hermeneutic historicism*. Already in his essays on Shakespeare and Ossian for the famous *Sturm und Drang* manifesto of 1773, *On the German Manner and Art,* he had argued for the developmental character of language, literature, and society and for human situatedness in a historical-cultural context, the key tenets of hermeneutic historicism. For Herder, the task of historical reconstruction was always to explain an author in terms of his own time, not to transfigure him according to the taste of one's own century. History should define the triad of antecedents, the moment, and the posterity of an author: what the first offered him, what the second helped or hindered, and what the third carried further.

The main target for Herder's first book was the "philosophical history" articulated by Voltaire. The latter clearly believed European civilization, especially his own country France in the age of Louis XIV, to be at the forefront of progress in history, wherein reason brought about liberation from religious obscurantism and traditional domination. However, considerable ethnographic and historical evidence was emerging that contradicted the timelessness and ubiquity of European conceptions of reason, moral improvement, and political order. Variety in values across geographical and historical contexts challenged not only the doctrine of progress but also the very idea of the universality of reason. Herder championed this historicist counterpoint, and Voltaire's complacent Eurocentric presentism especially offended him. Already in 1769, Herder could comment ironically that his century was too refined, too political, and too philosophical to appreciate earlier epochs. By 1774, his outrage with smug European ethnocentrism and concomitantly brutal imperialism erupted in the scathing polemic of *Another Philosophy of History.* He lambasted the Enlightenment propensity to take the polish of its century for the *non plus ultra* of mankind. Earlier epochs and different cultures could not be read off simply as stages on the way to some later, higher order: Every nation had its own center of well-being within itself, just as every globe had its center of gravity. Herder found symbolic integrity and intelligibility in human artifacts where the Enlightenment could find only fantastic excess or benighted superstition. His conception of history as composed of individualities with their own intrinsic principles of unity, together with his method of

empathetic understanding without moral condescension, disputed the Enlightenment's privilege of the (European) present and doctrine of linear progress. While Herder still articulated a developmental scheme for world history, his metaphor of the phases of a life also gave distinctive value and merit to earlier phases of history and their expressive and cultural powers.

A decade passed before his second great work began to appear. The difference in tone and approach of the new work was striking. It was both more irenic and more synthetic. Crucially, Herder was now convinced that there could be no categorical divide between nature and history. Adopting Buffon's strategy of a "natural history of man," [*sic*] his grand project in the *Ideas for a Philosophical History of Mankind* was to find how man as a creature of nature figured in man as an artifice of culture. He proposed to combine cultural history with geography and natural history to create a natural history of peoples. Works of human purpose had a structure analogous to that of living organisms, for their various parts were coordinated within a whole whereby their particular nature and function became comprehensible. Not only might a poem or a genre be read in this new manner, but so could peoples, cultures, states, and epochs. Thus, Herder helped establish in German the terms for a distinctive "spirit" unique to a people, a nation, or an epoch: *Volksgeist, nationaler Geist, Zeitgeist*. This spirit informed every artifact of a culture, so that it could be read out of all forms of its practice—from folkways to political constitutions, from musical compositions to business contracts. But the highest and most revealing form would be the literary expression of that culture.

Herder believed in grasping "universal history," as it was called in the late 18th century. For him, the Enlightenment was wrong not in seeking such a comprehensive vision but in identifying the whole with the end or *telos*. He called for "history of mankind" not to trace the trajectory of "progress" but to discriminate the varieties of human excellence. Totality, for Herder, could only signify a historical ensemble of distinctive actualizations of human potential over the course of time—not in hermetic isolation, not without partial cumulation and mutual influence, but emphatically without a linear, progressive *telos*. Combining organicism with development, Herder could recognize higher-order meaning in history. This is the essential feature of his concept of *Humanität*. In *Ideas,* Herder wrote that this term encompassed everything he was trying to say concerning man's disposition to reason and liberty, to refinement and taste. In *Letters for the Advancement of Humanity,* he elaborated that the term evoked the character of our kind, but we were born with this character only as a disposition, which needed to be expressed concretely to be fulfilled.

Herder first effectively asserted the principle that history must judge epochs, peoples, or cultures according to their own intrinsic principles, not by some external standard imposed from the historian's own time. While, to be sure, Giambattista Vico had argued earlier for such interpretive principles, he was not read widely until much later; thus, it was with Herder that the historicist view entered decisively into the human sciences.

Hermeneutics, Phenomenology, and Meaning

Both hermeneutics and phenomenology have been influential in the development of certain schools of social science as well as in the philosophy of social sciences. Recently, rereadings of certain schools of

phenomenology by Anglo-American philosophers and European cognitive scientists have led to a renewed interest in phenomenology, especially in contemporary accounts of embodied cognition. This entry surveys the history and main tenets of hermeneutics and phenomenology, presents the protagonists, and explains the central place accorded to meaning.

Hermeneutics

Hermeneutics as the art of interpretation or understanding has a long history in theology, particularly in relation to the interpretation of *written* texts (especially the Bible), and in law with regard to the establishment of legal precedents, but in the 19th century, it was expanded into a general theory of human interpretative understanding. Aristotle's *On Interpretation* is often regarded as an early treatise on hermeneutics, and St. Augustine's *On Christian Doctrine* proposes some classic hermeneutical principles—for example, that the part must be read in relation to the spirit of the whole text. Hermeneutics was revised by theologians in the 19th century and was integrated into European philosophy in the 20th century by Wilhelm Dilthey, Martin Heidegger, Hans-Georg Gadamer, Paul Ricoeur, and others.

In the 19th century, hermeneutics was developed especially by Friedrich Schleiermacher (1768–1834). Schleiermacher wanted to recover the original meanings of the events of the New Testament with all layerings of subsequent tradition stripped away. This required attempting to reconstruct the original meanings of terms in ancient texts and reconstructing the original worldview of the participants. Hermeneutics, for Schleiermacher, proceeded through empathic intuition; it was necessary to put oneself in the shoes of one of the original, unlettered hearers of Jesus' parables, for instance. His assumption that there is a single underlying meaning (often called the "intent of the author") has been criticized by deconstructionists such as the 20th-century French philosopher Jacques Derrida. Wilhelm Dilthey (1833–1911) broadened hermeneutics to be a general theory of human experience in history. The German phenomenologist Martin Heidegger (1889–1976) was influenced by reading Dilthey and by his Marburg colleague, the Lutheran theologian and New Testament scholar Rudolf Bultmann (1884–1976). In *Being and Time* (1927), Heidegger claimed that phenomenology had to be pursued in a hermeneutic manner and proposed the new methodology of *hermeneutical phenomenology*. In that work, Heidegger also announces a procedure of historical "destruction" (*Abbau, Destruktion, Zerstörung*) of the history of philosophy, aimed at recovering the original sense of the fundamental concepts of the philosophical tradition—for example, recovering what the Ancient Greeks originally meant by terms such as *being* (*ousia*) or *nature* (*physis*) prior to their reification in the Western metaphysical tradition.

Hermeneutical phenomenology was subsequently developed in Germany by Heidegger's student Hans-Georg Gadamer (1900–2002) and in France by Paul Ricoeur (1913–2005). A basic tenet of hermeneutics is that all understanding involves interpretation on the basis of certain presuppositions, prejudgments, or prejudices. In this sense, Gadamer claims, all understanding involves misunderstanding. There is no neutral view from which to grasp meaning; we understand situations from the perspective that we occupy. Often, hermeneutics works on written texts, but Gadamer, following Heidegger, broadened hermeneutics to the whole project of human self-understanding. Human beings are finite beings, limited by their particular language, their education, and their standpoint in history. All understanding has to recognize the finitude of human participants. Humans are essentially involved in the historically situated and finite task of understanding the world, a world encountered and inhabited in and through language. Human existence is characterized by "linguisticality" (a term Gadamer takes from Schleiermacher). Gadamer speaks of hermeneutical understanding on the model of conducting a conversation. A genuine conversation will go to places that none of the participants anticipated. Understanding is something that *happens* to people rather than something they control. What is aimed at is mutual understanding through a "fusion of horizons."

Phenomenology

Phenomenology emerged at the end of the 19th century as a systematic methodology aiming at describing human experience and its objects precisely in the manner in which they are experienced, without applying any presuppositions and paying particular attention to the mode of givenness of experiences. Phenomenology is a discipline, therefore, that is

sensitive to the varieties of ways in which meaning presents itself to subjects open to this disclosure of meaning. Both hermeneutics and phenomenology are concerned with the nature of sense (*Sinn*) and meaning, or significance (*Bedeutung*). Both disciplines offer ways to disclose or uncover the meanings latent in texts or experiences, meanings that have become distorted or covered up due to the operation of prejudice, tradition, and general misunderstanding. Phenomenology attends to the way our experiences are actually given to us; it aims to recuperate the "givenness" (*Gegebenheit*—a term Heidegger says is the "magic word" of phenomenology) of experience and to resist reductionist efforts to construe experience in a naturalistic manner. Phenomenology pays attention to the nonlinguistic sense found, for instance, in human perception, whereas hermeneutics tends to focus on linguistic meaning.

Brentano and Husserl

Phenomenology was developed by Edmund Husserl (1859–1938), building on the descriptive psychology of his teacher Franz Brentano (1838–1917). Brentano's insight that mental acts were *intentional*—directed at an object—gave Husserl the inspiration to develop phenomenology as a method for describing the essences of experiences (perceptual, emotive, and cognitive) as well as their intended objects in a nonreductive way. Central to phenomenology is the idea that experience is intentional; it is directed at an object (Husserl speaks of *noema*—originally a Greek word meaning "meaning") and understands that object in a particular way (through a particular "mode of givenness"). Every experience intends an object in its own manner. Husserl speaks of this correlation between intention and the intended object as a *noetic-noematic* correlation. Husserlian phenomenology claims that entities in the world—and other people, animals, cultural products, and so on—are experienced in a particular way through the dominant "natural attitude." It requires a particular effort of suspension of belief, which Husserl calls the *epoché* (a Greek term that means "abstention" or "suspension"), in order to uncover the intentional achievements that underlie the world, as disclosed in the natural attitude. Husserl speaks of performing a "phenomenological-transcendental *epoché*" in order to lead back to the pure sources of intentional experience. Husserl then seeks to perform a number of "reductions," for example, the "eidetic reduction," in order to move from the individual experience to the essence (cf. the Greek word *eidos* for "essence") of that experience or its object. Phenomenology is, for Husserl, an a priori *eidetic description*. In order to arrive at essences, all belief in the actual world must be bracketed. Phenomenological insight—"eidetic viewing" (*Wesensschau*)—is achieved by carrying out a free eidetic variation to identify the invariant (*eidos*) and therefore necessary features of the object.

Husserlian phenomenology offers particularly powerful analyses of conscious experience, especially perception, memory, imagination, and judgment, as well as time consciousness and the experience of others in empathy (*Einfühlung*). Husserlian phenomenology also laid stress on embodiment and intersubjectivity. Traditional epistemology and philosophy of mind neglected the manner in which human beings are embodied.

In his later writings, Husserl concentrated on understanding how the sense of a common shared world is intentionally constituted. He contrasted the world as scientifically construed using formal methodologies with the "life-world" (*Lebenswelt*) in which human beings live and encounter each other most of the time. This led Husserl to a phenomenological critique of the manner in which modern scientific knowledge, as inaugurated by Galileo, had become distorted into a naturalistic ideology that reified objects as experienced "naively" in the natural attitude.

Hermeneutics and Phenomenology

Heidegger

Husserlian phenomenology exercises the *epoché* to lived experiences in order to reveal their meaning; hermeneutics, on the other hand, attempts to disclose meaning by liberating the experience from the historically transmitted tradition. Heidegger's introduction of hermeneutics into phenomenology was a way of neutralizing or at least exposing the operation of *prejudice* in our understanding. Prejudices for him cannot be eliminated, but at least they can be made transparent, acknowledged, and our corresponding insights put in correlation with these prejudgments so that our understanding progresses in a "circular" manner (Heidegger speaks

of the "hermeneutic circle"), going backward and forward between what is understood and the manner in which it is understood. To ask a question is already to anticipate in a certain sense what counts as an answer. There must be a fore-understanding to all understanding.

In *Being and Time* Heidegger proposes a radical description of human existence, which he prefers to call "existence'" (*Dasein*), since he regards terms like *consciousness* (favored by Husserl) to be too overlain with metaphysical presuppositions. Heidegger deliberately aims to make human existence unfamiliar by describing it in entirely novel terms. According to Heidegger, traditional philosophy since the Ancient Greeks has taken the nature of human existence more or less for granted. Human beings have been understood naturalistically since the time of Plato and Aristotle as "rational animals"; the religious traditions of the West, specifically Judaism and Christianity, have treated human beings as being somehow images of the divine nature and have sought to interpret human existence against the backdrop of the assumed eternal, unchanging existence of the divinity, in contrast with which human life is regarded as fleeting and inconsequential, a "vale of tears." Influenced by the idiosyncratic writings of the Christian existentialist Søren Kierkegaard (1813–1855), Heidegger wanted to revisit human existence and examine it in its concreteness, temporality, historicality, and finitude. To be human is to care about one's existence. Human existence is not something that simply "occurs," is "present-at-hand," is simply "there." Human existence is distinguished by the fact that individuals *care* about their lives; existence *matters* to the existing self. Human existence is individualized, and characterized by "mineness" (*Jemeinigkeit*), but at the same time human beings need familiarity, self-forgetfulness in the routines of the everyday, and understanding oneself as everyone else does, as "the one" (*das Man*). Human existence has a tendency to seek the familiar and the routine, what Heidegger calls "everydayness" (*Alltäglichkeit*). In this everydayness, time is experienced in a certain way that excludes the possibility of authentic selfhood, which Heidegger associates with free decision. The essence of human existence is, as Heidegger puts it, its "to-be." Humans are engaged in projects that cast them forward into the future; Heidegger speaks of the *ecstatic* (Greek *ekstasis,* "to stand outside") character of existence. Human beings are essentially temporal and finite and are essentially incomplete because of death. Human existence is characterized by "thrownness"; that is, humans find themselves in an always already constituted world of established meanings. In his later thought, Heidegger suggests that poetic creation offers a way in which language can become authentic, combating the "idle talk" (*Gerede*) of everyday inauthentic discourse.

Levinas

Influenced by Husserl and Heidegger, the Lithuanian-born Emmanuel Levinas (1906–1995), who became a French citizen, identifies a kind of immeasurable, even infinite, *desire* that drives human existence and goes far beyond the satisfaction of needs. Levinas is critical of the Western philosophical tradition for its pursuit of knowledge as a kind of domination over being, a will-to-power that undervalued the experience of recognition and respect for others. Levinas uses the term *face* to capture the uniqueness of our experience of the other. The face is something unique, irreplaceable, supremely individual, and expressive, and yet it is also vulnerable and, in a way, naked. The face presents the other in a very special way. Face-to-face relations with others are at the center of Levinas's phenomenology. The face of the other awakens a responsibility in me, and from that point of view, there is a kind of asymmetry in my obligation to the other person. From *my* perspective, I am more responsible than the other person. I can personally experience my own responsibility. Nevertheless, despite his criticism of the Western philosophical tradition, and despite his expressed wish to leave behind the "climate," as he put it, of Heidegger's philosophy, Levinas always presented himself as a disciple of Husserl and following in his tradition of phenomenology.

Sartre, Merleau-Ponty, and Ricoeur

After Husserl and Heidegger, phenomenology in France took an explicitly existentialist direction in the work of Jean-Paul Sartre (1905–1980) and Maurice Merleau-Ponty (1908–1961).

In his philosophical treatises and essays as well as in his novels and plays, Sartre provided brilliant phenomenological descriptions of human existence. Deeply influenced by his reading of Husserl and Heidegger (and, later, Karl Marx), Sartre expands

phenomenology in an existential direction, emphasizing human individuality, freedom, and finitude. His *Being and Nothingness,* published in 1943, is an essay in "phenomenological ontology." He characterizes human consciousness as a "negativity" or "nothingness" (*le néant*) that is the opposite of everything that has being (*l'être*). Consciousness is essentially intentional, it is directed at what it is not, and it is not any of the things it is conscious of. Human existence is essentially characterized by a kind of emptiness and void—this itself is the experience of freedom that people find frightening and dizzying (Sartre calls this experience "nausea," *la nausée*). Humans are not determined by some fixed set of characteristics (character) but are in fact always free—free to say no, free to resist. But existence itself is always contingent. Being just is; as such it is "superfluous" (*de trop*). There is no ultimate reason as to why things are the way they are. Things have sense and significance only insofar as they form a part of human projects. For Sartre, these "projects" come about by an act of fundamental decision or free choice. Ultimately, the human project is to be God, to be absolute master of one's actions, and also to be a complete being. This, however, is impossible. Human beings die. For Sartre, the experience of absolute freedom is so overwhelming that many people run away from it and try to shore up their lives with certainties, embracing social roles as if they were essential attributes of their being. This is what Sartre calls "bad faith" (*mauvaise foi*). In contrast, the authentic life is a life where one is always conscious of one's freedom to choose. In his later works, Sartre tried to integrate this existentialist account of the human condition into a more Marxist-inspired social philosophy.

In his major work, *Phenomenology of Perception* (1945), Merleau-Ponty offers a phenomenological account of human beings as embodied "being-in-the-world" (*être au monde*), a corrective to the one-sided accounts of experience found in what he calls generally "intellectualism" and "empiricism" (sometimes "sensationalism"). Merleau-Ponty's way of overcoming these oppositions is to focus on the complex and ambiguous nature of human embodiment or "incarnation." Phenomenology aims to disclose how we experience ourselves as embodied beings in the world. Merleau-Ponty stresses our implicit and unspoken knowledge of our own bodies. Merleau-Ponty wants to explore the complex ways our bodies relate to the world in "prereflective" lived, natural experience. He wanted to be present, as he put it, at the birth of our world. This interest led him in his later works to studies of infants (he succeeded the Swiss psychologist Jean Piaget), disabled people, and so on. Merleau-Ponty was particularly influenced by Husserl's exploration of embodiment in his *Ideas II* and by his later investigation of the pregiven life-world. Merleau-Ponty did not believe that this being-in-the-world can be uncovered by reflection alone. He sought to examine brain-damaged persons in whom the original assumed link with the world is broken, in order to display what is taken for granted in everyday experience. Contemporary cognitive scientists and philosophers have shown the importance of Merleau-Ponty's ideas (some directly inspired by him) in the growing interest in new theories of embodied cognition.

Finally, the French philosopher Paul Ricoeur has been quite influential in certain quarters in the philosophy of the social sciences on the Anglo-American side, introducing hermeneutics against what were considered positivist perspectives on social theory. Ricoeur was initially interested in the existentialist French philosopher Gabriel Marcel and the German philosopher Karl Jaspers, but he also read Husserl and Heidegger. His first publication was a study of Husserl's phenomenology, and in the same year, 1950, he published *Freedom and Nature: The Voluntary and the Involuntary,* the first volume of a phenomenology of the will. In this volume, he argued that human beings live at the intersection of the voluntary and involuntary. The second volume later appeared in two parts: *Fallible Man* and *The Symbolism of Evil.* In these works, Ricoeur moved to a new hermeneutical approach. For Ricoeur, an essential hermeneutical question is "Where are you coming from?" or, more literally, "From where are you speaking?" (*D'ou parlez vous?*). Phenomenology must involve a hermeneutical investigation of—or "detour" through—the symbolic domain of language and other forms of culture. For Ricoeur, we understand ourselves only through a long detour—through the way of symbols. Symbols give rise to and structure thought. Ricoeur went on to note that symbols are given radically conflictual readings from differing ideological standpoints. Always culturally situated, a hermeneutical phenomenology cannot finally resolve such conflicts. Its task is rather to uncover and delineate

the theoretical framework of each interpretative standpoint. In his terminology, a methodology of suspicion is to be coupled with one of affirmation. Ricoeur's hermeneutics always pays close attention to language, including the use of metaphor and the manner in which meaning is structured as a narrative. In his later work, he developed an account of the nature of the self involving the manner in which self always involves a relation to the other.

Conclusion

Phenomenology continues to have a strong influence because of its recognition of the first- and second-person perspectives that complement the objective, third-person approach found in the natural and social sciences. Phenomenology is particularly helpful in describing the life of embodied intentional consciousness, both singular and plural. Hermeneutics, and especially the emphasis that interpretation involves narrativity, continues to play a strong role in the cognitive and social sciences.

Heterodox Economics

Heterodox economics is now the fashionable expression describing the set of numerous nonorthodox schools of thought that have emerged through time. Heterodox economics is in opposition to orthodox economics, also known as mainstream economics or neoclassical economics. The purpose of this entry is to present the elements shared by the economists of the various heterodox schools of thought and to identify these schools.

Heterodox Schools in Economics

It is fruitful to start by making a distinction between dissenters in economics and heterodox economists. Dissent may express itself either within or outside the orthodoxy. Orthodox economics includes the mainstream—which roughly corresponds to the textbook view—and orthodox dissenters, who reject some assumptions of mainstream analysis, trying to push it to the frontier, while remaining within orthodoxy. By contrast, heterodox economists are dissenters who reject the validity of orthodox economics. While orthodox dissenters only deviate somewhat from the mainstream, heterodox dissenters are heretics.

There are a large number of heterodox schools of thought. While some of these distinctions reflect fundamental beliefs, they also occur as a result of field specialization. Obviously, Marxists, or radicals, are part of heterodox economics. So is Institutional economics, or at least Old Institutionalism. Post-Keynesian economics, associated with John Maynard Keynes, is usually subdivided into its Fundamentalist, Kaleckian, Kaldorian, and Sraffian (or Neo-Ricardian) branches and contains, with Neo-Marxism, the main heterodox contribution to macroeconomics. The French regulation school, with its U.S. version—the Social Structure of Accumulation school—is an attempt to achieve a grand synthesis by combining the Marxist, Institutionalist, and post-Keynesian insights, along with a historical analysis. Another important heterodox school is that of evolutionary economics, associated both with the Veblenian approach in institutional economics and with Schumpeterian economics, mostly concerned with innovations and their diffusion.

Other heterodox schools include the Structuralist school, mainly developed in Latin America; social economics and humanistic economics, which emphasize ethical norms, also tied to anti-utilitarism; the economics of conventions, which underline rules and accepted norms; feminist economics, with its focus on gender issues, most of which evades mainstream theory; ecological economics, which is the heterodox version of environmental economics; and behavioral economics, or more precisely the stream that studies economic psychology and behavior without attempting to repair mainstream rationality. There are many other heterodox schools or traditions, such as Buddhist economics, Gandhi economics, Gesell economics, and Henry George economics. As for Austrian economics, it is often included within heterodox economics, but as we shall see, this classification may not be appropriate.

Common Features of Heterodox Economics

Heterodox economists are more than mere critics of the mainstream. Besides the institutional and theoretical ties that unite the members of the various schools and the fact that the works of some authors are highlighted by several heterodox traditions, there are broad features that characterize heterodox schools in a positive and essential way—the *presuppositions* of their research programs.

Table 1 summarizes the methodological issues and beliefs that separate heterodox from orthodox economics. Heterodox economics is based on realism, reasonable rationality, some degree of holism, a

Table 1 Presuppositions of the Heterodox and Orthodox Research Programs

Presupposition	*Heterodox Schools*	*Orthodox Schools*
Epistemology/ ontology	Realism	Instrumentalism
Rationality	Reasonable rationality, satisficing agent	Hypermodel-consistent rationality, optimizing agent
Method	Organicism, holism	Individualism
Economic core	Production, growth	Exchange, allocation, scarcity
Political core	Regulated markets	Unfettered markets

Source: Author.

concern with production and growth instead of scarcity, and a belief in the need for regulated markets. Since economists of the Austrian school disagree with the last three of these five presuppositions, they cannot be included in heterodox economics.

Tony Lawson argues that realism is *the* key methodological distinguishing feature of heterodox economics, claiming that the other distinguishing factors derive from this one. While realism can be interpreted in many different ways, there is an agreement that the analysis must start with first approximations of the real world, not an idealistic one. This is in opposition to state-of-the-art orthodox models, the purpose of which is not even to represent reality.

Closely related to realism and instrumentalism is the kind of rationality that is assumed in our economic models. The only kind of rationality admissible to mainstream economists is constrained optimization with model-consistent expectations. Heterodox economics emphasize instead that economic agents in a world of fundamental uncertainty can at best satisfice some targets, adjusting to unfulfilled expectations by revising beliefs and norms.

The third pair of presuppositions concerns methodological individualism or atomicism versus holism or organicism. Orthodox economists believe that all analyses must start from the individual. By contrast, heterodox authors take a more holistic approach. They pay attention to the possibility of macroeconomic paradoxes, or fallacies of composition, such as Keynes's paradox of thrift.

About the fourth pair of presuppositions, readers should be reminded that the standard definition of orthodox economics is the study of scarcity. By contrast, heterodox economists are mostly concerned with unused productive capacity, the causes and the consequences of growth, and the ability of the economic system to create a surplus.

The fifth and last of our presuppositions is tied to the role of markets relative to that of the state. Mainstream economists exhibit confidence in the ability of unregulated markets to deliver stability and full employment. By contrast, heterodox economists are distrustful of unfettered markets. They suspect their inability to self-regulate, their tendency for destabilizing paths, and their squandering of resources. They believe that markets must be tamed. They argue that economic systems are not self-adjusting.

Some methodologists have an alternative view of what distinguishes orthodox and heterodox economics. They complain about the compulsive inclination of orthodox economists for formalistic modeling. They also argue that heterodoxy entails a belief in open systems, while orthodox economics needs to deal with closed systems.

Historicism

Historicism refers to an array of approaches within philosophy and the social sciences that insists that history is central to any understanding of human affairs. It emerged as a response to modern and Enlightenment European philosophy's sometimes excessive enthusiasm for scientific method and causal explanation. In a variety of sometimes inconsistent ways, historicists maintain that human life and society must be understood historically. Their emphasis on the uniqueness of individual lives (rather than universal laws of human nature) in culturally varying contexts is often associated with both normative and theoretical relativism.

This entry traces the different meanings the notion of historicism took in the history of philosophy and the social sciences.

An important 18th-century source of historicism, Giambattista Vico defended the humanities and rhetoric against the exclusive claim of the natural sciences to valid knowledge, which was supported by philosophers from Francis Bacon and Descartes to David Hume. Vico maintains that what we know best is what we have made or created ourselves. There is a connection between what is "true" (*verum*) and what is "made" (*factum*), a connection reflected in our word *fact*. We are able to understand human actions, expressions, and artifacts with an immediate insight impossible with *nonhuman* entities. At the same time, our immediate insight into all things human does not guarantee objective knowledge.

As Johann Gottfried Herder made clear, human beings can only be understood through, in part because they are *constituted by,* their culturally and historically variable expressions. By implication, we must recognize as illusory that eternal and universal "human nature" so often invoked by Enlightenment thinkers as the object of social-scientific explanation. The languages and artifacts of different peoples, studied by disciplines such as philology, art history and literature, anthropology, and archaeology, always reflect their unique and irreducibly historical temperament or spirit (*Volksgeist*).

The realization that the truth of humanity is not to be found in an unchanging biology or psychology inspired some philosophers to seek that truth in the ultimate meaning or goal (*telos*) of history. Herder and Immanuel Kant both wrote ambitiously synoptic and speculative histories in that spirit. It was Georg Wilhelm Friedrich Hegel, however, who most influentially fashioned a wealth of historical insights and observations into a systematic philosophy of history. At the heart of Hegel's system is his view of history as a complex *dialectic*. Like the philosophical discourses (*dialektikê*) portrayed in Plato's Socratic dialogues, history advances through a series of mutually contending and superseding stages. He shows how different religions, works of art, political institutions, moral values, and metaphysical systems can be understood as stages in a complex dialectical process. Hegel's philosophy aspires to be the ultimate or "Absolute" truth gradually revealed through history.

Hegel's philosophical system is, in Hegel's own terms, "transcended" or "sublated" in the *materialist* dialectic of Karl Marx and Friedrich Engels. Where Hegel's conservative followers regarded the dialectic as substantially complete, Marx and Engels set themselves the radical task of bringing about the overthrow of present society in order to fulfill the *future* goal of history. At the same time, Hegel's intellectual or *idealist* dialectic of cultures and worldviews is transposed into the *materialist* register of modes of production and revolutionary class struggle.

Hegelian idealism and Marxism are two principal targets of Karl Popper's polemical engagement with historicism, which is deployed against all those theories and ideologies claiming knowledge of the essential meaning and future goal of history. Such approaches imply both historical determinism and methodological holism or collectivism. They are both politically and morally dangerous, because they treat individuals as unwitting dupes who may be sacrificed in order to guarantee humanity's historical mission. Historical determinism is intellectually incoherent because it presumes to anticipate a future society that depends, at least in part, on unforeseeable advances in human knowledge. Designed to combat now largely discredited totalitarian ideologies such as National Socialism and Soviet communism, Popper's critique can still be applied to more persistent Enlightenment notions of the inevitability of progress or "improvement." Another contemporary critic of the, mainly political, pernicious effects of historicism has been Leo Strauss.

Hegel's philosophy—freed of unsustainable assumptions of the Absolute—encouraged a wide

range of historicist approaches in the humanities and social sciences. Critical philosophers of history sought rigorous standards for the documentation and validation of historical knowledge. The 19th-century German philosopher Wilhelm Dilthey formulated rigorous criteria of "understanding" (*verstehen*) designed for all those *hermeneutic* disciplines primarily concerned with interpretation rather than causal explanation. The German historian Leopold von Ranke (late 18th to early 19th century) pioneered modern methods of historical scholarship in order to ensure an understanding of the past undistorted by present concerns and assumptions. In a parallel way, Marxism encouraged studies of social and economic history. At the same time, critical Marxists like Antonio Gramsci and members of the Frankfurt School set out to preserve the historicist insights of Marxism without succumbing to historical determinism (or "historicism" in Popper's sense).

In other disciplines, Franz Boas's anthropological historicism emphasized the uniqueness and incommensurability of different cultures. Legal historicists sought to understand law as neither the "natural" product of reason nor the arbitrary prescription of rulers, but rather as the specific historical expression of particular peoples.

Sometimes historicists claim that all knowledge is historical in similar ways. The Italian Neo-Hegelian philosopher Benedetto Croce and the British idealist R. G. Collingwood extended the historicist approach to philosophy and metaphysics. In the 20th century, Martin Heidegger and his student Hans-Georg Gadamer posited an essentially hermeneutic and so historical foundation for all human life and experience. Philosophical historicism of this kind tends toward moral, cognitive, and cultural relativism. In a similar vein, contemporary poststructuralists and postmodernists are typically skeptical, not only of any speculative philosophy or "grand metanarrative" of history but of all claims to universal truth. Michel Foucault's critical genealogy of history is probably the most influential of such approaches. Finally, "a new historicism" has appeared in literary theory.

Hobbes's Philosophical Method: Nature–Man–Society

This entry presents a brief introduction to the relationship between Thomas Hobbes's method and his investigations into nature, man, and society. When Hobbes (1588–1679) first conceived his political project, he thought to proceed from an investigation of nature to man to political society. However, as political tensions rose in his own society and addressing political questions became more urgent, he discovered that his political doctrine did not stand in need of any prior inquiry into larger nature or specifically human nature.

Hobbes immodestly wrote that the science of politics was no older than his own book *De Cive* (1642, in Latin). Earlier writers on politics had failed to discover the necessary properties of stable states, the rights of sovereigns, and the duties of subjects, because they lacked proper scientific method. Extrapolation from past experience may, if we have had a lot of experience and are very good at extrapolating from it, yield prudence; but this lacks the certainty of that sapience gained only by correct reasoning from proper principles. Experiences may be incomplete or wrongly interpreted; even sense perceptions may lead to false judgments, as when we perceive a straight stick as bent when partially submerged in clear water.

The proper method for discovering truth is *definitional.* We reason from premises that are analytically true, that is, true by virtue of the meanings of their component terms. The meanings of those terms must themselves enjoy a fixed, settled signification, and we are to proceed syllogistically using settled rules of inference. The conclusions we reach thus enjoy the status of reliable, noncontingent truths.

Of course the worry one may have about this method is of how to settle the appropriate component definitions. Conclusions will be warranted by their premises but, we might say, "garbage in, garbage out." Just any old arbitrary definitions will not track the reality of human concerns and experience or offer us a practically useful science of politics. Furthermore, many of the premises that must go into any realistic science of politics will have to include claims about what interests humans have, how they are motivated, how they interact in groups, and so on, which will not be true by definition but rather will be warranted by experience. It looks as if despite his stated definitional method, Hobbes will be forced to depend on some empirical observations if his political science is to have any interest for or claim on humans as we are.

One can address this apparent problem by reflecting on Hobbes's *reason* for aspiring to employ a definitional method. He wants his readers to have confidence in his conclusions and the system constructed on the basis of those conclusions. A definitional method, of the sort he perceived in Euclid's proof of the Pythagorean theorem—which Hobbes declared a totally convincing proof of an astonishing conclusion—was what he wanted for his own political argument. He wanted the component conclusions of his political philosophy not to be doubted, and not contestable, at least by anyone prepared to consider them carefully and in good faith. Hobbes (1994) wrote that

> to reduce this doctrine to the rules and infallibility of reason, there is no way, but, first put such principles down for a foundation, as passion, not mistrusting, may not seek to displace; and afterwards to build thereon the truth of cases . . . till the whole have been inexpugnable. (Epistle Dedicatory, p. 19)

Because Hobbes was engaged in the practical project of showing his countrymen that they have good and sufficient reasons to submit to the authority of their existing government, it makes sense to distinguish between those improperly synthetic premises that are harmful to his project and those that are not.

Presumably with this in mind, Hobbes permits himself some empirical premises, but only those that would not be doubted by anyone. One may think of such premises as *indubitable introspectables,* premises that "passion not mistrusting, will not seek to displace." Such premises will be premises that each person can confirm by introspection to be true in her own case, and so not doubt.

Such premises will not include universal generalizations about what everyone desires or what everyone thinks, because these cannot be known by individual introspection. Hobbes (1996) insists, first, that our science is too primitive to give us knowledge of human nature.

> For it is supposed that in this natural kingdome of God, there is no other way to know anything, but by natural reason; that is, from the principles of natural science; which are so farre from teaching us anything of God's nature, *as they cannot teach us our own nature,* nor the nature of the smallest creature living. (*Leviathan,* chap. XXXI, p. 33)

Hobbes's second reason for thinking that no proper proof of political principles will include empirical generalizations about what humans desire or think is principled. Science may tell us something of the *mechanisms* by which we operate—explaining what it is to want something or to believe something—but it cannot tell us the object, that is, what everyone wants or believes, because "for these [the objects of the passions] the constitution individual, and particular education do so vary, and they are so easie to be kept from our knowledge [by lying] that the characters of mans heart . . . are legible only to him that searcheth hearts" (Hobbes, 1996, *Leviathan,* Introduction)—that is, to God.

It has sometimes been thought that Hobbes assumed a very simple human psychology in which the aversion to temporal bodily death is the dominant, overriding desire of every sane human being; but Hobbes himself worried about the disruptions to social order caused by people's giving precedence to their desires to do their perceived religious duty, secure their salvation, or avenge an injustice. It is precisely because humans do not care most about securing the present life that they will engage in the seriously dangerous activity of waging war.

Hobbes may have been among the first, and arguably the most significant, of political philosophers to assert the independence of political theory. Rather than treating it as an application of the ethics for natural man, Hobbes treated it as the science of an *artificial entity,* the Commonwealth. As such, it stood in need of no prior scientific investigation into the natural world or into specifically human nature. Considerations of extrapolitical social dynamics do certainly play a role in his arguments as to what properties a political union, or commonwealth, must have in order to function well and remain stable over time. But these serve as background assumptions helping to specify the best definition of a commonwealth, from which Hobbes proceeds to derive his specific political conclusions.

Holism, in the Philosophy of Language

Holism covers a wide variety of theses, according to each of which the whole of a theory or a language or a system has some property that its parts lack and, further, this property cannot be defined or otherwise characterized by the properties of these parts. In epistemology, holism is the view that whole theories are the smallest units of confirmation. Single hypotheses yield observational predictions only with the aid of a body of background theory. This means that a failed prediction does not conclusively refute the hypothesis from which it is derived. This sort of holism has been defended by many 20th-century thinkers, including Pierre Duhem, W. V. O. Quine (cf. his phrase "the web of belief"), and Rudolf Carnap. The transition from epistemic holism to meaning holism was pushed by empiricist philosophers who wished to explain the meaning of symbols in terms of their verification conditions. Meaning holism (with variants such as "semantic holism" and "linguistic holism"), then, became the view that more inclusive bodies of theory serve as the basic units of meaning, and not the intuitive position on words as the fundamental bearers of meaning.

Meaning Holism

Historically, philosophers have been divided over whether meaning properties of expressions, such as a linguistic item expressing a concept or a proposition, or having a referent, or truth conditions, are holistic or atomic.

Those in the atomist tradition proceed from British empiricism to American pragmatism, the *locus classicus* being the word, as in the Vienna Circle; its contemporary proponents include most model theorists (Richard Montague, John Perry, and Jon Barwise), behaviorists (e.g., the psychologists B. F. Skinner and John B. Watson), and those philosophers whose work concerns so-called informational semantics (e.g., Fred Dretske, Jerry Fodor, and Ruth Millikan). People in these traditions think that the semantic properties of a symbol are determined by its relations to things in the nonlinguistic world.

The holist tradition, on the other hand, proceeds in linguistics from the structuralist tradition

and in philosophy from Ludwig Wittgenstein, W. V. O. Quine, Donald Davidson, Daniel Dennett, Ned Block, Hilary Putnam, Richard Rorty, Wilfred Sellars, and Robert Brandom; and it further includes almost everyone in the fields of artificial intelligence (AI) and cognitive science. People in this tradition hold that the semantic properties of a symbol are determined by its role in a language. So construed, meaning holism is a metaphysical thesis about the nature of representation in which the meaning of a symbol is relative to the entire system of representations containing it. Thus, a linguistic expression can have a meaning only in the context of a language; analogously, a hypothesis can have significance only in the context of a theory; and similarly, a concept can have intentionality only in the context of the belief system.

Meaning holism has profoundly influenced virtually every aspect of contemporary theorizing about language and mind, not only in the philosophy of language and the philosophy of mind but also in anthropology, linguistics, literary theory, AI, psychology, and cognitive science.

According to W. V. O. Quine, there can be no nonquestion, begging way of distinguishing (analytic) statements that are true in virtue of meaning alone from (synthetic) statements whose truth depends on facts about the world beyond meaning. This thesis serves as a premise in practically all arguments for holism about meaning. If the meaning of an expression is determined partly by its role in a language and if the analytic/synthetic distinction is infirm, then there can be no principled distinction between those aspects of a word's linguistic role that are relevant to determining its meaning and those that are not. The invited inference, obviously, is that the meaning of a word is a function of its whole linguistic role in the language. As Quine (1951) famously put it, "The unit of empirical significance is the whole of science" (p. 42).

Because holism, as we are construing it, is a metaphysical thesis, it is not a semantic (empirical) one, and so two theories might agree about the semantic facts but disagree about holism. For example, nothing in the logician Alfred Tarski's writings determines whether the semantic facts expressed by the theorems of an absolute truth theory are holistically determined or not. Yet Davidson, an ardent semantic holist, argued that the correct form for a semantic theory for a natural language *L* is an absolute truth theory for *L*. Semantic theories, like other sorts of theories, need not wear their metaphysical commitments on their sleeves.

Meaning holism has startling implications: Suppose that you think Barack Obama owned a dog and I think he did not. Because our beliefs differ, there are inferences about dogs you are prepared to accept and I am not. But holism says that what "dog" means in your mouth depends on the totality of your beliefs about dogs, including your beliefs concerning who owns them. It would thus seem to follow that you and I must mean different things by our shared word *dog*. This line of argument leads, more or less directly, to surprising consequences—for instance, that natural languages are not, in general, intertranslatable (W. V. O. Quine, Ferdinand de Saussure); that there may be no fact of the matter about the meanings of texts (Hilary Putnam, Jacques Derrida); and that scientific theories that differ in their basic postulates are "empirically incommensurable" (Paul Feyerabend, Thomas Kuhn). Moreover, *meaning holism* seems to imply that there cannot be a science of mental phenomena. For if meaning holism is true, then no two people can have the same beliefs or desires. But then no two people can fall under the same psychological law; indeed, no two time-slices of the same person can fall under the same psychological law.

Reactions to Holism

Philosophers react to holism and its implications in a variety of ways. A number of them just bite the bullet: Strictly speaking, they say, there are no such things as mental states, no such things as determinate translations or shared psychologies. Variations on this skepticism can be found in W. V. O. Quine, Donald Davidson, Daniel Dennett, Hilary Putnam, Stephen Stich, and Paul and Patricia Churchland, among others. These philosophers are sometimes called *semantic nihilists*.

Semantic nihilism is, of course, the most radical response to the consequences of holism. It is the view that, strictly speaking, there are no semantic properties. Strictly speaking, there are no mental states; words lack meanings. At least for scientific purposes (and perhaps for other purposes as well), we must abandon the notion that most people are moral or rational agents and that they act on their beliefs and desires.

Other philosophers have sought to avoid the dreaded consequences of holism by developing a

sort of mitigated holism according to which a notion of similarity of meaning (of mental or linguistic content) somehow replaces the notion of meaning identity that appeals to the analytic/synthetic distinction. This approach is also popular among cognitive scientists (Hartry Field, Gilbert Harman, and Paul Smolensky, among others). And still others suggest that perhaps an analytic/synthetic distinction can be preserved from Quine's attack by developing a "graded" notion of analyticity (Ned Block, Michael Devitt) or by arguing that there must be a viable analytic/synthetic distinction because the consequences of there not being one are simply too awful to contemplate (Michael Dummett). These philosophers are sometimes called *semantic molecularists*.

Semantic molecularism, like semantic holism, holds that the meaning of a representation in a language *L,* is determined by its relationship to the meanings of other expressions in *L* but, unlike holism, not by its relationships to every other expression in *L*. Molecularists, instead, are committed to the view, contra Quine, that for any expression *e* in a language *L,* there is an in-principle way of distinguishing between those representations in *L* the meanings of which determine the meaning of *e* and those representations in *L* the meanings of which do not determine the meaning of *e*. Traditionally, this in-principle delimitation is supposed by an analytic/synthetic distinction. Those representations in *L* that are meaning constituting of *e* are analytically connected to *e,* and those that are not meaning constituting are synthetically connected to *e*. Meaning molecularism seems to be the most common position among philosophers who reject meaning holism.

A different sort of reaction to holism is *atomism*. Meaning atomists hold that the meaning of any representation (linguistic, mental, or otherwise) is not determined by the meaning of any other representation. Historically, for example, Anglo-American philosophers in the 18th and 19th centuries thought that an idea of an *X* was *about* *X*s in virtue of this idea's physically resembling *X*s in the world. These sorts of resemblance theories, of course, are no longer fashionable, but a number of contemporary meaning atomists continue to believe that the basic semantic relation is between a concept and the things to which it applies, not an inferential relationship among the concepts themselves.

Holism, in the Social Sciences

Within the debate on holism in the philosophy of social sciences, it is common to distinguish between two issues. One is the ontological question of whether social phenomena exist, or exist in their own right. Ontological holists maintain that they do, whereas ontological individualists deny this. The other is the methodological question of the proper focus of explanations. Here, methodological holists hold that the social sciences should offer holist explanations, that is, explanations in terms of social phenomena. By contrast, methodological individualists insist that the social sciences should provide only individualist explanations, that is, explanations exclusively in terms of individuals, their actions, beliefs, desires, and so on.

The debate on holism has mainly concentrated on the methodological issue. Accordingly, this will

be the main focus of the present entry. The first section contains a brief presentation of ontological holism. Next follows a more thorough outline of methodological holism. Finally, various arguments in support of methodological holism are examined.

The Thesis of Ontological Holism

Ontological holism is sometimes characterized as the view that social phenomena exist. More often, however, it is phrased as the claim that social phenomena exist in their own right or as sui generis. Two aspects of this thesis deserve further comment.

To begin with, it is common to distinguish between different kinds of social phenomena, such as organizations (e.g., a school or a nation), the statistical properties of a group (e.g., its literacy rate or suicide rate), and the rules and norms within a group (e.g., the rule to drive to the right). The debate on ontological holism has mainly concentrated on social phenomena in the form of organizations.

Regarding the notions of existence and sui generis existence, there are various stances as to what exactly it takes for social phenomena to enjoy existence or sui generis existence. For instance, social phenomena may be said to exist in their own right (a) if they are composed of something more than constellations of individuals; (b) if they have causal powers that are independent of, and outstrip, the causal powers of individuals; or (c) if predicates such as "school" or "nation" that refer to social phenomena cannot be translated into statements about individuals. As a result of there being multiple criteria of existence and sui generis existence, ontological holists and ontological individualists may—and often do—have different things in mind when discussing whether social phenomena exist or exist sui generis.

Ontological holism is compatible with both a holist and an individualist position on the methodological issue. Thus, a commitment to ontological holism does not in itself entail a commitment to methodological holism, and vice versa. It is only when a given criterion of existence or sui generis existence is combined with suitable assumptions that a holist stance on ontology implies a holist stance on methodology, and vice versa. Within the individualism/holism debate, this insight did not receive much attention until the 1950s. At that point, the distinction between the ontological and methodological dimension of the debate began to gain currency. Equipped with this distinction, many methodological holists began to stress that they were not committed to, and did not endorse, the thesis of ontological holism. They distanced themselves from the view that social phenomena are composed of something more than constellations of individuals, just as they rejected the contention that social phenomena have causal powers that are independent of, and outstrip, the causal powers of individuals. Today, the majority of participants in the debate, methodological holists included, consider themselves to be ontological individualists. Typically, they take this to mean that social phenomena are nothing but mere constellations of individuals.

The Thesis of Methodological Holism

Methodological holism is the view that holist explanations, that is, explanations in terms of social phenomena, should be advanced within the social sciences. As it stands, this thesis raises three issues in need of clarification.

1. *First, when does an explanation qualify as being holist, that is, as being in terms of social phenomena?* There are various stances on this matter. For instance, one is that an explanation is holist if the explanans, that is, what does the explaining, refers to social phenomena. Another is that an explanation is holist if the explanans contains social predicates or social descriptions referring to corresponding social phenomena. In turn, both these proposals may be further—and differently—spelled out depending on what counts as social phenomena and what as social predicates, respectively. This point may be illustrated in relation to the suggestion that an explanation is holist if the explanans contains social predicates used as a reference. Here, it is generally agreed that social predicates are exemplified by descriptions such as "school," "government," "a decrease in unemployment," "a rise in crime," "the rule that . . . ," and "the norm that. . . ." At the same time, there are other types of predicates where it is a matter of dispute whether they should be classified as social descriptions. Most notably, some insist that social predicates should be used broadly to include descriptions of relations between individuals and role predicates such as "bank clerk" and "policeman." On the contrary, others argue that these predicates should be regarded as descriptions that may figure in individualist

explanations. As these considerations show, it is possible to distinguish between broader or narrower conceptions of what to count as a holist explanation. The broader conceptions draw the line between holist and individualist explanations such that more explanations come out as holist explanations. The narrower ones regard fewer explanations as holist by allowing more explanations to qualify as individualist. Very often, methodological holists subscribe to broader conceptions, whereas methodological individualists favor narrower ones. As a result, they tend to talk past each other: Each offers arguments presupposing a conception of holist explanations that is unacceptable to their opponent. This being the case, their arguments fail to impress the other.

2. *Second, what is meant by an explanation?* Again, there are different answers to this question since there are various notions of what to count as an explanation. Consequently, methodological holism may be variously spelled out depending on the notion of explanation adopted. Much of the earlier debate is conducted in terms of the covering-law model of explanation. According to this model, a scientific explanation takes the form of a deductive or inductive argument that shows why the phenomenon in need of explanation was to be expected. For quite a while now, the covering-law model has been under heavy attack, to say the least. Not surprisingly, therefore, more recent specifications of methodological holism typically rely on alternative notions of explanation. For instance, they subscribe to the causal-information view of explanation, which states that an explanation provides information about the causal process leading to the phenomenon in need of explanation. Or they embrace the erotetic model of explanation, which states, roughly speaking, that an explanation is an answer to a why-question. It is important to note here that irrespective of the notion of explanation adopted, methodological holists regard holist explanations as finished and complete explanations. Thus, they deny that holist explanations are only tolerable as unfinished explanatory stopping points on the way to individualist explanations considered as finished explanations. Likewise, they reject the stance that holist explanations are incomplete unless they are supplemented by accounts in terms of individuals. To be a methodological holist is to hold that holist explanations are just fine as they stand.

In addition to diverse *notions* of explanation, it is possible to distinguish between various *kinds* of explanation. Two examples of different kinds of explanation are functionalist and straightforward causal explanations. Historically speaking, methodological holism has often been associated with the advancement of functionalist explanations. Applied by methodological holists, these assert that the continued existence of some social phenomenon is explained by its function or effect. For instance, it may be suggested that the state continues to exist because it furthers the interests of the ruling class. Nowadays, functionalist explanations are generally regarded as having a very limited applicability to social phenomena. Currently, the kind of explanation that is mostly used is probably the straightforward causal explanation. It is exemplified by the claim that the rise in unemployment caused the rise in crime and that the government's decision to lower the taxes led to an increase in the consumption of luxury goods. Needless to say, it is possible to distinguish further kinds of holist explanations, just as more fine-grained or completely different classifications of kinds of holist explanations may be adopted. The methodological holist who relies on a given *notion* of explanation may, to a varying extent, make use of different *kinds* of explanation.

3. *Third, to what extent should holist explanations be advanced within the social sciences?* As formulated above, the thesis of methodological holism leaves this question open. One option is to further specify that holist explanations *alone* should be offered within the social sciences. Individualist explanations should not be put forward. Among methodological holists, this is the minority view. Most of them adopt the more moderate stance that *on some occasions* holist explanations are in order. On other occasions, individualist explanations may well be provided.

As these considerations bring out, it is possible to distinguish between numerous versions of methodological holism depending on how the thesis is spelled out. In the 1950s, some versions of the thesis were strongly opposed by methodological individualism. As a result, methodological holism came to be seen as a position on the defensive. Methodological individualism was the dominant position. Today, this is no longer obviously the case. Or at the very least, it may be registered that a number of influential

theorists are currently defending their favorite version of the holist stance on explanation.

Arguments in Support of the Indispensability of Holist Explanations

Different arguments have been offered in support of methodological holism. Here follows an examination of four main arguments. In different ways, they purport to show that holist explanations are indispensable.

Arguments From Causal Powers

One type of argument appeals to the causal powers of social phenomena. It comes in different versions. One version proceeds like this: Social phenomena exist sui generis in the sense of having causal powers that are somehow independent of, and outstrip, the causal powers of individuals. This means that when social phenomena exercise their independent and outstripping causal powers, their effects may not be explained merely by appealing to individuals with their limited causal powers. Instead, it is necessary to offer explanations that refer to the social phenomena that brought about the effects. In short, only holist explanations will do. This being the case, on pain of leaving these effects unexplained, the social-scientific use of holist explanations is indispensable.

An argument along these lines is sometimes implicit or explicit in the writings of theorists working within a Hegelian, Marxist, or functionalist tradition. Today, the argument does not enjoy much, if any, support. It is simply too hard to make sense of, and render plausible, the contention that social phenomena have causal powers that are independent of, and outstrip, the causal powers of individuals.

Another version of the argument from causal powers avoids this problem. Here, it is acknowledged that the causal powers of social phenomena depend on, and do not outstrip, the causal powers of single individuals. Still, it is held that the causal powers of social phenomena are distinct from the causal powers of single individuals. Consequently, when social phenomena exercise their distinct causal powers, explanations of their effects must point to these social phenomena. The explanations offered must be holist. It will not do to use individualist explanations since single individuals do not bring about the effects in question. Therefore, in order not to leave the effects unexplained, holist explanations must be advanced within the social sciences.

This version of the argument is currently being defended by some of the theorists working within the tradition of critical realism. Among other things, the argument has been criticized for not presenting convincing reasons to the effect that the causal powers of social phenomena are indeed distinct from the causal powers of individuals.

Arguments From the Impossibility of Translation

Another type of arguments focuses on whether holist explanations may be translated into individualist explanations. More specifically, it is first pointed out that holist explanations contain social predicates. Then, it is maintained that the meaning of social predicates cannot be captured solely in terms of descriptions of individuals. Or, as it is also put, social predicates are not exhaustively analyzable, or reductively definable, in terms of descriptions of individuals only. This being the case, it is impossible to translate holist explanations into individualist explanations. Finally, it is then concluded that since holist explanations may not in this manner be replaced by individualist explanations, holist explanations are indispensable.

But why hold that this translation is impossible? The most famous and widely discussed argument to this effect was advanced in the 1950s. It states that the definition of social predicates will inevitably contain other social predicates. For instance, the definition of "bank teller," here considered as a social predicate, must mention a bank. And the definition of "bank" must, in turn, contain notions such as "legal tender" and "contract." And these social predicates, in turn, may only be defined in ways that involve yet other social descriptions, and so on. In this fashion, it is impossible to capture the meaning of social predicates exclusively in terms of descriptions of individuals.

Today, there are few, if any, proponents of this argument. Instead, other reasons are given to show that holist explanations cannot be translated into individualist ones. This point, though, does not receive much attention in the current debate. It is generally held that in order to show that holist explanations are indispensable it does not suffice to demonstrate that they cannot be translated into individualist ones.

Arguments About the Impossibility of Intertheoretic Reduction

A third type of arguments purports to demonstrate the impossibility of intertheoretic reduction. Arguments of this sort take it that holist explanations always draw on holist theories, whereas individualist explanations always involve individualist theories. Against this background, it is then maintained that holist theories are oftentimes irreducible to individualist theories. By implication, holist explanations that make use of irreducible holist theories cannot be substituted by individualist explanations, which involve individualist theories. Thus, on pain of leaving various phenomena unexplained, the use of these holist explanations is indispensable within the social sciences.

The notion of intertheoretic reduction may be specified by applying a standard model of reduction to holist theories. A holist theory contains social predicates. It must first be shown that its social predicates may be linked, on a one-to-one basis, with descriptions of individuals via bridge laws. The bridge laws express that the linked predicates are coextensive, that is, have the same reference, in a lawlike manner. Then, the holist theory must be deduced from, and in this sense explained by, an individualist theory plus the bridge laws. When these conditions are met, the holist theory has been reduced to an individualist theory.

One of the arguments that methodological holists have offered against the possibility of intertheoretic reduction is the argument from multiple realization. Applied by methodological holists, the argument states that many, if not most, types of social phenomena may be realized by multiple types of constellations of individuals. When this is the case, the corresponding social predicates may not be linked up with single descriptions of individuals via bridge laws. For instance, consider bureaucracies: Individuals may be organized in multiple ways while still realizing or constituting a bureaucracy. Consequently, the social predicate "bureaucracy" must be linked not with a single description but with multiple descriptions of how individuals may realize this kind of social phenomenon. Whenever this happens, the first condition of intertheoretic reduction is not met. Intertheoretic reduction fails.

Methodological holists began to advance the argument from multiple realization in the early 1980s. Presently, it is regarded as *the* argument against reduction. However, the argument has also been disputed on various accounts. Moreover, the model of reduction and its applicability to the debate about methodological holism has been challenged.

The Argument From Explanatory Interests

The last type of argument to be considered here has the following structure: At first, it is made clear that a certain notion of explanation is adopted. By appeal to this notion, it is then argued that a holist explanation may serve interests that are not satisfied by an individualist explanation of the same particular event or state. This being the case, it is concluded that since the social sciences should serve these interests, holist explanations are indispensable.

Arguments of this type have mainly been advanced since the early 1980s while relying on either the causal-information or the erotetic view of explanation. According to the former, an explanation provides information about the causal process leading to the event or state in need of explanation. Equipped with this notion of explanation, consider an example of a holist and an individualist explanation of the same particular event. The methodological holist might explain the rise in crime in Copenhagen last year by pointing to a rise in unemployment. By contrast, the methodological individualist might say that the crime rate went up because certain individuals had lost their jobs and felt frustrated about having very little money and no job opportunities. The holist explanation conveys that given the rise in unemployment, a rise in crime was almost bound to occur. If those particular individuals had not lost their job and begun to commit crimes, then others would have. As such, it provides a different sort of information than the individualist explanation. The individualist explanation confines itself to pointing out that these particular individuals with a changed job situation and incentives were responsible for the rise in crime. In this fashion, the example illustrates how holist and individualist explanations satisfy different interests in the causal history of the same particular events or states.

Among other things, the argument has been criticized on the ground that it does not sufficiently bring out that the dissimilar causal information provided by holist and individualist explanations

may serve different theoretical *as well as* pragmatic interests. Also, it has been argued that the argument from explanatory interests is better made by relying on the erotetic notion of explanation, that is, the view that an explanation is an answer to a why-question.

Homo Economicus

Homo economicus is a model of human behavior that explains social phenomena (including social interaction outside the market) in terms of economic behavior or what the received view construes as rational economic behavior: namely, as opportunity taking or (opportunistic) rational action. This basically Hobbesian model of man underlies most of the modern, rational choice approaches to explaining social phenomena. The choice-making behavior of homo economicus is characterized by future directedness, case-by-case motivation, and subjectivism.

Rational economic (wo)men strictly distinguish between what is and what is not a causal consequence of each of their acts taken separately. A rational person complies with a norm if and only if compliance is judged to have better consequences than noncompliance. Intrinsic motivation by the norm or rule is not operative. Whether it would be good or bad for a choice maker to act always in the same way or whether it would be good or bad if all would act in a specific way is irrelevant. Any regularity in choice-making emerges from the fact that the same external incentives operate on the opportunistic choice-making entity regularly.

Consistency Assumption

Whatever it is that the rational individual/homo economicus does, as long as choice making fulfills the axioms that guarantee "consistency"—it is not possible to make somebody pay to get A for B and have the same person pay to trade B for A—the behavior can be described "as if" utility maximizing, by assigning higher utility indicators to the (consistently) chosen alternatives than to the nonchosen. Egoistic as well as nonegoistic choice behavior can be represented "as if" maximizing. For, according to the classical model of "utility maximization,"

an alternative is preferred because it has higher utility. According to the modern model, utility is not among the reasons for choice. By choosing an alternative—for whatever (un)selfish motives—the preference is assumed to be revealed. Higher utility is assigned to the chosen alternative merely to indicate the preference. Homo economicus behaves as if she were maximizing a utility function, yet the higher or lower values of that function are not among the reasons for preferring.

Case-by-Case Motivation

The *core assumption* of case-by-case opportunistic—rather than rule-guided—choice making in view of the *causal future consequences of each act taken separately* goes beyond the *consistency assumption.* It has far-reaching implications. These can best be illustrated in terms of the theory of (repeated) games. As a specific example, take a classical one-off, two-by-two Prisoner's Dilemma (PD) game. In this game, moves are made separately and in isolation and therefore cannot causally influence each other. No player can make her own choice causally dependent on that of the coplayer. Each actor has a dominant choice alternative that leads to better results for her regardless of what the coplayer chooses. If both actors do what is better for them regardless—that is, act rationally—they end up in a (Pareto inferior) situation to which another situation exists in which both would fare better.

As long as each actor assumes that the choices of the other individual are causally independent from her own, nothing will alter the dominance characteristics of the actions in the basic PD game. However, if the PD is repeated, actions performed on a former round of play can causally influence actions on later rounds of play. It is often thought that through this mechanism the so-called Hobbesian problem of explaining social order in terms of case-by-case maximizing of future-directed behavior could be solved. In repeat interaction, it is claimed, homo economicus would rationally show reciprocity: If *other* cooperated on the last, *self* will do so on the next round of play, and if *other* defected on the last, *self* reciprocates on the next. Then, opportunistic behavior would seem as if guided by "norms" of reciprocity. However, though such "tit-for-tat" behavior has a basis in the retributive emotions, it is not for strictly rational homo economicus. Taking seriously the future directedness of rational choice making the past behavior can never matter as such (bygones are bygones).

In a finitely repeated game, on the last round the dominance properties of the normal game apply. There is no future beyond the last round. Therefore, no relevant causal influence could induce individuals to deviate from their dominant strategy choices on the last round. This infects the next to last round, and so on. Rational reciprocal cooperation would unravel among rational actors who would foresee this.

If the model of rational economic man is taken seriously and only causal influences on the future matter, then any past history of play must be irrelevant. This applies as well if the game is identically and indefinitely repeated in the future. After removing at most finitely, many initial rounds of play still infinitely many remain. *Independent of history,* the future remaining game—except for renumbering—is structurally identical. For rational economic (wo)men it follows that in view of the structurally identical future they should always make the same choices regardless of the past. Strategies such as "tit for tat," which make behavior contingent on behavior on previous rounds of play will not make sense, and the alleged rational choice solutions of the Hobbesian problem of social order fail.

Homo economicus acts upon a model of the situation according to what she judges right with respect to future consequences. This brings "teleology" into a causal world. Distinguishing between what is and what is not a causal consequence is itself a process subject to causal laws, however. Homo economicus will explore these and other laws that govern the process by which the past transforms itself into the expected future.

Human Cultural Niche Construction and the Social Sciences

Niche construction theory (NCT) is a novel theoretical perspective in evolutionary biology that has challenged the hitherto dominant, one-sided view of Neo-Darwinian evolution, with gene-driven evolution as the sole protagonist. NCT posits an alternative paradigm to human sociobiology or evolutionary psychology. It has important repercussions beyond biology as such, being also applicable to the human species and its cultural practices, showing that human cultural interventions and social processes can have feedback effects on the selection pressures on genes. NCT can, furthermore, have an impact on the human and social sciences, affecting the way social explanation works. Some go so far as to claim that "niche construction theory potentially integrates the biological and social aspects of the human sciences" (Kendal et al., 2011).

Niche construction is the process whereby organisms, through their activities and choices, modify their own and each other's niches. By transforming natural selection pressures, niche construction generates feedback in evolution, on a scale hitherto underestimated and in a manner that alters the evolutionary dynamic. Advocates of the niche construction perspective seek to develop a new approach to evolution—one that treats niche construction as a fundamental evolutionary process in its own right. This approach has become known as NCT.

Niche construction also plays a critical role in ecology, where it supports ecosystem engineering and eco-evolutionary feedbacks and partly regulates the flow of energy and nutrients through ecosystems. NCT is also starting to have an impact in a variety of other disciplines, including the human sciences, philosophy of biology, medicine, developmental biology, and conservation biology. In any one discipline, the effect of NCT may still yet be modest, but across them collectively, it is starting to become a powerful interdisciplinary movement.

NCT is also relevant to the philosophy of science because it challenges certain fundamental aspects of orthodox Neo-Darwinism.

The Reference Device Problem

The evolutionary biologist Richard Lewontin drew attention to a problem within evolutionary biology by summarizing standard evolutionary theory as follows:

$$\frac{dO}{dt} = f(O, E) \tag{1a}$$

$$\frac{dE}{dt} = g(E) \tag{1b}$$

Evolutionary change, dO/dt, is assumed to depend on both organisms' states, O, and environmental states, E (Equation 1a), but environmental change, dE/dt, is assumed to depend on environmental states only (Equation 1b). With many caveats and complications, organisms are not generally regarded as causing evolutionarily significant changes in their environments. While organismal change of environments is clearly recognized by biologists to occur, this has typically been assumed to operate on temporal and spatial scales that are irrelevant to evolutionary analysis. The exceptions are when the selective environment is provided by other organisms, as in the case of coevolution or sexual selection.

For Lewontin, a more accurate general description of how evolution actually works is as follows:

$$\frac{dO}{dt} = f(O, E) \tag{2a}$$

$$\frac{dE}{dt} = g(O, E) \tag{2b}$$

where environmental change also depends on the environment-modifying activities of organisms. The philosopher of biology P. Godfrey-Smith drew

attention to the same problem by describing standard evolutionary theory as "externalist," by which he meant that it seeks to explain the internal properties of organisms, their adaptations, exclusively in terms of external properties, that is natural selection pressures, in their external environments. The principal point that the conventional approach obscures is that organisms change some of the selection pressures in their environments.

The "reference device problem" is that the causal arrow in Equation 2 representing niche construction points in the "wrong" direction, from organisms to environments, and is therefore not compatible with the externalist assumption of standard evolutionary theory. As a result, it is difficult for evolutionary biologists to describe changes in selection caused by niche construction as evolutionarily causal. Instead, standard evolutionary theory is forced by its own explanatory reference device to "explain away" all observed instances of niche construction as phenotypic, or extended phenotypic, consequences of prior natural selection. Standard evolutionary theory can recognize niche construction as a consequence of evolution, but it cannot recognize it as a cause in its own right.

The Devaluation of Proximate Causes

Responding to structuralist critics, in 1984 Ernst Mayr wrote, "All of the directions, controls and constraints of the developmental machinery are laid down in the blueprint of the DNA genotype as instructions or potentialities" (p. 126). For Mayr, developmental processes cannot be regarded as independent causes of evolutionary events, since their characteristics, including their ability to control and constrain, are themselves fully explained by prior natural selection. If developmental processes direct evolutionary events, this is only the *proximate* manifestation of the *ultimate* cause of natural selection; conversely, those aspects of development that have not been shaped by selection play no evolutionary role.

Mayr was extremely influential in bringing this commonly made distinction between "proximate" and "ultimate" causes to prominence within biology. In an article published in 1961, Mayr argued that natural selection should be regarded as the *ultimate* cause of phenotypic characters, thereby effectively devaluing so-called proximate causes as explanatory tools within evolutionary biology. Since niche construction includes developmental processes, this stance also prevented evolutionary biologists from recognizing niche construction as an evolutionary process and thus hinders the integration of evolutionary and developmental biology.

Instead, niche construction is perceived to have no *independent* evolutionary significance because, to the extent that it is evolutionarily consequential, it is regarded as fully explained by a preceding cause, natural selection. Niche construction effects are treated as merely extended phenotypes, and extended phenotypes play the same role in evolutionary biology as ordinary phenotypes—namely, to affect the replication potential of the alleles contributing to those phenotypic effects. While this stance recognizes that modification of the selective environment does occur, it does not view environmental modification as a process with quasi-independent causal significance.

There are two major problems with this line of reasoning. First, not all evolutionarily consequential niche construction, or all development in general, is under genetic control. For instance, dairy farming is an instance of human cultural niche construction that is mediated by cultural processes. There are no genes for dairy farming (i.e., no genes selected specifically for that function). Yet in spite of the fact that dairy farming is not caused by genes and is not a biological adaptation, it has clearly had evolutionary consequences.

Second, even if it were the case that the niche-constructing activities of organisms were under genetic control, it would still not follow that niche construction was a mere effect of the prior selection of these controlling genes. For in many cases, these "controlling genes" have themselves been selected as a result of prior niche-constructed changes in selective environments. For example, it is tempting to assume that the "ultimate" explanation for why earthworms modify soils is that prior selection has furnished them with genes for burrowing, tunneling, exuding mucus, and so forth. However, it is no more than a convention within evolutionary biology that natural selection should be regarded as the ultimate cause of such phenotypic characters. One might equally argue that the cause of the selection pressures that favored earthworm soil-processing adaptations is the prior niche-constructing activities of ancestral worms, without which there would be no soil environment to act as a source of natural selection. The niche construction perspective rejects Mayr's proximate–ultimate causation reasoning, replacing it with the notion of "*reciprocal* causation."

Misleading Metaphors

Lewontin argues that some unfortunate legacies of Darwin and Mendel are misleading metaphors. Mendel's (1983) view of organisms as the manifestation of autonomous internal "factors" with their own laws germinated into a post-Synthesis metaphor in which ontogeny "is seen as an *unfolding* of a form, already latent in the genes" (p. 276). Darwin's view of organisms as passive objects molded by the external force of natural selection encouraged a conception of evolution in which "the environment poses the problem"; the organisms posit "solutions," of which the best is finally "chosen" (p. 276). The metaphor of selection, inspired by the efficacy of artificial selection, continues to encourage a view of organisms as passive objects on which external forces act.

The Niche Construction Revision

The niche construction perspective differs from the conventional perspective in recognizing *two* major adaptive processes in evolution, natural selection *and* niche construction, and two general forms of inheritance in evolution, genetic *and* ecological inheritance (the latter including cultural processes). There are two legacies that organisms inherit from their ancestors, genes and modified environments, incorporating modified selection pressures. Ecological inheritance is not a high-fidelity template-copying system such as genetic inheritance. Instead, organisms transmit to their offspring, and subsequent descendents, physically (and in the case of humans, culturally) altered selective environments, both through actions on their biological and nonbiological environments and by their habitat choices.
